Asians and Asian Americans experienced an increase in exposure to racial discrimination during the COVID-19 pandemic. Ethnic minorities may counter discrimination by actively strengthening their ethnic identity and engaging in behaviors designed to enhance ethnic and cultural identification, such as reaching out to people who personify their culture. Grandparents are one such resource to whom young adults may turn to learn about their cultural heritage. The current study examined the degree to which facets of Asian and Asian American grandparent-grandchild relationships were related to ethnic identity, particularly in response to exposure to discrimination. Asian and Asian American young adults ($N = 102$) completed survey questions related to their experiences with COVID-19-related racial discrimination, ethnic identification, and relational closeness and frequency of contact with grandparents. Overall, exposure to discrimination was not significantly associated with strength of ethnic identity. However, there was a significant positive association between strength of ethnic identity and frequency of synchronous contact with grandparents, $rs(100) = .329$, $p < .001$. Strength of ethnic identity and relational closeness with grandparents were also significantly positively correlated, $rs(100) = .383$, $p < .001$. In contrast to some previous research, results show that discrimination encountered during the pandemic may not be related to strength of ethnic identification. However, there is a strong relationship between Asian and Asian American young adults' strength of ethnic identification and the nature of their relationships with their grandparents. These findings enhance understanding of how intergenerational relationships are related to ethnic identity.

DO OPPOSITES ATTRACT OR AGGRAVATE? THE IMPACT OF INTERGENERATIONAL SOLIDARITY ON WELL-BEING

Rachel Scott[1], Acacia Lopez[1], Marin Olson[2], and Danielle Nadorff[2], *1. Mississippi State University, Starkville, Mississippi, United States, 2. Mississippi State University, Mississippi State, Mississippi, United States*

Family Systems Theory states that values are transmitted between generations within families and, while many of these values are similar between immediate generations, there may be more differentiation in values between generation gaps. Ideological differences between generations may potentially cause subsequent tension and fluctuations in well-being. The current study sought to examine the moderating effect of ideological differences (religious and political) on the relation between how emotionally close grandparents perceive themselves being with younger generations and grandparental well-being. Participants included 419 grandparents (age: $M = 76$, $SD = 5.33$), 716 adult children (age: $M = 53$, $SD = 4.16$), and 638 adult grandchildren (age: $M = 29$, $SD = 5.52$) from the 8th wave of the Longitudinal Study of Generations (LSOG) data set. Well-being in grandparents was positively correlated with perceived emotional closeness among both of the intergenerational dyads. Religious ideological differences between grandparents and grandchildren were found to negatively influence grandparental well-being; this relation was also found to be significantly different from political ideological differences within the same intergenerational dyad. While moderation was not achieved for either dyad, the overall model fit was found to be excellent, suggesting its utility for further research into the relation between the study variables. These findings indicate that there is a complex relation between perceived emotional closeness, ideological beliefs, and the well-being of grandparents that warrant additional attention within the literature and may inform interventions related to intergenerational communication and well-being. Further implications for these findings will be discussed.

WHAT CAUSES OLDER PARENT–ADULT CHILD ESTRANGEMENT?: A QUALITATIVE INTERVIEW STUDY

Julia Nolte, Marie Cope, and Karl Pillemer, *Cornell University, Ithaca, New York, United States*

The life-course perspective's emphasis on "linked lives" highlights the importance of positive parent-child relationships for adults' well-being in mid-life and beyond. However, one in ten Americans experiences parent-child estrangement, defined as ending all contact and communication for a period of time. Despite the prevalence, the reasons underlying family estrangements are poorly understood. In this study, we conducted in-depth, qualitative interviews with 43 middle-aged and older adults (age range = 46-81, M = 65.05 years) who are or were estranged from an adult child (estrangement range = 1-26, mean = 6.53 years). On the basis of a jointly developed codebook, independent coding from the first and second author revealed 22 estrangement reasons across eight categories, with parents citing reasons from across four categories on average. Estrangement was most often attributed to the behavior, issues, or traits of the child (79%), problems surrounding a difficult in-law/ partner (72%), or disagreements about beliefs and values (67%). To a lesser degree, estrangements were linked to separation or divorce (49%), financial problems and conflicts (42%), adverse childhood experiences of the estranged child (30%), and interference from someone other than a partner (16%). More than half of the parents (58%) also endorsed other reasons, including their own traits and behaviors, communication issues, a family history of estrangement, and passive loss of contact. Older parent–adult child estrangements are perceived as multi-causal, with four out of five parents describing the estranged child as difficult or troubled. Implications of the findings for professionals working with older adults are discussed.

SESSION 6530 (POSTER)

FAMILY CAREGIVING, SOCIAL NETWORKS, AND SOCIAL SUPPORT

IMPACT OF THE COVID-19 PANDEMIC: HEALTH AND MENTAL HEALTH CAPACITY OF CAREGIVERS AND CARE RECIPIENTS

Christina Miyawaki[1], and Nina Tahija[2], *1. University of Houston, Houston, Texas, United States, 2. The Council on Recovery, Houston, Texas, United States*

We developed a depression intervention, Caregiver-Provided Life Review (C-PLR) for people living with dementia and their family caregivers in 2018 and pilot-tested (N=19 caregiver (CG)-care recipient (CR) dyads). Encouraged by the outcomes, in 2020 we expanded the study to long-term care facility (LTCF) residents. Due to the COVID-19 pandemic, we adapted the in-person mode to virtual and recruited CGs who provided care for >8 hours/ week and CRs who were community-dwellers or LTCF residents with mild depression and dementia. Between August 2020 and December 2021, we contacted 195 LTCFs, 29 senior/community centers, and 148 community-dwellers and recruited 12 dyads nationwide. CGs were on average 54 years old, working (67%), college-educated (83%), female (92%), and in good-excellent health (75%). CRs were 83 years old (mean), single (58%), female (92%), and in fair health (50%). CRs' depression score significantly improved ($p=0.0004$), however, CG's burden and positive aspects of caregiving scores worsened ($p=0.02$). Amid the pandemic, LTCF closures and staff turnover made recruitment challenging. Despite a small sample, we found CRs enjoy the LRs alleviating depressive symptoms. However, CGs experienced more burden, which could be due to COVID fatigue and the LR as an additional responsibility. These results reminded us of the COVID impact and adjusted the C-PLR model further. Instead of a weekly visit, each dyad can meet at its own pace. We developed the C-PLR to improve the health of the dyads. Thus, we must consider both CGs' and CRs' health capacity because CR's wellbeing is dependent on that of CGs.

SUPPORTING DEMENTIA CAREGIVERS IN HEALTHCARE DELIVERY: RECOMMENDATIONS FROM A NATIONAL CONSENSUS CONFERENCE

Catherine Riffin[1], Joan Griffin[2], Lauren Bangerter[3], Lilla Brody[4], Francesca Falzarano[5], Karl Pillemer[6], Sara Czaja[7], and Ronald Adelman[7], *1. Weill Cornell Medical College, New York, New York, United States, 2. Mayo Clinic, Rochester, Minnesota, United States, 3. United Health Group, Edina, Minnesota, United States, 4. Weill Cornell Medicine, New York, New York, United States, 5. Weill Cornell Medicine, Douglaston, New York, United States, 6. Cornell University, Ithaca, New York, United States, 7. Weill Cornell Medicine, New York City, New York, United States*

More than 6 million adults in the United States are affected by Alzheimer's Disease and related dementias (ADRD), the majority of whom rely on assistance from an unpaid caregiver (family, friends). The goal of the 2021 Conference on Engaging Family and Other Unpaid Caregivers of Persons with Dementia in Healthcare Delivery, funded by the National Institute on Aging, was to establish a policy- and practice-aligned research agenda for enhancing ADRD caregiver engagement and support in healthcare settings. The Conference convened multidisciplinary thought leaders from across the United States to establish a set of actionable recommendations to advance the field. Recommendations centered on five key topics: 1) Identification and assessment of ADRD caregivers, 2) Reimbursement and financing for provider time spent on ADRD caregiver, identification, assessment, and support, 3) ADRD caregiver training and support, 4) Healthcare provider education, and 5) Technology. To support future work in each of the five priority areas, conference participants highlighted the importance of leveraging lessons from implementation science and models of equity and inclusion. Recommendations are intended to inform federal agencies and foundations about high-priority areas and motivate multidisciplinary collaborations to design care delivery systems that effectively engage and support ADRD caregivers.

UNDERSTANDING CHALLENGES AND STRENGTHS EXPERIENCED BY CHINESE AMERICAN FAMILY CAREGIVERS OF PERSONS WITH DEMENTIA

Jessica Cassidy[1], and Kathy Lee[2], *1. University of Texas at Arlington, Arlington, Texas, United States, 2. University of Texas at Arlington, Coppell, Texas, United States*

Chinese American family caregivers of persons with dementia are often challenged by barriers to utilize caregiving support services due to language barriers, minimal understanding of dementia, limited numbers of culturally competent health care providers, as well as conflicting cultural norms, such as the disease related stigma. Subsequently, a delayed diagnosis and a hesitance to seek social support services and formal resources are prevalent among Chinese American families caring for persons with dementia. However, the resilience of these caregivers is often noted as a strength of this sub-population. We aimed to identify the challenges and strengths expressed by Chinese American family caregivers caring for persons with dementia by exploring their caregiving experiences. Using a qualitative study design, we conducted semi-structured, in-depth interviews with 26 Chinese American family caregivers of persons with dementia during the midst of COVID-19 pandemic. The data were analyzed using thematic analysis. Two themes emerged as challenges: lack of knowledge regarding early signs of dementia and family caregivers' social isolation and loneliness. Two additional themes emerged as demonstrated strengths: utilizing technology throughout the caregiving trajectory and family caregivers' helping behaviors. Our findings indicate potential to promote disease-related education and reduce feelings of social isolation and loneliness among Chinese family caregivers caring for persons with dementia by using technology and peer-led approaches. The examined coping strategies of Chinese American caregivers may be leveraged across disciplines to increase disease related knowledge, rates of early diagnosis, as well as the utilization of formal supports and resources.

"HE JUST WANTS HIS SERVICES BACK": IMPACTS OF HOME CARE WORKER DISRUPTIONS ON PATIENTS AND CAREGIVERS DURING COVID-19

Emily Xu[1], Patricia Kim[1], Meng Zhang[1], Jennifer Reckrey[1], Katherine Ornstein[2], and Emily Franzosa[1], *1. Icahn School of Medicine at Mount Sinai, New York, New York, United States, 2. Johns Hopkins University, Baltimore, Maryland, United States*

Home care workers (HCWs) have played a critical role in keeping homebound older adults safely at home during COVID-19, yet their essential work is often understudied. This study characterized the roles of HCWs during COVID-19 and examined how HCW service disruptions impacted patients and their caregivers. We performed a thematic analysis of medical records from 53 patients with HCWs in a home-based primary care practice in New York City. We abstracted unstructured clinical notes into a priori and emergent categories and identified core themes via team discussion. The following themes emerged: 1) Shifts to remote medical care and changing patient needs led to task shifting and new tasks for HCWs (i.e. getting food for patients experiencing food insecurity), 2) The risks associated with HCW tasks, such as exposure from caring for patients with COVID-19, increased during the pandemic, 3) Patient and family refusal of HCW services to avoid COVID-19 exposure as well as abrupt loss of HCW services due to HCW precarity or COVID-19 exposure left family caregivers with additional caregiving responsibilities, 4) Regulations surrounding return to work following COVID-19 exposure created additional difficulties in reinstating HCWs and left patients without adequate care, putting them at risk of hospitalization. In conclusion, pandemic-related disruptions created barriers to adequate home care, putting both patients and caregivers at risk. This analysis suggests a need for more robust HCW training and established regulations to protect HCW safety as well as a need for policies to support caregivers and ensure continuity of care during emergencies.

SOMEBODY ELSE TO THINK ABOUT BESIDES MYSELF: VOLUNTEER EXPERIENCES WITH THE CARING CALLERS PROGRAM DURING COVID-19

Noelle Fields[1], Kathy Lee[2], and Jessica Cassidy[3], *1. The University of Texas at Arlington, Arlington, Texas, United States, 2. University of Texas at Arlington, Coppell, Texas, United States, 3. University of Texas at Arlington, Arlington, Texas, United States*

Social distancing during COVID-19 had significant implications for older adults, a subpopulation already at greater risk of social isolation and loneliness prior to the pandemic. Emerging evidence showed promise for implementing peer- and volunteer-led, telephone-based support programs in collaboration with community agencies to reach older adults at-risk for loneliness. Given a need for research in this area, the Caring Callers Program was developed as a telephone-based intervention using Senior Companion volunteers for at-risk older adults in a large metropolitan area in Texas. Volunteers were provided training via zoom to prepare them to provide supportive, weekly calls as well as to share community resources with their Caring Callers clients. The purpose of this study was to qualitatively explore the experiences of Senior Companion volunteers (N = 20) in the Caring Caller Program through the lens of productive aging. Rapid and Rigorous Qualitative Date Analysis (RADaR) was used to analyze the data and yielded four themes: 1) reciprocity, reflecting how volunteers described the program mutually benefited their feelings of well-being as well as, those contacted.; 2) purposeful use of time, illustrating how the volunteers perceived their role as meaningful and fulfilled their value for civic duty; 3) learning new skills, such as active listening skills; and 4) gaining perspective, capturing how the volunteers gained new inspiration from their experiences in the program. Recommendations for future research and strategies for designing peer-led, telephone-based interventions to promote social connectedness among both older volunteers and socially isolated older adults are offered.

TRANSFERS, DIFFICULTIES, AND CARE STRESS AMONG FAMILY CAREGIVERS OF OLDER ADULTS LIVING WITH DISABILITIES IN CHINA

Lirong Yue, Shuangshuang Wang, and Nengliang Yao, *Shandong University, Jinan, Shandong, China (People's Republic)*

Family caregivers are critical sources of support to older adults living with disabilities, but they also need to cope with caregiving stress and difficulties brought by the caregiving process. This study aimed to explore the associations between family transfers (i.e., time transfer and financial transfer), perceived difficulties of caregiving, and caregiving stress among family caregivers of older adults living with disabilities. Respondents were randomly selected from 6 urban districts and 6 rural towns in Shandong province, China. Data from 220 older adults living with disabilities and their family caregivers were analyzed. Caregiving stress were divided into three categories (mild stress, moderate stress and high stress). Difficulties were divided into four categories (insufficient care abilities, economic hardship, time conflicts, and inadequate nursing equipment). Family caregivers reported moderate to high levels of caregiving stress. Results from multivariate ordinal logistic regression shows that family caregivers providing nine or more hours of care per day reported higher levels of caregiving stress than those who provided 8 or less hours of care per day (9 to 12 hours: OR=2.92, p<.05; 13 to 16 hours: OR=2.66, p<.05). Caregivers who perceived insufficient care abilities, economic hardship, and time conflicts were more likely to report caregiving stress. Respites in the forms of caregiver support group and day care attendance for older adults living with disabilities may reduce caregiver stress. Educational program and professional knowledge training courses may be helpful in reducing caregiving stress. The long-term care insurance system should be promoted to provide social support for family caregivers.

DYADIC COPING AND WELL-BEING AMONG COUPLES TAKING CARE OF EACH OTHER

Vivian Wei Qun Lou[1], Huiying Liu[2], and Wenmiao Wu[1], *1. The University of Hong Kong, Hong Kong, Hong Kong, 2. Central South University, Chang Sha, Hunan, China (People's Republic)*

Background: In the context of population aging, more and more couples would have the chance to taking care of each other when one or both of them experience functioning decline. Objective: Taking a dyadic perspective, the objective of this study is to examine collaborative dynamics in mastering daily stressors, and the relationship between couples' practice of dyadic coping and individual well-being. Method: A total of 77 dyads were recruited from community elderly centres located in four different geographic locations of Hong Kong. Potential participants who met the following inclusion criteria: (1) both partners aged 60 or above; (2) both partners living alone in the same household; (3) one or both partners reporting at least one limitation in performing ADLs and/or IADLs, were invited to complete a survey questionnaire interviewed by trained researchers. Standardized measures by Dyadic Coping Inventory (DCI), Centre for Epidemiological Studies-Depression Scale (CES-D), EQ-5D, and Relationship Assessment Scale (RAS), respectively. The Actor-Partner Interdependence Model (APIM) framework was used for data analysis. Findings: The most adopted collaborative coping strategies were non-negative dyadic coping of oneself, non-negative dyadic coping of the partner, and common dyadic coping. Supportive and delegated dyadic coping strategies were strongly associated with marital satisfaction and health-related quality of life.

Conclusion: Collaborative dynamics among couples when one or both experience functional impairment is associated with quality of relationship. The findings advocate a shift from individual-based stress process on caregiving to a dyadic-based process that address joint needs of both spouses in super-aging societies globally.Funding: RGC 17605119

UNDERSTANDING STROKE SURVIVOR–CARER DYNAMICS USING THE ACTOR-PARTNER INTERDEPENDENCE MODEL: A SYSTEMATIC REVIEW

Esther Chow, and Sai-fu Fung, *City University of Hong Kong, Kowloon, Hong Kong*

Background: Family members often take on the caregiver roles to stroke survivors due to kinships and cultural responsibilities. Yet, little is known about the the impact of survivor-caregiver dynamics on stroke rehabilitation. To understand the dyadic relationships between the dyads, a systematic review was conducted to examine studies which have adopted Actor–Partner Interdependence Model (APIM) analysis.

Methods: A systematic review and meta-analysis were conducted using the following electronic databases: PubMed, SAGE Journals, MEDLINE, PsycINFO and Cochrane Review to identify eligible studies published from their inception to December 2021, following the PRISMA guidelines.

Results: Nine studies involving 1183 stroke survivors (male = 57%) and 1181 caregivers (male = 37%) had met the inclusion criteria and were identified in this review. The interaction among the following outcomes were self-esteem, optimism, stress, depression, emotional distress, quality of life, and life satisfaction. The review provided evidence that (1) APIM is valuable tool in analyzing dyadic interactions; (2) support from caregivers has a significant impact on the stroke survivor's recovery; (3) the mental health status of caregivers can influence that of stroke survivors and vice versa; (4) Due to the interconnected nature of dyadic interaction, providing dyadic intervention have positive impact on dyads.

Conclusion: These findings highlight the interdependence nature between survivor-caregiver dyads in the context of stroke rehabilitation. The APIM provides conclusive evidence on the effectiveness of survivor-caregiver dyadic interactions, with significant theoretical and practice implications for both health and social care professions. More research is needed to support dyadic strategies for stroke survivors.

CARING FOR THOSE WHO CARE: EVALUATION OF A COMPREHENSIVE CULTURAL COMPETENCY TRAINING CURRICULUM

Sara Powers[1], Rachel Cannon[1], David Bass[1], Lauren Pongan[2], Ocean Le[2], and Nina Darby[2], *1. The Benjamin Rose Institute on Aging, Cleveland, Ohio, United States, 2. Diverse Elders Coalition, New York, New York, United States*

By 2030, nearly 3 in 10 older Americans will identify as a member of a diverse or underrepresented group. To better support diverse, aging communities and help professionals meet the growing needs of family and friend caregivers, the Diverse Elders Coalition developed a comprehensive cultural competency training curriculum that, in the first year of development, engaged over 2,500 healthcare and social service providers. To evaluate the short and long-term impact of the training curriculum, this paper focuses on two types of anonymous evaluations that were electronically distributed to training attendees: 1) Subjective knowledge post-tests (n=162), and 2) 3-month post-training follow-ups (n=232). Majority of participants identified as female, White/Caucasian, and earned at least a college degree. Upon completion of the trainings, participants reported improved subjective knowledge about diverse communities, more confidence and preparedness to meet diverse caregivers' needs, and also indicated that because of the training they would engage in a variety of diversity related actions (e.g., use more inclusive language, share training resources with colleagues, attend additional diversity trainings). At the 3-month follow-up, 91.8% of respondents reported they engaged in two or more diversity related actions since attending the training. Respondents (73.8%) also indicated that their organization engaged in one or more diversity-related actions since attending the training (e.g., provided staff additional diversity-related trainings, translated materials). Discussion will focus on ways to improve healthcare and social service providers' advocacy efforts and awareness surrounding the needs of older adults and caregivers from diverse communities.

FACTORS PREDICTING FAMILY MEMBER PROVISION OF ASSISTANCE WITH ACTIVITIES OF DAILY LIVING FOR SENIORS

Joanne Spetz, and Leslie Ross, *University of California, San Francisco, San Francisco, California, United States*

The aging of the U.S. population is leading to greater demand for assistance with activities of daily living. Much of this support is provided by family members, but changing family sizes and locations have raised concern that those needing support will be increasingly reliant on non-family assistance. This study examined patterns of provision of family, non-family, and paid caregiving to those 65 years and older who need assistance with activities of daily living, focusing on the impact of geographic location. We used the National Health and Aging Trends Study Restricted Metro-Nonmetro round five data file. We identified individuals who needed assistance with activities of daily living and/or instrumental activities of daily living. We merged information about the primary survey respondent (subject person, or SP) with data on "other people" (OP) in their supportive network, excluding spouses living with the respondents because nearly all spouses provided support. The final analytic data file consisted of 5,234 unique SPs. We used weighted and unweighted bivariate analyses as well as weighted multivariate logistic regression models to examine the association of family or non-family support and geographical location. We found that SPs who never were unmarried were more likely to have a non-spouse family helper compared to those married or living with a partner. Family who lived near the SP had a greater likelihood of providing help. SPs who were Black, non-Hispanic, multi-racial, and other non-Hispanic had more than twice the likelihood of having a family member helping them compared to White non-Hispanic SPs.

AN EXPLORATORY DESCRIPTIVE STUDY OF CARE PARTNERS' PREFERENCES AND SKILL TRAINING NEEDS DURING HOSPITAL CARE

Kaitlyn Vanias[1], Andrea Yahr[2], and Beth Fields, *1. University of Wisconsin-Madison, Madison, Wisconsin, United States, 2. Geriatric Health Services Research Lab, Madison, Wisconsin, United States*

Care partners play a critical role in caring for an increasingly complex, aging population in the United States after hospital discharge. However, care partners' preferences and needs are often not formally assessed during their loved one's hospitalization. The Care Partner Hospital Assessment Tool (CHAT) is a standardized decision-support tool that facilitates the inclusion and training of care partners during hospital care. The purpose of this exploratory descriptive study was to understand the preferences and needs of 12 care partners of older adult patients admitted to a large academic hospital utilizing the CHAT. The majority (8 of 12) of care partners surveyed were spouses while the remainder were adult children of the patients. All care partners provided comparable support including physical and social support as well as healthcare management. Despite providing similar support, there were differences in the care preferences and needs of spouses compared to adult children. A greater proportion of spouses preferred to be present for care in the hospital and requested information on adaptive equipment and community services. All adult children desired access to the electronic medical record while there was a mixed response among spouses. The most common needs across care partners included training on mobility assistance and medical devices. Findings from this study demonstrate that care partners have varying preferences and training needs during hospital care and suggest differences across care partner relationships. Further investigation is necessary to better understand these patterns and improve hospital care for patients and their care partners.

ASIAN AMERICAN FAMILY CAREGIVING EXPERIENCES COMPARED TO CAREGIVERS OF OTHER RACIAL/ETHNIC GROUPS

Christina Miyawaki[1], and Erin Bouldin[2], *1. University of Houston, Houston, Texas, United States, 2. University of Utah, Salt Lake City, Utah, United States*

Asian Americans (AAs) are the fastest-growing immigrant group in the U.S. While otherwise highly heterogeneous, AAs value filial piety and eldercare. This study compared the prevalence, health, and caregiving experiences of AA caregivers (18+ years) to AA non-caregivers and caregivers in other racial/ethnic groups. Data from the 2015-2019 Behavioral Risk Factor Surveillance System were used (N=252,602). Caregivers were classified as those who provided care/assistance to a parent/parent-in-law/grandparent with a long-term illness/disability. Chi-square tests were used to compare weighted estimates. Among 4,564 AAs, 4.1% (n=321) were caregivers. They were single (55.6%), college-educated (84.2%), working (64.7%), young (< 45 years) (68.2%), male (60.0%), and in excellent/very good/good health (86.3%). Compared to non-caregivers, caregivers were more often unmarried with more chronic health conditions. They assisted a parent/parent-in-law (73.4%) with personal care (52.7%) and household tasks (77.9%). Although overall caregiving experiences were similar across racial/ethnic groups, the prevalence of caregivers was higher among other racial/ethnic groups than AAs (8.3%, Hispanic to 14.8%, American Indian/Alaska Native, $p< 0.001$), which was a surprise due to their caregiving culture. Because caregiving is expected, they may not identify themselves as caregivers. The data were collected in English and Spanish but 44% of AAs had limited English proficiency. Those limitations may have affected the sample size. Despite the limitations, this study was unique because of the comparison among different racial/ethnic groups of caregivers across the nation. However, to examine a full picture of AA caregivers, we need to administer surveys for each AA ethnic group in various languages.

IMPLICATION OF SLEEPING DURATION ON THE OVERALL HEALTH STATE OF FAMILY CAREGIVERS

Babatope Ogunjesa[1], Andiara Schwingel[2],
Tosun Ozgur[3], and Alice Oloo[2], *1. University of*

Illinois--Urbana-Champaign, Champaign, Illinois, United States, 2. University of Illinois, Urbana Champaign, Urbana Champaign, Illinois, United States, 3. Near East University, Nicosia, Nicosia, Cyprus

Family caregiving is integral to long-term care for older adults. The National Alliance for Caregiving and AARP Public Policy Institute in 2020 estimated there are 53 million Americans providing care for loved ones. Caregiving intensity often impacts the health and well-being of caregivers, including influencing their sleep duration. The Centers for Disease Control and Prevention (CDC) recommended an average of 7 or more sleeping hours for adults. Unfortunately, most caregivers' average hours of sleep per night do not meet this recommendation. Using secondary data from the Long-Term Caregiving study conducted by the AP-NORC Center for Public Affairs Research, the present study establishes the effect of sleep duration on the overall health of family caregivers while adjusting for socio-demographic factors. A binary logistic analysis was conducted to infer the effects of sleep duration, age, gender education, race, employment status, and household income relative to reporting high or low overall health wellbeing. The binary logistic model was statistically significant, $\chi 2(16) = 77.5$, $p < .0001$, Nagelkerke R2=0.111. Family caregivers with a sleeping duration of 7 hours or more were twice as likely to report a high overall health status than those who slept less than 7 hours (OR=2.08, 95%CI [1.52 – 2.84]). Increasing household income and being employed were positively associated with high overall health status. We do not find a statistically significant effect of gender, education level, age group, and race on overall health status. We recommend that policies that support family caregivers at a micro and macro level be implemented.

CULTURALLY CONCORDANT CARE: CLINICIAN PERSPECTIVES ON PROVIDING CANCER CARE TO SOUTH ASIANS

Nainwant Singh[1], Veena Manja[1], Ambri Pukhraj[2], Rashmi Risbud[3], Shreya Desai[4], Lidia Schapira[2], Karl Lorenz[5], and Ranak Trivedi[6], *1. VA Palo Alto, Palo Alto, California, United States, 2. Stanford University, Stanford, California, United States, 3. University of California, Davis, Davis, California, United States, 4. Veterans Affairs Palo Alto Health Care System, Menlo Park, California, United States, 5. Veteran Affairs Palo Alto Health Care System, Stanford, California, United States, 6. Stanford University, Palo Alto, California, United States*

In many South Asian (SA) cultures, cancer is stigmatized, and family members are expected to become primary caregivers. Clinicians need to be familiar with these SA needs and values to provide culturally concordant care. The South Asian Family Approaches to Disease (SAFAD) study aims to understand cultural needs of SAs managing breast cancer. We conducted semi-structured qualitative interviews with multidisciplinary clinicians at a major academic medical center about caregiver interactions, cultural dynamics affecting clinical practice, unmet patient needs, and perceptions of culturally concordant care. Participants included physicians(8), a nurse practitioner(1), a social worker(1), and a physician assistant(1) with experience in palliative care(5), hematology/oncology(4), breast cancer(3), critical care(2), and radiation oncology(1) with one to 42 years in practice. Participants identified as Caucasian/White(6), South Asian(3), African American/Black(1), and Chinese(1). Clinicians noted the following: 1)SAs have greater family involvement in care and may defer treatment decisions to family members; 2)SAs seek clinician support with cancer management and nutrition; 3)SA emotions and hesitation around sensitive topics may result in non-disclosure; 4)SAs have diverse caregiver roles; and 5)individual SA needs cannot be generalized within the diaspora. “There’s still some stigma… with breast cancer… [it] may lead a patient to not want to share their diagnosis… then set up a patient for having less support… [We can] help them feel more comfortable opening up selectively.” Understanding such cultural needs is essential to cultivating trust and providing person-centered care. Interventions and resources to promote culturally concordant cancer care can target education in these areas.

THE APPLICATION OF TIME BANKING IN ELDERLY CARING: A MIXED-STUDIES SYSTEMATIC REVIEW

Hui Ding[1], and Hui-Ling Li[2], *1. Soochow University, Suzhou, Jiangsu, China (People's Republic), 2. School of Nursing, Suzhou Medical College, Soochow University, Suzhou, Jiangsu, China (People's Republic)*

Aging has become a universal concern of the world, and its process is accelerating, which leads to the shortage of the care resources and increased burden of social development. Based on this problem, The concept of time banking has been gradually applied to geriatric caring, forming a model of mutual support for older people, which has been practiced in different countries. However, there is no consensus about the effect of time banking for older person. Thus, the aim of this review was to integrate research on the application of time banking to summarize the benefits for older people and challenges faced in different countries. Moreover, the review put forward solutions to provide references for the localization of time banking in China. PubMed, Wiley Online Library, Web of Science, SAGE Journals Online, Science Direct, EbscoHost, SpringerLink and CNKI databases were searched to include 22 eligible studies. Qualities of included studies were assessed, evidences about the benefits for older person and challenges regarding time banking was synthesized. Although the overall study quality was medium, consistent evidence was existed to indicate that time banking has beneficial effects which containing social values and personal values on the older people. Furthermore, the comprehensive evidences also showed that time banking would be improved in the following four aspects: diversity of volunteers, improvement of service quality, variety of incentives and scientific management. Additional well-designed and high-quality studies are needed for us to better understand the opportunities and challenges of time banking.

EXAMINATION OF THE HEALTHY CAREGIVER EFFECT AMONG OLDER ADULTS FINDING FROM THE CANADIAN LONGITUDINAL STUDY ON AGING

Lun Li[1], Andrew Wister[2], and Barbara Mitchell[2], *1. MacEwan University, Edmonton, Alberta, Canada, 2. Simon Fraser University, Vancouver, British Columbia, Canada*

Objective. The Healthy Caregiver Hypothesis (HCH) suggests that caregiving is associated with beneficial health impacts for family caregivers. However, mixed results have been reported, particularly when different levels of caregiving intensity were examined. This study analyzes the relationship between caregiving intensity and three health indicators (functional health, chronic illness, and self-rated general health) among Canadian older adults over three years. Method. We drew upon a sub-sample of 11,344 participants aged 65 and older from the Baseline and Follow-up 1 data of the Canadian Longitudinal Study on Aging and used linear mixed models to test the hypothesis based on different levels of caregiving intensity. Results. Older adults who provided low-intensity care recently or continuously reported better functional health and self-rated health than non-caregivers. In contrast, older adults with low-intensity caregiving responsibility developed more chronic conditions over time compared to non-caregivers, but this association was not found for high-intensity caregivers. Discussion. This study elucidates the HCH by incorporating caregiving intensity to understand patterns of better functional health and perceived health, but more chronic conditions. The findings yielded from different health indicators suggest the impact of caregiving on health may be domain specific.

SESSION 6540 (POSTER)

LONG TERM SERVICES AND SUPPORTS

COMORBIDITIES AMONG RESIDENTS DIAGNOSED WITH DEMENTIA IN RESIDENTIAL CARE COMMUNITIES

Christine Caffrey, Jessica Lendon, and Sengupta Manisha, *National Center for Health Statistics, Hyattsville, Maryland, United States*

Residential care communities (RCCs) are an important source of care for older adults, particularly those with dementia. Nationally in 2018, 34% of RCC residents had been diagnosed with dementia. Other common chronic conditions among RCC residents were high blood pressure (55%), depression (27%), arthritis (20%), diabetes (20%), and heart disease (17%). RCC residents with dementia who have comorbidities could present greater challenges when managing their care. This report presents national estimates of comorbidities among RCC residents with dementia and compares these estimates by selected characteristics. Estimates are from the 2018 National Post-acute and Long-term Care Study conducted by the National Center for Health Statistics. Among RCC residents with dementia, 62% had also been diagnosed with high blood pressure, 28% with depression, 23% with arthritis, 16% with diabetes, and 16% with heart disease. Among RCC residents with dementia, 17% were diagnosed with only dementia, 38% were diagnosed with dementia and one other common condition, 31% were diagnosed with dementia and two other conditions, and 14% were diagnosed with dementia and three to five other conditions. A greater percentage of RCC residents with dementia and two or more common conditions compared to only dementia or dementia and one other condition were aged 85 years and older (69% vs 62%), needed help with three or more activities of daily living (82% vs 73%), were hospitalized (34% vs 28%), and were taking more than 10 medications (48% vs 32%). Results may benefit efforts focused on implementing long-term care practices to manage dementia and comorbidities.

PERCEPTIONS OF DEMENTIA CARE AMONG AFRICAN IMMIGRANTS IN MINNESOTA: INSIGHTS FROM COMMUNITY CONVERSATIONS

Hawking Yam[1], Manka Nkimbeng[1], Christina Rosebush[1], Wynfred Russel[2], Tetyana Shippee[1], and Joseph Gaugler[1], *1. University of Minnesota, Minneapolis, Minnesota, United States, 2. African Career Education And Resources Inc. (ACER), Brooklyn Park, Minnesota, United States*

Immigrants and persons from diverse racial and ethnic backgrounds have a higher prevalence of dementia compared with their U.S.-born counterparts, yet the estimates of dementia prevalence, perceptions, and needs among African immigrants are not fully understood. This qualitative study examined African immigrants' perceptions of dementia and dementia care. Specifically, it explored the community's attitudes, care practices, and barriers toward dementia care. Community conversations (focus groups) were conducted with 24 African immigrants residing in the Northwest Minneapolis suburbs. Conversation transcripts were analyzed using thematic analysis in Nvivo. The majority of participants were women, 79% from Liberia, 43% were over the age of 65 years, and 65% held a bachelor's degree or higher. Three themes were identified: 1) Perceptions of and attitudes toward mental health and dementia, which indicated that cultural issues limit awareness of dementia, but 2) Family care of a person living with dementia, meaning care happens in the home, and receiving care in a facility is the last resort; 3) Facilitators and barriers to dementia care, including distrust of health systems, immigrant status, and limited finances. This project offers unique insights on the dementia care and caregiving beliefs and attitudes among African immigrants that can inform policy and intervention efforts aimed at decreasing dementia care barriers in the African immigrant community.

THE DEVELOPMENT OF AN UNMET NEEDS APPRAISAL SCALE FOR LONG-TERM CARE SERVICE USERS

Ya-Mei Chen, Shih-Cyuan Wu, Zi-Ting Zhong, and Yu-Chien Chang, *National Taiwan University, Taipei City, Taipei, Taiwan (Republic of China)*

Background: Taiwan's Long-Term Care (LTC) Plans 1.0 and 2.0 aimed to provide accessible LTC services since 2007. Currently, >40% of the people needing LTC are covered by these plans. Past studies have indicated that high unmet needs among LTC users may lead to adverse outcomes. Thus, whether the LTC services meet the needs of both the care recipients and their family caregivers merits further study. The purpose of this study was to develop a suitable "unmet needs appraisal scale (UNAS) for long-term care service users" and pilot test this tool on older Taiwanese adults.

Methods: The tool was developed through a systematic literature review. The tool underwent two rounds of the Delphi method with 26 experts, and the tool reached a high consensus among the experts. The UNAS includes 11 items assessing activities that need more assistance, including daily activities, psychological health, and spiritual health. We pilot tested the tool in older Taiwanese adults and examined the tool properties, including reliability and validity. We included short-form 8 as a concurrent validity measure. Result: The survey was conducted in 6 counties, and 255 service user questionnaires were collected. The overall Cronbach's α value was 0.91, indicating good internal consistency. Our confirmatory factor analysis also showed good construct validity [$\chi 2 = 146.514$, $p < 0.001$, CFI = 0.98, RMSEA = 0.06, SRMR = 0.02]. The UNAS scores showed a moderate negative correlation with quality of life scores ($r = -0.452$, $p < 0.001$), demonstrating good concurrent validity of the unmet needs scale.

LONG-TERM CARE RESIDENT PERSPECTIVES ON PERSON-CENTERED CARE: INTERSECTIONS OF PRACTICE AND THEORY

Mary Lou Ciolfi[1], Catherine Taylor[2], Tracy Ericson[3], David Wihry[4], Jennifer Crittenden[5], Angela Hunt[3], Lenard Kaye[2], and Paul Nebenzahl[6], *1. University of Maine Center on Aging, Bangor, Maine, United States, 2. University of Maine, Bangor, Maine, United States, 3. The Cedars, Portland, Maine, United States, 4. University of Maine, Orono, Maine, United States, 5. UMaine Center on Aging, Bangor, Maine, United States, 6. The Mayer-Rothschild Foundation, Chicago, Illinois, United States*

The Designation of Excellence in Person-Centered Long-Term Care is a multi-year study to redefine standards of long-term care delivery according to the preferences of residents, family, staff, and leaders. During 2021, as one component of the study, 247 residents from 23 communities across the country engaged in a participatory message board activity inquiring about their lived experiences of receiving care and services in their long-term care communities. Residents commented on their personal care, personal and shared spaces; family, friends, and community; and wishes and feelings. Using a phenomenological approach to data analysis to better understand the universal and the unique aspects of the experience of living in long-term care, key themes centered on the importance of staff (1) knowing, responding, and being attentive to the details of residents' life history, care needs and preferences; (2) treating residents respectfully and as mature adults; and (3) demonstrating care and connection in resident interactions. These key themes and their related sub-themes intersect with several social science theories that underscore those factors promoting adaptability to changed environments while trying to preserve identity, belief systems, and values. Applying a conceptual lens to resident comments suggests programmatic strategies that long-term care providers can prioritize for promoting and operationalizing person-centered care. The poster will present a graphic representation of the intersections of person-centered care and existing theoretical frameworks using resident remarks to highlight central tenets of continuity theory, person-environment fit theory, and social identity theory.

A SCOPING REVIEW OF HOW NURSING HOME STAFFING LEVELS AND QUALITY OF CARE ARE MEASURED

Mutian Zhang, Shelby Brown, Weizhou Tang, and Reginald Tucker-Seeley, *University of Southern California, Los Angele, California, United States*

The Centers for Medicare & Medicaid Services (CMS) is the largest payer of nursing home care in the US. CMS defines staffing levels as hours per resident day (HPRD) and staff turnover rates; it defines quality of care as nurse staffing levels, hospitalization rates, resident outcomes, and deficiencies (violations of regulations). However, these definitions have been inconsistently applied in the research literature, which has led to equivocal results in research on the association between staffing levels and the quality of care in nursing homes. We conducted a scoping review of how nursing home staffing levels and quality of care have been defined and measured in the research literature, guided by the PRISMA (Preferred Reporting Items for Systematically reviews and Meta-Analyses) framework. Out of the N=423 initially identified studies through PubMed, N=67 articles were selected, based upon the following inclusion criteria: 1) published after January 1, 2010; 2) published in the US; 3) focused on determinants of nursing home staffing levels or determinants of quality of care. Two independent reviewers conducted abstract screening and data extraction. The findings from our review showed that approximately 50% of studies partially adopted the definitions from CMS. For example, HPRD and deficiencies were utilized to measure staffing levels and quality of care in N=37 and N=12 studies, but none of them included all suggested measures. Future studies should carefully consider the approriate definitions as specific measures can yield contradictory associations between staffing level and quality of care, easily leading to confusion for policymakers.

REGULATORY COMPLIANCE AND RESIDENT OUTCOMES IN OREGON ASSISTED LIVING COMMUNITIES

Ozcan Tunalilar[1], Sunny Lin[2], and Paula Carder[1], *1. Portland State University, Portland, Oregon, United States, 2. Washington University School of Medicine in St. Louis, St. Louis, Missouri, United States*

The outsized negative impact of the COVID-19 pandemic among residents of assisted living (AL) communities has drawn attention to the existing challenges that licensing agencies face in providing oversight in this setting. While regulatory compliance inspections in AL may be a critical tool for promoting high-quality care, no published research has examined the association between deficiencies and resident outcomes in AL. Using novel data collected from 331 AL communities in Oregon (response rate=62%) merged with deficiency data from inspections, we examined whether the number of deficiencies is associated with the following resident outcomes as measured at the community level: share of residents who fell at least one time (fall rate), who were hospitalized overnight (hospitalization rate), and who were treated in the hospital emergency room (ER rate) in the last 90 days. Negative binomial regression models that controlled for a robust set of community (e.g., size, rurality, profit status, "memory care" units) and resident (e.g., age, Medicaid use, ADL needs) characteristics showed a weak, but statistically significant, association between deficiencies and hospitalization rate (IRR=1.05). However, there was no statistically significant association between deficiencies and falls or ER visits among residents. The time lag between inspections and the resident outcome data did not moderate these observed associations. With more states moving to make available such deficiency data on public-facing websites, these results have policy implications for the role and content of regulatory compliance inspections for ensuring quality in AL communities and informing the public.

NOWHERE ELSE TO GO: EFFECTIVENESS OF THE PASRR PROGRAM TO MEET THE NEEDS OF RESIDENTS WITH SMI ADMITTED TO NURSING HOMES

Taylor Bucy[1], Tetyana Shippee[2], Mark Woodhouse[2], John Bowblis[3], Shekinah Fashaw-Walters[1], and Nathan Shippee[1], *1. University of Minnesota School of Public Health, Minneapolis, Minnesota, United States, 2. University of Minnesota, Minneapolis, Minnesota, United States, 3. Miami University, Oxford, Ohio, United States*

The number of adults with serious mental illness (SMI) who receive care in nursing homes (NHs) continues to rise. The Preadmission Screening and Resident Review (PASRR) program requires screening for SMI prior to NH placement, in order to avoid inappropriate admission and unnecessary institutional care. We interviewed staff responsible for the processing of PASRR documentation at four NHs in Minnesota (n=15), and obtained and analyzed all completed PASRR-II assessments in Minnesota from 2019 (N=532). PASRR assessments overwhelmingly recommended 24-hour NH care (94.7%) with 94% of assessments indicating a need for mental health services while at the NH. Most NH staff interviewed noted that PASRR is not used in the care planning process and described PASRR as a regulatory hoop. Staff shared that PASRR assessments could provide insight into an individual's mental health history, current and future needs, and can be helpful in assessing NH capacity to provide such services. Although mental health services provided while at the NH are supposed to be facilitated in partnership with the county, there is a lack of follow-up and NH staff are largely left to deal with SMI in isolation. PASRR assessments are supposed to be a tool for care coordination, but leave the NH as the sole responsible point of contact for residents with SMI. A more integrated PASRR program that better focuses on incorporating PASRR into care planning and mental health service delivery in NHs and the broader community is necessary to improve the lives of individuals with SMI.

SERIOUS MENTAL ILLNESS IN MINNESOTA NURSING HOMES: THE ROLE OF RESIDENT AND FACILITY CHARACTERISTICS

Tetyana Shippee[1], Taylor Bucy[2], Weiwen Ng[2], Mark Woodhouse[1], Shekinah Fashaw-Walters[2], and John Bowblis[3], *1. University of Minnesota, Minneapolis, Minnesota, United States, 2. University of Minnesota School of Public Health, Minneapolis, Minnesota, United States, 3. Miami University, Oxford, Ohio, United States*

Multiple studies have shown an increasing prevalence of adults with serious mental illness (SMI) in nursing homes. As adults with SMI age, the reality of care needs that span physical, medical, and psychosocial services necessitates further consideration of the role of comprehensive, ancillary mental health services in nursing homes (NH). Yet, little work examines characteristics of those with SMI, their care needs & the role of facility structural factors. Using the 2011-2017 Minimum Dataset (MDS) assessment data for Minnesota, we examined resident-level demographic characteristics of NH residents with and without SMI, and facility-level characteristics including quality of life (QoL), quality of care (QoC), and state recertification survey scores. We defined SMI as a diagnosis of bipolar disorder, schizophrenia or schizoaffective disorder, or psychotic conditions other than schizophrenia present on the reference assessment. Individuals admitted with SMI were younger, had better physical health, were more likely to be racial/ethnic minorities, and more likely to be admitted to a facility with a higher proportion of racial/ethnic minority residents. SMI-only admissions were concentrated in larger, for-profit facilities with a high-reliance on Medicaid. Lastly, SMI-only admissions were more likely to occur in facilities with lower QoL, QoC, and inspection scores. There is a growing need for behavioral health services in NHs, yet access to services is inadequate and lacks equity based on geography, race/ethnicity and other system-level disparities.

NURSING HOME PALLIATIVE CARE DURING THE PANDEMIC: DIRECTIONS FOR THE FUTURE

Kacy Ninteau[1], and Christine Bishop[2], *1. Dana Farber Cancer Institute, Boston, Massachusetts, United States, 2. Brandeis University, Waltham, Massachusetts, United States*

For this qualitative, pilot study, seven Massachusetts nursing home Directors of Nursing (DONs) were interviewed remotely about palliative care provision before and during the COVID-19 pandemic. Interview data were analyzed using thematic analysis. Palliative care addresses physical, emotional, psychological, and spiritual suffering that accompanies serious illness. Symptom management and goals of care is especially valuable for seriously ill nursing home residents. We investigated the solutions nursing home staff developed to provide palliative care during the COVID-19 pandemic despite restrictions on external resources. Before the pandemic, palliative care was delivered primarily by nursing home staff depending on formal and informal consultations from palliative care specialists affiliated with hospice providers. When COVID-19 lockdowns precluded these consultations, nursing staff did their best to provide palliative care, but were often overwhelmed by shortfalls in resources, resident decline brought on by isolation and COVID-19 itself, and a sense that their expertise was lacking. Advance care planning conversations focused on hospitalization status and options for care given COVID-19 resource constraints. Nevertheless, nursing staff discovered previously untapped capacity to provide palliative care on-site as part of standard care, building trust of residents and families. Nursing staff rose to the palliative care challenge during the COVID-19 pandemic, albeit with great effort nursing home payment and quality standards should support development of in-house staff capacity to deliver palliative care while expanding access to the formal consultations and family involvement that were restricted by the pandemic.

ROLE OF ACTIVITY PROFESSIONALS IN APPLYING APIE MODEL TO ENHANCE RESIDENTS' ACTIVITY IN LONG-TERM CARE SETTINGS

xiaoli li, *University of North Texas, Frisco, Texas, United States*

Background: Residents' activity is a strong contributor to quality of life in long-term care facility. Hence, activity professionals (AP) have an essential role to play in enhancing resident activity and engagement. The service process of AP includes Assessment, Planning, Implementation, and Evaluation (APIE model). Although AP have made significant advances in demonstrating its value, few studies have focused on the APIE model for activity professionals. Method: A survey was conducted to help define the role of AP in using APIE in long-term care. Questionnaires were completed by 195 AP working as activity directors and activity staff in long-term care settings. The major factors studied were job background and certification, and performance of AP using the APIE model.

Results: Findings showed that 11.8% of AP only had a high school education, while 12.3% of participants had no certification and 9.2% of activity professionals had invalid certifications. When examining the APIE model, the activity professionals used person-centered approaches when they assessed residents` needs and wants, planned and implemented the activities, but lacked evaluation when measuring the outcomes, 79.5% of the participants were not tracking the number of minutes residents spent on activities, and 72.8% did not measure the impact of resident engagement on clinical outcomes such as falls, depression, cognition, and medication use.

Conclusion: Lack of professional training and meaningful evaluation could lead administrators to underestimate the value and role of activity professionals. The study advocates for applying APIE mode and increased evidence-based research on the benefits of residents` activity and engagement.

COMPLAINT PATTERNS IN US NURSING HOMES: 2013–2017

Kallol Kumar Bhattacharyya, and Victor Molinari,
University of South Florida, Tampa, Florida, United States

Nursing home (NH) quality of care is often short of meeting residents' and family expectations to maintain optimum quality of life. Using complaints as a facility-level outcome (i.e., complaints per NH), this study updates earlier published findings by replicating prior analyses with more recent data, and by analyzing the number of complaints, complaint allegations, and deficiency citations separately. This will allow us to determine whether any major change has taken place in the consumer complaint pattern in recent years. The result reveals, in the entire study period (2013-2017), overall, 458,101 complaints (5.9/NH/year) were identified that contain 949,466 allegations (12.2/NH/year), which resulted in the issuance of 156,135 deficiency citations (2.0/NH/year) in about 15,600 NHs across the country. Regarding the number of complaints, substantiated complaints, and deficiency citations, the results show a steady increase compared to previous years. Furthermore, there are marked differences among the ten CMS survey regions on the prevalence of overall complaints, substantiated complaints, and deficiency citations. The current study found a lower number of NHs with zero complaints and a higher number of NHs with five/more complaints in later years suggesting a steady increase in the number of complaints over the years. However, the average rate of substantiation of complaint allegations is showing a decreasing trend in recent years. This may be because people are now complaining more due to higher care expectations. Alternatively, it may be simply be because of the easier complaint lodging process developed in recent years. Other policy and practice implications will be discussed.

THE IMPACT OF DIFFERENT PATTERNS OF HOME- AND COMMUNITY-BASED SERVICES AND FACTORS ON MULTIDIMENSIONAL UNMET NEEDS

Ya-Mei Chen, Zi-Ting Zhong, and Shih-Cyuan Wu,
National Taiwan University, Taipei City, Taipei, Taiwan (Republic of China)

Background: Long-Term Care (LTC) in Taiwan has been implemented over the last 15 years, focusing on providing home- and community-based services (HCBS). Previous studies have shown that care recipients' level of unmet needs is associated with adverse health outcomes. This study aimed to identify HCBS use patterns among LTC care recipients and examine the impact of different patterns of HCBS on unmet needs.

Methods: Surveys of service users were conducted in eight counties. Latent class analysis was used to identify the underlying subgroups of LTC recipients. Multiple regression analysis was used to assess the impact of HCBS patterns and care recipients' predisposing, enabling, and need factors on the level of unmet needs.

Results: A total of 952 participants from northern, middle, and southern Taiwan completed the surveys. Three subgroups based on HCBS use were identified, including home-based personal care (HB-PC), home-based personal care and medical care (HB-PC/MC), and community care (CC). Care recipients in the HB-PC group ($\beta = -1.922$, $p = 0.028$) and the CC group ($\beta = -2.177$, $p = 0.019$) had lower unmet needs than those in the HB-PC/MC group. A lower disability level, living in a highly urbanized city, and lower levels of quality of life were associated with higher unmet needs ($p < 0.05$).

Conclusions: Our results demonstrating that care recipients with lower disability levels had higher unmet needs may indicate insufficient funding support from Taiwan's LTC plans. However, multiple service users had high unmet needs, which warrants further investigation.

ACTUAL AND DESIRED SERVICE USE OF COMMUNITY-DWELLING CONSUMERS OF HOME- AND COMMUNITY-BASED SERVICES

Taylor Bucy[1], John Mulcahy[2], Eric Jutkowitz[3], and Tetyana Shippee[2], *1. University of Minnesota School of Public Health, Minneapolis, Minnesota, United States, 2. University of Minnesota, Minneapolis, Minnesota, United States, 3. Brown University, Providence, Rhode Island, United States*

Federal and state long-term care policies are focused on helping people age in their community rather than in nursing homes or other institutional settings. Through home- and community-based (HCBS) waiver programs, states have the flexibility to target specific populations, providing supportive services meant to promote residence in the community. Although consumer needs and goals are a key component of HCBS delivery and effectiveness, little is known about how actual service use differs from the services individuals desire to meet their needs. Using the National Core Indicators-Aging and Disability (NCI-AD™) survey responses from 2018-2019 (N=14,202), an effort by state agencies to measure and track performance outcomes using standardized measures, we examined differences in actual versus desired use of HCBS among people living in the community. Services were categorized as delivered in home-based setting, day services, transportation, support/modification services, health and therapeutic services, and respite. Among NCI-AD respondents in the community (n=9,860), 11% used one service area, 49% used two service areas, and 36% used three or more service areas. The most common service area was home-based services (57%). About a third of community-dwelling respondents desired at least one additional service area. Factors significantly associated with wanting more services included being in combined Medicaid-Medicare, managed LTSS, a woman, an adult aged >65, living alone, and having a physical disability. While the majority of community-dwelling HCBS recipients do not list unmet service needs, there is heterogeneity by program category and other key demographic and social characteristics.

SESSION 6550 (POSTER)

PERSONALITY

PERSONALITY FUNCTIONING FEATURES OF CLINICAL ANXIETY AND COVID-19 ANXIETY AMONG OLDER ADULTS

Lisa Stone, Colleen Mock, and Daniel Segal, *University of Colorado Colorado Springs, Colorado Springs, Colorado, United States*

Introduction: Anxiety is a significant mental health problem among older adults and is commonly comorbid with personality disorders (PD). However, specific relationships between personality functioning (a proposed feature of PDs) and late-life anxiety remain unclear. This study examined relationships between two models of personality functioning with late life clinical anxiety and COVID-19 anxiety. Method: Older adults (n = 222) completed the Geriatric Anxiety Scale (GAS), Coronavirus Anxiety Scale (CAS), Levels of Personality Functioning Scale-Self-Report (LPFS-SR), and Severity Indices of Personality Problems-Short Form (SIPP-SF).

Results: The GAS and CAS were significantly correlated to all LPFS-SR and SIPP-SF domains with large effect sizes (> .78); higher clinical and COVID-19 anxiety was associated with increased personality dysfunction. In regressions, the LPFS-SR domains significantly accounted for 65% of variance in the GAS and 59% of variance in the CAS. Identity and Self-Direction were the strongest predictors of each anxiety scale, with Empathy also significantly related to coronavirus anxiety. The SIPP-SF domains significantly accounted for 65% of variance in the GAS and 58% of variance in the CAS. Responsibility and Social Concordance were the strongest predictors of each anxiety scale, with Self-Control also significantly related to clinical anxiety. Discussion: Results indicate theoretically-supported and meaningful overlap between clinical and COVID-19 anxiety with personality dysfunction according to two different models. This extensive overlap questions the extent to which personality functioning differentiates from affective distress. The two personality dysfunction models also differed somewhat in their relationships to anxiety, suggesting the need for further research especially among older adults.

MEASURING PERSONALITY IN DAILY LIFE: EVIDENCE FROM AN AGE-HETEROGENEOUS ADULT SAMPLE

Giselle Ferguson[1], Giancarlo Pasquini[2], Martin Sliwinski[3], and Stacey Scott[1], *1. Stony Brook University, Stony Brook, New York, United States, 2. Stony Brook University, Port Jefferson Station, New York, United States, 3. The Pennsylvania State University, University Park, Pennsylvania, United States*

Research on personality has theorized that repeated short-term experiences can lead to changes in personality traits across years or decades. Whereas much research on these short-term experiences relevant to personality has been done in samples of college students, this study intended to measure personality-relevant short-term experiences among an age-heterogeneous sample of adults. As part the Effects of Stress on Cognitive Aging, Physiology, and Emotions study, 260 participants (Mage=46.49 years, range=25-65 years) completed a measure of Big Five personality traits before completing a 14-day ecological momentary assessment (EMA) period during which participants reported their momentary negative and positive thoughts, emotions, and social interactions up to six times per day on study-provided smartphones. We hypothesized that these EMA reports could be used as daily markers of trait extraversion and trait neuroticism such that these daily experiences could be interpreted as manifestations of personality traits in daily life. Results of parallel multilevel confirmatory factor analyses showed good model fit (extraversion: CFI=0.96; TLI=0.95; RMSEA=0.03; neuroticism: CFI=0.95; TLI=0.94; RMSEA=0.04). For both extraversion and neuroticism, the latent trait factor and the latent daily-marker factor were positively correlated (extraversion: r=0.36; SE=0.07; p<.001; neuroticism: r=0.45; SE=0.07; p<.001). Results suggest that among an age-heterogeneous adult sample, momentary thoughts, feelings, and behaviors across a two-week period represented expressions of extraversion and neuroticism in daily life. Measuring these short-term experiences is meaningful for understanding how personality changes across adulthood, and future work can use longitudinal data to test if daily markers of personality are sensitive to fluctuations and changes in personality.

ADIPOSITY CHANGE IN ADULTS: THE IMPACT OF TRAIT NEUROTICISM

Jacob Alderson, Meredith Willard, and Nicholas Turiano, *West Virginia University, Morgantown, West Virginia, United States*

Increased body weight is a risk factor for poor health and shortened life expectancy. Thus, it is imperative to understand how body weight changes across adulthood and to identify factors that predict weight gain so effective prevention strategies can be implemented. It is well-known that eating habits and physical activity are two of the most important factors (along with genetic factors) contributing to weight gain. However, we seek to determine if personality levels predict weight gain because individual differences in personality are thought to be the root-cause of many behaviors related to weight gain. We utilized longitudinal data on over 6,000 adults (aged 20-75 at baseline) from the Midlife Development in the U.S. Study (MIDUS). The Big 5 personality traits, body weight, waist circumference, and body mass index were measured three times from 1995-2015. We estimated a growth curve model to determine whether each adiposity measure changed over 20 years, controlling for age, gender, and education. There was a significant increase in all adiposity measures over time. The rate of adiposity change over time varied among persons (random: weight b = 0.543; waist b = 0.008; BMI b = 0.009; p values < .05). Higher levels of neuroticism predicted this variability (fixed: weight b = 0.211; waist b = 0.027; BMI b = 0.029; p values < .05) such that those scoring higher in trait neuroticism had a steeper increase in all three adiposity measures. These findings suggest that personality traits are important in the progression of weight-gain in adults.

HEALTH LITERACY ACROSS PERSONALITY TRAITS AMONG OLDER ADULTS: CROSS-SECTIONAL EVIDENCE FROM SHARE

Valerie-Anne Ryser[1], Clément Meier[2], Sarah Vilpert[2], and Jürgen Maurer[2], *1. Swiss Centre of Expertise in the Social Sciences, Lausanne, Vaud, Switzerland, 2. University of Lausanne, Lausanne, Vaud, Switzerland*

Introduction: Personality traits (PTs) - Neuroticism, Extraversion, Openness to experience, Agreeableness, Conscientiousness - are related to how older adults deal with health-related issues. However, little is known about the relationship between PTs and health literacy (HL). HL measures individuals' ability to find, understand, appraise, and use health information to deal with health-related outcomes. Objectives: This research tries to understand better differences in HL across PTs in a nationally representative sample of adults aged 58 years and older in Switzerland. Method: Multivariable probit regressions to explore how respondents' PTs are independently associated with HL after controlling individuals' social, regional and health characteristics are based on a paper-and-pencil self-completion questionnaire (N= 1'555) administered as part of wave 8 (2019/2020) of SHARE in Switzerland. HL is measured using the short version of the European Health Literacy Survey questionnaire (HLS-EU-Q16), whose scores of dichotomized responses is grouped into two categories: inadequate and adequate HL. PTs are measured with the Big-Five inventory ten (BFI-10).

Results: Results show that two out of five PTs are significantly associated with HL among older adults. Individuals who score higher on neuroticism and thus have a persistent tendency to experience negative emotions are more likely to have inadequate HL. More open individuals who are more prone to engage in self-examination are also more likely to have adequate HL.

Conclusion: These findings call for targeted interventions, such as using adjusted health or eHealth information tools that would consider individuals' PTs when designing health policies to improve HL in the population.

NEIGHBORHOOD CONDITIONS AND PERSONALITY CHANGE AMONG OLDER ADULTS

James Iveniuk[1], and Kathleen Cagney[2], *1. NORC at the University of Chicago, Chicago, Illinois, United States, 2. University of Michigan, Ann Arbor, Michigan, United States*

Conscientiousness is a key aspect of personality, associated with overall better health and wellbeing across the life course, including among older adults. The past ten years have seen a growing interest in how social-environmental factors impact personality traits, but the impact of neighborhood conditions is rarely investigated. Broken windows theory argues that changes to residents' character can be brought about through signals of disinvestment in local norms (i.e. visible disorder), pointing to neighborhood disorder as a possible environmental condition that can shape personality. Drawing upon three rounds of data from the National Social Life Health and Aging Project (2005/2006, 2010/2011, 2015/2016; N=1554), we investigate longitudinal associations between traits and changing neighborhood conditions using a Big Five self-assessment, and interviewer ratings of local disorder. Using a combination of mediation and cross-lagged models, we find mixed support for broken windows perspectives – significant mediation processes, but no cross-lagged effects.

SESSION 6560 (POSTER)

PERSPECTIVES ON FORMAL CAREGIVING: PRIMARY CARE, NURSING, AND LONG-TERM CARE

NEUROPSYCHIATRIC SYMPTOMS IN PRIMARY CARE PATIENTS WITH DEMENTIA

Constanca Paul[1], Laetitia Teixeira[1], and Susana Sousa[2], *1. University of Porto, Porto, Porto, Portugal, 2. ICBAS, University of Porto, Porto, Porto, Portugal*

Neuropsychiatric Symptoms of dementia are mostly valued within care and burden of formal and informal caregivers and less considered as diagnosis predictors. Diagnosis of dementia in Primary Care Service (PCS) is frequently late and based mostly in general clinic assessment, and patient/family subjective complaints. We study the association of Neuropsychiatric Symptoms (NPI-Q) and existing diagnosis of dementia in PCS. The objectives are to know 1) the prevalence of symptoms identified by familial caregivers in people with a diagnosis of dementia and 2) if there is an association of symptoms with the existence of a diagnosis.Method: we randomly select a community based sample of a pool (N=2734) of primary care users with mental health concerns referred by General Physicians, (N=154), mean age 76 years (sd 7.8), 57% women. Caregivers (N=39) were interviewed and fulfil NPI-Q. Results of descriptive and logistic regression analysis showed that 39% (60) had a formal diagnosis of dementia not differentiating men and women. The neuropsychological symptoms frequency varied between 3.1% (hallucinations) and 16.3% (apathy/indifference), and the symptoms' mean was 4.5(sd 2.1). The amount of symptoms was not associated with the diagnosis. The symptoms that predict the diagnosis were Apathy/ Indifference OR 5.24(1.25-22.0),p.024 and Motor Disturbance OR 5.70(1.17-27.6), p.031. Qualitative data from caregivers interview show that they are not very comfortable with the terminology of NPI-Q, which may limit the accuracy of assessment.

Conclusion: some neuropsychological symptoms identified by caregivers seems to be relevant as predictors of diagnosis of dementia in Primary Care.

PERSPECTIVES ON THE RISK FACTORS ASSOCIATED WITH MISSING INCIDENTS IN PERSONS LIVING WITH DEMENTIA

Christine Daum[1], Hector Perez[1], Antonio Miguel-Cruz[2], Elyse Letts[1], Emily Rutledge[1], and Lili Liu[1], *1. University of Waterloo, Waterloo, Ontario, Canada, 2. University of Alberta, Edmonton, Alberta, Canada*

Persons living with dementia are at higher risk of getting lost and going missing. The adverse outcomes of missing incidents are stressful for persons living with dementia and those who care for them. This study aimed to identify and describe the perspectives of persons with dementia, caregivers and community support organizations on risk factors. Generic qualitative description informed our methods. We conducted 30 virtual interviews with persons who live with dementia, professional and family caregivers and community support organization representatives. We used a card sort to elicit and describe perspectives on the importance of 27 risk factors commonly associated with missing incidents in persons living with dementia. Interviews were digitally recorded, transcribed verbatim, and subjected to content analysis to determine the presence of relevant words, themes, and concepts. Participants reported multiple experiences of a person going missing, impressions, and suggested relationships between factors such as environmental contexts. The most critical risk factors associated with getting lost and going missing were cognitive impairment, unmet needs, and inadequate concentration of services and resources. In contrast, race, education, and gender were perceived as unimportant pertaining to risk factors related to missing incidents in persons living with dementia. An understanding of the perceived importance of risks associated with missing incidents enhances a person-centered approach to addressing unmet needs, services and resources that balances quality of life with maintaining safety.

SOCIAL INTERACTIONS BETWEEN CERTIFIED NURSING ASSISTANTS AND CLIENTS WITH DEMENTIA: A QUALITATIVE STUDY

Elizabeth Braungart Fauth, Jacob Gossner, Malinda Dokos, and Rebecka Schultz, *Utah State University, Logan, Utah, United States*

Certified nursing assistants (CNAs) provide direct care for persons with dementia in formal settings and are therefore positioned to engage socially with clients during care. Our prior published observational study in memory care (7000 minutes of observation over 1 year) identified infrequent negative interactions of CNAs with clients, but many opportunities where CNAs did not socially engage a client, including ignoring attempts for engagement. This followup study seeks to understand CNAs experiences and attitudes towards social interaction with clients with dementia. Through semi-structured interviews with 11 CNAs at two care facilities (not included in the prior study), we examined the perceived role that CNAs have towards engaging socially with clients with dementia, barriers to interactions, and behaviors and attitudes that promote quality social interactions. Thematic analyses with multiple trained coders identified that all CNA participants reported feeling personally responsible for engaging with clients socially, having learned this through observation and trial and error, rather than formal training. Barriers to social interaction were lack of time, training, and managing symptoms of dementia. In describing quality social interactions, CNAs highlighted multiple verbal and nonverbal behaviors, including touch, eye contact, body posture, and volume and tone of voice. CNAs emphasized that quality social interactions were facilitated by internal attitudes of valuing personhood, getting on the client's level, and being a friend. Our findings highlight that CNAs identify the importance of social interactions in their work in memory care, and they identify needing training in effective interaction techniques, specifically with their clients with dementia.

DEFICIENCY CITATIONS ON INAPPROPRIATE PSYCHOTROPIC MEDICATION USE WHEN CARING FOR BEHAVIORAL SYMPTOMS OF DEMENTIA

Jung Min Yoon[1], Alison Trinkoff[2], Elizabeth Galik[3], and Nicole Brandt[3], *1. Stony Brook University, Saint James, New York, United States, 2. University of Maryland Baltimore School of Nursing, Baltimore, Maryland, United States, 3. University of Maryland, Baltimore, Baltimore, Maryland, United States*

The National Partnership to Improve Dementia Care in Nursing Homes in 2012, initiated by the Centers for Medicare and Medicaid (CMS), helped decrease antipsychotics use. However, inappropriate psychotropics use to control behavioral symptoms associated with dementia remains. Nursing homes (NHs) can be flagged for inappropriate psychotropics use as a deficiency of care citation (F-758 tag). The purpose of this study was to explore the nature of inappropriate psychotropic medication use deficiency, F-758 citations, in caring for NH residents with dementia using a mixed-methods study design. During the first quarter of 2018 (January–March), 444 NHs received F-758 tags related to care of residents with dementia. Information on deficiencies were obtained from 2018 Certification and Survey Provider Enhanced Reporting (CASPER) data. Deficiency reports were obtained from CMS Nursing Home Compare and ProPublica. Quantitative analysis was done to examine the frequency of involved psychotropic medications, scope and severity of F-758 tags, and reasons for the citations. Qualitative data analysis was conducted using content analysis with an inductive coding approach to summarize the inspection reports. Antipsychotics were the most involved drug category for F-758 tag citations. The three most common reasons for F-758 citations included failure to: identify and/or monitor behavioral symptoms (178 NHs), attempt gradual drug reduction (131 NHs), and maintain 14-day limitations on PRN psychotropic orders (121 NHs). This study suggests areas for improvement that could potentially reduce inappropriate psychotropics use. Supporting quality dementia care workforce and improving cooperation within healthcare professionals are recommended to ensure proper non-pharmacological and pharmacological interventions.

DISTRICT NURSES' ATTITUDES TOWARD INVOLUNTARY TREATMENT IN DEMENTIA CARE: A CROSS-SECTIONAL STUDY

Vincent Moermans[1], Michel Bleijlevens[1], Hilde Verbeek[1], Valeria Lima Passos[1], Koen Milisen[2], and Jan Hamers[1], *1.*

Maastricht University, Maastricht, Limburg, Netherlands, 2. KU Leuven, Leuven, Vlaams-Brabant, Belgium

Persons Living with Dementia (PLWD) prefer to live in their home environment, making their own choices and living a self-determined life for as long as possible. However, recent studies have shown that one in two PLWD receives involuntary treatment. Involuntary treatment is care provided that they resist to and/or have not given consent to, such as physical restraints, psychotropic medications. Although district nurses play a key role in the care of PLWD, it is unknown how their attitudes and opinions influence the use of involuntary treatment. This study aims to investigate the attitudes of district nurses towards the use of involuntary treatment in dementia care at home, determinants, and their opinion about its restrictiveness and discomfort. In a cross-sectional study, data were collected in a convenient sample of 296 Belgian district nurses using an online version of the Maastricht Attitude Questionnaire - Home Care. Results show that district nurses perceive involuntary treatment as a regular part of nursing care, having neither positive nor negative attitudes towards its appropriateness. They consider involuntary treatment usage as moderately restrictive to PLWD and feel moderately uncomfortable when using it. Nursing staff with more years of experience in dementia care, perceiving care for PLWD as burdensome, and having a lower educational background were more accepting towards involuntary treatment, rating it as a regular measure in the nursing care repertoire. These findings underscore the need to increase the awareness of district nurses regarding the negative consequences of involuntary treatment use to PLWD.

EXPERIENCES OF DISTRICT NURSES WITH MAKING DECISIONS ABOUT THE USAGE OF INVOLUNTARY TREATMENT.

Vincent Moermans[1], Michel Bleijlevens[1], Hilde Verbeek[1], Bernadette Dierckx de Casterlé[2], Koen Milisen[2], and Jan Hamers[1], *1. Maastricht University, Maastricht, Limburg, Netherlands, 2. KU Leuven, Leuven, Vlaams-Brabant, Belgium*

District nurses play a key role in care of older Persons Living with Dementia (PLWD) who still live in their own home environment. Studies show that they often have to deal with decision-making about and the usage of involuntary treatment. Involuntary treatment is care provided that they resist to and/or have not given consent to, such physical restraints, psychotropic medication. This study aimed to describe district nurses' experiences regarding the decision-making processes about and the usage of involuntary treatment among PLWD. A qualitative study design with a grounded theory approach was used. During semi-structured interviews, 16 district nurses shared experiences in 31 different cases of involuntary treatment use among PLWD. Results show that district nurses were often not involved in the decision-making process. In most cases, family caregivers decided solely to use involuntary treatment, and district nurses were asked to do also. District nurses experienced these situations as difficult to deal with. They felt that they were torn between providing "good care", wishes of PLWD, and meeting the expectations of family caregivers. Their experiences were negatively affected if PLWD verbally rejected the care provided, they were unable to enter into a dialogue with the caregivers about the care provided, and if they did not have sufficient knowledge about how to deal with PLWD. These findings indicate the importance, of proactive case management in dementia care at home. District nurses can facilitate this by going into dialogue between PLWD and his caregivers, in order to provide person-centered dementia care at home.

NJGWEP RESUSCITATING THE VA COGNITIVE CLINIC: REBUILDING COMMUNITY PARTNERSHIPS DURING A PANDEMIC

Lisa Bodenheimer[1], Kevin Overbeck[1], Elyse Perweiler[1], Jennifer DeGennaro[1], Anita Chopra[1], Lavona Toplyn3, Richard Cetkowski[2], and Renee Berna[2], *1. Rowan University School of Osteopathic Medicine, Stratford, New Jersey, United States, 2. VA Wilmington, Vineland, New Jersey, United States*

The New Jersey Geriatrics Workforce Enhancement Program (NJGWEP), in collaboration with the Wilmington Veteran's Administration Community-Based Outpatient Clinic (VA-CBOC) in Vineland, NJ, implemented a multidisciplinary comprehensive, evidence-based geriatric care program to assess cognitive health and geriatric syndromes as well as offer caregiver support, dementia disease education and referrals to VA and community resources. The "Cognitive Clinic" evaluated 15 veterans during a 3-month pilot phase before suspension due to COVID-19 in March 2020. To maintain momentum established prior to COVID-19, NJGWEP/VA clinical providers routinely met virtually to update each other on their organizations' status, policies, and progress providing clinical care during the pandemic. These meetings offered opportunities to retain rapport and brainstorm strategies to modify the cognitive clinic.NJGWEP/VA providers successfully pivoted to include a telehealth model of care when appropriate and feasible; also helping to reduce barriers that limited the number of in-person contacts allowed on any given day. Implementation of telehealth proved successful at capturing caregivers who otherwise cannot attend appointments. The VA suggested de-coupling the back-to-back social work/physician appointments to ease scheduling concerns for VA providers. The Cognitive Clinic resumed employing a hybrid model of in-person physician assessments with referrals to social work for caregiver support offered via telehealth. From 1/19/22-3/2/22, 10 veterans were evaluated by a physician; 5 were diagnosed with dementia, all of whom identified a caregiver and received education, resources and referrals. In the upcoming year, the plan is to evaluate 4 veterans per month and train a VA geriatric APN to support program sustainability.

SESSION 6570 (POSTER)

PHYSICAL ACTIVITY AND FUNCTION

FEASIBILITY OF AN EXERGAMING-BASED DANCE TRAINING PARADIGM IN THE HOME SETTING AMONG PEOPLE WITH CHRONIC STROKE

Savitha Subramaniam, and Tanvi bhatt, *University of Illinois at Chicago, Chicago,, Illinois, United States*

Background: Dance-based exergaming (DBExG) from laboratory (phase 1 -p1) to a safe and feasible home-based exercise program (HEP- phase 2-p2) could enhance physical activity (PA) behavior, and can be used as a maintenance therapy in PwCS. However, traditionally structured HEP are interfaced with impediments for employing best practice for fall prevention safety approach at home settings in PwCS, thus, making it essential to evaluate training strategies that foster safety. Aim: To evaluate the feasibility, compliance, and safety of a safety harness augmented rehabilitation using DBExG training paradigm (SHARP).

Methods: Community-dwelling PwCS (n=7) participated in the study and received DBExG training using the commercially available Kinect dance gaming "Just Dance 3". The first 6 weeks training (20 sessions) was provided in the laboratory setting (health coach stand by assistance – SBA). Followed with 4 more weeks (12 sessions) of SHARP in the participant's house with health coach SBA.

Results: The primary focus was feasibility, addressed by acceptability, and retention. All the seven participants completed the laboratory, and home-based DBExG. All participants reported enjoying the sessions and felt they were beneficial. Study retention and session adherence was 90% and 98%, at p1, and p2 respectively. There were no falls, and adverse safety events reported in either phase of the study. The intervention was safe with no falls, and major adverse events.

Conclusion: SHARP appears feasible and safe, thus promising for home-based PA rehabilitation for PwCS. A larger randomized controlled trial is recommended to further investigate efficacy.

PHYSICAL FITNESS MODERATES THE AGE-RELATED ASSOCIATION BETWEEN EXECUTIVE FUNCTIONING AND MOBILITY

Emma Dupuy[1], Florent Besnier[1], Christine Gagnon[2], Juliana Breton[2], Catia Lecchino[2], Mathieu Gayda[1], and Louis Bherer[3], *1. Université de Montréal, Montreal, Quebec, Canada, 2. Montreal Heart Institute, Montreal, Quebec, Canada, 3. University of Montreal, Montreal, Quebec, Canada*

In older adults, executive functions are important for daily-life function and mobility. Evidence suggests that the relationship between cognition and mobility is dynamic and could vary according to individual factors, but whether cardiorespiratory fitness reduces the age-related increase of interdependence between mobility and cognition remains unexplored. One hundred eighty-nine participants (aged 50-87) were divided into three groups according to their age: middle-aged (MA; < 65), young older adults (YOA; 65-74), and old older adults (OOA; ≥75). Participants performed Timed Up and Go and executive functioning assessments (Oral Trail Making Test and Phonologic verbal fluency) remotely by videoconference. Participants completed the Matthews questionnaire to estimate their cardiorespiratory fitness (VO2 max in ml/min/kg). A three-way moderation was used to address whether cardiorespiratory fitness interacts with age to moderate the relationship between cognition and mobility. Results showed that the cardiorespiratory fitness x age interaction moderated the association between executive functioning and mobility ($\beta = -.05$, $p = .047$) (R2 = .18, $p < .0001$). At lower levels of physical fitness (< 19.16 ml/min/kg), executive functioning significantly influenced YOA's mobility ($\beta = -.48$, $p = .004$) and to a greater extent OOA's mobility ($\beta = -.96$, $p = .002$). Our results support the idea of a dynamic relationship between mobility and executive functioning during aging and suggest that physical fitness could play a significant role in reducing their interdependency.

THE EFFECT OF ACTIGRAPHY MEASURED PHYSICAL ACTIVITY ON EXECUTIVE FUNCTION IN OLDER ADULTS

Pilar Thangwaritorn[1], Hilary Hicks[2], Alex Laffer[3], Genna Losinski[2], Kayla Meyer[4], Elizabeth Tran[4], Keri Cox[4], and Amber Watts[2], *1. University of Kansas, LAWRENCE, Kansas, United States, 2. University of Kansas, Lawrence, Kansas, United States, 3. University of Kansas, Lawrencee, Kansas, United States, 4. University of Kansas Alzheimer's Disease Research Center, Kansas City, Kansas, United States*

Executive function (i.e., decision making, self-control, planning) is important for facilitating independent living in older adults. Physical activity may preserve executive function, but previous research has demonstrated sex differences in both physical activity and executive function among older adults. Few studies have investigated sex differences in the association between the two. We examined associations between objectively measured physical activity and executive function with attention to sex differences. We recruited N = 204 participants (Mage =71, SD=6.36; 57% women) with (n=47) and without (n=157) Alzheimer's disease from the University of Kansas Alzheimer's Disease Research Center. We used wrist-worn accelerometers (Actigraph GT9X) to measure physical activity 24 hours a day for 7 days in a free-living environment. We categorized physical activity as moderate to vigorous (MVPA) based on the Montoye (2020) Adult Vector Magnitude cut-points. We evaluated sex differences in the association between executive function and MVPA using multiple regression with an interaction term, adjusting for age, education, and dementia status. We used a composite score to combine tests of executive function (Digit Symbol Substitution, Stroop Interference, Trail making Part B, and Verbal Fluency). Results indicated, older age and lower education were associated with lower executive function scores (β=-2.12, $p < 0.001$; B=2.13, $p < .05$). In contrast to previous research, we did not find evidence for sex differences in the MVPA, executive function, nor the association between the two in our sample. Future research should investigate whether individualized exercise-based interventions and treatment between men and women may differentially benefit cognitive function.

PHYSICAL ACTIVITY MEDIATES LATIN DANCE PARTICIPATION AND FITNESS OUTCOMES IN OLDER LATINOS

Navin Kaushal[1], Guilherme Balbim[2], Michelle Jaldin[3], and David Marquez[3], *1. Indiana University, Indianapolis, Indiana, United States, 2. University of British Columbia, Vancouver, British Columbia, Canada, 3. University of Illinois Chicago, Chicago, Illinois, United States*

Background: The benefits of engaging in physical activity (PA) for older adults (OA) are well documented; however, participation rates remain low, especially among OA Latinos. Latin dance expresses and promotes culture among Latinos, and can be an effective approach to promote PA. However, the physical function and cardiorespiratory fitness (CRF) benefits of OA engaging in Latin dance have not been investigated. The purpose of this study was to test if PA from an 8-month dance trial yielded and explained improvements in physical function and CRF.

Methods: The study analyzed physical function and CRF outcomes from the BAILA trial. Participants (n= 333) were Latinos (age 55+) who were randomized to a dance or control condition for an 8-month study. PA was assessed using the Community Healthy Activities Model Program for Seniors (CHAMPS), physical function was assessed with the short physical performance battery protocol (SPPB) and estimated CRF was assessed using the Jurca non–exercise test model. Results. ANCOVA models found significant change in SPPB total scores(F1, 331= 4.01, p=0.046) and estimated CRF (F1, 331= 7.66, p= 0.006) over eight months in favor of the dance group. Follow-up mediation models found MVPA to mediate between group and SBBP scores, (β= 0.05, 95% CI [0.0128, 0.1147]). MVPA also mediated between group and CRF, (β= 0.06, 95% CI [0.0164, 0.1197]). Conclusion. The study supports organized Latin dance programs to be effective for improving physical and cardiorespiratory benefits among older adults. The findings also encourage future investigations to promote PA in culturally relevant forms.

IMPROVEMENTS IN HEALTH-RELATED QUALITY OF LIFE FOR BINGOCIZE CLINICAL TRIAL PARTICIPANTS

Emily Smith[1], Matthew Shake[2], Callie Hamm[1], and Jason Crandall[2], *1. Western Kentucky University, Louisville, Kentucky, United States, 2. Western Kentucky University, Bowling Green, Kentucky, United States*

With the number of older adults increasing rapidly, researchers have increasingly focused on designing interventions to improve health-related quality of life (HRQOL) in older adulthood. However, many interventions struggle with adherence because older adults often perceive them as unenjoyable, condescending, or painful. Here, we report results from a clinical trial of Bingocize®, a community-based "in vivo" exercise and health education intervention for older adults, to determine if participation impacts participants' HRQOL. One-hundred and forty-three older adults ages 60+ were randomly assigned to one of four conditions that contrasted exercise and health education to non-intervention control groups. All conditions were matched on social engagement and met in group sessions twice weekly for 12 weeks. The CDC HRQOL measure was administered before and after the intervention. Session adherence was >90% across all sessions. Results from 2 (Time: Pre/Post) x 4 (Condition: Bingo-only Control vs. Bingo+Health Education vs. Bingo+Exercise vs. Bingo+Health Education+Exercise) ANOVAs found that all participants reported better sleep quality, reduced pain, and increased energy after completing the program (p-values <.05). Results from 2 (Time: Pre/Post) x 2 (Exercise/No Exercise) ANOVAs revealed interactions showing that exercise participants experienced greater decreases in days with anxiety and physically unhealthy days as compared to non-exercise participants (p-values <.05). These findings suggest that elements of Bingocize can contribute to improvements in older adults' mental and physical quality of life. The current research can help researchers and professionals further elucidate which intervention mechanisms play a role in determining older adults' health-related quality of life.

USING ACTIGRAPHY TO ASSESS CHRONOTYPE AND PHYSICAL ACTIVITY IN OLDER ADULTS

Hilary Hicks[1], Genna Losinski[1], Pilar Thangwaritorn[2], Alex Laffer[3], and Amber Watts[1], *1. University of Kansas, Lawrence, Kansas, United States, 2. University of Kansas, LAWRENCE, Kansas, United States, 3. University of Kansas, Lawrencee, Kansas, United States*

Chronotype refers to the time of day that people prefer to be active or to sleep and varies predictably across the lifespan. In younger samples, the morning-chronotype is related to greater levels of physical activity (PA) and improved health outcomes. It is unclear whether this pattern holds in older adults, a group that commonly exhibits an "early bird" preference. We investigated differences in PA patterns between chronotypes in 109 older adults (Mage = 70.45 years) using wrist-worn ActiGraphs in a free-living environment. ActiGraphs captured data about PA and sleep using a novel approach to measuring chronotype with the mid-point of the sleep interval. We categorized participants as morning-, intermediate-, or evening-chronotypes. We used ANCOVA to predict total and average peak PA from chronotype, adjusting for age, sex, education, and BMI. Total PA significantly differed between chronotypes such that evening-types engaged in less PA than both morning- and intermediate-types, F (2,102) = 4.377, p =.015. Average peak activity did not differ between chronotypes, p =.112. Consistent with findings in younger samples, our evening type participants engaged in less overall activity. A unique finding was that evening-types did not differ from their morning- and intermediate-chronotype peers in peak activity levels. This implies a key distinction between total activity and peak activity levels consistent with recent trends in PA research using a 24-hour-a-day framework instead of average or total activity levels. Future research should consider whether these differences in activity patterns translate into meaningful differences in health benefits in this age group.

SESSION 6580 (POSTER)

PSYCHOSOCIAL WELL-BEING

SENSE OF PURPOSE IN LIFE AND ALLOSTATIC BURDEN IN TWO LONGITUDINAL COHORTS

Nathan Lewis[1], Scott Hofer[1], and Patrick Hill[2], *1. University of Victoria, Victoria, British Columbia, Canada, 2. Washington University in St. Louis, St. Louis, Missouri, United States*

Sense of purpose in life has been linked with better physical health, longevity, and reduced risk for disability and dementia, but the mechanisms linking purposefulness with diverse health outcomes is unclear. Chronic activation and dysregulation of neural, immune, and other bodily systems, known as allostatic load, may contribute to these underlying mechanisms. Specifically, sense of purpose may promote better physiological regulation in response to stressors and health challenges, leading to lower allostatic burden and disease risk over time. Data from the nationally representative US Health and Retirement Study (HRS) and English Longitudinal Study on Ageing (ELSA) (Total N=5846; Mean Age=67.24, SD=10.68, 59.08% female) were used to examine associations between sense of purpose and repeated assessments of allostatic load across 8 and 12 years of follow-up. Allostatic load scores were constructed from 12 blood-based and anthropometric biomarkers of cardiovascular, metabolic, immune, and lung function, with higher scores representing higher allostatic burden. Population-weighted multilevel models revealed that sense of purpose in life was associated with lower overall levels of allostatic load in HRS (b = -0.22, 95% CI: -0.27,-0.17) and in ELSA (b = -0.19, 95% CI: -0.35,-0.03). Sense of purpose in life did not predict rate of change in allostatic load in either sample. Associations with sense of purpose were highest among cardiovascular and immune biomarkers, suggesting that preservation of these bodily systems may underlie associations between purposefulness and reduced risk for chronic health conditions. Discussion will focus on biological and behavioral pathways connecting sense of purpose in life and health.

COPING STRATEGIES AND THEIR INFLUENCE ON DEPRESSIVE SYMPTOMS DURING THE SECOND COVID-19 PANDEMIC WAVE IN SWITZERLAND

Charikleia Lampraki[1], Daniela Jopp[1], Adar Hoffman[1], Angélique Roquet[1], Kim Uittenhove[1], and Stefan Sieber[2], *1. University of Lausanne, Lausanne, Vaud, Switzerland, 2. LIVES Centre, University of Lausanne, Lausanne, Vaud, Switzerland*

Coping strategies help individuals face stressful events and adapt to them. During the second wave of the COVID19 pandemic, individuals were confronted with increased governmental restrictions that aimed in impeding the propagation of the virus, but affected, at the same time, the life as we knew it, with negative consequences for mental health. This study aims at identifying the coping strategies that individuals used during this period, whether they changed over time and how they affected depressive symptoms in a life span sample in Switzerland. Our sample consisted of 736 individuals with age ranging between 18 and 81 years. The study was conducted in three waves with one-month intervals during the second pandemic-wave (i.e., October, November, December 2020). We used multilevel modelling to identify within-subject change and between-subject differences in depressive symptoms, with coping strategies and sociodemographic variables included as predictors. Older age, male gender, cohabiting with others, and being employed protected from feeling depressed. Results also indicated that seeking functional support, seeking emotional support, positive reappraisal and acceptance decreased, while self-distraction and depressive symptoms increased. When positive reappraisal decreased or/and when self-distraction increased, depressive symptoms also increased. This protective effect of positive reappraisal on depression differed in magnitude for younger and older individuals: Reduction in positive reappraisal was more strongly related to increases in depression for younger individuals. In sum, to adapt to the pandemic stress individuals changed the frequency of coping strategy use, but only changes in positive reappraisal and in self-distracting had an influence on depressive symptoms.

GOAL ADJUSTMENT CAPACITIES DURING COVID-19: CONTEXT-DEPENDENT BENEFITS FOR EMOTIONAL WELL-BEING

Jeremy Hamm[1], Meaghan Barlow[2], Jaron Tan[1], Odalis Garcia[1], and Katherine Duggan[1], *1. North Dakota State University, Fargo, North Dakota, United States, 2. Wilfrid Laurier University, Waterloo, Ontario, Canada*

Increased constraints and lost opportunities inherent in the COVID-19 pandemic can threaten important life goals and erode emotional well-being. Theories of lifespan development have identified goal adjustment capacities (goal disengagement and goal reengagement) as core self-regulatory resources that can buffer against declines in well-being. However, little is known about the pandemic-related contextual circumstances under which goal adjustment capacities may become more or less beneficial for well-being. Using longitudinal data from a nationally-representative sample of Americans across the adult lifespan (aged 18-80, n=286), we examined the consequences of goal adjustment capacities for emotional well-being under circumstances when individuals reported lower or higher constraints than normal in their lives. Specifically, multilevel models tested whether the influence of between-person differences in (Level 2) goal disengagement and goal reengagement on well-being were moderated by (Level 1) within-person fluctuations in perceived constraints. Analyses controlled for age, sex, education, and income. We observed cross-level Goal Reengagement x Perceived Constraints interactions for depressive symptoms, perceived stress, and positive affect (bs = -.11 to .07, ps < .05), but not negative affect. Results showed that the benefits of goal reengagement for depressive symptoms, perceived stress, and positive affect were pronounced on occasions when participants reported lower (vs. higher) than average perceived constraints in their lives. Findings point to the moderating role of pandemic-related contextual circumstances and suggest that goal reengagement may be most beneficial when individuals have fewer constraints than usual in their lives and may thus able to capitalize on opportunities to pursue new attainable goals.

WELL-BEING BEFORE AND DURING THE COVID-19 PANDEMIC: ASSOCIATIONS WITH RESILIENCE AND CHRONIC CONDITIONS

Jay Kayser, and Jacqui Smith, *University of Michigan, Ann Arbor, Michigan, United States*

Adults over the age of 60 tend to have higher well-being than younger adults, and high well-being is associated with a range of favorable mental and physical health outcomes. Resilience is related to the maintenance of well-being in the presence of challenging circumstances and stressors. Chronic health conditions are common in older adults and represent a stressor. Using longitudinal data, we address two research questions: 1) Are chronic health conditions and resilience predictive of changes in well-being before and during Covid-19? 2) Does the number of chronic health conditions and resilience interact in predicting changes in well-being before and during Covid-19? To answer these questions, we analyzed data from participants in the Health and Retirement Study (HRS) who completed both the 2016 and 2020 waves

(N = 2276). On average, these participants were age 71.44 (SD = 7.35) and reported 2.40 chronic conditions. In unadjusted models, both the number of chronic conditions (β = -.21) and resilience (β = .09) were related to changes in well-being (R2 = .32). When covariates were added, these values were attenuated but remained statistically significant. The interaction between resilience and chronic health conditions was not statistically significant. Though the number of chronic health conditions and resilience play an important role in well-being for older adults, high resilience does not moderate the relationship between the number of chronic health conditions and changes in well-being. Further investigations using longitudinal data are needed to understand the relationship between resilience and well-being for those with chronic health conditions.

ASSOCIATION BETWEEN QUALITY OF LIFE AND DEPRESSION IN DYADS OF OLDER PRIMARY CARE PATIENTS AND FAMILY MEMBERS

Nicole Fowler[1], Anthony Perkins[1], Seho Park[1], Matthew Schroeder[2], and Malaz Boustani[3], *1. Indiana University School of Medicine, Indianapolis, Indiana, United States, 2. Regenstrief Institute, Inc., Indianapolis, Indiana, United States, 3. Indiana University School of Medicine, IU Center for Aging Research, Indianapolis, Indiana, United States*

Familial dyads experience illness as an interdependent unit. We evaluate the association of quality of life (QOL), as measured by physical (PCS) and mental health component (MCS) scores, with depression in dyads of older primary care patients and a family member. This is a cross sectional, descriptive study where QOL and depression were measured concurrently in the dyad using baseline data from 1809 dyads enrolled in a trial testing the benefits and harms of Alzheimer's disease and related dementias (ADRD) screening. QOL was measured with the SF-36, depression was measured with the PHQ-9, and the association of depression with QOL was examined using an actor-partner interdependence model with distinguishable dyads. Patient mean (SD) age was 73.7 (5.7) years; 53.1% women; 85.1% white; 13.4% black. Family member mean (SD) age was 64.2 (13) years; 67.7% women; 13.4% black. A patient's spouse/partner were 64.8% of family members. After controlling for dyadic relationship and gender, significant actor effects of depression on PCS for patient (β= -1.39; p< 0.001) and family member (β =-0.954; p< 0.001), and significant partner effects of depression on PCS for patient (β=-0.15, p< 0.05) and family member (β =-0.18; p< 0.01). There were significant actor effects of depression on MCS for patient (β =-1.2; p< 0.001) and family member (β=-1.2; p< 0.001), but depression had a significant partner effect on MCS only for patient (β = -0.08; p< 0.05). Among dyads participating in an ADRD screening trial, dyads with higher depression had lower QOL. Family member depression was associated with decreased family member and patient QOL.

INTERPERSONAL DYSFUNCTION PREDICTS SUBSEQUENT FINANCIAL EXPLOITATION VULNERABILITY IN OLDER ADULTS

Duke Han[1], Aaron Lim[1], Laura Mosqueda[1], Annie Nguyen[1], Tyler Mason[2], Gali Weissberger[3], Laura Fenton[1], and Peter Lichtenberg[4], *1. University of Southern California, Alhambra, California, United States, 2. University of Southern California, Los Angeles, California, United States, 3. Bar Ilan University, Ramat Gan, HaMerkaz, Israel, 4. Wayne State University, Detroit, Michigan, United States*

The goal of this study was to test whether interpersonal dysfunction, characterized by loneliness and/or dissatisfaction with relationships, is an imminent predictor of financial exploitation vulnerability (FEV) among older adults within a 6-month observation period. This study also tests whether FEV prospectively predicts interpersonal dysfunction. Twenty-six adults aged 50 or older completed a study involving baseline data collection and 13 follow-ups over 6 months. Linear mixed models were used for primary analyses. After adjustment for demographic, psychological, and cognitive covariates, there were between-person effects of FEV and interpersonal dysfunction across follow-ups, suggesting that those with generally higher interpersonal dysfunction compared to other participants also reported greater FEV (B(SE)=1.09(.33), p=.003). There was a within-person effect (B(SE)=.08(.03), p=.007) of elevated interpersonal dysfunction predicting greater FEV two weeks later across all follow-ups. Within-person effect of FEV was not predictive of interpersonal dysfunction (B(SE)=.25(.15), p=.10). Among older adults, individuals with higher interpersonal dysfunction relative to others in the study reported greater FEV throughout the 6-month observation period. Increased loneliness and social dissatisfaction, relative to one's average level, predicts subsequent increases in FEV, and may be an imminent risk factor for exploitation.

GIVING BACK TO FEEL GOOD? SOCIAL RESPONSIBILITY, AGE, AND NEGATIVE AFFECT

Madeline Nichols[1], Dakota Witzel[2], and Robert Stawski[1], *1. Oregon State University, Corvallis, Oregon, United States, 2. Penn State University, State College, Pennsylvania, United States*

Developmental theories suggest that midlife and older adulthood are stages in which individuals may begin to focus their time on contributing to society (Erikson, 1969). During these stages, individuals may engage in socially responsible behaviors that protect against negative affect resulting from a lower sense of purpose in later life (Greenfield & Marks, 2004). Social responsibility includes both subjective measures of an individual's felt contribution to society (i.e., generativity) and objective measures reporting actual time volunteering in different settings (Rossi, 2001). We utilized data from the Midlife in the United States Refresher survey study and Biomarker Project (N=735, Mage=51.56, SD=13.59, 50.20% Male) to explore how self-perceptions of generativity and time spent volunteering predicted negative affect for individuals in midlife and older adulthood. Preliminary analyses indicate that higher generativity (p<.001) and older age (p<.001), but not average time spent volunteering, were associated with higher negative affect. Further, we considered age as a potential moderator for the associations between generativity, volunteering, and negative affect. Age significantly interacted with generativity (p<.01), such that the effects of generativity on reducing negative affect decrease with age. Age did not significantly interact with time spent volunteering. Discussion will focus on how actual engagement in socially responsible behaviors and perceived societal contributions might yield different outcomes regarding protection against negative affect in mid- and later-life. Future directions may include exploring daily indicators of time spent volunteering, generative beliefs, and affect.

MODERATION OF CUSTODIAL GRANDPARENT'S WELLNESS AND GRANDCHILD'S BEHAVIOR BY RELATIONSHIP QUALITY

Marin Olson[1], Karly Pyles[1], Acacia Lopez[2], Rachel Scott[2], and Danielle Nadorff[1], *1. Mississippi State University, Mississippi State, Mississippi, United States, 2. Mississippi State University, Starkville, Mississippi, United States*

A growing number of grandparents are assuming care of their grandchildren, and both grandparents and children report higher levels of stress than their peers, although the source of this stress remains largely unexplored. In Conger & Donnellan's Family Stress Model, a parent's distress can impact the levels of distress experienced by their child, and previous research indicates that parent/child relationship quality impacts children's mental health. This study extended this to custodial grandfamilies, by investigating whether the relationship quality of custodial grandparents (GP) and grandchildren (GC) would moderate the relation between the health of GC and the wellness of their GP. Participants include 322 custodial grandparents within the United States recruited via Qualtrics Research Panel Survey (m age = 55.66 yr., 86.1% female). Measures included the Achenbach Child Behavior Checklist, Kivnick's Grandparent Meaning Scale, and grandparents' wellness. Moderation of relationship quality on the relation between the GP's wellness and internalizing behaviors of the GC was tested using SPSS' Process macro. A significant interaction was found ($t = 2.31$, $p = .02$) wherein GP's wellness was not predictive of changes in GC's behavior for the group with high relationship quality, but greater GP wellness was associated with less GC internalizing behaviors when relationship quality was low ($p < .001$). These findings indicate that when a GP feels that they have a more positive relationship with their GC, there is a greater likelihood that they will report fewer health concerns and fewer GC's internalizing behavior symptoms.

OLDER ADULTS' RESILIENT IDENTITY APPRAISALS: WHO AM I COMPARED TO MYSELF AND OTHERS?

Lauren Bouchard[1], and Lydia Manning[2], *1. Portland State University , Portland , Oregon, United States, 2. Dele Health Tech, Naperville, Illinois, United States*

Resilience is the adaptation of bouncing back from adverse life events. Older adults provide rich and varied resilience narratives of personal growth across the life course, especially related to others. Many people describe resilience as part of their identity, formed in childhood and maintained throughout adulthood. As adults age, they continually integrate new information into their identity, and aging presents long-term adversity and new life course challenges that older people must navigate. This qualitative study explored how older adults describe their sense of resilient identity compared to their younger selves and other older adults in their lives. Our narrative findings indicate resilience narratives often include comparative appraisals to the strengths and weaknesses of younger selves (e.g., "I am more emotionally resilient, but not as physically strong as I used to be"). Additionally, our findings show older adults comparing their resilience to others in a similar age category (e.g., "I do not complain like my friends"). Comparisons to other older adults fit two themes: empathic and connected and judgmental and distanced. We conclude the participants who view other older adults in an empathic and connected way maintained solid social connections and a general sense of interconnectedness, while those in the judgmental and distanced category might be reacting to internalized ageism. The social implications of these findings will be discussed in detail. In addition to specific examples, our study also provides limitations and future directions in resilient identity and resilience appraisals.

THE PROTECTIVE EFFECT OF RESILIENCE ON SHRINKAGE OF FRIENDSHIP IN LATER LIFE

Ikuko Sugawara[1], Midori Takayama[2], and Yoshiko Ishioka[3], *1. Bunri University of Hospitality, Suginami-ku, Tokyo, Japan, 2. Keio University, Yokohama, Kanagawa, Japan, 3. O.P. Jindal Global University, Sonipat, Haryana, India*

The purpose of this study was to examine the protective effect of trait resilience, a positive personality characteristic that enhances individual adaptation to life events and adversity, in the face of declining social relationships in later life. Social relations have a significant effect on our development and well-being throughout life. However, it is known that a decline in physical, cognitive, and mental functioning makes it difficult to maintain active participation in society and leads to shrinking social networks in later life. Therefore, it is important to identify protective factors that enable people to maintain positive social relations when functioning in daily life declines in old age. We analyzed longitudinal survey data from a representative sample of older Japanese adults aged 74 to 86 years (N=1064). The interaction effect of resilience in the relationship between functions (physical, cognitive, and mental) and relationships with friends (social support exchange and companionship) was examined using multi-group Structured Equation Modeling (SEM). Respondents were divided into upper quartile and lower quartile groups according to their Resilience Scale (RS-14) scores. The results showed significant group differences for the effect of cognitive function on friendship. The positive correlation between cognitive functioning and friendship was stronger among respondents with low resilience. For high resilience participants, cognitive functioning was not associated with friendship. The results suggest that resilient older adults cope well with poor cognitive health and maintain positive social relationships in very late life.

INCREASING THE SENSE OF IDENTITY AND INTEGRITY: AN INTERVENTION STUDY OF ACTIVE AGING AND AUTOBIOGRAPHY WORKSHOPS

Tomoko Ikeuchi[1], Mayuko Ono[1], Sachiko Yamazaki[2], Cullen Hayashida[3], Michiyo Tomioka[3], Chiho Shimada[4], and Hisao Osada[5], *1. Tokyo Metropolitan Institute of Gerontology, Tokyo, Tokyo, Japan, 2. Bunkyo Gakuin University, Fujimino, Saitama, Japan, 3. University of Hawaii, Honolulu, Hawaii, United States, 4. Saku*

University, Saku, Nagano, Japan, 5. J.F. Oberlin University, Machida, Tokyo, Japan

Identity and integrity (i.e., a sense of coherence and wholeness) are important elements for psychosocial development in later stages of life as described in Erikson's life-span developmental theory. This study aimed to develop an intervention program to increase the sense of identity and integrity among older adults. The program included two types of workshops to examine the combined impact of searching for one's post-retirement identity and clarifying personal goals and purpose for later life. The first workshop, Introductory of Active Aging, focused on providing the knowledge and skills necessary to prepare for life after retirement. The second workshop, Creating Your Life History, focused on a life review and composing one's life history using the guided autobiography method developed by Birren. The study used a crossover design with a one-week break interval between the two workshops. Each workshop was conducted weekly with a two-hour session over four weeks. Thirty-eight participants aged 60 to 80 attended both workshops between October and December 2021 at a community center in Tokyo, Japan. The sense of identity and integrity were assessed using the Japanese version of the Erikson Psychosocial Inventory Scale (EPSI) at baseline and after completing both workshops (9th week). The scores of both identity and integrity increased significantly among participants who completed two workshops in sequence. This crossover study showed no statistical difference in the effects of each workshop. Further work is needed to monitor the long-term impact of these workshops in clarifying one's identity and achieving satisfaction with self in later life.

HOW GOAL REPRESENTATIONS MODULATE ASSOCIATIONS BETWEEN EVERYDAY AFFECT AND GOAL PURSUIT AMONG OLDER ADULTS

Yoonseok Choi[1], Denis Gerstorf[2], Maureen Ashe[3], Kenneth Madden[1], and Christiane Hoppmann[1], *1. University of British Columbia, Vancouver, British Columbia, Canada, 2. Humboldt Universität zu Berlin, Berlin, Berlin, Germany, 3. The University of British Columbia, Vancouver, British Columbia, Canada*

Individuals differ in the extent to which they represent their goals as hoped-for versus feared states. We examined the role of such goal representations for how everyday affective experiences and goal pursuit are intertwined. When goals are represented as hoped-for states, we expected stronger associations between daily positive affect and goal pursuit. In contrast, when goals are represented as feared states, we expected stronger associations between daily negative affect (particularly fear) and goal pursuit. We used seven days of repeated daily life assessments from 238 older individuals (Age: M = 70.5 years, SD = 5.99, 59-87 years; N = 119 couples). At baseline, participants reported three goals they planned to pursue over the study period and the extent to which each goal referred to something they hoped-for or feared. During the daily life assessments, participants reported their current affective states and momentary goal pursuit (goal engagement and goal progress) three times per day (11 AM, 4 PM, 9 PM). Multilevel analyses regarding participants' most salient goal provide initial evidence supporting the expected interactions of goal representations on everyday affect–goal pursuit links. Specifically, individuals with a strong hope-focus in their goals engaged in more goal pursuit when positive affect was up than individuals whose goals were low in hope-focus. In contrast, those with feared goals engaged in more goal pursuit when reporting increased fear. Findings are discussed in the context of the possible selves literature. Future analyses will examine lead-lag effects to address the temporal order underlying affect-goal pursuit associations.

THE MEDIATING EFFECT OF SELF-OBJECTIFICATION AND BODY ESTEEM ON AGE AND MOOD

Sydney Tran, and Aurora Sherman, *Oregon State University, Corvallis, Oregon, United States*

Objectification theory is a well-established framework that outlines the consequences of being sexually objectified (Fredrickson & Roberts, 1997). One of the major consequences of sexual objectification is self-objectification, or the tendency to internalize an observer's perspective on one's own body and the learned behavior to value one's physical appearance over one's body functionality. Self-objectification has been linked to poorer subjective well-being and poorer body image in college-aged women but has not yet been examined among older adult women. This study recruited a group of younger (N = 132 ; M age = 20.93, range = 18-26) and older (N = 86; M age = 67.83, range = 48-90) adult women to examine age differences in self-objectification and their relationships with body esteem and negative mood and anxiety. This study tested a serial mediation model using Model 6 of the Hayes PROCESS Macro in SPSS, in which self-objectification and body esteem were hypothesized to mediate the relationship between age and negative mood and anxiety. After controlling for sexual orientation, marital status, and education, results indicated that the standardized indirect effect was significant, B = -.09, SE = .03, 95% CI [-.16, -.04], suggesting that self-objectification and its related consequences are not unique to young adult women and that women of all ages are negatively impacted by self-objectification.

IN THE SHADOW OF THE GREAT RECESSION: THE ASSOCIATION BETWEEN RECESSION EXPERIENCES AND DAILY INDICES OF WELL-BEING

Jonathan Rush[1], Aarti Bhat[2], Duncan Thomas[3], Arun Karlamangla[4], David Almeida[5], and Teresa Seeman[6], *1. University of Victoria, Victoria, British Columbia, Canada, 2. The Pennsylvania State University, State College, Pennsylvania, United States, 3. Duke University, Durham, North Carolina, United States, 4. University of California, Los Angeles, Los Angeles, California, United States, 5. The Pennsylvania State University, University Park, Pennsylvania, United States, 6. University of California Los Angeles, Los Angeles, California, United States*

The current study examined the associations of positive and negative experiences during the Great Recession (GR) with levels of daily well-being. In 2012, participants from the Midlife in the United States Refresher survey reported on their positive or negative GR experiences related to job, housing, or finances. A subsample, selected into the National Study of Daily Experiences (N=782), also reported on their daily levels of health and well-being across eight consecutive days and provided saliva samples, from which cortisol was assayed. The number of negative GR experiences reported related to poorer daily well-being (negative and positive affect, physical symptoms, stress severity, and cortisol daily peak-to-nadir ratio), whereas, the number of positive GR experiences was only related to lower severity of daily stressors (β=–0.03, p=.03). Examining specific GR experiences revealed that individuals who reported bad housing experience during the GR reported higher daily levels of negative affect (β=0.14, p<.001), physical symptoms (β=0.90, p<.001), and frequency of stressor days (β=0.01, p<.001), and lower daily levels of positive affect (β=–0.19, p=.02). Bad financial experience was related to more physical symptoms (β=0.62, p<.001) and greater severity of daily stressors (β=0.14, p=.03). Conversely, positive financial experiences were related to greater cortisol daily peak-to-nadir ratio (β=1.98, p=.03), but also greater frequency of stressor days (β=0.05, p=.01). Results highlight the potential influence of major economic strains on our ongoing daily experiences. This work has implications for policy and interventions around supporting midlife and older adults facing economic strains, in order to improve daily well-being.

PROFILES OF PERSONAL DETERMINANTS OF HEALTH AND ASSOCIATED HEALTH OUTCOMES IN OLDER ADULTS: A LATENT CLASS ANALYSIS

Melanie Serrao Hill[1], Timothy Barnes[1], Lizi Wu[1], Rifky Tkatch[1], Sandra Kraemer[2], James Schaeffer[1], and Charlotte Yeh[3], *1. Optum Labs, Minnetonka, Minnesota, United States, 2. UnitedHealthcare, Minnetonka, Minnesota, United States, 3. ASI, Inc., Washington, District of Columbia, United States*

Personal Determinants of Health (PDOH) are considered personal resources that contribute to successful aging. Positive PDOH factors have been associated with better health outcomes in older adults; however, research in this area is still limited. Using survey and claims data among adults age 65+ (N=2,866), profiles were identified based on five key PDOH factors (resilience, purpose in life, optimism, self-perception of aging, and social connection via loneliness) utilizing Latent Class Analysis (LCA). Differences in socio-demographics and healthcare outcomes were then explored utilizing multivariate regression models. Outcomes included emergency room (ER) visits, inpatient (IP) admissions, total medical cost, and quality of life (physical and mental health component scores). LCA models yielded three main classes within our sample: high PDOH (56%, n=1,150), moderate PDOH (40%, n=1,611), and low PDOH (4%, n=125). Those within the high PDOH class were significantly younger (Mage=75.6) compared to those within the moderate (Mage=78.2) and low (Mage=78.9) PDOH classes. In addition, the high PDOH class was significantly less likely to have an ER visit (OR=1.81, 95% CI:1.23-2.66) and had 28% better physical health and 52% better mental health components scores as compared to the low PDOH class. Results demonstrate support for the PDOH model as a potential successful aging model. Combinations used to create classes using resilience, purpose in life, optimism, self-perception of aging, and social connection via loneliness indicates that those who are positive in all five aspects show the most promising health outcomes. Future implications include targeting interventions at improving these variables for at-risk older adults.

RURAL-URBAN DISPARITIES IN COMORBIDITY BETWEEN OBESITY AND DIABETES AMONG OLDER ADULTS

Youngjoon Bae, *University of Massachusetts Amherst, Amherst, Massachusetts, United States*

Obesity and diabetes are common among older Americans. While obesity is a risk factor for diabetes, research on rural-urban health disparities among older adults has reported paradoxical results. That is, living in rural areas is a risk marker of obesity, whereas rural residency is inversely associated with diabetes. This study utilized multiple national data resources to diagnose the inconsistency, including the 2006-2016 RAND HRS Longitudinal data, biomarker data, the 2010 US Census, and the USDA food access information. HRS survey participants 65 to 97 years of age comprised the study sample (N=6,476). General generalized estimating equation models with survey weights were used to estimate associations with measured obesity and diabetes. Age, race, Hispanic status, foreign-born status, education, marital status, working status, wealth, physical activity, smoking, drinking, ADL, IADL, loneliness, depression, cholesterol, HDL, CRP, and Cystatin C were included as control variables. Findings suggest that rurality is associated with a higher likelihood of obesity and a lower likelihood of diabetes, particularly for older women. However, by adjusting for confounders, these relationships disappeared. Instead, social isolation indicated significant associations with a lower likelihood of obesity and a higher likelihood of diabetes among older women. Contrary to prior research, the food desert and food insecurity measures did not correlate with both outcome variables. Further investigation on food consumption and dietary behavior among socially isolated older women is needed.

VISION IMPAIRMENT AND SOCIAL ISOLATION IN OLDER AFRICAN AMERICANS: THE IMPACT ON COGNITIVE DECLINE

Emily Hayes[1], Avalon White[2], Corinna Trujillo Tanner[2], and Jeremy Yorgason[2], *1. Brigham Young University--Provo, Provo, Utah, United States, 2. Brigham Young University, Provo, Utah, United States*

Evidence suggests a consistent correlation between vision impairments, social isolation, and cognitive decline. The National Eye Institute reports that African Americans have an increased risk of developing certain vision impairments such as cataracts, glaucoma, and diabetic retinopathy. At the same time, older African Americans often receive care from family members and this family care may act as a buffer against social isolation and resulting cognitive decline. Using data from 737 African Americans that participated in waves 5, 6, and 7 of the National Health and Aging Trends Study (NHATS), we explored associations between vision impairment, social isolation, and cognitive functioning. Results showed that vision impairment at round 5 was related to increased social isolation, and higher social isolation at round 5 was related to decreased delayed word recall scores at the same wave. No significant longitudinal associations were found between these constructs. Findings suggest that concurrent associations exist between sensory impairments, social isolation, and cognitive functioning, but that these relationships are not robust across time. Despite support provided by unpaid family caregivers, African American older adults with vision impairment are at an increased risk for concurrent social and cognitive challenges. It may be that family support of those with sensory impairments helps so that these impairments aren't related to social isolation or cognitive functioning across time. Researchers and clinicians could benefit older African Americans with sensory impairments by providing and encouraging support during early stages of vision loss.

CHILDHOOD MALTREATMENT AND PROSOCIAL BEHAVIOR: A QUALITATIVE COMPARATIVE STUDY OF IRISH OLDER ADULT SURVIVORS

Shauna Rohner[1], Aileen Salas[2], Alan Carr[3], and Myriam Thoma[4], *1. University of Zürich, Zürich, Zurich, Switzerland, 2. University of Zürich, Zurich, Zurich, Switzerland, 3. University College Dublin, Dublin, Dublin, Ireland, 4. University of Zurich, Zurich, Zurich, Switzerland*

Although childhood maltreatment can have lasting effects into later life, positive outcomes have also been observed, including an increased tendency towards prosocial behavior. However, little is known about the link between childhood maltreatment and later life prosocial behavior. Therefore, this study aimed to explore older adult's experiences of childhood maltreatment and identify mechanisms linked to prosocial behavior in later life. The individual level, but also broader cultural and contextual mechanisms, were considered by comparing two adversity contexts and applying conceptual frameworks (socio-interpersonal framework model of trauma and recovery, motivational process model of altruism born of suffering). Semi-structured interviews (60-120 minutes) were conducted with 29 Irish (older) adult survivors of childhood maltreatment: 17 institutional (welfare care) abuse survivors (mean age: 61 years, range: 50-77), 12 familial abuse survivors (mean age: 58 years, range: 51-72). Interviews were analyzed using Framework Analysis. In both groups at the individual level, enhanced empathy, amelioration, and identity-related mechanisms were linked to prosocial behavior, with connections to caring roles and coping strategies from childhood. On a social contexts level, the limited resources or opportunities for help in childhood, and the social norms and beliefs of that time, influenced participants' motivation to help others in later life. Group-specific mechanisms were also observed, such as compassion fatigue in the familial sample; and denouncing detrimental societal values in the institutional sample. The identification of individual, adversity-context, and culture-specific mechanisms linked to later-life prosocial behavior can promote a greater understanding of resilience and adaptability in older adult survivors of childhood maltreatment.

SESSION 6590 (POSTER)

QUANTITATIVE RESEARCH METHODS

USING AGILE METHODOLOGY AND NUDGE STRATEGIES TO IMPROVE ENROLLMENT IN CLINICAL TRIALS

Peggy Bylund[1], Jade Mehta[2], Nandini Mathavan[3], Kimberly Trowbridge[1], Britain Taylor[4], Husam El Sharu[5], and Noll Campbell[6], *1. Regenstrief Institute, Inc., Indianapolis, Indiana, United States, 2. Indiana University School of Medicine, Indianapolis, Indiana, United States, 3. Indiana University School of Medicine/Center for Health Innovation and Implementation Science, Indianapolis, Indiana, United States, 4. Indiana University Bloomington, Bloomington, Indiana, United States, 5. Indiana University, Indianapoilis, Indiana, United States, 6. Purdue University, Indianapolis, Indiana, United States*

The enrollment of human subjects is crucial for the success of clinical trials. In the ongoing "Reducing the Risk of Dementia through Deprescribing" trial, the initial approach for enrolling subjects did not meet expected goals in the first 6 months, creating the need for innovative nudge strategies. We used an Agile methodology as the framework to understand the problem, then find and implement a solution. Our study aimed to examine the effectiveness of utilizing a texting nudge to enhance post-agreement recruitment of subjects with cognitive impairments. Prior to enrollment, eligible potential participants were contacted using a texting nudge. Potential participants received a second contact call to remind subjects of the enrollment appointment, introduce the person and the phone number that would call them, and the option of confirming or rescheduling. During the 1-week text-message experiment, 8 out of 9 subjects who agreed to participate in the study and received the text message enrolled, yielding an 89% post-agreement enrollment rate compared to a baseline rate of 44% prior to introducing this nudge. After implementing into the standard operating procedures, the 6-month average rate of enrollment among those that agreed rose to 80%, nearly doubling the rate from the first 6 months of the study and quadrupling the number enrolled each month. Inadequate recruitment has necessitated the use of innovative recruitment methods. Using the Agile problem-solving mindset, the texting nudge was developed to leverage the behavioral influences of the messenger, social commitments, priming and affect to increase subject enrollment.

DISSOCIATING RETEST EFFECTS FROM DEVELOPMENTAL CHANGE FOR PREDICTING COGNITIVE STATUS

Nicholas Tamburri[1], Cynthia McDowell[2], and Stuart MacDonald[2], *1. University of Victoria, Montreal, Quebec, Canada, 2. University of Victoria, Victoria, British Columbia, Canada*

In longitudinal designs, unadjusted retest effects can confound developmental change estimates. This study utilized a measurement burst design and three-level multilevel modeling to a) independently parameterize short-term retest and long-term developmental change and b) employ these estimates as predictors of cognitive status at long-term follow-ups. Using data from Project MIND , participants (N=304; aged 64-92 years) were assessed across biweekly sessions nested within annual bursts (spanning up to 17 total assessments over four years). Cognitive impairment no dementia (CIND) status was classified at Years 4 (the final burst assessment) and 8 (the study end date). Response time inconsistencies (RTI) were computed to index intraindividual variability across RT trials of a one-back response time (BRT) task. Three-level multilevel models simultaneously yet independently estimated BRT RTI change across weeks and years, indexing short-term retest and long-term developmental change, respectively. Individual slope estimates were extracted and utilized in multinomial logistic regression models contrasting short- vs. long-term RTI change as predictors of long-term cognitive status. Results from the three-level models indicated that retest and developmental slopes yielded non-redundant sources of variance, providing unique estimates of change that would otherwise be confounded. Further, short- and long-term RTI differentially predicted cognitive status at Years 4 and 8; failing to benefit from retest effects on the BRT task was associated with increased likelihood of cognitive impairment. This innovative approach to parameterizing retest effects can reduce systematic bias in estimates of long-term developmental change, as well as highlight the utility of retest effects as predictors of cognitive health.

STRATEGIES TO ENSURE AUTHENTIC PARTICIPANTS AND VALID DATA WITH ONLINE RECRUITMENT OF FAMILY CAREGIVERS

Henrietta Armah[1], Jasmine Vickers[1], Danny Wang[2], and Carolyn Pickering[2], *1. University of Alabama at Birmingham, Birmingham, Alabama, United States, 2. The University of Alabama at Birmingham, Birmingham, Alabama, United States*

Over the past years, recruitment of participants for behavioral and biomedical research through the internet has become more popular. Online has become an advantageous approach to recruitment, especially since the covid pandemic has posed a great challenge to most in-person research activities. Typically, internet-based recruitment strategies include website posting, emailing list of potential participants as well as using social media such as Facebook, Twitter, and Instagram to deliver recruitment information to groups who are often unrepresented in research. Although this mechanism has reduced barriers to participation, it has posed serious threats to data quality and validity. For example, some studies on data validity estimate that up to 90% of online survey responses are fraudulent when they rely on screening questions and CAPTCHA alone. Others have shown that vetted panel data such as Mechanical Turk (mTurk), has high rates of participant misrepresentation. Therefore, the aim of this paper is to highlight the challenges associated with internet-based recruitment of family caregivers and describe strategies for researchers to ensure data integrity. We discuss multi-faceted approaches to detect and prevent fraudulent and suspicious activities such as duplicate and automated enrollment by software applications known as bots as well by fraudulent human participants. We discuss data on several strategies that have proven effective in our previous and ongoing trails. We will also demonstrate the need to implement several strategies and a “fail-safe” to detect fraud after enrollment. It is imperative that researchers understand the need to address these challenges to preserve data integrity and replicability.

HAIR CORTISOL FEASIBILITY AND DEMOGRAPHIC CORRELATES IN A SAMPLE OF OLDER ADULTS FROM PUERTO RICO

Erin Ballard[1], Bulent Turan[2], and Michael Crowe[3], *1. University of Alabama at Birmingham, Hoover, Alabama, United States, 2. Koc University, Sariyer, Istanbul, Turkey, 3. University of Alabama-Birmingham, Birmingham, Alabama, United States*

Hair cortisol is increasingly being used as a biomarker of chronic HPA-axis activation. Studies using older adults often exclude a substantial portion of participants due to insufficient hair or non-detectable cortisol levels, but do not provide details on correlates of these factors. We examined feasibility of hair measurement and cortisol detectability in an ongoing study of older adults in Puerto Rico. Among the first 537 participants in the current follow-up of the Puerto Rican Elder Health Conditions (PREHCO) study (now age 78-106 years old), approximately 11% of participants refused to give a hair sample and 20% did not have enough hair to sample. Women (13%) were significantly more likely than men (4%) to refuse hair collection. However, men (47.7%) were significantly more likely than women (4.8%) to not have enough hair. Of participants with enough hair to take a sample (n=372), 23% had non-detectable levels of cortisol. Black participants were the most likely to have non-detectable hair cortisol (43%), followed by multiracial mestizo (32%). The two most common racial categories in our sample, multiracial trigueño (23%), and white (17%) were the least likely to have non-detectable cortisol. In terms of hair products (including frequency of hair washing and use of conditioner, dye, or perm), only the use of chemical hair straighteners was associated with higher likelihood of non-detectable cortisol (38%). Findings underscore the importance of measuring hair products when examining hair cortisol in older adults and suggest that older black participants may be disproportionately excluded due to non-detectable cortisol levels.

TIME IS OF THE ESSENCE: RELIABLE MEASUREMENT OF HEART RATE VARIABILITY IN OLDER ADULTS

Cristina Pinheiro, Suzanne Segerstrom, and Justin Karr, *University of Kentucky, Lexington, Kentucky, United States*

Heart rate variability (HRV) decreases with age and is an important correlate of psychosocial and physical health. Recommendations for the minimum duration of EKG to accurately derive HRV vary from 1 minute to several minutes. However, the definition of “accuracy” or reliability depends on study design, including whether the focus of the study is on stable or momentary between-person differences or within-person changes in HRV. In a sample of 216 older adults (Mage = 72.7, 62.5% women), ECG was measured at 1000 Hz for 10 minutes every 6 months for up to 6.5 years. HRV was high-frequency power (0.15–0.40). A generalizability study determined the variance due to minute, occasion, person, and their interactions. The most variance was due to idiosyncratic occasion differences (46%), followed by stable person variance (18%). A decision study determined how accuracy in HRV measurement could be achieved. Between-person differences in HRV at a specific occasion could be reliably measured with 6 minutes of ECG (.80); within-person changes in HRV between occasions could be reliably measured with 3 minutes of ECG (.83). For stable individual differences, 10 or more occasions of 1-minute duration produced a more reliable estimate (.73) than increasing the length of a single ECG recording to 10 minutes (.25). The necessary duration of ECG for measuring HRV reliably depends on the study design and research question. Ultra-short durations (1-2 minutes) are generally not recommended for older adults.

OPPORTUNITIES, FEASIBILITY, AND CHALLENGES OF USING IMMERSIVE VIRTUAL REALITY IN AGING RESEARCH

Cornelia Wrzus, *Ruprecht Karls University Heidelberg, Heidelberg, Baden-Wurttemberg, Germany*

Immersive virtual reality (iVR), that is, 3D-scenarios presented in head-mounted displays, is rarely used in aging research, although it gained much popularity recently in medical, educational, consumer, and gaming contexts and offers advantages such as real-life scenarios under experimental control. Still, iVR might be less suited for older adults, if they do not experience realism (i.e., presence) or feel strong cyber-sickness (e.g., nausea, headaches). The current preregistered project (osf.io/ryz2c) examined the opportunities, feasibility, and challenges of immersive Virtual Reality for studying age differences in socio-emotional processes. Up to now, 50 younger (age M = 23.5) and 50 older adults (age M = 67.9) saw different socio-emotional situations in iVR using a HTCvive headset, which included eye tracking, and then rated experiences of presence and cyber-sickness. Results showed that feelings of being present in the virtual reality were moderate to high, while cyber-sickness was generally low, and did not differ significantly between younger and older adults. Further analyses explore associations with technology acceptance, health, and personality. The findings suggest that using iVR with older adults is feasible, and creates similar levels of realism and low cyber-sickness as among young adults. The discussion highlights the opportunities and challenges of using iVR for studying age differences in cognitive, emotional, or social processes in experimentally controlled, real-life scenarios.

SESSION 6600 (POSTER)

SLEEP

THE EFFECTS OF SLEEP DEFICIENCY ON MULTIMORBIDITY AMONG OLDER ADULTS IN THE PHILIPPINES AND VIETNAM

Tuo-Yu Chen[1], Grace Cruz[2], Nguyen Vu[3], and Yasuhiko Saito[4], *1. Taipei Medical University, Taipei City, Taipei, Taiwan (Republic of China), 2. University of Philippines, Diliman, Quezon, Philippines, 3. Institute of Population, Health and Development, Hanoi, Ha Noi, Vietnam, 4. Nihon University, Chiyoda-ku, Tokyo, Japan*

Multimorbidity increases the risks of disability and death and are prevalent among older adults. Evidence shows that sleep might play an important role in multimorbidity. However, previous research studies sleep quality and quantity in isolated manners, where in reality sleep quality and quantity are likely to affect each other. Besides, no study has been done to understand such relationship among older adults in low- and middle- income counties where the prevalence of multimorbidity increases rapidly. This study investigated the relationship between sleep deficiency (i.e., poor and insufficient sleep) and multimorbidity among community-dwelling older adults in the Philippines and Vietnam. Cross-sectional data were obtained from the Longitudinal Study of Ageing and Health in the Philippines (N = 3,562) and the Longitudinal Study of Ageing and Health in Vietnam (N = 3,936). Multimorbidity was defined by having two or more of chronic conditions (i.e., heart disease, heart attack, cardiovascular disease, hypertension, diabetes, lung diseases, renal diseases, liver diseases, and arthritis). Sleep deficiency was conceptualized as self-reported short sleep duration (< 6 hours), having trouble with falling asleep or maintaining sleep, and/or experiencing non-restorative sleep. Logistic regression was used to analyze the data adjusting for demographics, body mass index, sleep medications, naps, mental health, and lifestyle. The results showed that having deficient sleep was significantly related to increased odds of experiencing multimorbidity by about 81% in the Philippines and Vietnam. Our findings revealed that treating sleep deficiency among older adults in the Philippines and Vietnam can potentially reduce the risks of multimorbidity.

THE MEDIATING ROLE OF FATIGUE/SLEEPINESS BETWEEN STATE MINDFULNESS AND SUBJECTIVE COGNITION

Aziz Rehman, Christina Mu, and Soomi Lee, *University of South Florida, Tampa, Florida, United States*

Previous studies have established a connection between higher mindfulness and cognitive abilities; however, few studies have considered the mechanism underlying this relationship. The cognitive benefit of mindfulness may be through reduced fatigue and daytime sleepiness. This study examined if higher, naturally occurring mindfulness is associated with higher subjective cognition and whether lower fatigue or sleepiness mediate this relationship. Two independent samples of nurses (N1=60 inpatient (IP); N2=84 outpatient (OP)) completed 14 days of ecological momentary assessment (EMA). Fatigue/sleepiness, mindfulness, and subjective cognition (mental speed, processing sharpness, memory) were assessed using EMA. The 5-item Mindful Attention Awareness Scale assessed state mindfulness. Multilevel mediations were conducted in Mplus to account for the nested data. At the within-person level, daily subjective cognition was higher than average on days when mindfulness was higher in both OP and IP samples. This association was mediated by lower levels of fatigue (IP indirect effect: B=2.08, p<.001; OP indirect effect: B=2.57, p<.001) and lower sleepiness (IP indirect effect: B=1.72, p=.001; OP indirect effect: B=0.92, p=.027). The daily indirect pathways were found after controlling for between-person differences; those with higher mindfulness reported higher subjective cognition through lower fatigue, and this effect was only significant in OP nurses (indirect effect: B=11.61, p=.001). Results highlight the importance of monitoring momentary mindfulness and intervening on daily fatigue and sleepiness as these may influence one's subjective cognition and ultimately their objective performance. These findings may help identify modifiable factors to promote quality of care in nurses and their own well-being.

WORKING AROUND THE CLOCK: THE EFFECT OF SHIFT WORK AND SLEEP ON DEPRESSIVE SYMPTOMS

Cleothia Frazier, *Duke University, Durham, North Carolina, United States*

Shift work is increasingly prevalent in a 24-hour society where there is increased demand for round the clock service. However, shift work can disrupt circadian rhythms, which can negatively impact sleep. In turn, diminished sleep is associated with poor mental health. To expand prior research that reveal the independent effects of shift work and sleep on mental health, this study focuses on the interconnection between shift work, sleep, and depressive symptoms. Guided by the Stress Process Model (SPM), I examine the association between shift work and depressive symptoms and investigate whether sleep duration, sleep quality (insomnia symptoms), and sleep latency (the time it takes to fall asleep) mediate this relationship. Data was drawn from the age 50 health module of the National Longitudinal Survey of Youth 1979 cohort. The sample consisted of noninstitutionalized adults aged 51-60 (N=5,386). Findings show that shift workers had increased odds of short sleep, insomnia symptoms, and increased sleep latency compared to non-shift workers. Moreover, shift work was associated with increased depressive symptoms. However, part of the effect of shift work on depressive symptoms was indirect, operating through sleep. Specifically, short sleep during the week and on the weekend as well as insomnia symptoms mediated the relationship between shift work and depressive symptoms. The findings suggest that while engaging in shift work can negatively affect mental health, improving sleep duration and sleep quality can be effective in reducing the harmful effects of engaging in shift work during late midlife.

CAREGIVER OUTCOMES RELATED TO SLEEP DISTURBANCES IN PEOPLE LIVING WITH COGNITIVE IMPAIRMENT

Miranda McPhillips[1], Darina Petrovsky[2], Justine Sefcik[3], Junxin LI[4], Glenna Brewster[5], Nalaka Gooneratne[1], Subhash Aryal[1], and Nancy Hodgson[1], *1. University of Pennsylvania, Philadelphia, Pennsylvania, United States, 2. Rutgers, The State University of New Jersey, New Brunswick, New Jersey, United States, 3. Drexel University, Philadelphia, Pennsylvania, United States, 4. Johns Hopkins University, Baltimore, Maryland, United States, 5. Emory University, Atlanta, Georgia, United States*

Sleep disturbances in people living with cognitive impairment (CI) may impose a great burden on caregivers. We examined the relationship between objective and subjective sleep measures in people living with CI and caregiver depression and mastery via a secondary analysis of The Healthy Patterns Clinical Trial (NCT03682185) baseline data (n=170). Objective sleep variables included total sleep time and sleep efficiency derived from 3 nights of actigraphy. Subjective sleep measures included PROMIS Sleep Related Impairment, Pittsburgh Sleep Quality Index, and Epworth Sleepiness Scale. Caregiver measures included Center for Epidemiological Studies Depression Scale and Caregiver Mastery Scale. People living with CI were female (67%), Black (80%), with mean age 73.4 ± 8.7. Caregivers were female (81%), family caregivers (80%) with mean age 56.5 ± 14.7. We used multiple regression analysis, adjusting for cognition, and examined if there were differences by caregiver gender. Poorer subjective sleep quality was significantly associated with more caregiver depression (B=0.407, SE= 0.198, p = 0.042). There were no significant sleep predictors for caregiver mastery; however, there was a moderating effect of gender on the association between subjective sleep quality and caregiver mastery. Female caregivers had increased caregiver mastery compared to males when the person living with CI had better sleep quality (B=0.555, SE= 0.218, p = 0.012). This study found that people living with CI sleep characteristics differentially influence caregiver outcomes. Sleep should be assessed using a combination of objective and subjective sleep measures in people living with CI to inform providers when interventions are needed.

GOLDILOCKS AT WORK: JUST THE RIGHT AMOUNT OF JOB DEMANDS MAY BE NEEDED FOR YOUR SLEEP HEALTH

Monica Nelson[1], Soomi Lee[1], Tammy Allen[1], Orfeu Buxton[2], David Almeida[2], and Ross Andel[1], *1. University of South Florida, Tampa, Florida, United States, 2. The Pennsylvania State University, University Park, Pennsylvania, United States*

Objectives: It has been reported that job demands affect sleep, but how different levels of job demands affect sleep remains unclear. We examined whether curvilinear relationships exist between job demands and multiple sleep health outcomes. Design: Cross-sectional analyses with linear and quadratic effects, using self-administered survey data. Setting: A national sample of U.S. adults. Participants: Workers from Midlife in the United States Study (MIDUS2; n=2,927). Measurements: The Job Content Questionnaire assessed overall and five specific aspects of job demands (intensity, role conflict, work overload, time pressure, and interruptions). Habitual sleep health patterns across five dimensions (regularity, satisfaction/quality, daytime alertness, efficiency, and duration) were assessed. Age, sex, race/ethnicity, marital/partnered status, education, job tenure, work hours, body mass index, smoking status, and study sample were covariates.

Results: There were significant linear and quadratic relationships between job demands and sleep outcomes. Specifically, the linear effects indicated that higher job demands were associated with degraded sleep health, such as shorter duration, greater irregularity, greater inefficiency, and more dissatisfaction. The quadratic effects, however, indicated that the rate of degrade was decelerated in terms of sleep regularity and efficiency, such that these sleep outcomes were best with moderate levels of job demands. These effects were found for overall job demands as well as specific aspects of job demands. Stratified analyses further revealed that these curvilinear associations were mainly driven by participants with low job control.

Conclusions: Moderate levels of job demands, especially if combined with adequate job control, are related to better sleep health.

SESSION 6610 (POSTER)

SOCIAL DETERMINANTS OF HEALTH AND AGING

HOSPITALIZATION AT HOME MAY ADDRESS SOCIAL DETERMINANTS OF HEALTH: RESULTS FROM A QUALITATIVE STUDY

Gabrielle Schiller[1], Heather Wurtz[2], Sybil Masse[2], Abigail Baim-Lance[2], Alex Federman[2], Emily Franzosa[2], Ksenia Gorbenko[2], and Linda DeCherrie[3], *1. CUNY School of Public Health, Astoria, New York, United States, 2. Icahn School of Medicine at Mount Sinai, New York, New York, United States, 3. Medically Home, Boston, Massachusetts, United States*

This project evaluated implementation of the Acute Hospital Care at Home (AHCaH) waiver from the U.S. Center for Medicare & Medicaid Services (CMS), launched in November 2020 to ensure availability of acute care as COVID-19 cases overwhelmed hospitals. We interviewed 18 HaH program leaders of 14 programs, from both existing and newly launched HaH programs, about their experiences applying for and implementing HaH under the CMS waiver. A thematic analysis of the interviews was completed. Informants described HaH programs as an opportunity for healthcare professionals to have “eyes in the home,” referring to ways in which the HaH team was able to observe and intervene in aspects of the patient’s life not accessible from traditional in-patient care. Informants described various ways that HaH programs addressed Social Determinants of Health (SDoH) including assessing patients’ ability to obtain healthy foods, reducing potential safety hazards in the home, and providing education and support to patients’ caregivers. Informants also suggested that HaH may reduce anxiety associated with hospital stay and separation from loved ones, helping people already contending with social inequities. Addressing SDoH is important for ensuring quality care and long-term positive changes in the patient’s lifestyle and environment. As CMS shifts their aims to further address the SDoH, our findings suggest that the interdisciplinary care approach of HaH programs may be a model of addressing both social and medical needs.

HOME AWAY FROM HOME: SOCIODEMOGRAPHIC AND HUMAN CAPITAL PREDICTORS OF NURSING HOME USAGE

Cayley Ryan, and Liying Luo, *Pennsylvania State University, University Park, Pennsylvania, United States*

The U.S. is experiencing a demographic shift characterized by a significant segment of the population entering older age groups and beginning to require specialized eldercare, however little is known about the influence of demographic characteristics on individuals’ involvement with long-term care institutions. I use data from the Health and Retirement Study and logistic regression models to examine how the identities and resources people bring to the later stages of their lives influence their use of nursing homes. I find that individuals’ levels of human capital – measured through their educational attainment – have the strongest influence on their use of nursing homes, with individuals with college degrees having significant increases in the odds of reporting any nursing home stay and in the expected count of nursing home stays. I posit multiple pathways by which education could increase the likelihood of using institutionalized care, including through the social mobility of other family members as well as the ability to navigate healthcare resources and evaluate eldercare options. This detailed examination of the intersection between older ages, individual characteristics, the accumulation of different kinds of capital over the life course, and the involvement with formal care facilities provides valuable insight into the relationship between individuals and institutions across older ages and can inform policies attempting to prepare the landscape of formal care institutions for the influx of possible consumers.

DO AGE-FRIENDLY COMMUNITIES PROMOTE OLDER ADULTS’ HEALTH?

Kyeongmo Kim[1], Denise Burnette[1], Thomas Buckley[2], and Seon Kim[3], *1. Virginia Commonwealth University, Richmond, Virginia, United States, 2. University of Pittsburgh, Pittsburgh, Pennsylvania, United States, 3. Virginia commonwealth university, Richmond, Virginia, United States*

The WHO developed the concept of age-friendly environments that contribute to older adults' better health and well-being. However, research on the effects of age-friendly communities (AFCs) on their health is limited. As AFC initiatives grow, it will be essential to examine whether older adults who live in an AFC have better health than those in other environments. This study uses data from the 2017 AARP AFC Surveys and the AARP Livability Index to assess whether AFCs promote the health of older adults. We analyze data for 3,027 adults aged 65 and older who reside in 262 zip code areas. Following AARP guidelines, we allocated the sample into two groups: the AFC group (livability score of 51+; n=2,364) and the non-AFC group (score≤50, n=663). The outcome variable was self-rated health (M=3.47; SD=1.09; range: 1-5). Findings employing an inverse probability weighting approach showed that older adults who lived in an AFC had better self-rated health than those in a non-AFC (b=0.08, p=.027). Compared to non-Hispanic whites, Black and Hispanic older adults reported worse self-rated health. Oldest old individuals had better health status than young-old adults. Consistent with previous literature, higher education, and frequent social interaction were associated with better self-rated health. The study adds to the growing literature on the role of age-friendly environments in older adults’ health and suggests directions for future research. Since living in an AFC can promote the well-being of older adults, policymakers and practitioners should continue to build high-quality, accessible built and social environments.

A CLINICAL-COMMUNITY PARTNERSHIP TO ADDRESS OLDER ADULTS’ SOCIAL DETERMINANTS OF HEALTH NEEDS

Cory Bolkan[1], Raven Weaver[2], Erik Geissal[3], and Breanne Wise-Swanson[4], *1. Washington State University Vancouver, Vancouver, Washington, United States, 2. Washington State University, Pullman, Washington, United States, 3. The Vancouver Clinic, Vancouver, Washington, United States, 4. Area Agency on Aging & Disabilities of Southwest Washington, Vancouver, Washington, United States*

Social determinants of health (SDH) are non-medical social needs key to reducing health disparities and improving health outcomes. Adequately identifying patients' unmet SDH needs in primary care (PC) is a critical first step in addressing them, yet many questions remain regarding feasibility and implementation of screenings and how to effectively meet patients' needs and improve their outcomes. With formative and process evaluation analyses, we report on the development and implementation of a community-based pilot study to proactively target high-risk, low-income, older patients with SDH needs. Over a six-month planning period, leadership from a PC clinic and a community based aging services organization (CBO) collaboratively created a shared infrastructure for in-office SDH screening by clinicians with direct referral to CBO for SDH support. The research team addressed challenges of workflow and barriers to sharing/accessing electronic health records. The pilot program will cover a 2-year period (12-month enrollment; 12-month follow-up) in which patients are screened at annual visits and followed-up in the community. In the first 6 months, 286 patients were screened, from which 34 (12%) CBO referrals were made, and nine patients were receptive to receiving more information, suggesting a need to explore patient barriers and receptiveness to services/supports. We report on lessons learned, adaptations to the pilot, efforts to increase identification of eligible patients, and strategies to enhance uptake of services beyond the traditional health care setting. Investment in health and aging services partnerships is a viable pathway to reducing health care use and spending, especially for older adult populations

HOUSING CONDITIONS, SOCIAL CAPITAL, AND SUBJECTIVE WELL-BEING AMONG MIGRANT OLDER ADULTS IN INDIA

SRUTHI ANILKUMAR HEMALATHA, and
NAWAJ SARIF, *International Institute for Population Sciences, Mumbai, Maharashtra, India*

Aging and migration are complex multidimensional processes affected by various factors at different levels. According to the most recent Census of India (2011), more than half of the older adults in India are migrants. Migration at an older age is considered risky and vulnerable because it may lead to many problems. Changes in the environment and living place at an older age may disconnect their social network and affect their health. Therefore, this study examines the housing conditions, social networks, and subjective well-being of older adult migrants in India using data from Longitudinal Aging Study in India, Wave 1 (2017-18). The bivariate and multivariate analyses show significant socio-economic differences in living arrangements and access to better housing facilities among older adult migrants. Additionally, there exist state-wide differences in the social capital of older migrant adults. The likelihood of having poor social capital is higher among migrant older adults than non-migrant older adults. It also reveals that the subjective well-being of older adult migrants is strongly associated with their housing conditions, social networks, and other socio-economic factors. Thus, the paper finds environmental factors and social support essential for better health and well-being, especially for older adults, especially those in new surroundings. Therefore, extensive research is needed to understand the situation of migrant older adults in India to formulate appropriate policies for the same.

NEIGHBORHOOD IMPACTS ON KOREAN OLDER ADULTS' DEPRESSION

Seon Kim, *Virginia commonwealth university, Richmond, Virginia, United States*

Older adults are more influenced by their neighborhood than young adults, however neighborhood impacts on older adults are little known. In response to the increasing depression of older adults in Korea, this study aims to identify the effect of perceived and objective neighborhood characteristics in depression and find differences between rural and urban areas. This study uses the Korean Elderly Survey conducted in 2020 on 10,097 older adults aged 65 and over residing in 17 states, and Korean administration data by connecting them. Multilevel modeling results show that after controlling individual characteristics, depression decreases when older adults perceive their housing condition (b=-.64, p<.001), interaction with neighbors (b=-.29, p<.001), overall neighborhood environment (b=-.26, p<.001) positively. Although objective neighborhood characteristics do not significantly reduce depression in older adults living in urban area, for older adults living in rural areas, the number of social worker (b=- .42, p <.001), the number of senior center (b=-6.70, p<.001), and home care services (b=-49.5, p <.001) are negatively associated with depression in older adults. This study discusses that neighborhood characteristics may play an important role in older adults' depression, and that their effects may differ between rural and urban areas. This study encourages policy makers to consider neighborhood characteristics to improve the mental health of Korean older adults.

OBJECTIVE AND SUBJECTIVE POVERTY AMONG OLDER PEOPLE AND ITS ASSOCIATION WITH HEALTH, FUNCTION, AND MORTALITY

Jeremy Jacobs[1], and Jochanan Stessman[2], *1. Hadassah Medical Center, Mount Scopus, Jerusalem, Yerushalayim, Israel, 2. Hadassah Medical Center, Jerusalem, Yerushalayim, Israel*

We examined objective and subjective poverty between ages 70-95, comparing and contrasting frequency, associated subsequent medical, functional, psychosocial impairment, and mortality. Data collection by the Jerusalem Longitudinal Study, following a representative community dwelling sample (born 1920-1921), assessed at ages 70, 78, 85, 90, and 95. We defined "objective poverty" as sole income from "national old-age pension" necessitating "supplemental income benefit" from the National Institute for Social Security; "subjective poverty" as "financial difficulty getting through each month". Subjective and objective poverty differed: frequency of objective poverty remained 13% throughout follow-up period, while subjective poverty was more frequent at younger age, decreasing from 24% at ages 70-85, to 14% at ages 90-95. Subjective poverty was significantly associated with depression at all ages (from HR=3.2, CI 95%:1.73-5.93 at age 70, to HR=2.45, CI 95%:1.32-4.54 at age 95), and poor self-rated health (from HR=2.69, CI 95%:1.63-4.46 at age 70, to HR=1.96, CI 95%:1.11-3.43 at age 95), however no consistent associations with objective poverty was observed. Both objective and subjective poverty were associated with low levels of physical activity, impaired functional and cognitive status. Mortality was significantly increased among subjects with subjective poverty at ages 70, 85, and 90 (ranging from HR=1.33, CI 95%: 1.02-1.74 to HR=1.50, CI 95%:1.11-2.03), while objective poverty was significantly associated with increased mortality at ages 78 and 85 (HR=1.43, CI 95%:1.01-2.03, and HR=1.55, CI 95%:1.16-2.07 respectively). In conclusion, subjective and objective poverty differ in their association with health, functional and psychosocial status, and mortality between ages 70-95.

SESSION 6620 (POSTER)

SPIRITUALITY AND RELIGION

LONGITUDINAL ASSOCIATIONS BETWEEN SPOUSAL LOSS, RELIGIOUS INVOLVEMENT, AND COGNITIVE HEALTH IN LATER LIFE

Xinfang Yu, and Hyo Jung Lee, *Nanyang Technological University, Singapore, Singapore*

Death of a spouse is one of the major stressors which is more frequently observed in one's late life. Previous literature showed a link between the death of a spouse and late-life cognitive health and suggested a benefit of having more religious involvements. Applying Stress Process Model, this study examines multiple dimensions of religious involvements and whether they buffer a negative impact of spousal loss on cognitive health in old age. Using data from the Health and Retirement Study (2006 – 2016 waves), we selected older adults who were married at baseline (N = 6658). We conducted a) regression analyses to examine the main effect of spousal loss on cognitive health as well as buffering effect of religious involvement and b) growth curve modeling to analyze the trajectories of cognitive functions. Preliminary analyses showed that spousal loss in late life was associated with poorer cognitive function among older adults at baseline and follow-ups. More frequent attendance at religious services and prayer in private setting were associated with better cognitive function, yet, no buffering effect was found. We observed a gradual decline in cognitive function over time among the widowed respondents. Findings confirm that widowed individuals are more likely to experience cognitive decline over time, compared to married counterparts. While religious involvement might not mitigate the negative impact of spousal loss on cognition, the study supports that each dimension of religious involvement may exert different outcomes in terms of older individual's cognitive health during widowhood.

THE RELATIONSHIP BETWEEN RELIGIOSITY AND NURSING HOME SERVICE UTILIZATION: A LONGITUDINAL ANALYSIS

Corina Ronneberg[1], and Edward Miller[2], *1. University of Massachusetts Boston, Chicago, Illinois, United States, 2. University of Massachusetts Boston, Boston, Massachusetts, United States*

On any given day 3.9% to 4.2% of the US population receives nursing home (NH) care. Given the critical role NHs play in caring for older adults, research has identified various demographic, biological, psychological, and social factors associated with NH utilization. Few studies, however, have explored religiosity as a predictor; none, longitudinally. This study thus aims to examine how one's religiosity (organizational, non-organizational, intrinsic) affects NH use. A total of n=7,564 respondents (>51 years) from the 2006 wave of the Health and Retirement Study, with no prior NH use, were assessed every two years, until 2014. Hierarchical modeling techniques (i.e., Generalized Estimating Equations Multinomial Logistic Regression) were used to model the relationship between religiosity and subsequent NH use, while controlling for other factors. Results indicate that high levels of organizational religiosity (i.e., service attendance) is associated with higher rates of NH utilization (B= 0.13, p < 0.001). Conversely, they indicate that higher non-organizational religiosity (i.e., private prayer) is associated with a lower likelihood of NH care use (B= -0.03, p < 0.05). Sex and race served as moderators in these relationships. The association between higher levels of service attendance and higher rates of NH utilization may reflect the sharing of information about available resources such as long-term care through one's social support networks, including congregations. In contrast, individuals who were more likely to pray on their own, may lack the social support provided by congregations, and as a result, experienced more limited knowledge transfer about available resources such as NHs.

TESTING A PORTION OF THE OKLAHOMA AGING INMATE FORGIVENESS MODEL

George Randall[1], Alex Bishop[2], and Sydney Bellah[2], *1. Sam Houston State University, Huntsville, Texas, United States, 2. Oklahoma State University, Stillwater, Oklahoma, United States*

The study assessed the viability of the published Oklahoma Aging Forgiveness Model on women in custody using cross-sectional data collected from females, violent and non-violent, in custody in Oklahoma. The theoretical model led to a hierarchical regression of a measure of positive mental health (Positive Evaluation of Life) on a block of control variables (age, education, and crime type), a block consisting of items from the Duke Religiosity measure, and a final block utilizing forgiveness of self, others, and situation (Heartland Forgiveness Scale). Results from the complete sample, N=447, explained 36% of the variance in the outcome. Significant individual predictors included in the final model were crime type, religiosity, and forgiveness of self and situations. We split the sample on crime type and found that for the violent offenders (N=228), 39% of the variance in the outcome was explained; in addition to religiosity, all three assessments of forgiveness were significant predictors. For the non-violent offenders (N=209), 35% of the outcome's variability was explained. Religiosity, forgiveness of self and situation were significant predictors for this sub-sample. Discussion will focus on the Oklahoma Aging Forgiveness Model and how it works similarly for men in custody (published) and for women in custody. Further, the discussion will focus on the significant role played both by religiosity and forgiveness for those in custody. Findings from this study and that of studies with men clearly demonstrate that religiosity and forgiveness are important aspects of a prisoner's life.

FAITH, HOPE, AND LOVE: UNDERSTANDING RELIGIOSITY AND HOPE AMONG OLDER AFRICAN AMERICAN COUPLES

Antonius Skipper[1], and Andrew Rose[2], *1. Georgia State University, Atlanta, Georgia, United States, 2. Texas Tech University, Lubbock, Texas, United States*

Older African Americans frequently turn to their religion or spiritual faith as a source of coping and resilience. Disproportionately burdened by numerous disparities and stressors, many African American utilize religion as a source hope for the future. Existing studies suggest that higher levels of positive religious coping are associated with higher levels of hope, and more frequent experiences with negative religious coping are associated with lower levels of hope. However, the relationship between religious coping and hope is underexamined among one of the most religious dyads in the U.S., older African American couples. This study utilizes data from 194 older African American couples (146 married and 48 cohabiting), with each partner between the age of 50 and 86 years, to examine the dyadic relationship between religious coping and hope. Actor Partner Interdependence Models revealed that men's religious coping was associated with their own hope, and women's religious coping was associated with their own hope. One unexpected partner effect was identified and found that women's positive religious coping was negatively associated with men's hope. Given the dearth of research on older African American couples, along with the need to better understand religious significance in psychosocial dyadic outcomes, this study offers several implications for engaging African American couples in relational counseling and therapy across the life course.

THE ROLE OF SPIRITUALITY IN LATER LIFE: A STUDY OF OLDER ADULT UNIVERSITY STUDENTS IN PORTUGAL

Giuliana Casanova, *University of Aveiro/ University of Porto , Leca do Balio , Porto, Portugal*

In Portugal, little has been done to investigate spirituality and its impact on later life. This study aims to discover whether spirituality contributes to successful aging in the lives of Portuguese older adults. This mixed-methods research study is based in Porto, Portugal. The sample size is 58 students from universities of the third age, ages 65 to 89 with no cognitive deficit. Data was collected by a demographic questionnaire, Spirituality Scale, Scale of Psychological Well-Being, and a mix method questionnaire. The data analysis was conducted by descriptive statistics and thematic analysis.

Results: Participants rated high in both the Spirituality Scale and the Psychological Well-Being Scale. The data also showed a significant and positive correlation between the dimension of hope/optimism from the Spirituality Scale and the dimension of autonomy from the PWB Scale; as well as between global spirituality and the dimension of autonomy. The mix-methods questionnaire showed 90% of the participants believe in God or a higher power, 81% considered themselves spiritual while 89.4% felt spirituality had always been a part of their lives. The three most significant themes that emerged were the connection to a higher power/divine, personal well-being, and the importance of spirituality throughout their lifetime. Discussion: Spirituality demonstrated to be correlated with the participant's ability and perception of autonomy and independence; having their spirituality as a coping mechanism to deal with life´s adversities while being able to look at the future with optimism. Spirituality can provide purpose, guidance, and meaning in the later years of life.

SESSION 6630 (POSTER)

ADULT PROTECTION, ELDER ABUSE, AND AGEISM

ATTITUDES TOWARD AGING AMONG COLLEGE STUDENTS: RESULTS FROM THE INTERGENERATIONAL CONNECTIONS PROJECT

Ling Xu[1], Noelle Fields[2], Alan Adolfo Kunz Lomelin[1], Kathryn Daniel[1], Daisha Cipher[2], and Brooke Troutman[3], *1. University of Texas at Arlington, Arlington, Texas, United States, 2. The University of Texas at Arlington, Arlington, Texas, United States, 3. Air Force Academy, Air Force Academy, Colorado, United States*

To improve college students' attitudes toward aging, an intergenerational intervention was implemented to connect them with community-dwelling older adults with cognitive impairment. College students were trained to make weekly phone calls to Meals on Wheels clients (age 65+). This study was an investigation of changes in college students' attitudes toward aging over the course of study participation.College students aged 18 to 30 from a large public university in North Texas were recruited. Participants (n = 41) completed surveys through QuestionPro at baseline, midway, and at the end of the study. The Fraboni Scale of Ageism was used to measure attitudes toward aging. Friedman tests and one-way repeated measures ANOVAs were computed. Results indicated that college students' total ageism scores significantly improved over time (F(2, 76)=4.491, p=.014), as well as their antilocution ageism scores (F(2, 76)=5.075, p=.007), and their avoidance ageism scores (F(2, 76)=3.844, p=.026). In addition, scores on six specific items significantly improved after participating in the study: "Many old people are stingy and hoard their money and possessions", "Many old people are not interested in making new friends,", "Many old people just live in the past", "I personally would not want to spend much time with an old person", "Most old people should not be trusted to take care of infants", and "Most old people would be considered to have poor personal hygiene". Results suggest that weekly engagement with older adults offers promise for improving attitudes towards aging among college students. Implications for research and practice are discussed.

EXPLORING AGEISM WITHIN THE FAMILY

Stacey Gordon, and Ernest Gonzales, *New York University, New York, New York, United States*

It is well documented that ageism negatively affects older people's opportunities for productive aging, and access to the workplace and healthcare. Ageism as it manifests within families, however, has not yet been well studied despite significant implications for the wellbeing of older adults and families. This study presents the problem of ageism in the family through the lens of larger social structural factors shaping meso- and micro-level behaviors. Negative implicit ageism and stereotype embodiment theory underscore the unconscious perpetuation of negative age stereotypes and attitudes in families. To illustrate this concept, we describe three evidence-based case examples involving interactions among family members observed by a geriatric care manager. The first describes how ageism expressed by an adult child undermines choice, opportunity, and power of the parent when an older adult enlists the help of her adult children in downsizing from the family home to a smaller apartment. The second explores ageism when adult children attempt to persuade their older father to leave his home, pointing out dangers living alone at his age. The third describes a relatively healthy newly widowed woman who is coerced by her adult children to move to an assisted living facility by threatening social and emotional abandonment. These examples demonstrate how macro and meso-level factors combine with the implicit ageism of both adult children and older adults converge, influencing pathways to create healthy, tolerable and toxic living conditions within the family.

ELDER MISTREATMENT AND RELATIONSHIP QUALITY: SECONDARY DATA ANALYSIS USING DATA FROM THE NSHAP

Wei-Lin Xue[1], Zach Hass[2], and Pi Ju Liu[1], *1. Purdue University, Lafayette, Indiana, United States, 2. Purdue University, West Lafayette, Indiana, United States*

As social networks shrink with age, older adults value the importance of interpersonal relationships with close others, such as partners, family and friends. Previous studies focused on perpetrators' and victims' characteristics; however, few studies examined the relationships with close others and the incidence of elder mistreatment. This study used the National Social Life, Health, and Aging Project Wave 1 data (2005-06) to examine the correlations between relationship quality with close others and the occurrence of mistreatment among older adults (N = 3005). Based on spousal relationship literature using the NSHAP data, factor analysis was used to estimate factor scores conceptualizing two domains of relationship quality: relationship support (positive dimensions of relationship), and relationship strain (negative dimensions of the relationship). Logistic regression models were used to test the relationship between the relationship quality factor scores and the likelihood of each mistreatment type while controlling for gender, education, age, and race. Psychological abuse was more likely for older adults experiencing relationship strain with spouse (OR=1.82, p<.001), family (OR=1.75, p<.001), and/or friends (OR=1.67, p< 0.001). Financial abuse was more likely for those experiencing poor relationship support with family (OR=1.34, p<.05) and those experiencing relationship strain with friends (OR=1.47, p<.01). However, relationship quality was not correlated with likelihood of physical abuse. Interpersonal relationships with close others could provide stronger support and care, but relationship strain might contribute to mistreatment. When determining safeguarding gatekeepers to protect older adults from potential mistreatment, interventions should consider the quality and composition of interpersonal relationships with close others.

IS ACTIVE AGING POSSIBLE IN ETHIOPIA? PERCEPTIONS OF RURAL OLDER ADULTS

Abraham Teshome[1], Messay Kotecho[2], and Margaret Adamek[1], *1. Indiana University, Indianapolis, Indiana, United States, 2. Addis Ababa University, Addis Ababa, Adis Abeba, Ethiopia*

Despite historical veneration of elders, older adults are increasingly viewed as a burden in many Sub Saharan African nations. Using a hermeneutic phenomenological approach, in-depth interviews were conducted to explore the aging experiences of 20 adults aged 70 and older in rural Ethiopia. Themes that emerged from the interviews were analyzed in light of the three pillars of the World Health Organization's Active Aging Framework: health, security, and participation. Despite facing multiple barriers to active aging including lack of health care, financial hardship, ageism, and social exclusion, study participants were determined not to withdraw from activities in an effort to retain their autonomy, independence, and sense of dignity. As one participant shared, "the government does not care about us because it considers us as a useless segment of the society." Three themes reflected their major struggles: dwindling health and lack of access to health care, financial hardship, and social exclusion tied to ageism. The fourth theme--willful and purposive engagement--reflects the older adults' response to these struggles. Contrary to myths about rural aging, study participants faced multifaceted challenges that kept them from realizing active ageing as they were not provided with sustained opportunities for health, security, and participation. Study findings point to the need for policymakers and other concerned bodies to develop supportive policies and programs to promote older adults' well-being. The study calls for a paradigm shift that involves adopting the WHO's Active Aging Framework, developing rights-based policies and programs, popularizing active aging, and revitalizing intergenerational solidarity.

A STUDY COMPARING TRENDS IN NUMBER OF AND CONTENT IN ARTICLES ABOUT DOMESTIC VIOLENCE AND ELDER ABUSE IN JAPAN

Asako Katsumata[1], and Noriko Tsukada[2], *1. Rehabilitation Institution, Chiba, Chiba, Japan, 2. Nihon University, Tokyo, Tokyo, Japan*

Since enactment in 2000, Japan's Domestic Violence (DV) Law has been amended four times. No amendments have been made to Japan's Elder Abuse Prevention Law, despite awareness of its imperfections. This study examined trends in the number of journal articles, and titles by content of those articles, using a KJ Method, to determine how the research literature has informed DV law, and to identify gaps in knowledge and further research needs related to elder abuse that could inform policy change. Using the CiNii database, in 2005-2021, we found1020 elder abuse articles (average 60 articles/year), and in 2001-2021, 836 DV articles (average 40 articles/year). Preliminary analyses revealed the per year annual average has been decreasing for each. Although the most used term was similar in both DV and elder abuse articles, which was "responses of professional personnel," 15.4% for elder abuse and 13.4% for DV, title terms differed, with titles of elder abuse articles are more likely to be related to caregiving, such as "support for caregiver" (who are actually abusers) (4.7%) and "dementia" (3.6%), while terms found in DV but not in elder abuse articles included "supports for victims" (7.1%) and "responses to abusers" (5.3%). Our findings indicate that more research on supporting victims of elder abuse may be imperative to inform lder abuse law changes.

SESSION 6640 (POSTER)

AGEISM: EDUCATION, INTERVENTION, AND ADVOCACY

ASSESSING STEREOTYPES OF OLDER ADULTS THROUGH DRAWING: IMPLICATIONS FOR PEDAGOGY IN UNDERGRADUATE AGING COURSES

Melannie Pate, and Elizabeth Fugate-Whitlock, *University of North Carolina Wilmington, Wilmington, North Carolina, United States*

Negative stereotypes and ageism toward older adults remain an insidious problem in the United States. These harmful views of older adults can lead to disparities in health care, social isolation, and loss of functional ability. In order to supplement current research on the perceptions of older adults, the researchers focus on the views of undergraduate students before and after taking an aging course. The students included in this study are enrolled in an undergraduate health and aging course or an undergraduate introduction to gerontology course. Before beginning any coursework, students were asked to draw an older adult, using any combination of colored markers available and to write one sentence describing an older adult. At the end of the course, students were again given the same directive to draw an older adult, using any combination of colored markers, and write one sentence describing an older adult. Content analysis was used to analyze the drawings and the phrases. Colors used and depictions of activity in the drawings changed from the first day of class to the end of the course, showing a progression of their views. Drawings were chosen specifically to elicit honest responses and perceptions of older adults. The results of this study can be used to inform pedagogical choices made when teaching courses on aging to undergraduate students.

CENTENARIANS IN SWEDISH MASS MEDIA: IS IT REVERSE AGEISM?

Cristina Torgé, and Rosita Nyman, *Jönköping University, Jönköping, Jonkopings Lan, Sweden*

Studies on ageism often deal with negative stereotypes due to increasing age. Seldom studied is the increase in status that seems to occur at the turning point of 100 years. This study explores how centenarians are portrayed in Swedish media texts and relates this to mechanisms of ageism and age coding. We used Retriever database, which is the biggest Nordic database containing news media, to search for press articles concerning 100- to 105-year-olds. Our search resulted in 1468 articles, consisting of both news articles and feature articles. Excluding articles that did not deal with persons, articles with a paywall and redundant articles resulted in 235 articles. We analyzed (1) the contexts in which centenarians appeared, (2) the relevance of the persons' age to the event and (3) feelings and values evoked in the articles. On the one hand, news reports evoke how centenarians ought to be shielded from harm and emphasize the indignity of even small wrongdoings. On the other hand, feature articles often use superhuman adjectives to describe centenarians, and emphasize their "youthfulness". In birthday features, there was also an expectation for centenarians to publicize their celebrations and there was a recurrent trope was that centenarians held well-kept secrets about ageing well. Portrayals of centenarians show that they are an esteemed group. However, we also interpret that these portrayals can hide other forms of ageism, particularly compassionate ageism, and a stereotyping of centenarians that play down ill health and emphasize youthfulness at the extremes of old age.

EXAMINING CHANGES IN STUDENTS' ATTITUDES TOWARD WORKING WITH OLDER ADULTS

Christopher O'Brien, *Chatham University, Pittsburgh, Pennsylvania, United States*

Curricular intervention studies have examined if instruction in aging and gerontology affects undergraduates' attitudes, knowledge, and perceptions towards older adults. However, less is known about curricular impact on undergraduates' intentions to work with older adults. By identifying factors that increase undergraduates' intentions to work with older adults we may elucidate meaningful points of intervention to enhance pursuit of careers in the geriatric workforce. The current study examined baseline data from a longitudinal study examining the impact of an upper-level adult development psychology course on student attitudes towards working with older adults. It was hypothesized that there would be positive associations between attitudes towards working with older adults, knowledge about aging, and positive attitudes towards older adults. Participants were 19 undergraduate students enrolled in upper-level undergraduate psychology courses. Participants completed validated, self-report questionnaires related to their attitudes towards working with older adults, ageism attitudes, and attitudes and knowledge about aging. Bivariate correlation analyses were used to examine cross-sectional associations among main outcome variables. More positive explicit attitudes towards older adults were significantly associated with more willingness to work with older adults (r= .49 , p=.04). Additionally, knowledge of aging was positively correlated with perceived social norms around working with older adults (r= .49, p=.04). These initial findings suggest that knowledge and positive attitudes about aging may positively impact attitudes towards working with older adults. Future work will assess curricular impact on undergraduates' intentions to work with older adults, as well as evaluate predictors of change in intentions.

STANDING UP TO AGEISM: PERCEPTIONS OF SIXTY AND EIGHTY YEAR-OLD ADULTS WHO REJECT BENEVOLENT AGEISM

Alison Chasteen[1], Zainab Saleem[1], and Michelle Horhota[2], *1. University of Toronto, Toronto, Ontario, Canada, 2. Furman University, Greenville, South Carolina, United States*

Older people encounter ageism in a variety of daily contexts, yet the consequences of confronting ageist behavior by older targets are not well understood. The present study asked whether the age of the older target who accepts versus rejects an act of benevolent ageism results in different impressions of the older target. Young (N = 368) and older (N = 388) adults read a scenario in which either a 60 or 80 year-old individual accepted or rejected benevolent ageism in the form of unwanted help. Participants then evaluated the older target's warmth, competence, and overall impression of the target. Consistent with pre-registered hypotheses, competence ratings increased but warmth and overall impression ratings decreased when the older target rejected benevolent ageism compared with accepting it. Also consistent with predictions, older participants rated the older target more positively on all measures compared with younger participants. Surprisingly, the 80 year-old target was rated as warmer and made a more positive overall impression than did the 60 year-old target. Target age did not moderate reactions to accepting or rejecting unwanted help, suggesting that perceivers did not distinguish between young-old and old-old targets when evaluating an older target that confronts benevolent ageism. Taken together, these findings are consistent with research on confronting prejudice in general, whereby such confrontations can result in both positive and negative outcomes. Although older adults may reaffirm their competence through rejecting benevolent ageism they will also face the social cost of being viewed as less warm.

THE IMPACT OF COGNITIVE BEHAVIORAL THERAPY ON RELIEVING NURSES' AGEISM TOWARD OLDER ADULTS

Mohammad Rababa, *Jordan University of Science and Technology, Irbid, Irbid, Jordan*

Background: Previous research has approved the effectiveness of cognitive-behavioural therapy (CBT) in managing some psychological problems. However, no previous has examined its impact on nurses’ death anxiety and ageism.

Methods: A randomized controlled trial was conducted on a total of 110 nurses who were randomly assigned to the study groups to test the effectiveness of CBT to reduce nurses’ death anxiety and ageism. The intervention was comprised of multiple training sessions delivered in five modules with the incorporation of several CBT exercises which are guided by the principles of Terror Management Theory.

Results: Overall, using CBT revealed a significant improvement in nurses’ level of death anxiety and ageism among the intervention group compared to the control group. CBT nurses had lower levels of ageism and death anxiety than those in the control group.

Conclusions: the use of CBT is very effective in relieving nurses’ death anxiety and ageism. The findings of the study have proved CBT is an innovative and creative psychological intervention that improves nurses’ psychological well-being and relieves stress and anxiety experiences associated with caring for older adults such as death anxiety which is the precursor of ageism. Future studies are recommended to examine the impact of CBT on other types of prejudices, including sexism and racism among nurses.Relevance to clinical practice: These findings could contribute to improved quality of life and healthcare provided to older adults. CBT could be a crucial component of the ongoing training program for gerontological nurses to target their ageism.

THE RELATIONSHIP OF AGEISM, INTENTION TO WORK WITH OLDER ADULTS, AND SOCIAL DESIRABILITY

Maria MacLean, and Jessica Strong, *University of Prince Edward Island, Charlottetown, Prince Edward Island, Canada*

Previous research demonstrates: 1) men and younger adults have higher negative ageism scores than women and older adults 2) higher scores of negative ageism are associated with lower intention to work with older adults and 3) women and older adults have higher scores for social desirability. It remains unclear how these factors interact. University students (N=547) aged 16 - 59 (Mean = 20.6) completed a survey measuring positive and negative attitudes towards older adults, intention to work with older adults, and social desirability. ANOVAs found a significant effects in negative ageism based on age, $F(1, 3) = 6.69$, $p = 0.01$, $\omega2 = 0.01$, and gender, $F(1, 3) = 11.43$, $p = 0.001$, $\omega2 = 0.02$, with a small effect size, but no significant interaction between age and gender. Young adults ($M = 22.3$) and males ($M = 21.5$) demonstrated more negative ageism than middle aged adults ($M = 23.1$) and females ($M = 22.7$) (lower scores indicate negative attitudes). An ANOVA of gender x age x social desirability was also significant for negative ageism, $F(11) = 2.00$, $p = 0.03$. However, there were no significant effects or interactions for gender or age on positive ageism and intention to work with older adults, or when social desirability was added. Although there were differences between demographic and social desirability groups for negative ageism, this relationship was not found for positive ageism. We expected social desirability to play a role in ageism, but this was not the case in the current sample.

PERCEIVED WORKPLACE AGEISM AND OLDER WORKERS DURING THE GREAT RECESSION

Duygu Basaran Sahin, *The Graduate Center & CUNY Institute for Demographic Research, Brooklyn, New York, United States*

Age discrimination claims filed with the U.S. Equal Employment Opportunity Commission increased sharply at the beginning of the Great Recession (GR) and stayed elevated. Moreover, despite having lower unemployment rates compared to younger workers, older workers' unemployment lasted longer. Previous studies suggest that age discrimination might have extended the unemployment duration for older workers. However, no study has examined the role of perceived workplace ageism in older workers’ employment outcomes during the GR. This paper uses longitudinal data from the Health and Retirement Study to answer the following question: Were older workers who reported to perceive workplace ageism more likely to be unemployed or quit the labor force during the Great Recession? The baseline sample consists of workers aged 51 or older in 2006 (N=4,176). Multinomial logistic regression results show that older workers who agreed that in decisions about promotion, their employer gives younger people preference over older people, were more likely (RRR 2.05, $p=0.01$) to lose employment in 2008 than being employed, controlling for age, gender, race, education, health, marital status and job characteristics. Older workers who agreed that their co-workers make older workers feel that they have to retire before age 65, were more likely (RRR 1.63, $p=0.002$) to quit the labor force in 2008 than being employed, controlling for the aforementioned variables. These findings shine light on the important role that perceived workplace ageism played in older workers' employment outcomes during the GR.

DEVELOPMENT AND VALIDATION OF THE FAMILIAL AGEISM SCALE

Ruth Walker[1], Emily Kinkade[2], and Alexandra Zelin[1], *1. The University of Tennessee at Chattanooga, Chattanooga, Tennessee, United States, 2. North Dakota State University, Fargo, North Dakota, United States*

Researchers have found a tie between family relationships and the physical and mental health outcomes of older adults (Kelly et al., 2017; Silverstein & Giarrusso, 2010). Researchers have also established the negative impact of ageism on the physical and mental health of older adults (Chang et al., 2020; Lyons et al., 2018). However, studies studying the impact of ageism perpetuated by family members is relatively unexplored. This may be due to a lack of measures to assess ageism perpetuated by family members specifically. To address this gap, the goal of the current study was to design a tool to measure experiences with familial ageism. Scale items were created based on the review and analysis of qualitative data on this topic (Walker & Kinkade, in prep). Items were reviewed by scholars for content and clarity. Two studies were then conducted to develop and validate our measure to assess experiences with ageism within the family context. In the first study, 151 participants completed the familial ageism items. The factor structure, convergent and divergent validity of the items were examined. We found evidence of strong psychometric properties for five related, but unique, factors in the retained items: Benevolent Ageism, Technological Competency, Out of Touch, Aging Appearance, and General Competence. Construct, convergent, and divergent validity was supported with small to large correlations with scales measuring general ageism, depression, and ego integrity. A second study with 282 participants confirmed the five-factor structure. Implications and recommendations for scale utilization will be discussed.

CULTURAL VARIATION OF AGE DIFFERENCES IN DEVELOPMENTAL TRANSITIONS AND ATTITUDES

William Chopik[1], Alejandro Carrillo[1], and Hannah Giasson[2], *1. Michigan State University, East Lansing, Michigan, United States, 2. Arizona State University, Tempe, Arizona, United States*

The age-group dissociation effect posits that, as negative age stereotypes become more salient, older adults will psychologically distance themselves from their own age group. This phenomenon is also seen in various attitudes about development and older adulthood, such as how relatively old or young individuals feel and the point at which older adulthood starts. Previous research has shown that people push older adulthood further into the future with every year of life—placing it perpetually on the horizon. However, most research on age attitudes and age-group dissociation have been conducted within one culture, and variation across settings is rarely examined. A sample of 1,007,956 participants ranging in age from 10 to 89 ($M = 27.45$, $SD = 12.45$; 67.1% women) from 13 different countries completed attitudinal measures about aging and developmental transitions. Across all countries and attitudinal measures, we replicated the age-group dissociation effect ($\beta s > .36$). However, culture moderated many of the effects. For example, relative to the U.S., Chinese and Korean participants reported a younger age at which older adulthood started but showed a more dramatic age-group dissociation effect. In contrast, other countries reached an asymptote where older adults did not push the transition into the future as dramatically as middle-aged adults. Relative to the U.S. (and controlling for age), most countries showed a younger subjective age, and countries varied according to cultural values. The current project sheds light on how age-related attitudes and perceptual processes vary (and don't) across cultural contexts.

AGEISM IN ARTIFICIAL INTELLIGENCE: A REVIEW

Charlene Chu[1], Kathleen Leslie[2], Shehroz Khan[3], Rune Nyrup[4], and Amanda Grenier[1], *1. University of Toronto, Toronto, Ontario, Canada, 2. Athabasca University, Athabasca, Alberta, Canada, 3. KITE-Toronto Rehab, Toronto, Ontario, Canada, 4. University of Cambridge, Cambridge, England, United Kingdom*

Background: Artificial intelligence (AI) has emerged as a major driver of technological development in the 21st century, yet little attention has been paid to algorithmic biases towards older adults. "Digital ageism" is a new form of ageism that is embedded into technology and AI systems. Aim: This review aimed to explore how age-related bias is encoded in AI systems to better understand digital ageism.

Methods: The scoping review follows a six-stage methodology framework developed by Arksey and O'Malley. The search strategy has been established in six databases and we will investigate grey literature databases, targeted websites, popular search engines. An iterative search strategy was used. Studies meet the inclusion criteria if they are in English, peer-reviewed, available electronically in full-text, and included the concepts 'bias' and old age. At least two reviewers independently conducted title/abstract screening and full-text screening.

Results: Our database searches resulted in 7 595 manuscripts that underwent title and abstract screening. Of these 49 papers, were included in the study. The word "ageism" was explicitly mentioned only in about half of these papers. Approximately half the papers mentioned how age-related bias could be encoded into AI systems. The most commonly used AI applicaiton was computer vision.

Conclusions: Our preliminary findings contribute foundational knowledge about the age-related biases that were encoded or amplified in AI systems. This work advances how AI can be developed in a manner consistent with ethical values and human rights legislation, particularly as it relates to an older and aging population.

SESSION 6641 (POSTER)

DISEASES, AGING, AND GEROSCIENCE

KNEE OA AS A SYSTEMIC MODEL OF AGING

Dennis Lox, *Clearwater Fl, Clearwater, Florida, United States*

Knee osteoarthritis (OA) and aging, may be viewed differently by various patients and health care providers. Aging is now considered as a systemic interplay of molecular, cellular, tissue, hormonal, and body dysfunctions. Important drivers of these factors lead to osteoarthritis, coronary artery disease, cancer and dementia. An understanding of each as its progresses can alter morbidity. The proposed theories of aging hold true for knee OA. A simple joint compartment model, such as the knee, may help this understanding. A degenerative knee OA joint is a progressive disorder, just like aging. Knee OA may be accelerated by trauma, aging, decreased autophagy, cellular changes, cytokine production, disruption of the matrix, and cellular senescence. The associated SASP leads to the progressive cascade of degenerative changes. Understanding how to mitigate these affects provides a framework for a longer healthspan. Obesity, and it's adipokines exacerbate the inflammation, and compound weigh bearing stress. Promotion of longevity pathways, stimulate repair via Sirt, AMPK, FOXO and decreased stimulation of MTor, and FOXO4- P53 coupling. The resulting changes can altering the nature of the accelerated nature of progressive knee OA. Joint conservation, unregulated IL-4, IL-10, IRAP, and down regulation of NF-kB, and the ensuing cascade of HMBG1, and DAMP. Hippocrates wrote walking is man's best medicine, however, with knee OA this may need amendment, to encourage proper medical guidance for appropriate exercise and diet. It is time to merge knee OA and aging models to work in harmony for prolonged health span.

STABILIZING ROLE OF HCN CHANNELS ON POST-CAMP MECHANISMS OF DETRUSOR MYOCYTE CONTROL

Ramalakshmi Ramasamy[1], Alya AlObaidi[2], and Phillip Smith[1], *1. UConn Health, Farmington, Connecticut, United States, 2. U Hart, Hartford, Connecticut, United States*

Aging is associated with an increased incidence of co-morbidities, including detrusor underactivity (DU). DU is defined as the failure to create sufficient and durable expulsive force to adequately empty the urinary bladder during a normal voiding timespan. DU is prevalent in older adults, as evidenced by its prevalence in nearly two-thirds of nursing home residents. Current treatments are mostly palliative or come with many side effects. β-adrenoceptor-mediated relaxation is the primary mechanism of detrusor relaxation, and Hyperpolarization-activated Cyclic Nucleotide-gated (HCN) channels have previously been identified by us and others as a very important mediator of this relaxation, however the role of HCN in detrusor relaxation has not been elucidated. Hence, we seek to characterize its role in adrenergic relaxation mechanisms and spontaneous myocyte activity. Male and female 10–12-month-old C57Bl/6 mice were used for this study. Pharmacomyography studies were performed to assess the effect of different drugs that act at various steps along the adrenergic relaxation pathway, +/- CsCl, an HCN blockade at [5mM]. As expected, we saw that increasing HCN opening probability by isoproterenol or forskolin (adenylyl cyclase/cAMP-agonist) or lamotrigine (HCN-activator) resulted in decreases in tonic tension, but were diminished in the presence of CsCl. Mechanisms modulated by H89 (PKA-inhibitor) and NS1619 (BK-channel-agonist) show no change in tonic tension, however spontaneous phasic activity significantly increases. These data support increased cAMP, not hyperpolarization, as the key inductor of HCN in adrenergic relaxation.

THE ROLE OF PLATELET ENERGY METABOLISM IN PAIN AFTER WALKING IN BLACK ADULTS WITH KNEE OSTEOARTHRITIS

Jennifer Klinedinst[1], Weiliang Huang[2], Maureen Kane[3], Gary Fiskum[4], Apruva Borcar[4], Parisa Rangghran[4], and Susan Dorsey[5], *1. University of Maryland School of Nursing, Baltimore, Maryland, United States, 2. School of Pharmacy, Baltimore, Maryland, United States, 3. University of Maryland Baltimore, Baltimore, Maryland, United States, 4. University of Maryland School of Medicine, Baltimore, Maryland, United States, 5. University Of Maryland School of Nursing, Baltimore, Maryland, United States*

Nearly 30% of adults aged 60 or older suffer from knee osteoarthritis (KOA) that causes significant pain and disability. Walking is considered a "gold standard" treatment option for reducing KOA pain and maintaining joint mobility. However, pragmatic trials have shown that walking increases pain for some and relieves pain for others. The mechanism by which walking is helpful for KOA pain is unclear. The purpose of this study was to gain a better understanding of the mechanisms underlying walking for knee pain. We conducted a pre-test/post-test study using quantitative sensory testing to measure pressure pain sensitivity at the knee and examined protein signatures and measured energy metabolism in platelets in six adults with KOA before and after six weeks of walking three days/week at 100 steps/minute. All participants identified as Black/African American, five were female, average age 57±5.8. Pressure pain sensitivity increased for three participants and decreased for three participants. Protein signatures among KOA participants indicated differences in immune and energy metabolism pathways. Proteins in the energy metabolism pathways were significantly downregulated after walking in participants whose pain increased compared to participants whose pain decreased. Platelet energy metabolism was also lower among participants whose pain increased as compared to participants whose pain decreased. One goal of developing individualized interventions for KOA pain is to elucidate the mechanisms by which self-management interventions impact pain. The addition of therapies that target cellular energy metabolism may lower pain with walking among Black adults with KOA.

COMMON NONCARDIOVASCULAR MULTIMORBIDITY PATTERNS AND OUTCOMES IN OLDER ADULTS WITH MAJOR CARDIOVASCULAR DISEASE

Stephanie Denise Sison[1], Joshua K Lin[2], Mehdi Najafzadeh[2], Elisabetta Patorno[3], Lily G Bessette[4], Heidi Zakoul[2], and Dae Kim[5], *1. Beth Israel Deaconess Medical Center, Brookline, Massachusetts, United States, 2. Brigham and Women's Hospital, Boston, Massachusetts, United States, 3. Brigham and Women's Hospital, Harvard Medical School, Boston, Massachusetts, United States, 4. Department of Medicine, Boston, Massachusetts, United States, 5. Hebrew SeniorLife, Boston, Massachusetts, United States*

Non-cardiovascular multimorbidity often coexists in older adults with cardiovascular disease (CVD), but their clinical significance is uncertain. Using Medicare data, we examined common non-cardiovascular comorbidity patterns and their association with clinical outcomes in beneficiaries with congestive heart failure (CHF), acute myocardial infarction (AMI), or atrial fibrillation (AF). We created 3 CVD cohorts of beneficiaries diagnosed with CHF (n=57,285), AMI (n=24,808), and AF (n=36,277) before January 1, 2016. Within each cohort, we applied latent class analysis to classify beneficiaries based on 7 non-cardiovascular comorbidities, including dementia, cancer, chronic kidney disease (CKD), chronic lung disease, depression, diabetes, and musculoskeletal disease. Mortality, cardiovascular and non-cardiovascular hospitalization, and home time lost until December 31, 2016 were compared across non-cardiovascular multimorbidity classes. Similar non-cardiovascular multimorbidity classes emerged from 3 CVD cohorts: 1) minimal, 2) depression (or lung-depression in AMI cohort), 3) diabetes-CKD, and 4) multi-system class. Compared to minimal class, multi-system class had the highest risk of mortality (hazard ratio [HR], 3.0 to 3.7), cardiovascular hospitalization (HR, 1.6 to 3.4) and non-cardiovascular hospitalization (HR, 2.8 to 6.0), and home time lost (rate ratio, 2.8 to 4.8), followed by lung-depression/depression or diabetes-CKD classes. In CHF and AF cohorts, multimorbidity classes were associated with greater increase in non-cardiovascular hospitalizations than cardiovascular hospitalizations. Our findings emphasize that improving health of older adults with CVD requires attention to non-cardiovascular multimorbidity.

ELDERLY MOUSE DETRUSOR MAINTAINS ITS PEAK FORCE OF CONTRACTION OVER TIME

Nadav Mortman[1], Ramalakshmi Ramasamy[2], and Phillip Smith[2], *1. University of Connecticut School of Medicine, FARMINGTON, Connecticut, United States, 2. UConn Health, Farmington, Connecticut, United States*

Aging is a risk factor for urinary dysfunction. Detrusor weakening has been thought to contribute to the old bladder phenotype. Animal detrusor strips have been used to study bladder function. Strength of contraction in detrusor strips depends on length. This is referred to as the “length-tension relationship.” The aim of our study was to investigate this relationship in a mouse model by comparing the length-tension relationship in old and mature mice. We hypothesize that aging is associated with no change in active detrusor tension capability, however maximal tension will occur at longer lengths.We used two groups of male C57/Bl6 mice for this study, mature 11-12 month old mice and old 22-23 month old mice. Longitudinal intact bladder strips were harvested and placed in a vertical tissue bath between tension recording transducer hooks. Passive tensions and KCl induced contraction tensions for step-wise increments of stretch were observed.In the old group, normalized strip length at the point of maximum active tension was increased by ~13% on average as compared to the mature group with a statistically significant difference (P value 0.0171). Interestingly, the maximum active tension between groups did not differ by age. In conclusion, detrusor from old mice achieve similar maximum active tensions as that from mature mice, however at an increased length. This finding argues against a common belief that the bladder weakens with age. Instead, the aging bladder may adapt to increased filling volumes with an ability to operate at a similar strength of a younger bladder.

A ROUTINE BLOOD PARAMETER BIOLOGICAL AGE COMPOSITE IS ASSOCIATED WITH FRAILTY IN THE BERLIN AGING STUDY II (BASE-II)

Ilja Demuth[1], Valentin Vetter[2], Johanna Drewelies[3], Sandra Duezel[4], Dominik Spira[2], Elisabeth Steinhagen-Thiessen[2], Lars Bertram[5], and Denis Gerstorf[6], *1. Charité Universitätsmedizin Berlin, Berlin, Berlin, Germany, 2. Charité - Universitätsmedizin Berlin, Berlin, Berlin, Germany, 3. Humboldt University Berlin, Berlin, Berlin, Germany, 4. Max-Planck-Insitute for human developement, Berlin, Berlin, Germany, 5. University of Lübeck, Lübeck, Schleswig-Holstein, Germany, 6. Humboldt Universität zu Berlin, Berlin, Berlin, Germany*

High-quality biomarkers are needed to predict age-related phenotypes and evaluate health-related interventions. Telomere length has been known as a biomarker of aging for some time, however, its potential for clinical use is limited. Epigenetic age estimators and biological age (bioage) composites have been developed and refined over the past decade and their evaluation is ongoing. Aim of the current study was to further evaluate a recently developed bioage composite based on 12 routine laboratory blood parameters which have been shown to individually predict mortality risk. To this end, we assessed the relationship between the bioage composite, frailty and a number of functional assessments. The bioage composite was calculated for participants of the Berlin Aging Study II (BASE-II) aged ≥ 60 years (N=1,278, mean age 68.6 ±3.7 years, 53.3% women). Frailty was operationalized by Fried’s five-point frailty score. Functional capacity was assessed with a battery of tests including the Tinetti mobility test, finger-floor distance (FFD), Mini-Mental State Examination (MMSE), Center for Epidemiologic Studies Depression Scale (CES-D), activities of daily living (ADL) and instrumented ADL (IADL). In covariate adjusted regression analyses the deviation of the bioage composite from chronological age was significantly associated with frailty (beta = -0.014, p= 0.014), the CES-D and ADL in men, and with the FFD in women. These results will be discussed with respect to their clinical relevance and compared to previously reported BASE-II data on the relationship between frailty, functional assessments and the biomarkers of aging derived from epigenetic clock algorithms and telomere length.

REDUCED LEVELS OF NAD IN SKELETAL MUSCLE IN PEOPLE AGING WITH HIV INFECTION ON TREATMENT

Monty Montano[1], Karol Pencina[1], Michael Schultz[1], Thanh Tran[2], Zhuoying Li[1], Catherine Ghattas[3], Jackson Lau[4], and David Sinclair[1], *1. Harvard Medical School, Boston, Massachusetts, United States, 2. Boston University, Boston, Massachusetts, United States, 3. Brigham and Women's Hospitial, Boston, Massachusetts, United States, 4. Brigham and Women's Hospital, Boston, Massachusetts, United States*

People living with HIV (PLWH) are disproportionately burdened with multimorbidity and decline in physiologic function compared to their uninfected counterparts, but biological mechanisms that differentially contribute to the decline in muscle function in PLWH compared to uninfected people remains understudied. The study site was Brigham and Women's Hospital, Harvard Medical School, Boston MA. We evaluated skeletal muscle tissue for levels of total NAD, NAD+ and NADH in middle-aged asymptomatic PLWH, coinfected with hepatitis C virus (HCV) and/or cytomegalovirus (CMV) and compared them to uninfected control participants. Of the 54 persons with muscle biopsy data, the mean age 57 years with 33% women. Total NAD levels declined in skeletal muscle in association with HIV infection, and was exacerbated by HCV and CMV coinfection, with lowest levels of total NAD, NAD+ and NADH among persons that were coinfected with all three viruses (P=0.015, P=0.014, P=0.076; respectively). Levels of total NAD, NAD+ and NADH in skeletal muscle were inversely associated with inflammation (P=0.014, P=0.013, P=0.055; respectively). Coinfections were also associated with measures of inflammation (CD4/CD8 ratio: P< 0.001 and sCD163: P< 0.001), immune activation (CD38 and HLA-DR expression on CD8 T cells: P< 0.001). Additionally, coinfection was associated with increased physiologic frailty, based on the VACS Index 1.0 assessment (P=0.001). Further research is warranted to determine the clinical relevance of preclinical deficits in NAD metabolites in skeletal muscle in association with viral coinfection and inflammation, as well as the observed association between viral coinfection and physiologic frailty.

OLDER PEOPLE LIVING WITH DEGENERATIVE SPINE DISEASE WHO UNDERGO SPINE SURGERY—TRYING TO BE NORMAL

Andrea Strayer[1], and Barbara King[2], *1. University of Iowa College of Nursing, Iowa City, Iowa, United States, 2. University of Wisconsin-Madison School of Nursing, Madison, Wisconsin, United States*

Lumbar degenerative spine disease (DSD), a consequence of aging, occurs globally in 266 million persons annually. As the population ages, the number of spinal surgeries will increase. The purpose was to investigate older peoples' understandings of living with and having surgery for DSD and the process they engage in to return to normal. Grounded theory (GT) was used to guide this study. Fourteen older people (≥ 65yrs) were recruited for 2 in-depth interviews (audio-recorded/transcribed verbatim) at 2-time-points: T1 during hospitalization and T2, 1-3-months post-discharge. All 14 interviewed at T1; 10-T2 (1mo); 2-T2 (2mo); 2-T2 (3mo) post-discharge (N=28 interviews). Consistent with GT, purposive and theoretical sampling was used. Data analysis (interdisciplinary team) included open, axial, and selective coding. A conceptual model was developed illustrating the phases older persons with DSD go through in their trajectory of trying to return to normal. Three key categories were identified (1) Losing Me (2) Fixing Me and (3) Recovering Me. All described a prolonged process of losing functional independence and being able to socialize. Fixing Me was proving they needed surgery and preparing for surgery. Recovering Me involved monitoring and ongoing progress. Conditions, including setbacks and delays, slowed recovery. Throughout, participants had to continually adjust their expectations. The conceptual model details how older people engage in living with and undergoing DSD surgery. Our model can serve as the foundation for developing interventions to guide older patient education programs, improve care transitions and develop patient-centered approaches for treating older people with DSD and spine surgery.

OBESITY MAY UNDERLIE SKELETAL MUSCLE AUTOIMMUNITY IN OLDER ADULTS

Tan Zhang[1], Xin Feng[1], Juan Dong[1], Kristen Beavers[2], Stephen Kritchevsky[1], and barbara Nicklas[1], *1. Wake Forest School of Medicine, Winston-Salem, North Carolina, United States, 2. Wake Forest University, Winston-Salem, North Carolina, United States*

A mechanistic understanding of the biological basis for sarcopenia could lead to novel biomarkers and intervention targets. We recently reported a novel role of autoimmunity in sarcopenia, which is potentially mediated through cardiac troponin T (cTnT) and its autoantibody. Given the known role of obesity in both autoimmunity and sarcopenia, we further explored the association between circulating cTnT or skeletal muscle IgG and obesity in older adults. We found that, in 37 older adults (NCT01049698, BMI: 30.8 ± 2.3 kg/m^2; Age: 69 ± 3.5 yrs) without any cardiac abnormality, serum cTnT was negatively correlated with skeletal muscle volume ($r = -0.37$, $p = 0.02$) and leg extension strength ($r = -0.38$, $p = 0.02$), but positively correlated with body fat/muscle volume ratio ($r = 0.37$, $p = 0.03$). In two other studies including older adults (n = 11 & 12) from a subset of subjects (NCT01049698 & NCT01298817), skeletal muscle IgG1 (GAPDH normalized level by immunoblot) was found to be positively associated with BMI or dual-energy X-ray absorptiometry derived regional fat measurements, including fat mass, abdominal subcutaneous fat, abdominal fat, or thigh fat. We also found that subjects with higher skeletal muscle IgG1 protein levels have significantly higher BMI but lower knee extensor strength. Our finding suggests that obesity may underlie increased circulating cTnT and skeletal muscle IgG infiltration. It also warrants additional investigation into its role in skeletal muscle autoimmunity in older adults.

SESSION 6650 (POSTER)

CHRONIC DISEASE MANAGEMENT

CHRONIC CONDITION DISCORDANCE AND ALCOHOL USE AMONG OLDER COUPLES: THE MODERATING EFFECTS OF MARITAL QUALITY

Courtney Polenick, Angela Turkelson, James Cranford, Frederic Blow, and Kira Birditt, *University of Michigan, Ann Arbor, Michigan, United States*

Chronic condition discordance (i.e., the extent that two or more conditions have non-overlapping self-management requirements that heighten self-management complexity) may be stressful and contribute to increased alcohol use over time among older adults, especially for those with greater marital stress. In this study, we examined how chronic condition discordance at the individual level (i.e., within individuals) and the couple level (i.e., between spouses) predicted alcohol use across an 8-year period, and whether these links varied by negative marital quality. The U.S. sample included 1,116 wives (M = 54 years) and husbands (M = 57 years) from five waves (2006-2014) of the Health and Retirement Study. Dyadic growth curve models controlled for age, minority status, education, and own and partner time-varying number of chronic health conditions and depressive symptoms. Wives with greater individual-level discordance reported fewer initial drinks per week. Marital quality moderated the links between chronic condition discordance and alcohol use over time. Notably, when husbands reported lower negative marital quality and had greater individual-level chronic condition discordance, they had faster decreases in their own drinks per week over time. By contrast, when husbands reported higher negative marital quality and had greater individual-level discordance, their wives had faster increases in drinks per week over time. Overall, these findings indicate that better quality marriages may protect against increased alcohol use for both wives and husbands in the context of greater chronic condition discordance among husbands.

APPLYING STRESS AND COPING THEORY TO UNDERSTAND DIURETIC ADHERENCE EXPERIENCES IN THOSE WITH HEART FAILURE

Rebecca Meraz[1], Kathryn Osteen[2], Jocelyn McGee[3], Paul Noblitt[4], and Henry Viejo[5], *1. Baylor University, Dallas, Texas, United States, 2. Baylor University Louise Herrington School of Nursing, Dallas, Texas, United States, 3. Baylor University, Waco, Texas, United States, 4. Baylor Scott & White Medical Center at Irving, Irving, Texas, United States, 5. Baylor Scott & White Heart and Vascular Hospital-Fort Worth, Fort Worth, Texas, United States*

Heart failure (HF) is a chronic and costly condition, affecting at least 6 million Americans. The ventricular dysfunction associated with HF results in fluid volume overload, which is commonly managed with diuretics. Despite the benefits of diuretics, some individuals with HF report bothersome and stressful side effects and intentionally do not adhere. Positive intrinsic motivators, such as positive emotions, may benefit individuals in their adaptation to medication-related stress. However, there has been limited study of these potential motivators in older adults with HF. The purpose of this descriptive qualitative study was to understand intrinsic factors underlying diuretic adherence in adults with HF using the transaction theory of stress and coping. Using a descriptive qualitative approach, 82 adults who were hospitalized for HF and prescribed home diuretics were interviewed. The findings of the current study revealed the ways participants appraised diuretics and how they overcame the perceived medication effects so they could adhere to the medication. Data analysis revealed three themes: (1) diuretics are bothersome (2) staying positive in the midst of hardship, and (3) adapting to endure. Adherent participants stayed positive amid the perceived medication-related hardship, maintaining resilient and grateful attitudes. Adherent participants adapted to bothersome diuretic effects and utilized creative strategies for adherence. More research is needed to understand the relationships between resilience, adaptive coping, and adherence to diuretics.

STRUCTURAL EQUATION MODELING OF HEALTH-RELATED QUALITY OF LIFE AMONG PEOPLE WITH VISUAL IMPAIRMENT

Eunjin Yang[1], and Sun Ju Chang[2], *1. Yonsei University, Seoul, Seoul-t'ukpyolsi, Republic of Korea, 2. Seoul National University, Seoul, Seoul-t'ukpyolsi, Republic of Korea*

Visual impairment can lead to limited accessibility and activities and a decreased quality of life. This study aimed to test a hypothetical model based on the International Classification of Functioning, Disability, and Health to predict the health-related quality of life (HRQOL) of people with visual impairment. Data from 202 people with visual impairment were collected from August 2020 to November 2020 via telephone or e-mail. The overall fitness indices of the model for physical HRQOL (Normed $\chi2$=2.076, GFI=.878, TLI=.900, CFI=.928, RMSEA=.073) and the model for mental HRQOL (Normed $\chi2$=2.232, GFI=.884, TLI=.904, CFI=.932, RMSEA=.078) complied with the recommended criteria of structural equation model fitness, indicating that the models were appropriate for predicting the HRQOL of people with visual impairment. The socioeconomic status, multimorbidity, perceived environmental barriers, and activity limitation/participation restriction directly affected the participants' physical HRQOL. Moreover, depression, disability identity, and activity limitation/participation restriction directly affected participants' mental HRQOL. Age, socioeconomic status, depression, social support, and perceived environmental barriers affected the participants' physical and mental HRQOL by means of activity limitation/participation restriction. The findings of the study suggest that the strategies aimed at increasing the activity/participation of people with visual impairment will be helpful in improving their HRQOL. Based on the results of this study, nursing intervention programs and services for people with visual impairment should be developed and implemented to provide more comprehensive care for this group and expand nursing science.

CHRONIC BACK PAIN, LIMITATIONS ON USUAL ACTIVITIES, AND TREATMENT AMONG OLDER BRAZILIANS

Flavia Andrade[1], and Xiayu Chen[2], *1. University of Illinois--Urbana-Champaign, Urbana, Illinois, United States, 2. University of Illinois at Urbana-Champaign, Urbana, Illinois, United States*

Chronic back pain is prevalent among Brazilian older adults, leading to substantial social and healthcare costs. It also disproportionately affects low-income and less-healthy people. Using the latest Brazil's National Health Survey (PNS-2019), multivariate logistic regressions were conducted to examine how biopsychosocial factors correlate with chronic back pain, limitations on usual activities, and pain treatment (N=17,184). PNS-2019 data showed that 31.3% (95% CI 30.1-32.5) of older adults ages 65 to 112 reported back pain. Chronic back pain was positively associated with being female, having more chronic conditions, depressive symptoms, and lower education. Among those who reported having back pain, 19.2% reported that pain limited their usual activities. Higher odds of having limitations were found among older adults with three or more chronic conditions, obesity, and depressive symptoms. However, it was lower among those with higher levels of alcohol consumption. Among older adults with back pain, 69.2% received some treatment for their pain - 24.1% exercised regularly, 14.3% received physical therapy, 48.1% medications/injections, 6.1% alternative methods, and 30.7% regularly visited health professionals. Treatment was higher among women and those with higher education. The results show significant disparities in the prevalence, limitations, and treatment of chronic back pain among older adults in Brazil. The findings point to the need for prevention and treatment programs for older Brazilians with lower socioeconomic and worse health conditions.

INDIVIDUAL FACTORS AFFECTING GLYCATED HEMOGLOBIN LEVELS AMONG OLDER ADULTS WITH DIABETES: A CROSS-SECTIONAL STUDY

Jungkyung Min[1], and Idethia Harvey[2], *1. Texas A&M University, College Station, Texas, United States, 2. University of Missouri, Columbia, Missouri, United States*

Introduction: Many older adults fail to maintain glycemic control even though reasonable glucose control can prevent the onset of macro- and microvascular complications. This present study aimed to determine the independent association of demographic characteristics, clinical factors, treatment modalities, and lifestyle behaviors with glycated hemoglobin levels (HbA1c) among Korean older adults, a group at a very high risk of diabetes.

Methods: We analyzed data from a representative sample of participants (N = 707) aged > 65 years in the Korea National Health and Nutrition Examination Survey (KNHANES), 2016-2018. Participants were classified into two groups according to their age [group 1 (ages 65 to 74) and group 2 (age ≥75)]. Data were analyzed using t-test, analysis of variance, Pearson's correlation, and hierarchical multiple regression.

Results: Age (p=0.003), place of residence (p=0.01), treatment modality (p< 0.001), sedentary behavior (p=0.04), and moderate activity (p=0.002) significantly affected HbA1c levels. In comparison to the factors in two age groups, duration of diabetes was the variable more strongly associated with HbA1c levels (p< 0.001, β=0.283) in group 1, whereas treatment modality was the one strongly associated with HbA1c levels (p< 0.001, β=0.249) in group 2.

Conclusion: It is essential to consider the age duration of diabetes, and biochemical factors to manage HbA1c levels in older adults. Furthermore, our findings suggest including physical activity in the educational program to provide information for diabetes management. In the clinical setting, more close attention should be taken among healthcare providers to control the glucose level for older adults with diabetes.

CHRONIC CONDITION SELF-MANAGEMENT FOR OLDER AFRICAN AMERICANS: THE CHALLENGE OF COMPLEXITY

Heather Fritz, and Malcolm Cutchin, *Pacific Northwest University of Health Sciences, Yakima, Washington, United States*

Older African Americans have higher rates of comorbidity and face substantive challenges with chronic condition self-management (CCSM), including less effective and supportive CCSM care than their white counterparts. Such disparities in care stem, in part, from physicians' lack of understanding about challenges older African Americans face as they engage in CCSM. Yet little is known about the CCSM experiences of older African Americans with comorbidity. In this study, we aimed to determine the central dynamics of those experiences. As part of a larger study on African American CCSM and physician empathy, we conducted in-depth qualitative interviews with 30 older African Americans living in Detroit aged 65 years and older with comorbidity. We used grounded theory analysis to distill findings into a core conceptual category as well as component domains and dimensions. "Complexity" emerged as the core category to describe CCSM in our sample. Complexity resides often at the intersection of race, age, and social position making the older African American CCSM experience inherently difficult for those of different races, ages, and social positions to understand. Data illustrate that domains of complexity include "care time", "care roles", "social context", "logistics", "learning", and "pain management". Each domain is composed of 2 to 4 dimensions, further fleshing out the nature of CCSM complexity for older African Americans with comorbidity. Findings provide a basis to enhance understanding and empathy for older African Americans with comorbidity. We discuss how the model will be used to test understanding of older African American CCSM by medical students.

PHYSICAL FUNCTIONING AND BODY SIZE IN MID-LIFE WOMEN: THE STUDY OF WOMEN'S HEALTH ACROSS THE NATION

Minsuk Oh[1], Kelly Ylitalo[2], Aleda Leis[3], Brittney Lange-Maia[4], Elsa Strotmeyer[5], Jane Cauley[6], and Carrie Karvonen-Gutierriez[3], *1. Baylor University, Woodway, Texas, United States, 2. Baylor University, Waco, Texas, United States, 3. University of Michigan, Ann Arbor, Michigan, United States, 4. Rush University, Chicago, Illinois, United States, 5. School of Public Health, University of Pittsburgh, Pittsburgh, Pennsylvania, United States, 6. University of Pittsburgh, Pittsburgh, Pennsylvania, United States*

To evaluate patterns of age-related changes in physical functioning (PF) and associations with body size, we utilized data from the longitudinal Study of Women's Health Across the Nation (SWAN). Participants (n=1,793) with self-reported SF-36 PF data at visit 4 (2000-01; mean age:50.0 years ±2.7), visit 15 (2016-17), plus one additional visit were included. Body weight and waist circumference were measured at each visit; change from visits 4 to 15 was calculated. Five PF trajectories were identified using latent class growth modeling (% of women): (1) persistently low (4.1%); (2) start moderate and improve slightly (5.4%); (3) start high and decline slightly (24.0%); (4) persistently high (59.5%); and (5) start high and decline substantially (7.0%). Participants with persistently low PF (Group 1) lost weight during follow-up (mean change: -3.2% body weight) whereas there was little change in all other groups (ANOVA p< 0.0001). Women with persistently low PF (Group 1) had < 2% increase in waist circumference over follow-up; all other groups had more than double that increase (range: 4.1%-6.1%; ANOVA p=0.002). No statistically significant differences in anthropometry changes across the PF groups were observed after adjustment for sociodemographic and time-variant health characteristics. PF trajectories may be associated with changes in body weight or waist circumference during midlife and transition to older adulthood; however, these associations may be explained by other major health-related variables. Future research is needed to understand the complex interplay between PF and body size, particularly for women at-risk for late-life disability that may benefit from preventive efforts in mid-life.

THE FIT OF THE HAPA MODEL TO THE EXPERIENCE OF EXERCISING AFTER STROKE: A DEDUCTIVE CONTENT ANALYSIS

Amy Silva-Smith, *University of Colorado at Colorado Springs, Colorado Springs, Colorado, United States*

Sustained physical activity is recommended for secondary stroke prevention. Persons with stroke leave rehabilitation having learned exercises to reduce disability. However, once discharged, people may be on their own to navigate psychological, emotional, social, and physical challenges of maintaining those activities and starting new ones. The Health Action Process Approach (HAPA) provides a framework for understanding how self-efficacy differs depending on where a person is in the process of engaging in physical activity. The purpose of this study was to assess the qualitative fit of the HAPA model to the experience of exercise after discharge from formal stroke rehabilitation using a deductive (directed) content analysis approach. Interviews with 12 stroke survivors were analyzed deductively using the HAPA model concepts task self-efficacy, coping self-efficacy, and recovery self-efficacy to create the analysis matrix. In this sample, a period of psychological adjustment interfered with maintaining exercise and included anxiety, depression, embarrassment, and fear of falling that affected motivation and intention to exercise. Experiences with physical activity and exercise as a child and routines prior to the stroke were factors influencing task, coping, and recovery self-efficacy and ease of dealing with interruptions in exercise, including the discharge from formal rehabilitation. The findings support the qualitative fit of the HAPA model with the experience of exercise after having a stroke. A HAPA model framed intervention is being developed to support the transition from formal rehabilitation support to living in the community.

COMPARING OLDER ADULTS' EXPOSURE TO AND SHARING OF HEALTH-RELATED MESSAGES ON FACEBOOK BY CHRONIC CONDITION STATUS

Matthew Schroeder[1], Carrie Miller[2], and Sherry Pagoto[3], *1. Regenstrief Institute, Inc., Indianapolis, Indiana, United States, 2. VCU Fuemmeler Lab, Richmond, Virginia, United States, 3. University of Connecticut, Storrs, Connecticut, United States*

We compared older adult Facebook users with and without a chronic health condition on their frequency of exposure to and posting health-related messages. Demographics, social media use, and chronic condition status were collected via survey. Regular Facebook users aged 50+ years were recruited via Qualtrics. Participants reported if they had seen, posted, or shared: health-related information; about others'/their own health behaviors (e.g., exercise); and about others'/their own chronic condition. Responses were dichotomized as "Rarely" or "At least once a month". Six logistic regression models, controlling for demographics and Facebook login frequency, assessed whether viewing and/or posting health-related messages differed by chronic condition status. Respondents (N=697; 77.9% female; 87.9% non-Hispanic White) were on average 61.2 years old (SD=7.9). One-half reported a chronic condition (n=351; 50.4%). In adjusted models, those with a chronic condition had a higher likelihood of seeing posts from others with health information (OR=1.37; 95% CI: 1.01, 1.86) and about others' health conditions (OR=1.64; 95% CI: 1.20, 2.23) ≥ monthly (vs no chronic conditions). Similarly, those with a chronic condition had a higher likelihood of posting or sharing health information (OR=1.52; 95% CI: 1.03, 2.24) and about their chronic condition (OR=1.93; 95% CI: 1.16, 3.21) ≥ monthly. People with and without chronic conditions did not differ in how often they saw or posted about health behaviors. Older adults with chronic conditions were more likely than those without chronic conditions to regularly see and share health information on Facebook. The content and accuracy of this health information should be explored.

INTEGRATING TELEHEALTH AND COMMUNITY HEALTH WORKERS TO ENHANCE QUALITY CARE ACCESS: A NARRATIVE REVIEW

Ilana Engel[1], Alice Zhang[2], Robert Stiles[2], Eve-Lynn Nelson[2], and Amber Watts[1], *1. University of Kansas, Lawrence, Kansas, United States, 2. University of Kansas Medical Center, Kansas City, Kansas, United States*

Community Health Workers (CHWs) often share cultural, geographic, or other lived experiences with patients and provide health education and support. Use of CHWs and telehealth approaches are promising strategies for addressing the needs of patients with metabolic syndrome (MetS). This narrative review analyzed how these approaches were integrated into programs expanding care access for patients with MetS. Searching PubMed, PSYCInfo, Embase, Web of Science, and Google Scholar resulted in 1,630+ abstracts screened and 12 articles meeting inclusion criteria. These studies examined implementation of tele-mentoring approaches (n=4), patient group classes via videoconferencing (n=2), or individual telehealth consultations facilitated by CHWs (n=7), with some programs including multiple intervention types. This review included adults ranging from 37-79 years old. Most studies focused on late mid-life (ages 50-64). Because health behaviors in midlife have important implications for MetS and related health concerns in later life, it is important to consider midlife interventions. Using the RE-AIM framework, we evaluated studies on five dimensions: reach, effectiveness, adoption, implementation, and maintenance. Reach and implementation indicators suggest reducing barriers to engagement (e.g., home visits) allows for higher participation and program completion rates. Measures of MetS-related behavioral outcomes were heterogeneous across study designs, making overall effectiveness difficult to determine. Adjusting time spent with patients according to health literacy and clinical needs is a strategy CHW programs use to provide equitable, cost-effective care. Programmatic considerations for implementing programs that include both CHWs and telehealth are discussed, with special consideration for what works in late middle age and in older adulthood.

SESSION 6670 (POSTER)

CIVIC ENGAGEMENT

EXPOSURE TO GENERATIVE MESSAGES BOOSTS COGNITIVE PERFORMANCE IN OLDER ADULTS

Tara Gruenewald, Natalie Standridge, and Clarissa Tadros, *Chapman University, Orange, California, United States*

Both self-perceived and primed generativity has been found to be linked to better cognitive and physical functioning, psychological well-being, and longevity in older adulthood. A prior experiment also found that priming older individuals with messages regarding the generative, or contributory value of their social group (older adults) boosted cognitive performance compared to exposure to a message about the societal burden of one's group (Hagood & Gruenewald, 2018) . A key limitation of this earlier work was the lack of a neutral prime condition to determine whether being exposed to messages regarding the generativity of older adults enhanced their cognitive performance or being exposed to negative messages regarding the social burdens of one's age group suppressed performance. This limitation was addressed in the current online experiment of 300 U.S. adults age 55 and older who were randomly exposed to either a social generativity, social burden, or neutral prime presented as a test of reading comprehension and recall. Participants completed other measures of cognitive ability before and after the priming task, including an assessment of verbal memory. An ANCOVA model including age as a covariate indicated a significant effect of priming condition (F(2,296) = 3.30, p = .038). Mean verbal memory performance did not vary between the neutral and social burden priming conditions, while performance was significantly higher in the generativity prime condition (d=.29). Experimental findings provide support for the hypothesis that exposure to generative messages about one's social group can boost cognitive performance in a national sample of older adults.

THE EFFECT OF STRUCTURAL AND FUNCTIONAL SOCIAL SUPPORT OF OLDER KOREAN VOLUNTEERS ON LIFE SATISFACTION

Meeryoung Kim, *Daegu University, Daegu, Kyongsang-bukto, Republic of Korea*

As well as helping others, senior volunteers, like other seniors, need their own social support. However, unlike general older adults, older volunteers can build many social networks through volunteering. This study aims to examine how structural and functional social support of older volunteers affects their life satisfaction.This study used the sixth additional wave (2016) and the seventh wave (2017) of the Korean Retirement and Income Study. The subjects of this study were volunteers who are aged 60 and older, and the sample size was 241. Multiple regression was used for data analysis. Demographic variables were controlled. As for independent variables, structural and functional social support were used. For the dependent variable, life satisfaction was used. Structural social support was measured by the number of related subjects. For functional social support, Cohen and Syme (1985)'s social support scale, which includes instrumental, emotional, informational, and evaluative support, was used.According to the results of the study, structural support did not significantly affect the life satisfaction of older volunteers, but functional support had a significant effect on life satisfaction. Structural support was not significant because volunteers had many networks through volunteering. However, the functional social support of receiving practical help significantly increased the life satisfaction of the volunteers. These findings imply that having someone who can help them is an important factor in increasing life satisfaction.

THE ROLE OF EDUCATION AND LITERACY SKILLS ON MIDDLE-AGED AND OLDER VOLUNTEERS BY RACE AND ETHNICITY IN THE US

Donnette Narine[1], Takashi Yamashita[2], Wonmai Punksungka[3], Abigail Helsinger[4], Jenna Kramer[5], Rita Karam[6], and Phyllis Cummins[7], *1. University of Maryland, Baltimore, Baltimore, Maryland, United States, 2. University of Maryland, Baltimore County, Baltimore, Maryland, United States, 3. University of Maryland - Baltimore County, Baltimore, Maryland, United States, 4. Miami University, Oxford, Ohio, United States, 5. RAND Corporation, Arlington, Virginia, United States, 6. RAND Corporation, Santa Monica, California, United States, 7. Miami University, Oxford, Ohio, United States*

Volunteer participation is a form of civic engagement that benefits both the individual and society over the life course. Although education, basic skills (e.g., literacy), and race/ethnicity are individually associated with volunteering, detailed interrelations are yet to be explored. Guided by the integrated theory of volunteer work and the notion of productive aging, the goal of this study was to examine the roles of education and adult literacy in the context of volunteering in later life across racial and ethnic groups (Whites, Blacks, Hispanics) in the U.S. Using the nationally representative sample of middle-aged and older adults (age 45+; n = 3,770) from the 2012/2014/2017 Program for International Assessment of Adult Competencies (PIAAC), structural equation modeling was constructed to evaluate mediation relationships among education, literacy, and volunteering by racial and ethnic groups. Results show no statistically significant mediation (a.k.a., indirect) effect of education on volunteering through literacy, nor was there statistically significant difference in the mediation effect across racial and ethnic groups. However, there were statistically significant differences in the direct effect of education on volunteering between Black adults and White adults [b(Black) = 0.44 versus b(White = 0.24), $p < 0.05$], as well as Black adults and Hispanic adults [b(Black) = 0.44 versus b(Hispanic) = 0.08, $p < 0.05$]. These findings indicate that higher education was more strongly associated with volunteering among older Black adults, compared to White and Hispanic counterparts. Suggested policy implications include support for the promotion of volunteer participation through culturally and socioeconomically sensitive approaches.

TYPES OF CULTURAL TOURISM PARTICIPATION AMONG KOREAN BABY BOOMERS

Kyungmin Kim[1], Bon Kim[2], Hwasung Song[3], Jeffrey Burr[4], and Gyounghae Han[1], *1. Seoul National University, Seoul, Seoul-t'ukpyolsi, Republic of Korea, 2. Jeju National University, Seoul, Gyeonggi, Republic of Korea, 3. Suwon*

Research Institute, Suwon-si, Kyonggi-do, Republic of Korea, 4. University of Massachusetts Boston, Boston, Massachusetts, United States

Cultural tourism (e.g., attending festivals, visiting museums and heritage sites) is an important part of leisure activity in middle and later life. As they age, midlife adults may anticipate more time for these activities when their family and work demands are less intense. However, the leisure-as-career perspective suggests that preferences, knowledge and skills for leisure and tourism activities develop throughout the life course. This study examines how Korean middle-aged adults participated in cultural tourism activities and whether their willingness to be involved in active leisure in later life differed by their current patterns of cultural tourism activities. We utilized data from the 2014 Korean Baby Boomer Panel Study (N = 4,053; age 51–60). Latent class analyses were applied to five types of activities (i.e., local festivals and events, exhibitions, museums, heritage sites, and international travels), and three distinct patterns were identified. The majority of the Korean baby boomer sample (81%) belonged to "Inactive cultural visitors"—not participating in any type of activities in the past two years, which may reflect persistent time pressures at midlife. "Casual cultural visitors" (11%) mainly visited local festivals and heritage sites. "Serious cultural visitors" (7%) engaged in all types of activities; they appeared to have more time and financial resources. Further, "serious cultural visitors" showed higher willingness to engage in active later life leisure compared to other two patterns, supporting the continuity of leisure/tourism activities. Our findings highlight the importance of prior leisure and tourism behaviors for understanding future leisure activity expectations.

SESSION 6680 (POSTER)

COGNITION AND AGING

RETURNED MISSING PERSONS WITH DEMENTIA: WHAT ROLE CAN FIRST RESPONDERS AND SERVICE PROVIDERS PLAY?

Christine Daum[1], Lauren McLennan[1], Elyse Letts[1], Cathy Conway[2], and Lili Liu[1], *1. University of Waterloo, Waterloo, Ontario, Canada, 2. University of Waterloo, Toronto, Ontario, Canada*

The number of people living with dementia that wander and go missing is increasing. First responders and service providers play a role in the return of a missing person living with dementia. In the United Kingdom (UK), "return home interviews" are discussions between police and returned missing persons that offer support to the returned missing person to prevent repeat incidents. This study aims to explore and understand the role of first responders and service providers who follow-up with returned missing persons living with dementia. Eight service providers (e.g., social workers) and seven first responders (e.g., police officers) from Canada and the UK participated in online semi-structured interviews. Data were concurrently collected and analyzed using conventional content analysis. In the UK, police conduct "return home interviews" within 72 hours of the missing person's return. Some charities conduct interviews with vulnerable populations to prevent repeat missing incidents by understanding the circumstances of the missing incident and connecting the person to community supports. In Canada, although follow-up with returned missing persons is not routine, some police units offer support to returned missing older adults. Government and community support organizations also offer supports to returned missing older adults such as referrals for in-home support, technologies, and vulnerable person registries. Service providers and first responders have an important role to play in the prevention of repeat missing incidents. Findings will contribute to the development of a Canadian practice guide for conducting interviews with returned missing persons living with dementia.

FAMILY SUPPORT AS A MEDIATOR OF COGNITIVE FUNCTIONING AMONG HISPANIC OLDER ADULTS WITH SENSORY IMPAIRMENTS

Corinna Trujillo Tanner[1], Jeremy Yorgason[1], Avalon White[1], Joshua Ehrlich[2], and Antonia Cash[1], *1. Brigham Young University, Provo, Utah, United States, 2. University of Michigan, Ann Arbor, Michigan, United States*

Background: Understanding the intersection of age, ethnicity, and disability will become increasingly important as the U.S. population ages and becomes more diverse. By 2060, Hispanics, the largest ethnic minority, will comprise 28% of the population. Although a heterogeneous group, originating from a variety of countries, Hispanics may share common cultural values. These familistic values may act as a buffer against social isolation and cognitive decline, commonly associated with sensory disabilities including vision, hearing, and dual sensory disabilities.

Methods: Our sample consisted of 557 Hispanic older adults that participated in the National Health and Aging Trends Study. Longitudinal mediation models across a three-year span were estimated using Mplus with vision, hearing, and dual sensory disabilities predicting cognitive decline directly and indirectly through social isolation. Bootstrapping with 5,000 draws adjusted the standard errors of indirect effects. Results and Discussion: Results suggest that vision disability and dual sensory disability were associated with declines in various cognitive functioning scores. Social isolation was linked with declines in some concurrent and some longitudinal cognitive measures. Although dual sensory disability (i.e., both vision and hearing disability) were linked with social isolation, individual vision or individual hearing disability were not associated with social isolation in this sample. Historically, vision and hearing disabilities have been associated with social isolation, yet in Hispanic cultures, social connections between generations may provide a buffer to this common result of sensory disabilities. Findings from this research suggest that Hispanic older adults experiencing dual sensory disabilities may benefit from interventions that foster social support.

COGNITIVE DECLINE PUBLIC HEALTH SURVEILLANCE: EXPERT-GUIDED COLLABORATION FOR BRFSS MODULE REVISION

John Shean[1], and Benjamin Olivari[2], *1. Alzheimer's Association, Chicago, Illinois, United States, 2. CDC, Atlanta, Georgia, United States*

The Behavioral Risk Factor Surveillance System (BRFSS) Cognitive Decline Module collects population level data on subjective cognitive decline (SCD) — self-reported difficulties in thinking or memory — which can be one of the earliest warning signs of dementia. Originally devised in 2009, the module undergoes periodic revision to ensure it remains current, the data collected are actionable, and to encourage uptake of the module by state health agencies. In 2021, the Alzheimer's Association and the Centers for Disease Control and Prevention's Alzheimer's Disease Program formed an expert workgroup to examine the ongoing value and relevance of the module and propose any improvements. Workgroup members included researchers, chronic disease directors, epidemiologists, survey methodologists, policy analysts, and BRFSS coordinators. Using a consensus-building process, the workgroup utilized pre-meeting worksheets to identify areas of agreement and disagreement which informed key debates during subsequent meetings. Among many factors, the workgroup assessed the existing module for accuracy and utility. Discussion centered on aligning language and concepts contained within the module's questions with current scientific research on SCD and how to accurately and adequately assess the associated burden SCD imposes. People living with cognitive impairment were consulted during the revision process to ensure phrasing reflected their lived experience. The result was a consensus set of suggested revisions to the Cognitive Decline Module, submitted to CDC for review and approval. The robust process, involving a variety of stakeholders and perspectives, can serve as an efficient and effective model for ensuring the longevity and usefulness of population health surveillance.

THE EFFECTS OF LIFETIME EXPERIENCES OF HOMELESSNESS AND INCARCERATION ON COGNITIVE AGING

Douglas Hanes, and Sean Clousten, *Stony Brook University, Stony Brook, New York, United States*

Alzheimer's disease and related dementias (ADRD) remain a pressing health concern in the U.S., and this burden and access to care are unequally distributed across the population. The U.S. has one of the highest incarceration rates globally, which is also unequally distributed; and groups like veterans, formerly incarcerated people, and sexual and gender minorities (SGM) face high risk of homelessness. Homelessness and incarceration are potentially traumatic experiences in themselves. Both experiences are more likely among people with less formal education, less economic security, and racialized groups, even as they reduce educational and economic opportunities. Using data from the Health and Retirement Study (HRS; 1998–2016), we investigate whether self-reported lifetime experiences of homelessness and incarceration (including time spent incarcerated) are associated with cognitive functioning and risk of possible dementia. Multilevel modeling adjusted for age, education, and other demographic covariates revealed that lifetime experiences of homelessness and incarceration are associated with lower cognition (Homelessness: $\beta=-1.231$, $p< .001$; Incarceration: $\beta=-0.929$; $p < .001$), but slower aging-related declines (Homelessness-slopes: $\beta=0.044$, $p<.001$; Incarceration-slope $\beta=0.041$; $p<.001$), and homelessness moderated the impact of prior incarceration ($\beta=-1.789$; $p<.001$), but less-steep declines ($\beta=0.092$; $p <.001$). Homelessness and incarceration, independent of their other risk factors and associated harms, have associations with ADRD risk.

CHILDHOOD SOCIOECONOMIC POSITIONING AND LATE-LIFE COGNITIVE FUNCTIONING: A CRITICAL REVIEW

Hanamori Skoblow, and Christine Proulx, *University of Missouri, Columbia, Missouri, United States*

The predictors of cognitive functioning are varied and complex. Gerontologists are increasingly interested in the long arm of childhood, suggesting that late-life cognitive functioning may be partly the result of influences across the life span. Research shows that childhood economic hardship is associated with disparities in cognitive functioning in older adulthood. Framed by the life course perspective, we reviewed 27 articles that examine associations between childhood socioeconomic positioning (SEP), commonly assessed via parents' educational attainment, and late-life cognitive functioning in 11 different US datasets. The influence of childhood SEP on cognitive functioning is stronger when cognitive functioning is assessed at a single time point rather than as change over time, suggesting that childhood SEP might not affect the rate at which cognition declines in later life, but does impact where decline begins. The majority of research supported the pathway hypothesis, suggesting that childhood SEP's influence on adult cognitive functioning works primarily through the mechanism of adults' own educational attainment and SEP. Several studies support the accumulation of (dis)advantage hypothesis and point to the compensatory potential of upwards social mobility. Support for the latency model, which posits that early-life economic hardship results in enduring outcomes that influence cognitive functioning in older adulthood, above and beyond one's adult SEP, is present, although weaker than the other hypotheses. Implications include strengthening policies that relieve economic strain and promote educational access among families with young children and also among young adults, as addressing the precursors of cognitive functioning in tomorrow's older adults is paramount.

RELATIONSHIP BETWEEN PHYSICAL AND MENTAL HEALTH WITH SUBJECTIVE COGNITIVE DECLINE AMONG OLDER ADULTS IN PUERTO RICO

Thomas Buckley, *University of Pittsburgh, Pittsburgh, Pennsylvania, United States*

Worse physical and mental health are risk factors for cognitive decline in older adults. In Puerto Rico, existing healthcare services are lacking, further exacerbating this risk. This study examines how mental and physical health factors affect subjective cognitive decline for older adults in Puerto Rico. Data comes from the 2020 Behavioral Risk Factor Surveillance System, restricted to adults age 60+ residing in Puerto Rico (n = 1603). Subjective cognitive decline was measured with two dichotomous variables (no/yes): increases in confusion or memory loss and difficulty making decisions in the past year. Multivariate logistic regression models were run for each outcome variables. Predictor variables were number of days in past month with poor mental health, diagnosis of depression or mood disorder, self-rated health, and access to healthcare services, along with covariates. Higher number of days with poor mental health (B = 2.44, p < .001), diagnosis of depression or mood disorder (B = 3.76, p < .001), and cost barriers to accessing healthcare (B = 2.90, p = .002) were associated with increased odds of increased confusion or memory loss. Significant predictors of increased odds of decision-making difficulty included higher number of days of poor mental health (B = 1.88, p < .001), diagnosis of depression or mood disorder (B = 3.80, p < .001), and worse self-rated health (B = 2.13, p < .001). To promote better cognitive health, intervention efforts should focus on those with poor mental and physical health, including identify strategies to improve access to healthcare services.

IMMIGRATION EXPERIENCES AND COGNITIVE TRAJECTORIES AMONG OLDER CHINESE IMMIGRANTS

Fengyan Tang[1], Ke Li[1], Mary Rauktis[1], and Iris Chi[2], *1. University of Pittsburgh, Pittsburgh, Pennsylvania, United States, 2. University of Southern California, Los Angeles, California, United States*

Some studies have documented cognitive health among older immigrants in the United States; however, little is known about how the life-course immigration experiences were associated with cognitive trajectories among older Chinese immigrants. This study filled the research gap by identifying the patterns of cognitive change trajectory among older Chinese immigrants and examining the associations of immigration experiences (that is, age at migration, reasons for migration, acculturation, perceived discrimination, and preferred dialects) with cognitive trajectories. The sample comprised 2,075 participants from the Population Study of Chinese Elderly (PINE), who completed a battery of cognitive tests at four time points (2011-2019). Latent class growth analysis and multinomial logistic regression were utilized. Three latent classes of cognitive trajectories were identified: the low functioning with the fastest decline (LCF, 12%), the moderate functioning with a medium decline rate (MCF, 39%), and the high functioning with the slowest decline (HCF, 48%). Perceiving more discrimination reduced, while speaking Taishanese increased the odds of being in the LCF and MCF. High acculturation only distinguished MCF from HCF after controlling for the known factors of cognition such as age, education, and social engagement. This study identifies a group of older Chinese immigrants who are especially vulnerable to cognitive impairment, and indicates that the immigration-related risks for cognitive decline, such as late-life migration and lower acculturation, could be buffered by education in early life and social engagement post immigration. Practice and policy efforts are needed to increase socioeconomic and cultural opportunities for social integration among older immigrants.

EXPLORING THE EFFICACY OF MOCA SCORE CORRECTIONS IN REDUCING THE INFLUENCE OF RACE/ETHNICITY

Rachel McCray[1], Omonigho Bubu[2], Judite Blanc[3], Azizi Seixas[3], Girardin Jean-Louis[3], and Arlener Turner[3], *1. New York University, New York City, New York, United States, 2. NYU Grossman School of Medicine, New York, New York, United States, 3. University of Miami, Miami, Florida, United States*

As studies have highlighted significant differences in test score distributions between ethnicities, we chose to examine if the MoCA corrections for education curb racial differences. Therefore, we use data from the NIA Alzheimer's Disease Research Center (ADRC) program to explore the efficacy of score corrections in reducing the influence of race/ethnicity. This study utilized the NACC dataset to analyze data covering UDS visits from September 2005 to February 2021. Participants included in the analyses (n= 11987, 64.9% women, 12.3 % Black/African American, mean age 73□9.460; 16□4.98 years of education) were all cognitively normal. The analyses uses the Montreal Cognitive Assessment (MoCA) with and without correction for education (addition of one point for less than 12 years of education), via cut off score derived cognitive status categories. A 2x3 contingency table revealed a statistically significant association between participants' race (black vs white) and performance on the uncorrected MoCA, X22,n=5291=188.971, p<.001, and the corrected MoCA X22,n=5282=167.073, p<.001. Additionally, a One-way ANCOVA analysis comparing the correlation of education and uncorrected MoCA score for Black/African American (r=.425, p<.001) and White participants (r=.198, p<.001) shows a significant difference between the two groups F1,5288=167.992, p<.001. Specifically, in Black/African American participants, the correlation is much stronger suggesting that years of education is a greater determinant of cognitive status. These results demonstrate that regardless of controlling for education via adding buffer points significant racial disparities in global cognition scores were still present. Alternative corrections for race and education should be considered for future test adaptations.

STRUCTURAL DISCRIMINATORY FACTORS RELATED TO COGNITIVE FUNCTIONING AMONG OLDER HISPANICS: RESULTS FROM HRS

Ernest Gonzales[1], and Cliff Whetung[2], *1. New York University, New York, New York, United States, 2. NYU Silver School of Social Work, New York, New York, United States*

A growing body of research reveals how interpersonal and structural discriminatory factors undermine cognitive functioning among older Black and White adults, yet few studies have focused on older Hispanics in the United States. We examined cognitive health trajectories among 1,513 Hispanic men and women in the Health and Retirement Study (2008-2020) with mixed-effects regression. The majority (71%) of older Hispanics reported less than a college education. This older Hispanic sample often attributed everyday and major discrimination to nativity, race, age, and gender. In multivariate analyses, education, marital status, total household assets, mental health (depression), physical activity (regular vigorous exercise), and multi-morbidity (a weighted index) were all associated with cognitive functioning and in the expected directions. Surprisingly, cognitive functioning did not vary by gender. Living in neighborhoods characterized by physical disorder and social cohesion by respondents, were associated with cognitive functioning at the bivariate level, but only neighborhood physical disorder held association at the multivariate level. Perceived everyday and major discriminatory experiences were not associated with total cognition at the bivariate or multi-variate levels. Results

from this study suggest interventions that target access to higher education, as well as chronic health conditions and neighborhood factors, can optimize cognitive functioning. Stratified analyses and interaction effects are needed to tease out the diversity of older Hispanic adults by nativity, acculturation, interpersonal discrimination, and cognitive health.

SESSION 6690 (POSTER)

DISABILITY AND HEALTH CARE

FOLLOWING PHYSICIAN'S ADVICE IN LATE LIFE: THE ROLES OF LOCUS OF CONTROL AND HEALTH STATUS

Poshan Dahal[1], and Eva Kahana[2], *1. Case Western Reserve University, Shaker Heights, Ohio, United States, 2. Case Western Reserve University, Cleveland, Ohio, United States*

Adherence to physicians' recommendations plays an important role in health maintenance in old age (Kravitz, Hays, Sherbourne & DiMatteo,1993). However insufficient attention has been paid to the influence of patients' mental and physical health and locus of control on adherence to physician's recommendations. This paper studied subjective health appraisals, chronic illnesses, functional limitations, and cognitive impairment along with internal or external locus of control as influences on adherence to physicians' recommendations. We explored these associations among 684 older adults (mean age = 80.71 years) living in a retirement community in Florida. Respondents participated in the Elderly Care Research Center successful aging study (Kahana, Kelley-Moore & Kahana 2012). Older patients and those with more functional limitations reported greater adherence to physicians' recommendations (b=.15, p< 0.05). Those respondents with greater cognitive impairment were less adherent (b=-.1, p< 0.05). Internal locus of control, reflected in beliefs that patients play a major role in health outcomes was associated with less adherence (b=-0.1, p< 0.05). The belief that health professionals influence health outcomes was associated with greater adherence (b=.1, < 0.05). Lower adherence was also associated with the stronger belief that health is a matter of good fortune (b=-.06, p< 0.05). Our findings offer useful insights about the role of internal vs. external influences on health outcome expectations in late life and health behaviors of compliance with medical regimens.

CHANGES TO CARE PROVISIONS TO OLDER ADULTS DURING COVID-19: IMPLICATIONS FOR CAREGIVER WELL-BEING

Esther Friedman[1], Allison Kirkegaard[2], and David Kennedy[2], *1. University of Michigan, Irvine, California, United States, 2. RAND, Santa Monica, California, United States*

Among the many consequences of the COVID-19 pandemic is its impact on caregiving for older adults. Pandemic-related physical distancing policies, avoidance of infection risk, and changing obligations at home and work has caused shifts in care that may not have occurred otherwise. We use nationally representative data on 2,363 caregivers to older family members and friends collected at the height of the pandemic to explore the extent to which family caregivers changed the amount and types of care they provided to a loved one with a disabling condition, and the impact of such changes on caregiver burden and wellbeing. About 41.5% of caregivers who continued to care for someone they helped prior to the pandemic, increased the amount of care provided, while only 7% reduced their intensity of help. Caregiving disruption in the amount of help – both increasing and decreasing care – was significantly associated with increased anxiety, depression, and loneliness of caregivers, but not with self-rated health. These findings persist even after controlling for a variety of sociodemographic, caregiving, and contextual characteristics, and the characteristics of support networks. This work points to an underexplored consequence of the pandemic: the impact on caregiving for older adults and caregiver burden. It will be important to explore the extent to which these effects persist as the pandemic runs its course.

UNDERSTANDING OLDER ADULTS' FLU VACCINE HESITANCY: THE ROLE OF MEDICAL MISINFORMATION

Jessica Hsieh[1], Raza Mirza[2], James Hull[2], Siyu Peng[1], Muhammad Ibrar Mustafa[2], Carley Moore[2], Deirdre Kelly-Adams[2], and Christopher Klinger[1], *1. University of Toronto, Toronto, Ontario, Canada, 2. National Initiative for the Care of the Elderly, Toronto, Ontario, Canada*

Influenza persists as a common communicable disease and remains a significant cause of disease burden across the world. Despite preventative therapies, such as influenza vaccination to reduce its spread and transmission, influenza continues to be a source of morbidity and mortality, even in developed countries. For the population over the age of 65, the effects of influenza virus may be more severe when they are compounded by pre-existing conditions and reduced natural immune function.In light of plateauing vaccination rates, a scoping review was conducted to map the literature and determine why seniors aged 65 and above refuse or fail to receive seasonal influenza vaccination. Nine peer-reviewed academic databases covering both social sciences and medical research were searched, along with the grey literature. A total of 6562 references were identified; after the screening process, 118 references were included in the final review. Thematic analysis focused on the broad areas that positively or negatively influence older adults' decision-making regarding influenza vaccination, and this resulted in five main themes: (1) barriers to obtaining vaccination; (2) social factors; (3) personal characteristics; (4) individual subjectivity; and (5) direct clinical interventions.This review aims to identify gaps in knowledge and synthesize currently available information to make recommendations for future research, policy development and clinical practice. Increasing the vaccination rate among Canadian older adults will contribute to ongoing efforts to reduce the spread of the influenza virus among the population, reducing influenza-associated hospital admissions and deaths.

ADVERSE CHILDHOOD EXPERIENCES (ACES) AND PARTICIPATION IN ROUTINE HEALTH SCREENING AMONG OLDER INDIVIDUALS

Ganesh Baniya[1], and Vijaya Tamla Rai[2], *1. University of Texas at San Antonio, San Antonio, Texas, United States,*

2. *University of Wisconsin - Milwaukee, Milwaukee, Wisconsin, United States*

Adverse Childhood Experiences (ACEs) are a collective term used to define traumatic events before the age of 18. Individuals with ACEs are at risk for various negative health behaviors and chronic diseases. Routine screenings help in early detection of the disease and minimize the impact of the disease, disability, early death, and higher medical costs. Research on ACEs focusing exclusively on older population has received inadequate attention. Additionally, it is not clear whether different types of childhood adversities impact older individuals to participate in routine health screenings. This study included 3997 individuals above 65 years from the 2015 Texas Behavioral Risk Factor Surveillance System (BRFSS) to examine the prevalence of ACEs and their health screening practices. The dependent variable was participating in routine health checkup in the past year and 8 ACEs were the independent variables where gender, age, race, and having a personal doctor were controlled. Logistic regression models showed that prevalence of four ACEs (Physical, sexual, and emotional abuses and parental divorce/separation) were likely to reduce older individuals' participation in routine checkup in the past year. Similarly, older individuals with personal doctor were twice more likely to visit for routine checkup compared to those without personal doctor. Lastly, older Black individuals were less likely to participate in routine checkup than their White counterparts. This study provided preliminary results to consider the impact of specific ACEs in routine health screening behaviors among older individuals. Future research might benefit from longitudinal study examining causal relationship between ACEs and health behaviors.

PHYSICAL FRAILTY AS A PREDICTOR OF INCIDENT DISABILITY IN SPECIFIC-IADL ITEMS AMONG OLDER ADULTS

Jane Lee[1], Miji Kim[2], and Chang Won Won[2], *1. Yonsei University, Seoul, Seoul-t'ukpyolsi, Republic of Korea,*
2. Kyung Hee University, Seoul, Seoul-t'ukpyolsi, Republic of Korea

This study investigated the 2-year impact of physical frailty on disability (activities of daily living [ADL], instrumental ADL [IADL], and mobility) and mortality among community-dwelling older adults in Korea. We used data from 2,905 older adults aged 70–84 years who participated in the Korean Frailty and Aging Cohort Study (KFACS) at baseline (2016–2017) and Wave 2 (2018–2019) with all five components of Fried's physical frailty phenotype. Of these,277 (7.8 %) were frail and 1,312 (45.2 %) were robust. In the 2-year follow-up, multivariate analysis showed significant differences in frailty status for all disabilities (ADL, IADL, mobility) and mortality incidence. Both prefrail (odds ratio [OR]=1.48, 95% confidence interval [CI]= 1.06–2.05) and frail (OR = 5.11, 95% CI=2.78–9.39) statuses showed increased risks of mobility disability. The incidence of ADL disability was significant only in frail older adults (OR =10.26, 95% CI=3.16–33.31). Both pre-frailty (OR =1.55, 95% CI=1.03–2.32) and frailty (OR =4.11, 95% CI=2.35–7.18) status were significantly associated with the incidence of IADL limitations. Frailty status was associated with disability in mobility-related items of IADL (going out, using transportation, and shopping) among men, and was associated with most IADL items among women after 2 years. The results of this study emphasize the need for sex-specific policies and frailty prevention programs, with a focus on detecting frailty before it leads to irreversible disability or other negative health outcomes. These findings may provide a framework for frailty prevention in community-dwelling older adults.

WHAT MOTIVATES PHYSICIANS TO ADDRESS CAREGIVER NEEDS? THE ROLE OF EXPERIENTIAL SIMILARITY

Taeyoung Park[1], Karl Pillemer[1], Corinna Löckenhoff[1], and Catherine Riffin[2], *1. Cornell University, Ithaca, New York, United States, 2. Weill Cornell Medical College, New York, New York, United States*

Despite the negative emotional and physical consequences of caregiving, caregivers' needs and risks are often overlooked in health care settings. This study used survey data from a national random sample of primary care physicians (N=106) to examine the factors associated with physicians' perceived responsibility to identify caregiver needs and risks, focusing on three theoretically implicated variables: 1) experiential similarity (i.e., physicians having personal experience with caregiving), 2) structural similarity (i.e., physicians being older and female), and 3) secondary exposure to caregivers (i.e., more time seeing older patients and a higher percentage of older adults in their patient panel). Physicians in our sample consisted of 42.5% women; most of whom were white (73.6%). The majority (76.5%) agreed or strongly agreed that they were responsible for identifying caregivers' needs and risks. Multivariable models controlling for physicians' age and gender revealed that physicians who had personal experience with caregiving were four times more likely than those without caregiving experience to feel responsible to identify caregivers' needs and risks (adjusted odds ratio [aOR] 3.90; 95% confidence interval [CI] 1.34-11.41) and to assess caregivers' mental health concerns (aOR 3.58; 95% CI 1.29-9.94). Structural similarity and secondary exposure did not play significant roles in motivating physicians. Findings highlight the role of experiential similarity in physicians' motivation to assess caregivers' needs and risks. Future work may benefit from designing intervention programs for physicians that incorporate experiential learning activities (e.g., conversations in which caregivers share their experiences) and evaluating whether such programs enhance physicians' sensitivity toward family caregivers.

SESSION 6700 (POSTER)

EMPLOYMENT, DIRECT CARE WORKFORCE, AND RETIREMENT

EXPERIENTIAL ASSESSMENT OF AN INNOVATIVE DEMENTIA CARE TRAINING SEQUENCE FOR HEALTH AND HUMAN SERVICES WORKERS

Susan Wehry[1], and David Wihry[2], *1. University of New England, Biddeford, Maine, United States, 2. University of Maine, Orono, Maine, United States*

This poster presents results of an assessment of an interdisciplinary dementia care training titled Dementia

Reconsidered (DR). In contrast to disease and deficit-focused training curricula, DR incorporates and emphasizes the strengths and humanity of people living with dementia and focuses on person-directed support for, and care of, persons living with dementia. For example, DR makes the case for an approach to shared and supported decision-making that optimizes the individual's— and significant others'—abilities. The on-line lectures were chunked to accommodate cognitive load and active learning; 20-30 second stretch breaks were interspersed to facilitate attention. This may account for the higher retention and utilization rates of DR than are often found in one-off trainings. A retrospective pre-post survey administered at the conclusion of DR sessions measured participant learning outcomes. Participants in DR sessions were representative of the fields of social work (42%), nursing (21%), and a significant "other" category (28%), mostly long-term care administrators. Among post-training survey respondents (N=36), 77% improved their knowledge of the key principles of person-directed dementia care; 73% (N=37) showed improved comfort in supporting residents with dementia during the CoVID-19 pandemic; 83% (N=24) showed improvement in ability to distinguish capacity and competency; and 83% (N=23) reported increased comfort in supporting people with dementia in making decisions in the face of diminished capacity. At six month follow-up, 63% (N=33) had used a skill gained from their training (17% no, 20% not sure). Implications for training in dementia care practices will be discussed.

ORGANIZATIONAL PRACTICES FOR THE AGING WORKFORCE: A CROSS-CULTURAL VALIDATION OF THE LATER-LIFE WORKPLACE INDEX

Juergen Deller[1], Julia Finsel[2], Anne Wöhrmann[3], Max Wilckens[2], Xiuzhu Gu[4], and Eduardo Oliveira[5], *1. Leuphana University of Lueneburg, Lueneburg, Niedersachsen, Germany, 2. Leuphana University Lueneburg, Lüneburg, Niedersachsen, Germany, 3. BAuA, Dortmund, Nordrhein-Westfalen, Germany, 4. Tokyo Institute of Technology, Tokyo, Tokyo, Japan, 5. University of Porto, Porto, Porto, Portugal*

Successful employment of experienced employees becomes more important for both, individuals and organizations. To identify organizational practices that foster the motivation, health, and performance of experienced employees in particular, a holistic assessment of relevant organizational factors is needed. The Later Life Workplace Index (LLWI) provides such a measure for organizational practices for older employees by differentiating nine domains, namely organizational climate, leadership, work design, health management, individual development, knowledge management, transition to retirement, continued employment after retirement, and health and retirement coverage. So far, a German-language and an English-language version of the LLWI have been validated in Germany and the U.S in a multi-study procedure. The psychometric properties and measurement invariance of the English-language version of the LLWI will be presented. Preliminary findings from Japan and Portugal show promising results regarding reliability and validity of the LLWI in the respective country. The findings suggest that the multidimensional measurement model developed in Germany and the U.S. could be applicable to other regulatory and cultural contexts as well. A focus group consisting of the original authors of the LLWI and international scholars, whose research expertise lies in the field of employment and older employees, is currently developing a short version of the LLWI. We aim to provide researchers and practitioners from different countries with a validated measurement to holistically assess organizational practices. Researchers can utilize the LLWI to gain a comprehensive understanding of organizational influences on later life work, while practitioners are able to assess their organizational readiness for an aging workforce.

PREPARING OLDER ADULTS FOR REMOTE EMPLOYMENT: OPPORTUNITIES AND CHALLENGES

Setarreh Massihzadegan[1], Shayna Gleason[2], Jan Mutchler[2], and Caitlin Coyle[2], *1. UMASS Boston, Cambridge, Massachusetts, United States, 2. University of Massachusetts Boston, Boston, Massachusetts, United States*

As Americans live longer, many are finding they need or want to remain longer in the workforce. When the COVID-19 pandemic transitioned much of the U.S. workforce into temporary or permanent remote employment, many older job seekers were left behind, wanting to compete in the ever-more technology-based job market but often without the requisite skills to do so. The present study evaluated a workforce training program (funded by a Department of Labor demonstration grant) that trained low-income workers over the age of 55 for remote employment. Approximately 60 older adults were trained across three 20-week cohorts. Our data sources included biweekly participant surveys, typing speed and Microsoft Office skill assessments, exit interviews with program "drop-outs," focus groups, training observations, data from participant applications, and instructor assessments of each participant's level of "job readiness" at the end of the program. Results revealed that participants had acute financial need for employment, a keen interest in working remotely, and a wide range of employment experiences and past job stability. Many of their career trajectories and workplace needs were affected by COVID-19. Results also showed promising improvements in participants' technology skills and confidence in their ability to conduct a job search over the course of the program. The need for greater connectivity between participants and employers was identified as an area for improvement for the program. The results of this study contribute to the literature on workforce development by exploring how training programs might better prepare older adults for an increasingly remote job market.

LONGITUDINAL INVESTIGATION OF FACTORS PREDICTING RETIREMENT ADJUSTMENT AMONG RETIREES IN TAIWAN

Shiau-Fang Chao[1], Wei Ye[2], and Wei-Cheng Liu[3], *1. National Taiwan University, Taipei, Taipei, Taiwan (Republic of China), 2. Nation Taiwan University, Taipei, Taipei, Taiwan (Republic of China), 3. Taiwan Social Welfare League, Taipei, Taipei, Taiwan (Republic of China)*

BackgroundRetirement can substantially affect one's lifestyle and self-identity. However, little research has focused on how pre-retirement conditions are associated with retirement adjustment.MethodThis study utilized data from 1989 to 2015 Taiwan Longitudinal Study on Aging. A total of 1,471 cases who experienced retirement between waves and completed the subsequent four year and eight year follow-up surveys after retirement were included for analyses. High life satisfaction and low depressive symptoms represented good retirement adjustment. Multiple regression analysis was applied to test the hypothesized relationships. ResultsThe findings were as follows: 1. Retirees experienced increased depressive symptoms and worsened family relationships when transiting from pre-retirement to post-retirement.2. High cognition functioning, ideal family relationships and sufficient financial resources before retirement were consistently associated with few depressive symptoms and high life satisfaction, both at four and eight year follow-ups. 3. Of the 10 different leisure activities investigated, physically active leisure activities such as walking and participating group exercise before retirement predicted few depressive symptoms and high life satisfaction four years after retirement, but not eight year follow-up. DiscussionCognitive functioning, financial status, and family relationship before retirement can significantly affect both short-term (four years) and long-term (eight years) retirement adjustment, whereas physically active leisure activities only link to short-term retirement adjustment. At policy level, pre-retirement financial security should be addressed and well-prepared. At practitioner level, maintaining ideal cognition level, positive family relationship, and engaging physically active leisure activities should be the central intervention target when serving employees who are approaching retirement.

DOES SOCIAL ENGAGEMENT FOSTER GENERATIVITY AND GOOD CITIZENSHIP AMONG THE THIRD AGERS IN JAPAN?

Keiko Katagiri, *Kobe University, Kobe, Hyogo, Japan*

The labor force rate of those in their sixties have been increasing in Japan. Active Theory assumes that continuing activity is good for their well-being. Several researches also elucidate positive effects of work on older adults. Further, Japan has a mandatory retirement age of 60 years; though, persons can restart their work under contract labor. Katagiri proposed a social engagement model for third agers, which assumes that work for third agers cannot be the purpose in life and suggests three activities social participation, civic activities and work. This study examines the effect of the three activities on third agers. Random sampling survey was conducted in 2019 on people living in Tokyo and Hyogo prefecture. The response rate was 43.0% (N = 665, aged 60-74). Hierarchical multiple regressions were conducted to examine the effect of the three activities on generativity, sense of community, social contribution orientation, interest in politics by gender, and the robust positive effects of social and civic activities for male and civic activities for female. Though no effect of work existed, interaction effects of work and other activities were observed. Those working with social or civic activities had higher generativity. Among people with civic activity, working males showed higher sense of community while working females showed higher interest in politics. Males engaged only in work showed no such sense. The results suggest engaging only in work do not foster their development and engagement in social and civic activities are required to enrich their lives.

JOB SEPARATION OF LONG-TERM CARE FRONTLINE STAFF IN ENGLAND

Florin Vadean[1], and Eirini-Christina Saloniki[2], *1. University of Kent, Canterbury, England, United Kingdom, 2. University College London, London, England, United Kingdom*

Staff turnover in the long-term care (LTC) sector in England is perceived to be relatively high. Most job leavers do not leave the sector, but rather move to other LTC employers. Nevertheless, there are concerns that the high ‘churn’ has a negative impact on continuity and quality of care, care providers’ recruitment and training costs, and the remaining staff workload and motivation. This study aimed to provide missing quantitative evidence on the drivers of LTC staff retention in England, with a focus on job quality. We used yearly data (2016 to 2019) from a large, employer-employee dataset covering about half of England’s LTC market: the Adult Social Care Workforce Dataset. After controlling for observed individual, organisational, and local market characteristics as well as unobserved worker and employer heterogeneity, we found that, everything else being equal, wages and employment conditions (i.e. full time contracts and contracts with guaranteed working hours) significantly reduce job separation. For example, a 10 per cent wage increase from the sample mean would have reduced the job separation rate by about 3 ppt. Our results also show that the wage effect was substantially downward biased (i.e. closer to zero) when not accounting for unobserved effects: the estimated reduction in job separation rate of a 10 per cent wage increase was only 1 to 1.5 ppt. Our findings show that improving pay and employment conditions for LTC staff can improve staff retention in LTC and stress the importance of accounting for unobserved variable bias.

NURSING HOME STAFF’S PERCEPTIONS AND EXPERIENCES COLLABORATING WITH HOSPICE

Susanny Beltran, Norma Conner, Adam Reres, and Morris Beato, *University of Central Florida, Orlando, Florida, United States*

Hospice has been associated with improved outcomes for terminally-ill patients and families, including in pain management, care satisfaction, and rates of hospitalizations. In 2016, 1/3 of Medicare hospice beneficiaries died in nursing homes (NH). The responsibilities for meeting the needs of the NH resident receiving hospice are shared by the NH staff and hospice team, making good communication and coordination of services between providers critical to the successful delivery of services. This exploratory study surveyed NH direct care and administrative staff about their perceptions of hospice, and barriers to collaboration. A total of 66 NH staff completed the online survey. The sample was 62.1% direct care staff (e.g., social work, nursing) and 37.8% administrators, predominately female (75%), non-Hispanic-white (43.9%), and employed full-time (87.8%). Over half of the NHs were non-profit organizations (56.1%). Respondents had on average 33.8 hours of hospice education and held positive hospice attitudes, with 76% strongly agreeing that hospice should be an option regardless of setting, and 87.8% believing they could collaborate with hospice toward the goal of a “good death.” Although participants cited barriers to hospice related to COVID-19, this was not associated with overall hospice attitudes. Respondents cited resistance from family as the primary barrier to hospice, indicating lack of knowledge and a need for family education. They also cited concerns surrounding duplication of roles. Family members in previous studies have identified care allocation as a challenge, based on expectations that hospice would bring additional contact/services instead of replacing NH services. Implications will be discussed.

INTERNATIONALLY EDUCATED NURSES CARING FOR OLDER ADULTS: A SCOPING REVIEW

SHERIF OLANREWAJU[1], Susan Loeb[2], and Manuel Rosaldo[2], *1. Penn State University, BOALSBURG, Pennsylvania, United States, 2. The Pennsylvania State University, State College, Pennsylvania, United States*

Internationally Educated Nurses (IENs) are nurses who are born and obtained their licenses in their home country and relocate to work in a different country. IENs are increasing being recruited to work in Western countries to address nursing shortages. Estimates indicate that IENs account for 5-8 percent of registered nurses in the United States (US). The purpose of this scoping review was to identify and synthesize research evidence on IENs' experiences caring for older adults. A 5-step process for Scoping Reviews was applied, which includes: identifying the research question; identifying relevant studies; study selection; charting the data; and collating, summarizing, and reporting the results. A search was conducted in Web of Science, PubMed, CINAHL, PsycINFO, and Google Scholar. Keywords included but were not limited to IENs, older adults, and long-term care setting. Inclusion criteria were (1) empirical studies examining IENs providing direct care for older adults in any healthcare settings and (2) original research published in English. A total of 13 articles were selected for inclusion (nine quantitative and four qualitative studies). The studies were conducted in the US (n=10), the Netherlands (n=1), Australia (n=1), and New Zealand (n=1). Results revealed three primary themes: transitional challenges, IENs' experiences working with older adults, and factors affecting IEN capacity to deliver services. Study findings are relevant to nursing leaders and policymakers in developing culturally relevant programs to help IENs transition successfully into the nursing workforce. Additional qualitative research is required to explore lived experiences of IENs caring for older adults.

DIRECT CARE WORKFORCE IN THE US BEFORE AND DURING COVID-19

Christopher Kelly, Jerome Deichert, and Lyn Holley, *University of Nebraska at Omaha, Omaha, Nebraska, United States*

Purpose: This study describes the changes in the direct care workforce between 2019 and 2020. Design and

Methods: Data were from the 1% Public Use Microdata Sample (PUMS) of the 2019 and 2020 American Community Survey (ACS). Logistic regression was used to compare demographic and employment characteristics of direct care workers (DCWs) in 2019 and 2020.

Results: While the total number of DCWs increased by 0.08% and the number employed in home care increased by 3.45%, the number of DCWs employed in hospitals decreased by 3.73% and the number employed in residential care facilities decreased by 4.01% from 2019 to 2020. Compared to 2019, DCWs in 2020 were more likely to be nonmedical aides, under 25, over 65, non-white, to purchase health insurance directly, and to receive health insurance from Medicaid. DCWs in 2020 were less likely to be widowed, to be recently married, to be non-English speaking, to work year-round and full-time, to have moved in the last year, and to be below poverty than they were in the previous year. Implications: By the end of 2020, the early effects of the COVID-19 pandemic on the direct care workforce could be seen. While the total number of DCWs increased slightly, this was due to the accelerated growth of DCWs in home care, as the decline in the number of DCWs in hospitals and residential care facilities also accelerated. The direct care workforce in 2020 was more nonmedical, part-time, entry-level or exit-level and non-white than in the previous year.

THE EFFECT OF EMPLOYMENT SUPPORT PROGRAM PARTICIPATION ON MID-LIFE AND OLDER ADULTS IN A STATE

Hyesu Yeo[1], and Steven Wilson[2], *1. University of Georgia, Athens, Georgia, United States, 2. echnical College System of Georgia, Atlanta, Georgia, United States*

BackgroundQuestions have been raised about the effectiveness of these government’s efforts as older people aged 50 or older are affected by restrictions to participate in the labor market. This study examined the impact of the total programs under the Workforce Innovation and Opportunity Act in a state on older participants. MethodsThe study used the Technical College System of Georgia data between 2016 and 2020, with 11,390 participants aged 50 or over. The outcome of the program participation was employment status. The participants’ characteristics consist of gender, race, age, earnings, and types of training they received. Bivariate analyses were performed to examine the relationship between the program’s outcome and individuals’ characteristics. ResultsIn 2016-2020, most older participants were female (60%), and they were African American (64%) and White (24%). Among the total participants (N=11,390), about 60% of older people received job training, and about 70 % of them completed their training. Many older participants received training in 1) health professions and related clinical sciences and 2) business, management, marketing, and related support services. A total of 3,143 older people succeeded in finding their jobs. As age increases, the probability of getting a job and wage increase in re-employed jobs decreases. Conclusion The study found that most older people participated in service profession-related training. Also, racial minorities were the majority of the participants, while the state’s racial majority was White. This suggests considering program development to enhance racial minorities’ job skills for increasing wages through the state’s job training programs.

SESSION 6710 (POSTER)

EMPLOYMENT, OLDER WORKERS, AND RETIREMENT

THE RELATIONSHIP BETWEEN EMPLOYMENT AND ALL-CAUSE MORTALITY IN JAPANESE COMMUNITY-DWELLING OLDER ADULTS

Yoshinori Fujiwara[1], Satoshi Seino[2], Yu Nofuji[2], Yuri Yokoyama[2], Takumi Abe[2], Toshiki Hata[2], Shoji Shinkai[3], and Akihiko Kitamura[4], *1. Tokyo Metropolitan Institute of Gerontology, Tokyo, Tokyo, Japan, 2. Tokyo Metropolitan Institute of Gerontology, Itabashi, Tokyo, Japan, 3. Kagawa Nutrition University, Sakado, Saitama, Japan, 4. Yao City Health Center, Yao City, Osaka, Japan*

It is well known that social contribution such as working maintains the functional health and prevents frailty of older adults. However, the effect of employment in old age with frailty on health outcomes is not well-established.This 3.6-year prospective study examined the influence of working on all-cause mortality in urban community-dwelling Japanese older adults. Participants were 10,591 initially non-disabled residents (5,180 men; 5,411 women) aged 65–84 years of Ota City, Tokyo, Japan. We applied the Cox proportional hazard model by gender and with/without frailty, controlling for age, years of education, equivalent income, number of chronic diseases, body mass index, instrumental activities of daily living (IADLs), smoking and drinking status, exercise habits, social activities, and social interaction for evaluating the predictive value of working status (full-time worker, part time worker, occasional worker and non-worker) at baseline for all-cause mortality.During a follow-up of 3.6 years, 328 (3.1%) individuals died. Compared with non-workers, independent multivariate-hazard ratios (95% confidence intervals) of part-time workers for all-cause mortality in men with/without frailty were 0.35 (0.13–0.97) and 0.54 (0.28–1.01), respectively. Corresponding female multivariate-adjusted HRs with/without frailty were 1.21 (0.34–4.34) and 0.23 (0.05–0.99). Also, for both genders, full-time workers and occasional workers did not have significantly lower adjusted hazard ratios of all-cause mortality, compared to non-workers, regardless of frailty. In conclusion, moderate employment resulted in lower risk of all-cause mortality, even in frail older men.

NUMERACY SKILL USE AMONG MIDDLE-AGED AND OLDER WORKERS IN THE US

Takashi Yamashita[1], Donnette Narine[2], Abigail Helsinger[3], Wonmai Punksungka[4], Phyllis Cummins[5], Jenna Kramer[6], Rita Karam[7], and Thomas Smith[8], *1. University of Maryland, Baltimore County, Baltimore, Maryland, United States, 2. University of Maryland, Baltimore, Baltimore, Maryland, United States, 3. Miami University, Oxford, Ohio, United States, 4. University of Maryland - Baltimore County, Baltimore, Maryland, United States, 5. Miami University, Oxford, Ohio, United States, 6. RAND Corporation, Arlington, Virginia, United States, 7. RAND Corporation, Santa Monica, California, United States, 8. Northern Illinois University, DeKalb, Illinois, United States*

In numeric information-rich societies, numeracy is essential both at work and in everyday life (e.g., calculating a budget). Numeracy skills generally decline with aging. Thus, among middle-aged and older workers, maintaining and improving numeracy skills is crucial to securing employment as well as managing everyday life. One of the counteracting strategies is to practice numeracy. However, little is known about how and what kinds of numeracy skills are used among older workers. We analyzed a nationally representative sample of U.S. workers aged 45 to 74 (n = 3,850) from the 2012/2014/2017 Program for International Assessment of Adult Competencies (PIAAC) restricted-use-file. Six dichotomous numeracy use indicators (e.g., calculating a budget, using advanced statistics) at work and in everyday life were considered. Survey weighted latent class analysis (LCA) identified three subgroups with distinctive numeracy skill use patterns, including ubiquitous (both at work and in everyday life) users, occupational users, and non-users. For example, calculating a budget was common both in non-users (40%) and ubiquitous users (84%), whereas uncommon among occupational users (25%). Also, only ubiquitous users practiced advanced math and statistics (14%), while others did not (nearly 0%). The subsequent regression analysis revealed that higher educational attainment, higher income, certain racial group (i.e., Whites), and better self-rated health were associated with greater numeracy skill use. The lack of numeracy skill use leads to lower skill levels and, in turn, social and economic disadvantages in later life. In addition to more detailed LCA results interpretations, possible policy and educational interventions are evaluated.

AGING ON THE JOB? THE ASSOCIATION BETWEEN OCCUPATIONAL CHARACTERISTICS AND ACCELERATED BIOLOGICAL AGING

Theresa Andrasfay[1], Jung Ki Kim[2], Jennifer Ailshire[2], and Eileen Crimmins[2], *1. University of Southern California, Leonard Davis School of Gerontology, Los Angeles, California, United States, 2. University of Southern California, Los Angeles, California, United States*

There is a common saying that demanding jobs can make workers age faster, but there is little empirical evidence linking occupational characteristics to accelerated biological aging. We examine how occupational category (professional/managerial, sales/clerical, service, and manual) and occupational characteristics (e.g., psychosocial stressors, physical demands) are associated with a novel measure of physiologic aging, expanded biological age, that incorporates 22 biomarkers and captures physiologic dysregulation throughout several bodily systems. We assess how occupational characteristics for working individuals aged 51-60 in 2010 Health and Retirement Study (HRS) are associated with expanded biological age in the 2016 Venous Blood Study (VBS). We find that, compared to same-age individuals working in professional or managerial positions, those working in manual occupations appear 0.96-years older biologically while those in service jobs appear 2.8-years older biologically. Individuals whose jobs are high-stress, physically demanding, or require long working hours are nearly one year older biologically than their same-age peers without these adverse working conditions. These findings largely persisted after adjustment for educational attainment. Together these findings suggest that occupational characteristics may be an independent social determinant of accelerated aging.

TRAJECTORIES OF INFORMAL AND FORMAL SOCIAL PARTICIPATION AFTER RETIREMENT

Jeremy Lim-Soh[1], Shannon Ang[2], and Rahul Malhotra[3], *1. Duke-NUS Medical School, National University of Singapore, Singapore, Singapore, 2. Nanyang Technological University, Singapore, Singapore, 3. Duke-NUS Medical School, Singapore, Singapore*

Literature suggests that social participation, a component of successful ageing, declines on average after retirement, but to whom does this experience apply? We sought to identify contrasting longitudinal trajectories of social participation after retirement, and their associated individual-level correlates. Seven waves of the Korean Longitudinal Study of Ageing provided data on the informal and formal social participation, measured by frequencies of meeting a friend and attending a group respectively, of individuals 45 years and older who left work. Group-based trajectory modeling captured heterogenous changes over time in social participation after retirement. Multinomial logit regressions estimated individual-level correlates of the trajectories, including whether the individual returns to work. While a sizeable minority of respondents did experience decreasing trajectories of informal (17%) and formal (23%) participation, a majority exhibited stable trajectories of either type of social participation, and some experienced increasing formal (9%) participation. Employment type, age, gender, education, marital status, region, health, and economic satisfaction were associated with the trajectories. Returning to work, versus stopping work for an extended period, was associated with moderate stable or increasing trajectories of social participation. The findings challenge the belief that decline in social participation is the norm after retirement. They underscore the presence of heterogenous experiences of social participation after retirement, and identify vulnerable sub-groups that do experience decline. Furthermore, as returning to work may be beneficial for social participation, future studies should examine ways in which bridge employment can support successful aging.

PRIMARY OCCUPATION AND PAIN AMONG ADULTS AGED 50 AND OLDER IN MEXICO

Sadaf Milani, and Rebeca Wong, *University of Texas Medical Branch, Galveston, Texas, United States*

Working in physically demanding jobs may be associated with pain in middle and old age. This has not been widely studied in Mexico, which has a rapidly aging population. We evaluated the association between primary occupation and pain over 17 years of follow-up among Mexicans aged 50 and older using data from the Mexican Health and Aging Study (2001-2018). Primary occupation was categorized as professional, agriculture, domestic/service, production/industrial, or no main job. We examined frequent pain (yes vs. no) and pain interference (none/non-interfering vs. interfering), defined as pain that limits daily activities. Mixed effects logistic regression was used to model the association between primary occupation and pain. In 2001, participants (n=11,339) were 62.1 years old on average (standard deviation: 9.3) and 55.7% female. About 25.1% of participants worked as professionals, 17.2% worked in agriculture, 16.9% in domestic/service, 22.4% in production/industry and 18.4% had no main job. Almost all of those reporting no main job were women (98.7%). Compared to professionals, those in production/industry had higher odds of frequent pain at baseline [odds ratio (OR): 2.42; 95% confidence interval (CI): 1.25, 4.67]. Those in agriculture had higher odds of frequent (OR: 2.09, 95% CI: 1.03, 4.25) and interfering pain (OR: 2.50, 95% CI: 1.10, 5.70) at baseline. Pain did not change over time by lifetime occupation. The final analysis will include an estimation of gender differences. Health care providers should consider lifetime occupational risks, which may help address pain and minimize pain interference in old age.

CORRELATES OF JOB SATISFACTION AMONG FULL-TIME EMPLOYED OLDER ADULTS WITH CHRONIC CONDITIONS

Matthew Smith[1], Chung Lin Kew[1], Caroline Bergeron[2], Martha Parker[1], Oluyomi Oloruntoba[1], Kaysey Aguilar[1], Mark Benden[1], and Ashley Merianos[3], *1. Texas A&M University, College Station, Texas, United States, 2. University of Ottawa, Ottawa, Ontario, Canada, 3. University of Cincinnati, Cincinnati, Ohio, United States*

With a rapidly aging workforce and the rising prevalence of chronic conditions, efforts are needed to better understand the needs of older adult workers and how to create supportive working environments for them. This study examines factors associated with job satisfaction among full-time employed adults ages 60+ years with 1+ chronic conditions. Data were collected with an internet-delivered survey in January 2022. Analyses included 337 older adult workers with chronic conditions. An ordinal regression model was fitted to assess factors associated with higher levels of job satisfaction. The model adjusted for sociodemographics, disease characteristics, social engagement, work logistics, and perceptions about the workplace. On average, participants were age 65.14(±4.56) years and self-reported 3.05(±2.09) chronic conditions. Twenty-eight percent reported being very satisfied with their current job and 48.4% worked remotely 1+ days per work week. Higher job satisfaction levels were positively associated with being Hispanic (β=0.68, P=0.030), exhibiting stronger organizational citizenship behavior (β=0.16, P< 0.001), and working more days remotely (β=0.12, P=0.026). Higher job satisfaction levels were negatively associated with job-related stress (β=-0.26, P< 0.001), feelings of social disconnectedness (β=-0.12, P=0.010), and greater intentions of leaving current jobs within the next three months (β=-0.70, P< 0.001). Findings suggest that job satisfaction among older adult workers is rooted in their compatibility with their organizations' work environment, management of job-related stressors, and opportunity to engage in meaningful and fulfilling interactions with others. Strategies such as remote working are encouraged to give older adults flexibility to promote work-life balance and self-manage their chronic conditions.

EXPLORING ADJUSTMENT TO RETIREMENT: LEISURE IN THE LIVES OF FIRST-GENERATION KOREAN IMMIGRANT MEN

Wonock Chung[1], and Toni Liechty[2], *1. University of Illinois at Urbana-Champaign, Champaign, Illinois, United States, 2. University of Illinois Urbana-Champaign, Champaign, Illinois, United States*

Baby boomers, born between 1946 and 1964, comprise a significant portion of the United States' older adult population. Retirement is also a hallmark of their current life stage. While a body of literature points to the benefits of leisure activities in later life, the roles and relevance of leisure during the retirement transition among first-generation immigrant baby boomers are not well understood. The purpose of this study was to explore leisure throughout the lifespan among first-generation Korean immigrant men (N = 19) and how their cultural values and leisure involvement played out during the retirement transition. Guided by continuity theory of normal aging (Atchley, 1989) and leisure innovation theory (Nimrod, 2008), findings from interview data through interpretive phenomenological analysis (Smith et al., 1995) indicated that (1) perceptions and definition of leisure is shaped by their cultural backgrounds; (2) leisure in the working years mostly involved family leisure activities with an emphasis on providing their children with educational values; (3) leisure activities such as golf and fishing were a particular interest for this demographic, but meanings changed over time; (3) leisure provided continuity during the retirement; and (4) retirement was viewed as an opportunity for new leisure activities, but limited availability of sport and recreation programs was perceived as a barrier. These findings yield meaningful implications in that (a) leisure engagement can provide continuity in maintaining their social roles over the lifespan; and (b) more community-based sport and recreation programs targeting older adults would help them successfully transition to retirement.

STRESSOR REACTIVITY DEPENDS ON THE CORTISOL AWAKENING RESPONSE AND REACTIVITY TO WORK OVERLOAD

MacKenzie Hughes[1], Christopher Hertzog[1], Shevaun Neupert[2], and Scott Moffat[1], *1. Georgia Institute of Technology, Atlanta, Georgia, United States, 2. North Carolina State University, Raleigh, North Carolina, United States*

Ecological momentary assessment (EMA) was used to understand the influence of individual differences in stress reactivity measured by the Perceived Stress Reactivity Scale (PSRS) and the cortisol awakening response (CAR) on emotional reactivity to stressors, operationalized as the within-person change in negative affect (NA) associated with stressor exposure. Five times per day for 10 days, 178 working adults ages 20-80 years old (M = 49.22, SD = 19.07) reported in EMAs their current NA and whether they had experienced a stressor since the previous survey. During the same period, participants provided seven salivary cortisol samples per day. Samples collected at awakening and 30-minutes post-awakening were used to calculate the CAR. Steeper CARs are hypothesized to have a role in preparing individuals to cope with upcoming daily demands. Before the EMA period, participants completed the PSRS, including its Work Overload Reactivity subscale. Multilevel models revealed a significant 3-way interaction between Stressor Exposure x CAR x Work Overload Reactivity predicting daily NA. Individuals with high Work Overload generally reported greater NA, regardless of stressor exposure or the magnitude of their CAR. Individuals with low Work Overload reported lower levels of NA on days they experienced more stressors than usual and had steeper CARs. Effects remained significant after controlling for neuroticism and the Perceived Stress Scale. Findings suggest the CAR's potential role of preparing individuals for upcoming demands is moderated by work-related stress reactivity. Steeper CARs on days with more stressor exposure may provide enhanced emotional benefits for individuals low in workload reactivity.

MEMBER CHECKING GERONTOLOGY: THE CASE OF RETIREMENT

David Ekerdt, *University of Kansas, Lawrence, Kansas, United States*

Gerontology has long been a public-facing field with an applied focus. As such, the credibility of gerontology's conclusions and guidance about aging are crucial, our advice having relevance and impact in proportion to its popular resonance. In 2021 I authored an article for a large-circulation newspaper that generated over 500 reader replies, creating an opportunity for member checking of a kind. The article reported my personal experience of having retired—what I expected and what was a surprise. All of my observations about emotions and lifestyle, while my own, were nonetheless grounded in the research literature. Public comments on the article came from a readership that skews male and highly educated, i.e., people like myself. Many comments affirmed my observations (e.g., about time use, awareness of finitude) as experiences we had in common. Some comments disputed my authority, as an academic, to say anything valid about the "real world." Opinion split on the value of continued work: it gives life meaning, it invites corrosive stress. Likewise, some retirees endorsed surrender to leisure while others urged engagement. One research takeaway: with no standard way to be retired or regard it, the quality of retired life remains a measurement challenge. Another takeaway: Retirees with partners commonly describe experience in the first-personal plural (we, us), suggesting that dyads are often apt units of analysis for retirement studies. This is but one case study, but it indicates that we must continually assess whether gerontology's knowledge is valid and whether the public is grateful for it.

OLDER ADULTS LEAVING THE WORKFORCE: SENSORY LOSS, RETIREMENT, AND DISABILITY

Emmanuel Garcia Morales[1], Lama Assi[2], and Nicholas Reed[3], *1. Cochlear Center for Hearing and Public Health, Baltimore, Maryland, United States, 2. Louisiana State University Health Center, New Orleans, Louisiana, United States, 3. Johns Hopkins Bloomberg School of Public Health, Baltimore, Maryland, United States*

Hearing loss (HL), vision loss (VL), and their combination (dual sensory loss, DSL) are common among older adults. Sensory loss impacts labor productivity which might result in departures from the workforce. Whether older adults leave due to retirement or a disability, and how these responses are associated with sensory loss remains unexplored. Using the 2004-2018 rounds of the Health and Retirement Study, self-reported sensory loss (No Impairment/HL/VL/DSL) at baseline, and reason for leaving the workforce (retirement or disability) were observed. Competing risk models models for departures from the workforce treating retirement or disability as a competing risk were estimated. Among 5,201 adults employed at baseline, ages 50-94, 3,436 reported retirement, and 4254 reported a disability as a reason for not working. In Fine-Gray models, treating retirement as a competing risk and adjusting for sociodemographic and clinical characteristics, we found that compared to older adults without impairments, DSL was associated with a 50% increase in the rate of departures from the labor force due to disability among adults in the in the risk group (SHR=1.51; 95% CI=1.09,2.11). In contrast, when treating disability as the competing risk, HL was associated with a 22% increase in the rate of departures labor force due to retirement (SHR=1.22; 95% CI=1.10,1.36) among adults in the risk group when compared to those without impairments. In sample of older adults, we provide evidence that the presence of sensory impairments is associated with departures from the workforce. Our results highlight differences in the type of departures by sensory loss.

STICKING WITH THE UNION? LABOR UNION MEMBERSHIP, WORKING CONDITIONS, AND POSTRETIREMENT HEALTH IN THE MIDWEST

Michal Engelman, and Yue Qin, *University of Wisconsin-Madison, Madison, Wisconsin, United States*

American Employment experiences over the past five decades have been shaped by growing prevalence of bad jobs – those that are precarious and offer few pension or health insurance benefits – and a marked decline in unionization. Previous health research has highlighted the deleterious implications of bad jobs and yielded mixed or inconclusive findings about union membership. However, most of this research focused on working-age adults, and few studies have examined the long-term impacts of working conditions and union membership. We fill this gap via data from the Wisconsin Longitudinal Study – a sample of men and women who graduated from Wisconsin high schools in 1957 and have been followed through their working years, past retirement, and into oldest-old ages. We estimated regression models examining the impact of union participation in 1975 on subsequent self-rated health and depressive symptoms (measured in 1993, 2004, and 2011). Our findings suggest that union participation was associated with poorer self-rated health in 1993 (OR=0.67, 95% CI (0.48, 0.96)), with a stronger negative effect for more active union members (OR=0.58, 95% CI (0.36, 0.96)), even after controlling for socioeconomic status in childhood and adulthood. This effect dissipated by 2004, when most WLS participants were nearing retirement and further diminished by 2011, when participants were in their 70s. We found no significant effects of union activity on depressive symptoms. Job characteristics and the historical decline in the prevalence and power of unions over the cohort's lifetime provide important contexts for interpreting these results.

TOWARD AGE-FRIENDLY WORKPLACES: IDENTIFYING FACTORS THAT SUPPORT COGNITIVE FUNCTION IN OLDER WORKERS

Ashley Price[1], and Soomi Lee[2], *1. University of South Florida-Tampa, Tampa, Florida, United States, 2. University of South Florida, Tampa, Florida, United States*

Older adults in the workforce face natural age-related decline that may impede their work performance. Sleep and cognitive function, both of which are degraded with age, may affect work performance in older workers. Workplace demands and support may also play roles in older workers' performance. Yet there remains a lack of effort in identifying modifiable factors that contribute to older workers' performance. This review compiled previous studies on modifiable factors across personal and workplace domains that support or impede older workers' performance at work. Databases utilized for this systematic review include Google Scholar, AgeLine, and APA PsycINFO. Inclusion criteria were empirical studies conducted in developed countries, published in 2000 or later, that focused on older adults (age >55) working full-time (≥ 35 hours/week). Keywords included: sleep, older adults, workforce, cognition, aging, work performance, aging workforce, workplace support, management strategies. Of the 32 studies initially identified, 13 qualified for this analysis. In 6 studies, poorer sleep (measured by actigraphy) was prevalent in older workers and was negatively associated with their cognitive performance at work. Across 7 studies, demanding and non-supportive workplace characteristics (i.e., greater job demands, lower supervisor support, and higher agism) were identified as common risk factors for poorer sleep, poorer cognitive function, and lower work performance in older workers. Bridging this information together may help identify specific factors that may be modifiable by workplace interventions to support optimal performance in workers and promote more age-friendly work environments.

SESSION 6720 (POSTER)

END OF LIFE, HOSPICE, AND PALLIATIVE CARE

TO TELL OR NOT TO TELL: TYPOLOGIES OF OLDER ADULTS PREFERENCES ON DIAGNOSIS DISCLOSURE OF CRITICAL ILLNESS IN CHINA

Yifan Lou[1], and Jinyu Liu[2], *1. Columbia University, New York, New York, United States, 2. Columbia University, New York City, New York, United States*

Background: A priori of advance care planning, that older adults should know their diagnosis, is not guaranteed nor legally supported in China. Typically, doctors will inform the family members of the diagnosis and prognosis of critical illness and let family members decide whether to inform or not. This study aims to explore how older Chinese prefer diagnosis disclosure of their critical illness and the factors related to each typology of desired roles.

Methods: We surveyed 571 older adults in Shanghai from late-2021. We included 7 items measuring values of diagnosis disclosure on three levels: to self, to significant others, and regarding physician disclosure approach. We characterized preference types using latent class analysis. Multinomial regression models on class memberships were used with cultural, sociodemographic, and healthcare experiences predictors.

Results: Three latent classes were identified: 34% of respondents preferred control over own diagnosis and respected significant others' rights to know their own diagnosis ("transparent"). 50% of respondents has conflicted values.

They preferred to know own diagnosis and to discuss with physicians privately, but chose to conceal others' diagnoses if their significant others have serious illness ("contradictory"). 16% preferred to delegate control over diagnosis to others and assumes that their families hold the same value ("avoidant"). Increased familism is significantly related to contradictory type. People with experience of hospitalization and making medical decisions for family members were more likely to be transparent. Discussions: We discussed research, practice, and policy implications on culturally-appropriate approaches to honor patients' autonomy with serious illness in China.

THE RELATIONSHIP BETWEEN ADVANCE CARE PLANNING AND COGNITIVE FUNCTION IN A MULTICULTURAL COHORT

Simone Camacho[1], Magdalena Tolea[2], Nicole Mendez[3], Joyce Jimenez Zambrano[3], and James Galvin[4], *1. University of Miami Miller School of Medicine, Boynton Beach, Florida, United States, 2. University of Miami Miller School of Medicine, Boca Raton, Florida, United States, 3. University of Miami Miller School of Medicine, Miami, Florida, United States, 4. University of Miami School of Medicine, Miami, Florida, United States*

Engagement in Advance care planning (ACP) – the process of communicating preferences for future medical decisions, has been linked to increasing age, greater decision-making capacity, and higher education, and is more prevalent in White older adults. To advance knowledge of ACP in multicultural populations, we examined variations in the relationship between sociodemographics, cognitive functionality and ACP. A total of 303 older (mean-age: 69.4±10.5; 69.9% females; 29.6% Non-Hispanic White, 21.2% African American, and 49.2% Hispanic) participants in a community-based dementia screening program were included. ACP measures included life insurance, disability insurance, long-term care (LTC) insurance, power of attorney (POA), living will, and having a health care proxy (HCP). Although most participants had health insurance (92.4%, no differences by race), low rates of ACP engagement were found in racial/ethnic minorities across multiple ACP measures (all ≤40%). Black older adults had the highest use of life insurance (p<.001). Higher ACP rates (i.e., LTC, HCP, living will) were associated with better global cognition (MoCA; p< 0.05). Higher POA rates were associated with lower AD8 scores (30.1% in AD8< 2 vs 15.4% in AD8≥2, p=0.003). Finally, ACP rates varied across racial-SES groups being highest in high SES White participants and lowest in minorities with low SES, regardless of subjective or objective cognitive performance. Findings link ACP to greater cognitive functionality and highlight racial and SES disparities in ACP engagement, particularly related to non-insurance-based planning. Understanding cultural differences in decision making can lead to targeted interventions to increase early ACP in cognitive aging and dementia for older adults.

URBANIZATION, FINANCIAL SOURCE, AND PLACE OF DEATH AMONG CHINESE LONGEVITY OLDER ADULTS

Rui Zhou, Shuangshuang Wang, and Nengliang Yao, *Shandong University, Jinan, Shandong, China (People's Republic)*

The research on place of death among Chinese oldest adults is scare. This study explored the associations of urbanization and financial source on the places of death among Chinese longevity older adults. The sample consists of 21,920 decedents (female=60%, died at home=89%, mean age at death=95) from 2000-2018 Chinese Longitudinal Healthy Longevity Survey (CLHLS), conducted by Peking University. Places of death were divided into two categories: home and other sites (including hospitals, institutions and others). Urbanization was measured by residential areas: rural or city. Financial source consisted of family financial support and retirement wage. Chi-square test showed that older adults living in rural areas and getting family finance support were more likely to die at home. Results from binary regression models show that controlling for covariates, decedents living in cities were 6.2 times more likely to die in other places than at home and those received retirement wage were 3.1 times respectively. Notably, older adults who lived in cities and also had retirement wage were 17.7 times more likely to die in other places comparing to those living in rural areas with only family finance support. Findings suggest that more older adults will choose to die at hospitals or institutions as the process of urbanization and the development of social pension system in China, which will put enormous pressure to the hospital-centered healthcare system. Improving the quality of healthcare in grassroots areas might be a feasible attempt to relive the pressure of hospital-centered healthcare system in cities.

MEDICAL AID IN DYING: DOES POLICY PREVENT SUFFERING AT THE END OF LIFE?

Todd Becker[1], Nancy Kusmaul[1], Allison Gibson[2], and Cara L. Wallace[3], *1. University of Maryland Baltimore County, Baltimore, Maryland, United States, 2. University of Kentucky, Lexington, Kentucky, United States, 3. Saint Louis University, Saint Louis, Missouri, United States*

Medical aid in dying (MAID) reflects the legal provision for qualifying, terminally ill individuals to receive a prescription from their medical provider for self-ingestion to hasten death. This policy analysis examines current MAID policy with a focus on MAID's intended relief of suffering. Using Wallace's (2015) policy model, we evaluated MAID on: policy description, historical context, development of the policy, efficiency, alternative programs, effectiveness, and unintended consequences. Policy description: Currently legal in 10 jurisdictions (nine states and Washington, DC), common goals include relieving suffering and promoting self-determination. Historical context: Following a failed attempt at federal legalization, the U.S. adopted an incremental, jurisdiction-based approach to legalization beginning in Oregon (1994). Development of the policy: Although all statutes imitate Oregon's model, subtle differences exist. Efficiency: Although each policy includes waiting periods that vary in sequential order and duration, revisions have targeted waiting periods to improve efficiency. Alternative programs: Frequently considered an alternative to MAID, existing statutes encourage providers to discuss palliative options. Effectiveness: Despite appearing effective in promoting self-determination, MAID-related complications (e.g., vomiting) may exacerbate suffering. Unintended consequences: MAID's requirement of clinician participation may place providers in situations that challenge their self-determination and provoke distress. In sum, many questions remain unanswered regarding MAID's effectiveness and efficiency. Thus, more data are needed. Ethical implications will continue to be debated, though policy implications (e.g., who uses MAID, the number of unique providers, the emergence of complications, those present during death) greatly impact implementation and overall choices to limit suffering at the end of life.

PALLIATIVE AND END-OF-LIFE CARE INTERVENTIONS FOR INDIVIDUALS EXPERIENCING HOMELESSNESS: A SCOPING REVIEW

Pilar Ingle, *University of Denver, Lakewood, Colorado, United States*

Despite the benefits of palliative and end-of-life (PEOL) care for individuals with life-limiting illness, barriers to accessing this care persist among older adults experiencing homelessness. A number of studies have identified barriers to PEOL care from the perspectives of unhoused individuals and other relevant stakeholders; however, few empirically studied interventions exist to support evidence-based guidelines for PEOL care for this population. This scoping review aimed to identify PEOL interventions for adults experiencing homelessness. The search was conducted in May 2021 and yielded 480 results, from which 50 full-text articles were closely reviewed for inclusion. Sources were included if they reported findings of original, empirical research or quality improvement projects evaluating PEOL services tailored for individuals experiencing homelessness. A total of 13 articles representing 12 studies published between 2006-2021 were included in the review. Over half (n = 7) of the studies described interventions to promote advance care planning documentation, five described interventions embedding PEOL services within homeless shelters, and one described a community outreach program to increase access to PEOL services. Nearly all studies reported positive outcomes on participant perspectives, advanced directive completion rates, or cost analysis. None of the studies included clinical palliative care outcomes. Although most studies reported promising results, service and healthcare providers expressed concerns about continuing challenges and longevity of the programs. The body of literature encompassing PEOL interventions for people experiencing homelessness is limited but growing. Future research may benefit from the inclusion of clinical outcomes and efforts to reduce structural barriers to providing care.

RECRUITING PATIENT-CAREGIVER DYADS IN A PANDEMIC: CHALLENGES AND OPPORTUNITIES IN HOSPICE AND PALLIATIVE RESEARCH

Cara L. Wallace[1], Karla Washington[2], Kathryn Coccia[1], Verna Ferguson[1], Anna Wingo[1], Leslie Hinyard[3], Marla Berg-Weger[1], and Stephanie P. Wladkowski[4], *1. Saint Louis University, St. Louis, Missouri, United States, 2. Washington University in St. Louis, St. Louis, Missouri, United States, 3. Advanced HEAlth Data (AHEAD) Institute. Saint Louis University, St. Louis, Missouri, United States, 4. Bowling Green State University, Bowling Green, Ohio, United States*

Hospice and palliative care (HAPC) research has shown participation in research benefits both patients and caregivers. However, recruiting participants for HAPC research can be difficult and requires flexible, adaptive, and creative strategies. This presentation will review ongoing efforts for recruitment and subsequent alterations for an active NIH study of patients and their caregivers who have been discharged alive from hospice. A live discharge occurs when a hospice patient medically stabilizes, no longer meeting policy's prognosis eligibility criteria. In 2019, hospices in the United States served more than 1.6 million people, and 17.4% were discharged alive from hospice care, with 6.5% due to being 'no longer terminally ill' (NHPCO, 2021). Currently, there is not an explicit discharge process available to guide practitioners in transitioning patients and caregivers out of hospice care, creating challenges and opportunities for collaborative research.Despite existing relationships with hospice networks, our initial recruitment strategy of recruiting patients and caregivers through direct referrals has been insufficient. Incorporating creative solutions to boost recruitment efforts appears to be effective. First, we developed partnerships with hospital/health systems for identification of eligible partnerships using existing information available in Electronic Medical Records (EMRs), yielding an initial 80% increase in referrals. Additional recruitment efforts include using brief informational videos on social media platforms, such as YouTube, Twitter, and TikTok. Promising recruitment strategies for hard-to-reach populations such as HAPC patients and their caregivers, including identification and outreach using existing EMRs, expanding eligibility to include retrospective data, and integrating efforts across social media platforms.

WHO GETS HOSPICE VISITS AT THE END OF LIFE: A LOOK AT MEDICARE'S HOSPICE SERVICE INTENSITY ADD-ON POLICY

Michael Plotzke[1], and Thomas Christian[2], *1. Abt Associates, Saint Louis, Missouri, United States, 2. Abt Associates, Cambridge, Massachusetts, United States*

In 2016, the Centers for Medicare & Medicaid Services (CMS) implemented the Service Intensity Add-on (SIA) payment for the Medicare Hospice Benefit. The SIA incentivizes direct patient care by registered nurses and medical social workers during the last seven days of life through additional payments to hospices. We examined 100% of Fee-for-Service Medicare hospice claims in Fiscal Year 2020 to determine whether SIA utilization varies by patient and hospice characteristics. Using hospice level fixed-effects regression, we examine the associations between SIA utilization and various beneficiary and hospice characteristics. Relative to beneficiaries with cancer as a principal diagnosis, we find that other diagnoses are associated with only a slight reduction in SIA utilization (a reduction between 0.6 and 1.1 percentage points - where the average SIA utilization overall is equal to 85.3%). Those identifying as black had a reduction in SIA of 1.3 percentage points compared to those identifying as white. Compared to a patient dying on a Sunday, a patient's death on Tuesday through Friday was associated with a higher likelihood of SIA (between 9.7 and 11.6 percentage points more likely) and more SIA minutes (between 29.9 minutes and 36 minutes). All reported results were statistically significant at the 0.1% level. Based on these results, we find that SIA utilization varied by certain characteristics. As a result, CMS should continue to monitor rates of SIA utilization to better understand whether any patient groups appear to be underserved at the end of life.

LIVE DISCHARGE FROM HOSPICE WITH DEMENTIA: CHALLENGES TO SUPPORTING THE PATIENT-CAREGIVER DYAD

Stephanie P. Wladkowski[1], Cara L. Wallace[2], and Karla Washington[3], *1. Bowling Green State University, Bowling Green, Ohio, United States, 2. Saint Louis University, Saint Louis, Missouri, United States, 3. Washington University in St. Louis, St. Louis, Missouri, United States*

A live discharge from hospice disrupts care continuity and results in burdensome transitions for individuals with a life-limiting illness and their caregivers. In 2019, hospices served more than 1.6 million people across the United States, with nearly 63% of Medicare decedents age 85 or older. Of these patients, nearly 350,000 (20.9%) had a principal diagnosis of Alzheimer's Disease/Dementia/Parkinson's Disease. Research demonstrates that hospice care improves end-of-life outcomes for adults with Alzheimer's Disease and related dementias (ADRD), yet with eligibility limited to a six-month prognosis, hospice is not structured to meet longer-term needs. The result is a live discharge from hospice. In 2019, 17.4% of hospice patients were discharged alive from hospice, with 6.5% discharged due to being 'no longer terminally ill.' The majority of live discharges are either hospice-initiated due to patient stabilization (extended prognosis resulting in a situation in which a patient no longer meets the life expectancy hospice eligibility criteria) or are patient-initiated (revocation) where a patient or proxy chooses to leave hospice care, typically to access disease-directed therapies or inpatient hospitalization. Both present unique challenges and opportunities for hospice providers. Informed by over 10 years of practice experience and research, this presentation will discuss the impact of live discharge from hospice and the unique impact for patients and primary caregivers of individuals with ADRD, the service gaps that exist for this population, and our recommendations for policy reform.

BUILDING A PROTOCOL FOR LIVE DISCHARGE FROM HOSPICE: UNDERSTANDING THE APPROACHES, CHALLENGES, AND OPPORTUNITIES

Stephanie P. Wladkowski[1], Tracy Schroepfer[2], and Susan Enguidanos[3], *1. Bowling Green State University, Bowling Green, Ohio, United States, 2. University of Wisconsin-Madison, Madison, Wisconsin, United States, 3. University of Southern California, Los Angeles, California, United States*

A live discharge from hospice can occur when a patient stabilized under hospice care no longer meets the life expectancy hospice eligibility criteria. In 2019, 278,400 hospice patients across the United States were discharged alive from hospice care, with 18,096 (6.5%) discharged due to being 'no longer terminally ill.' For these individuals and their caregivers, the result is a disruption of care continuity and an often burdensome transition. Hospice care improves end-of-life outcomes for some patients, and a live discharge results in lost access to important supportive services and resources, while the patient remains 'terminal.' Further, an increased burden is placed on primary caregivers who may be unprepared for this transition. Currently, there is no explicit discharge process available within hospice to guide practitioners in transitioning patients and their caregivers out of hospice care. This study aimed to garner a deeper understanding of current approaches and accompanying challenges to inform the development of an explicit live discharge protocol. Focus group interviews with hospice social workers at four hospice agencies across the U.S. were conducted. Using thematic analysis, four key themes emerged, including the logistical (n=13) and psychosocial (n=9) approaches, the need for clear professional roles during a live discharge (n=12), and specific challenges (n=14), such as needed services and desired discharge timeline to best support the patient-caregiver dyad. Findings demonstrate the complexities of conducting a live discharge, the uniqueness of each hospice agency, and the need for more research to support a standardized and reimbursable discharge process.

THE RELATIONSHIP BETWEEN PHYSICIAN VISITS AND ADVANCE CARE PLANNING

YuHsuan (Olivia) Wang[1], and Susan Enguidanos[2], *1. USC, Los Angeles, California, United States, 2. University of Southern California, Los Angeles, California, United States*

Some studies have shown that advance care planning (ACP), discussions about future care given a serious illness, are associated with improved quality of death and better end-of-life care. Studies also have found that physicians play an important role in ACP. In fact, in 2016 CMS began reimbursing physicians for ACP discussions. However, little is known about the relationship between the number of physician visits and engaging in ACP . This study investigated the association between outpatient physician visits and ACP engagement. Only respondents over 65 were included in our study. We conducted logistic regressions using the 2016 Health and Retirement Study. We used ACP engagement (n=9838), advance directive (AD; eg, living will) completion (n=9746), and healthcare power of attorney (e.g., proxy) assignment (n=9724) as outcome variables. In addition to the frequency of physician visits, we controlled for basic demographics (age, gender, marital status, race, and socioeconomic status), number of chronic conditions, and self-rated health in our models. For each additional physician visit, the probability of having an ACP conversation, (p<.001), AD completion (p<.001), and healthcare proxy assignment (p<.001) increased by 1.6%,1.4%, and 1.9% respectively after controlling for covariates. Number of chronic conditions also was independently and positively associated with ACP-related activities. Additionally, greater perceived health was associated with higher odds of AD completion (OR= 1.08, p<.05) and healthcare proxy assignment (OR= 1.07, p<.05). This study found that frequent encounters with physicians are associated with higher rates of ACP engagement even after controlling for health conditions.

DO DIFFERENT ADVANCE DIRECTIVES CREATE CONFUSION ON A PATIENT'S WISHES? (MOLST VERSUS FIVE WISHES)

Taylor Perre[1], and Yuchi Young[2], *1. Home Care Association of New York State, Albany, New York, United States, 2.*

SUNY at Albany School of Public Health, Rensselaer, New York, United States

Introduction. The objective of this study is to compare perspectives of young adults toward advance directives (ADs) and their preferences for life-sustaining treatment and care options. Methods. Participants include graduate students (n=30) attending a New York State university. Data were collected using a structured survey questionnaire, the Medical Orders for Life-Sustaining Treatment (MOLST) form and the Five Wishes form. Summary statistics were performed to address the study aim. Results. Of the participants, the average age was 24 years (60% were female, 60% White, and 27% Black). In Five Wishes, participants who are close to death, 70% wanted all or some forms of life support; when in a coma (47%), or with permanent and severe brain damage (36.6%) chose similar options. In MOLST, without pulse and/or breathing, 87% want CPR; while with pulse and breathing, 96% want artificially administered fluids and nutrition, 90% want mechanical ventilation, 67% want to be hospitalized, 67% want antibiotics, and 53% want unlimited interventions. Conclusion. (1) The majority of participants had not previously completed an AD; however, they were capable of making decisions about their life-sustaining treatments. (2) The discrepancies in treatment preferences may be due to the language of advance directives. Further studies in this respect are warranted.

EXPLORING FIVE WISHES AND END-OF-LIFE CARE PLANNING IN YOUNG ADULTS

Taylor Perre[1], Arianna Stone[1], and Yuchi Young[2], *1. Home Care Association of New York State, Albany, New York, United States, 2. SUNY at Albany School of Public Health, Rensselaer, New York, United States*

Introduction. Advance care planning (ACP) allows individuals to plan ahead and express their preferences for medical treatment and care options to health care providers, family, and loved ones before they are no longer able to make or voice decisions due to the event of a serious illness or injury. Advance directives (ADs) allow individuals to record their preferences. While unintentional injuries are the leading cause of death among young adults, limited studies focus on ACP, ADs, and end-of-life treatment and care. Our study aims to (1) examine the perspectives of young adults towards Five Wishes, and (2) measure their preferences related to personal, emotional, spiritual, and medical values in end-of-life care planning. Methods. Data were collected using Five Wishes and a one-time questionnaire. Participants include graduate students (n=30) at a New York State university. The average age was 24 years old (60% were female, 60% White, and 27% Black). Results. In the case of permanent and severe brain damage without expectation to wake up or recover, 63% do not want life-support treatment. In the event of coma without expectation to wake up or recover, 53% do not want life-support treatment. When close to death, 80% want to have religious or spiritual readings and well-loved - poems read aloud. Conclusions. Young adults are capable of making their decisions regarding appointing a health care proxy and giving specific instructions for personal, emotional, spiritual, and medical care. The present findings intend to make contributions in promoting population-based healthcare decision-making, education, and awareness.

ACCESS TO HOSPITAL-BASED PALLIATIVE CARE SERVICES FOR OLDER ADULTS IN IOWA

Hyesu Yeo[1], and Elisa Childs[2], *1. University of Georgia, Athens, Georgia, United States, 2. The University of Georgia, Athens, Georgia, United States*

Background: U.S. Medicare covers many palliative services; however, Iowa's rurality and high rate of older adults (OAs) aged 65 or over make it unclear whether older Iowans have equitable service access. Hospital-based palliative care services (HBPCSs) include curative treatment, whereas other providers of palliative care may not. Thus, this study only examined OAs' geographic access to HBPCSs in Iowa.

Methods: This study used the American Hospital Association and U.S. Census Bureau estimate in 2017. The geographical distribution of hospitals and HBPCSs was examined using a county-level approach, considering rural/urban status (using the Office of Management and Budget's definitions) and OA population proportion.

Results: Of the 99 counties in Iowa, 89 were rural. Of the 116 hospitals statewide, one urban county and nine rural counties had no hospital. A total of 52 hospitals provided HBPCSs in 43 counties across nine urban and 34 rural counties. HBPCSs were primarily located in central Iowa, with northern and southern Iowa having the lowest access to HBPCSs. The OA population ratio was higher in counties without HBPCSs (19%) than HBPCSs (15.7%). All 54 counties with over a 20% OA population were concentrated in rural counties, while only 37% of these rural counties had HBPCSs.

Conclusion: This study suggests a regional imbalance of HBPCS providers for OAs in Iowa. Results showed that rural communities with a high ratio of OAs lack HBPCSs and suggest HBPCSs should be expanded at hospitals in northern and southern Iowa counties where many OAs live.

STARTING THE CONVERSATION: FINDINGS FROM AN ADVANCE CARE DIRECTIVE WORKSHOP

Kelly Parsons, Justin Barber, Allison Gibson, Gregory Jicha, and Renee White, *University of Kentucky, Lexington, Kentucky, United States*

Every adult that enters a hospital is asked about an advance care directive (ACD) document. The completion rates of care directives started to grow in 2016, when Medicare provided a reimbursement benefit in the annual wellness exam. Previous data shows only 37% of older Americans have an ACD, of that 64% are white. Previous studies report data from medical visits, however, advance directive discussions conducted in a community setting has not yet been explored. This pilot study examines readiness to have discussions with your appointed decision-maker, primary care provider, and complete ACD document. This was a community workshop with a physician-led presentation regarding medical choices, followed by break-out groups with trained moderators reviewing ACD materials. Data from pre/posttest along with qualitative comments addressing information seeking (pre) and additional comments (post) are included. The workshop increased participants readiness to identify an individual to make medical decisions and put into writing the type of medical care they desire. It also showed resistance to having conversations with a person's primary care provider and chosen health care agent. Challenges included the pre/

posttest completion rate and the inability to compare a control group. Viewing advance directive completion within the self-determination theory assists in understanding the need for a novel setting to promote relatedness. Further research needs to be done on community setting ACD workshops to provide a space for participants to be better informed in the ACD process. Community workshops need to be examined to have a broader spectrum of inclusion within historically marginalized communities.

SESSION 6730 (POSTER)

END OF LIFE AND PALLIATIVE CARE

ORAL HEALTH AND MORTALITY AMONG OLDER ADULTS: A DOUBLY ROBUST SURVIVAL ANALYSIS

Weidi Qin[1], Jiao Yu[2], Wenxuan Huang[3], and Kristi Thomas[1], *1. University of Michigan, Ann Arbor, Michigan, United States, 2. University of Minnesota, Minneapolis, Minnesota, United States, 3. Johns Hopkins University, Baltimore, Maryland, United States*

Evidence on the association between oral health and mortality is inconclusive, and few studies have accounted for non-random selection bias in estimating their relationship. The present study aims to investigate the link between oral health and mortality in community-dwelling older adults by adjusting confounding factors with a doubly robust survival estimation. Data came from the third National Health and Nutrition Examination Survey (NHANES III, 1988-1994) and linked the National Death Index (NDI) mortality data through December 2015. The analytic sample consisted of 4,880 adults aged 50 years and above. Oral health measures included subjective oral health evaluation (self-rated oral health) and objective clinical indicators (edentulism, periodontitis, and untreated dental caries). Cox proportional hazards regression models and inverse probability weighting with regression adjustment (IPWRA) were utilized to assess the relationship between oral health and mortality. Good self-rated oral health was significantly associated with lower mortality risk (hazard ratio: 0.83, 95% CI: 0.74-0.93). Moderate periodontitis (hazard ratio: 1.18, 95% CI: 1.05-1.33), severe periodontitis (hazard ratio: 1.50, 95% CI: 1.21-1.87), and edentulism (hazard ratio: 1.13, 95% CI: 1.01-1.26) were significantly associated with higher risks of all-cause mortality, adjusting for socio-demographic characteristics, medical conditions, and health behaviors. Untreated dental caries was related to mortality in Cox models, but became non-significant when IPWRA estimators were applied. Both subjective and objective oral health are risk factors for mortality among older adults. Maintaining good oral health plays a crucial role in longevity.

AWARENESS OF PARTNER PREFERENCES FOR END-OF-LIFE ASPECTS AND TREATMENTS IN OLDER ADULT COUPLES

Sarah Vilpert[1], Clément Meier[1], Ralf J. Jox[2], Gian Domenico Borasio3, and Jürgen Maurer[1], *1. University of Lausanne, Lausanne, Vaud, Switzerland, 2. Lausanne University Hospital and University of Lausanne, Lausanne, Vaud, Switzerland, 3, Lausanne University Hospital and University of Lausanne, Lausanne, Vaud, Switzerland*

Surrogate medical decision-making at the end of life is common and the patient's partner is often the person who must make these critical decisions. The challenge of surrogate medical decision-making is to make decisions that best fit the patient's wishes. This study investigates how accurately older adult couples assess each other's preferences for eleven end-of-life aspects and three medical treatments in a nationally representative sample of adults aged 58 and over living in Switzerland (N=573). The contribution of factors including end-of-life (EOL) discussion and care planning, self-rated knowledge of partner preferences, and EOL preferences homogamy in scoring higher in accurately assessing partner's preferences for the end of life is examined. Weighted proportions, assessment accuracy scores and ordinary least squares regressions controlled for individuals' characteristics are calculated. Results show that 44% of respondents accurately assessed their partners' preferences for aspects related to medical, psychosocial, anticipatory and burden concerns at end of life, and 62% correctly predicted the preferences for cardiopulmonary resuscitation, life-prolonging measures, and palliative sedation. Respondents whose partner discussed their EOL preferences with them, completed an advance directive, designated them as their healthcare proxy, as well as respondents reporting very/rather good knowledge of their partners' EOL preferences were more likely to have a higher accuracy score for their partners' EOL preferences. Being a couple is not enough to assess one's partner's EOL preferences correctly. Communication about EOL wishes among the couple and individual EOL care planning should be encouraged, as both improve the assessment accuracy of partners' EOL preferences.

EFFECTS OF PATIENT QUESTION PROMPT LIST USE ON PARTICIPATION DURING OUTPATIENT PALLIATIVE CARE APPOINTMENTS

Meghan McDarby[1], Hannah Silverstein[2], and Brian Carpenter[2], *1. Memorial Sloan Kettering Cancer Center, New York, New York, United States, 2. Washington University in St. Louis, St. Louis, Missouri, United States*

Question prompt lists (QPLs) support patients who are seeking information during medical appointments by providing preset questions a patient might ask their provider. Prior research suggests that QPLs promote communication, including question asking, during appointments. The current study evaluated use of a 25-question QPL during initial outpatient palliative care appointments. We applied tenets of Social Cognitive Theory to investigate the relation between question asking and self-efficacy. Participants were patients attending their first outpatient palliative care appointment at an academic hospital. Participants were randomly assigned to receive the QPL before their appointment (n = 29) or to receive usual care (n = 30). Audio recordings of appointments were transcribed and coded for total questions asked. Participants also responded to a single-item measure of self-efficacy in question asking at pre- and post-appointment. On average, participants in usual care appointments asked 9.37 questions (SD = 10.3, range= 0 – 49), and participants in QPL appointments asked 11.24 questions (SD = 10.1, range = 0 – 45), but with no significant difference between groups, F(1,56) = 0.14, p = .71. All participants reported an increase in self-efficacy from pre- to post-assessment, F(1,83) = 18.76, p < .00, but there was no interaction effect of time and condition, F(1,83) = .81, p = .37. Despite their promise in previous studies, our results suggest QPLs may lack potency to shift question asking, at least in palliative care appointments, and that other mechanisms of Social Cognitive Theory may better characterize the relation between question asking and self-efficacy.

UNDERSTANDING THE RELATIONSHIP BETWEEN COPING STYLES AND DEATH ANXIETY IN OLDER ADULTS

Juliamaria Coromac-Medrano[1], Amber Watts[1], Christian Sinclair[2], and Ilana Engel[1], *1. University of Kansas, Lawrence, Kansas, United States, 2. University of Kansas Medical Center, Kansas City, Kansas, United States*

Research suggests that death anxiety stems from fear of pain, worry about loved ones, and uncertainty about what comes after death. Understanding the relationship between coping styles and attitudes towards death in older adults may help identify individuals who need support with death anxiety. This study explored the relationships between coping styles (active, disengaged, social) and death anxiety (fear, avoidance). We used the Death Attitude Profile Revised and three subscales from the Brief Coping Orientation to Problems Experienced (COPE) Inventory. We conducted linear regressions to determine which coping styles were associated with fear of death and death avoidance. In post-hoc analyses, we investigated the role of spirituality-based coping as a two-item subscale from the active coping scale. All models controlled for age, sex, marital and educational status. The sample included 87 community-dwelling older adults (Mage=72.72 (SD=5.88); 56.32% female; 86.21% White). Higher levels of disengaged coping were significantly associated with greater fear of death and death avoidance (p < .05). Use of social support coping was significantly associated with less fear of death (β = -.10, p < .05). Spirituality-focused coping was associated with lower death avoidance (p < .05). Disengaged coping may indicate higher death anxiety, whereas spirituality and social support coping strategies may indicate lower death anxiety. Our findings have implications for identifying individuals in need of extra support during critical points in the healthcare process. They may also inform design and implementation of psychosocial interventions for communication about healthcare goals in the context of serious or terminal illness.

A QUALITATIVE EVALUATION OF A POSITIVE REAPPRAISAL INTERVENTION FOR HOSPICE CAREGIVERS

HanNah Cho[1], George Demiris[1], Debra Parker Oliver[2], and Karla Washington[2], *1. University of Pennsylvania, Philadelphia, Pennsylvania, United States, 2. Washington University in St. Louis, St. Louis, Missouri, United States*

For older adults who receive hospice services in the United States, family members often become their primary caregivers playing an essential role in delivering care. Nearly 25% of hospice patients and families report the need for improved communication and additional emotional support. However, there are few interventions targeting specifically caregivers. Whereas the term caregiving implies a unidirectional flow of benefits from the caregiver to the care recipient, caregivers also experience emotional, cognitive, behavioral, or interpersonal rewards from caring for a loved one. Research has demonstrated that positive gains are common among caregivers, often manifested with negative experiences. Positive reappraisal, a form of emotion-focused coping, is especially relevant when dealing with intractable stressors. Positive reappraisal is supplemental to problem-solving therapy interventions, yet this component has never been tested in a hospice setting. In this study, we wanted to understand hospice caregivers' impressions of a problem-solving therapy intervention enhanced with positive reappraisal modules (called PISCESplus). We conducted a qualitative study examining hospice caregivers' perceptions of positive reappraisal. Participants received the intervention (as part of a larger clinical trial). Caregivers' exit interviews were audio-recorded and transcribed. Thirty hospice caregivers' interviews were analyzed. Many participants reported a paradigm shift in their thought processes. Positive reappraisal helped them reframe negative emotions to positive ones, declutter their minds, and acknowledge that caregiving required work and effort. Study findings demonstrate the potential of this intervention to improve the coping skills of caregivers in the hospice setting.

INDIVIDUALS' KNOWLEDGE ABOUT A LOVED ONE'S END-OF-LIFE CARE WISHES IS ASSOCIATED WITH THEIR OWN ADVANCE CARE PLANNING

Peiyuan Zhang[1], and John Cagle[2], *1. University of Maryland Baltimore, Baltimore, Maryland, United States, 2. University of Maryland, Baltimore, Baltimore, Maryland, United States*

Despite evidence that ACP can improve quality of life for both patient and family, it remains underutilized. Only 37% US adults have a complete advance directive (Kuldeep et al., 2017). Existing studies primarily examined factors associated with patients' ACP engagement but very few explored ACP among patients' family. The goal of this study is to examine whether individuals' knowledge about a loved one's end-of-life (EOL) care preferences is associated with their ACP engagement. Data are from the US arm of the 2015 Four-Country Survey on Aging and End-of-Life Medical Care. The sample included N=609 adults who experienced the death of a family or close friend in the past 5 years.Three binary dependent variables were measured by different facets of ACP: having a serious conversation about EOL medical care wishes (1) with loved ones, (2) with doctors and (3) documenting those wishes. The primary independent variable was participants' knowledge about their deceased family's EOL treatment wishes.Three separate logistic regression models were used. Individuals who had a greater knowledge about their loved one's EOL treatment wishes were twice as likely to have a conversation with family about their own EOL wishes (OR=2.32, P< 0.001) and documented wishes than those who didn't(OR=2.03, P< 0.05). Results have direct implications for clinicians who work with families in EOL care settings. They may have opportunities to engage individuals – other than patients – in ACP. Focusing the experience of involvement in a loved one's EOL care may be an effective strategy to enhance ACP engagement.

UCHINANCHU AMERICAN OLDER ADULTS' INFORMATION PREFERENCES AND BEHAVIORS IN END-OF-LIFE DECISION-MAKING

Kristina Shiroma[1], and Bo Xie[2], *1. University of Texas at Austin, Austin, Texas, United States, 2. The University of Texas at Austin, Austin, Texas, United States*

End-of-life (EOL) decisions are unique and sensitive, requiring nuanced health information. Careful examination of ethnic minority older adults' information preferences and behaviors in EOL decision making from a cultural perspective is increasingly necessary as the national and global population grows older and more diverse. Little is known about the information preferences and behaviors of Asian American older adults in EOL decision-making, especially for underrepresented ethnic minorities such as Uchinanchu American older adults. This pilot study examined Uchinanchu American older adult's information preferences and behaviors in EOL decision making. In November 2019, I interviewed 4 Uchinanchu American older adults (age range: 67-85 years; Mean: 76 years; SD: 8.04) recruited from personal contacts and through Uchinanchu cultural groups in Texas and Hawaii. The interviews took place in-person and via phone. Each interview lasted approximately 90 minutes. Interviews were transcribed verbatim and analyzed using inductive thematic analysis. I identified three themes from the data: (1) EOL decision-making information not coming from healthcare professionals; (2) Funeral planning easier to talk about than advance EOL medical decision making; and (3) Cultural traditions may exclude people (women; non-first born children) from EOL decision making. My findings suggest possible misalignments of EOL communication between medical professionals and Asian ethnic minority older adults. These findings may inform the development of culturally competent interventions to enhance EOL decision making.

INTERPROFESSIONAL TEAM MEMBERS' PERCEPTIONS OF PALLIATIVE SOCIAL WORKERS' CONTRIBUTIONS TO PATIENT-CENTERED CARE

Arden O'Donnell[1], and Judith Gonyea[2], *1. Boston University, Medfield, Massachusetts, United States, 2. Boston University, Boston, Massachusetts, United States*

Interprofessional collaborative practice (IPCP) is fundamental to the delivery of high-quality patient-centered care. An IPCP core tenet is that efficient and effective teams are crucial for the delivery of care that achieves patient satisfaction as well as positive patient-level outcomes. Although a growing number of IPCP studies explore how IPCP professionals work collaboratively, the vast majority focus on the interactions of physicians and nurses, few consider other professions or simply lump them into an "other" category. This qualitative study addresses this knowledge gap through the exploration of how hospital palliative care teams utilize the skills of advanced hospice and palliative care certified (APHSW-C) social workers to increase teams' overall effectiveness. A two-step recruitment process was used to create matched samples of 17 palliative social workers and 24 interprofessional team members (i.e., physicians, nurses, physician assistants, chaplains). Using a constructivist grounded theory approach, semi-structured interviews were conducted, recorded, and transcribed. Analysis revealed six themes surrounding other profession's perceptions of social workers' contributions: 1) providing continuity during and across admissions, 2) assessing and promoting the patient's biopsychosocial needs, 3) offering clinical expertise and support to patients with complex psychosocial needs, 4) allocating time to initiate, process and revisit difficult conversations with patients and families, 5) modulating the pace and intensity of emotionally laden conversations, and 6) supporting team well-being. Findings underscore that interprofessional team members view social workers as playing a significant role in developing, building, and sustaining a therapeutic alliance between the patient and the team.

SESSION 6740 (POSTER)

EPIDEMIOLOGY, BIOLOGY, CHRONIC DISEASES, AND FUNCTION II

AGE-RELATED IMMUNE CELL PHENOTYPES IN THE FRAMINGHAM HEART STUDY PARTICIPANTS

Yuan Fang[1], Jiachen Chen[1], Kathryn Lunetta[1], Joanne Murabito[2], and Margaret Doyle[3], *1. Boston University School of Public Health, Boston, Massachusetts, United States, 2. Boston University, Boston, Massachusetts, United States, 3. University of Vermont, Colchester, Vermont, United States*

Mounting evidence supports a role for the immune system in the pathophysiology of dementia. Alterations in the composition of circulating immune cells is one of the key changes associated with age. However, the role of age and sex on immune cell phenotypes and their contribution to disease pathogenesis remains to be unraveled. We identified a study sample of 996 participants (mean age 62 years, range 40 to 88 years, 52% female, 22% APOE-ϵ4 carriers) from the community-based Framingham Heart Study Offspring cohort who were dementia and stroke free at the seventh examination (1998-2001), the first exam with existing stored peripheral blood mononuclear cells (PBMC). We profiled 132 circulating immune cell phenotypes from cryopreserved PBMCs by flow cytometry using standardized protocols. T cells, B cells, NK cells, and monocytes were reported as percentage of gated lymphocytes or monocytes. All other subsets were reported as percentage of the appropriate parent (e.g. CD4+ and CD8+). We summarized the distributions of each phenotype with age, sex, and APOE-ϵ4 genotype. We also evaluated the differences in percentages of T-cell subtypes including CD4+, and CD8+ T cells and their naïve, effector memory, and central memory subsets across age groups and sex. We observed that for both CD4 and CD8, naïve cells decrease with age, whereas effector/memory cells increase with age with no difference by sex. Future analyses will explore the association between immune cell phenotypes with cognitive test performance and risk of dementia in the context of exposure to cytomegalovirus infection.

THE EFFECT OF SHORT DURATION BED REST AND TYPE 2 DIABETES MELLITUS ON ARTERIAL STRUCTURE AND FUNCTION IN OLDER ADULTS

Kseniya Masterova[1], Tatiana Moro[2], and Elena Volpi[3], *1. University of Texas Medical Branch at Galveston, Houston, Texas, United States, 2. University of Padua, Padova,* *Veneto, Italy, 3. University of Texas Medical Branch, Galveston, Texas, United States*

Type 2 diabetes mellitus (T2DM) and inactivity individually accelerate changes related to vascular aging. These changes increase cardiovascular risk and contribute to morbidity and mortality in the elderly. It is unknown if T2DM and bed rest have an additive, deleterious effect on vascular structure and function in older adults. The objective of this study is to determine the magnitude of the effect of bed rest on vascular structure in older adults with T2DM compared to healthy controls and determine if resistance exercise is protective of this effect. So far, we have recruited T2DM (n=9) and healthy control (n=17) subjects (age: 67.0 ± 6.7 years) to undergo five days of bed rest. During bed rest, subjects were randomized to receive intensive bedside resistance exercise physical therapy or standard of care in-bed passive physical therapy. On bed rest days 1 and 5, popliteal artery diameter, area, blood velocity, and blood flow were measured using Doppler ultrasonography. Our preliminary data show that the T2DM, non-exercise group had significantly greater decreases in popliteal artery diameter (-0.59 mm ± 0.18) than the control, non-exercise group (-0.17 mm ± 0.11). Resistance exercise did not prevent artery size changes in either controls or T2DM. Resistance exercise showed a trend in preventing blood velocity and flow reduction in both T2DM and control groups. These preliminary data suggest that older adults with T2DM had greater structural popliteal artery changes compared to controls. Resistance exercise appears to help maintain blood flow by maintaining/increasing popliteal artery blood velocity, but not size.

MULTISENSORY IMPAIRMENTS AND BRAIN VOLUMES IN MID-TO-LATE LIFE

Amal Wanigatunga[1], Chenxin Tian[1], Yang An[2], Yurun Cai[3], Alden Gross[1], Eleanor Simonsick[2], Jennifer Schrack[1], and Yuri Agrawal[4], *1. Johns Hopkins Bloomberg School of Public Health, Baltimore, Maryland, United States, 2. National Institute on Aging, Baltimore, Maryland, United States, 3. University of Pittsburgh, Pittsburgh, Pennsylvania, United States, 4. Johns Hopkins School of Medicine, Baltimore, Maryland, United States*

Age-related sensory impairment, such as loss in vision or hearing, have been linked to poor brain health. Yet, the relationship between co-occurring sensory impairments and brain volumes remains unclear. We used cross-sectional sensory and brain imaging data from 208 cognitively normal participants of the Baltimore Longitudinal Study of Aging (mean age 72 years; 59% women). Sensory impairments were separately identified with vision, hearing, smell, proprioception, and vestibular function testing. Brain imaging volumes were derived using an automated multi-atlas approach. Multiple linear regression models were used to estimate brain volumetric differences by number of sensory impairments (0-5) or by multisensory impairment status (MSI; ≥2 impairments). For every one additional sensory impairment, there was lower volume in the orbitofrontal gyrus (beta=0.35 cc [SE=0.17], p=0.04) but higher volumes in the caudate (0.14 cc [0.05], p=0.006) and putamen (0.13 cc [0.06], p=0.043). Participants with MSI (versus no MSI) had lower volumes in superior frontal gyrus (-1.01 cc [=0.34], p=0.003), lower orbitofrontal gyrus (-0.91 cc [0.38], p=0.018), superior parietal lobe (0.68 cc [0.27], p=0.011), and precuneus (-0.74 cc [0.35], p=0.038), but similar volumes in the caudate (p=0.12) and putamen (p=0.14). A negative relationship between MSI and brain volume across multiple regions was largely observed yet our exploratory findings raise the possibility that MSI is associated with compensatory maintenance of brain volume structures in the basal ganglia. Future directions include replication of these findings in other studies and longitudinal analyses to determine how MSI relates to brain atrophy.

UNTREATED OBSTRUCTIVE SLEEP APNEA INCREASES HOSPITALIZATION RISK IN MEDICARE BENEFICIARIES 65+ WITH HEART DISEASE

Jennifer Kirk[1], Emerson Wickwire[2], Virend Somers[3], and Jennifer Albrecht[4], *1. University of Maryland, Baltimore, Annapolis, Maryland, United States, 2. University of Maryland, School of Medicine, Balrtimore, Maryland, United States, 3. Mayo Clinic, Rochester, Minnesota, United States, 4. University of Maryland, School of Medicine, Baltimore, Maryland, United States*

Cardiovascular disease (CVD) is a leading cause of death and disability in the United States and worldwide. Untreated obstructive sleep apnea (OSA) is common among older adults with CVD and may increase their risk of hospitalization. However, prior research has been limited by smaller samples of participants undergoing diagnostic sleep testing. Our objective was to estimate the effect of untreated OSA on the risk of hospitalization among older Medicare beneficiaries with CVD age 65+. Using a 5% sample of Medicare administrative claims data from 2006 to 2013, beneficiaries were identified as cases diagnosed with OSA or controls without any sleep-related diagnoses. Then, we restricted only to beneficiaries with a CVD diagnosis by the index date (i.e., OSA diagnosis date or matched date in controls). Next, we assessed the risk of hospitalization, counting only one per beneficiary, during the year before the index date. Because OSA is typically present long before it is diagnosed, the year before OSA diagnosis was assumed to represent a period of untreated OSA. Covariates were balanced between cases and controls using inverse probability of treatment weighting (IPTW). Then using logistic regression, we estimated the risk of hospitalizations the year prior to the index date. Of the 142,893 beneficiaries with CVD, only 19,390 were diagnosed with OSA. In the IPTW model, beneficiaries with untreated OSA were more likely to be hospitalized (odds ratio, 1.82; 95% CI 1.77–1.87). Results suggest screening for OSA among Medicare beneficiaries with CVD may identify older adults at increased risk of hospitalization.

IMPACT OF SEX AND ANTIHYPERTENSIVE MEDICATION ON GLOBAL COGNITION IN PRIMARY CARE OLDER ADULTS

Adrian Noriega de la Colina[1], Helen-Maria Vasiliadis[2], Djamal Berbiche[3], Louis Bherer[4], helene Girouard[4], and Navin Kaushal[5], *1. McGill University, Westmount, Quebec, Canada, 2. Sherbrooke University, Longueuil, Quebec, Canada, 3. Sherbrooke, Sherbrooke, Quebec, Canada, 4. University of Montreal, Montreal, Quebec, Canada, 5. Indiana University, Indianapolis, Indiana, United States*

Hypertension is one of the strongest modifiable risk factors for the development of cognitive impairment and dementia. However, there are conflicting reports regarding which class of antihypertensive medication is the best for reducing the risk of cognitive decline. The objective of this study is to determine whether sex determines the pharmacological therapy that is the most effective in preserving cognitive outcomes. This study examined 1607 participants from the ESA Services Study, a longitudinal survey of older adults over 65 years old in Quebec-Canada. They were examined for the Mini-Mental State Examination(MMSE) at baseline (T1) and followed up three (T2) and four years after (T3). Hypertensive women had the highest mean MMSE score at each time point (T1 28.591 (SE .064); T2 28.282 (SE .118); T3 28.524 (SE.119)), while hypertensive men had the worst (T1 28.038(SE.070); T2 27.694(SE.125); 27.809(SE.128)). Women taking angiotensin II receptor antagonists (ARBs) showed the highest MMSE scores (p<.003), and men taking diuretics and other antihypertensives had the lowest MMSE scores(p<.001) after a 3-year follow-up. Combination therapy of two or three antihypertensives drugs was associated with higher scores in women at T1 and T2 (p<.001). In men, taking three antihypertensives showed a sharp decrease in MMSE scores from T1 to T3 (p<.001). Sex differences in global cognition outcomes in older adults are in part due to the heterogeneity in effects related to the type and number of antihypertensive drugs used. Effective antihypertensive treatment should consider the impact of sex to optimize the effect of pharmacological interventions on cognition.

SENSORY PROCESSING CORRELATES WITH DEPRESSION AND PERCEIVED STRESS IN OLDER ADULTS

Megan Chang[1], Chiung-ju Liu[2], and Erna Blanche[3], *1. San Jose State University, San Jose, California, United States, 2. University of Florida, Gainesville, Florida, United States, 3. University of Southern California, Los Angeles, California, United States*

Sensory processing is defined as the ability to respond to sensory information from the environment and to act accordingly to the situational demands. Sensory processing is associated with anxiety in middle-aged adults, specifically in those with sensory over-responsiveness and under-responsiveness. It remains unclear how age-related change in sensory processing is correlated with mental health. The purpose of this study is to examine the correlations between sensory processing patterns, depression, and perceived-stress in older adults. Respondents were recruited from community networks serving older adults. They were asked to complete an electronic survey, including the Adult Sensory Processing Scale (ASPS), the Perceived Stress Scale, and the Center of Epidemiologic Depression Scale-Revised. ASPS has 11 factors related to over-responsive, under-responsive, and sensory seeking in visual, auditory, tactile, vestibular and proprioceptive input.Of 148 older adults (Mean age = 72 years) completed the survey, 30% perceived moderate to high levels of stress, and 18% had depressive symptoms. The total score of the ASPS Scale is positively correlated with perceived stress (r=0.26; p=.001) and depression (r=0.27; p=.001). Specifically, those who were over-responsive to auditory and vestibular input, and under-responsive to proprioception had higher stress levels and greater depression.Sensory decline or impairment in older adults may alter older adults' ability to process sensory information. As sensory processing has significant impact on anxiety and perceived stress in older adults, it should be considered in evaluation and intervention, particularly on audition, vestibular and proprioception. Including sensory-based approach may help better manage their mental health.

FREQUENT CAUSES OF 30-DAY READMISSION FOLLOWING A FIRST EPISODE OF HEART FAILURE IN OLDER ADULTS

Ali Vaeli Zadeh[1], Andrew Crawford[2], Alan Wong[2], Elias Collado[1], and Joshua Larned[3], *1. Holy Cross Health-Jim Moran Cardiovascular Research Institute, Fort Lauderdale, Florida, United States, 2. Holy Cross Health-University of Miami, Fort Lauderdale, Florida, United States, 3. Holy Cross Health- University of Miami, Miami, Florida, United States*

Older adults with heart failure (HF) have a greater propensity to experience poor clinical outcomes, hospital readmission, and functional decline. It is important that healthcare workers are aware of the comorbidities that may lead to poor outcomes. A deeper understanding of potential causes of readmission will help in adequate prevention. Employing an all-payers claims database, we aimed to examine the diagnoses related to 30-day readmission in patients aged 65-75 with an Elixhauser-Comorbidity Index score < 4 upon the first episode of HF. Exclusion criteria included in-hospital death, readmissions for the same condition, and discharge against medical advice. Using ICD codes 9-10, a cohort of 323,678 patients (mean age: 70, SD: 3.22; male: 60%) with the first episode of HF between 2015-2019 were identified. We found 7,729 (2.4%) readmissions within 30 days and examined the frequency of 118 diagnoses as the primary cause. Cardiovascular etiologies including HF, hypertension, arrhythmias, and coronary artery disease were the most prevalent causes of readmission (40.64%), with HF being the most frequent (13.25%). Non-Cardiovascular causes included pulmonary (5.94%), sepsis (7%), renal (3.8%), and cerebrovascular (1.58%). Metabolic, liver, gastrointestinal diseases, and other infections accounted for 19.32%. Understanding the diagnoses related to readmissions in different populations is crucial for improving care, conducting research, and lowering costs. We focused on the first episode of HF in a relatively healthy older population to control for confounding factors. Further studies considering demographics, HF characteristics, and baseline comorbidities are needed.

HEALTHCARE UTILIZATION IN OLDER ADULTS (≥70 YEARS) UNDERGOING CELLULAR THERAPY FOR HEMATOLOGIC MALIGNANCIES

Christina Snider, Hina Budhwani, Melissa Logue, Parul Goyal, Kelly Pugh, Harvey Murff, Adetola Kassim, and Reena Jayani, *Vanderbilt University Medical Center, Nashville, Tennessee, United States*

Increasingly, older adults are receiving hematopoietic cell transplant (HCT) and chimeric antigen receptor T-cell therapy (CAR-T), intensive therapies for treatment of hematologic cancers which typically require prolonged hospital admissions. Older adults are at high risk of increased healthcare utilization and complications of prolonged hospitalization [Mudge, J Am Geriatr Soc, 2019]. We identified patients age ≥70 years who received HCT or CAR-T in a primary outpatient transplant program at Vanderbilt University Medical Center between 1/1/19 and 12/31/20. Healthcare utilization, including all visits and admissions, was captured from the start of conditioning chemotherapy through early post-therapy. Thirty-eight patients met inclusion criteria; 26 (68%) received autologous HCT (autoHCT), 7 (18%) allogenic HCT (alloHCT), and 5 (13%) CAR-T. Twenty-four patients (63%) had high HCT-Comorbidity Index (HCT-CI). Eighteen (69%) autoHCT, 6 (86%) alloHCT, and no CAR-T patients had at least one unplanned admission. The median number of total hospital days (LOS) was 7.5 (2-14), 8 (4-62), and 9 (7-9) days, respectively. One-year mortality was 12% (3) in autoHCT, 43% (3) in alloHCT, and 0% in CAR-T. Low performance status and high HCT-CI did not correlate with LOS (p=0.58 and p=0.16, respectively) or number of outpatient visits (p=1, p=0.19). In conclusion, most patients who received auto- or alloHCT in a planned primary outpatient setting experienced at least one unplanned admission. LOS duration varied widely with shorter LOS among autoHCT patients. Further research is needed to identify factors among older adults (≥70 years) at risk of increased healthcare utilization during HCT or CAR-T.

THE EFFECT OF AGE WHEN USING LLLT TO TREAT PAIN IN OLDER ADULTS

Alex Habegger[1], Danny Curtis[2], Dawn James[1], Alexis Kendrick[2], LaVona S. Traywick[2], Antonio Varela[2], Teressa Brown[2], and Reed Handlery[2], *1. Arkansas College of Health Education, Fort Smith, Arkansas, United States, 2. Arkansas Colleges of Health Education, Fort Smith, Arkansas, United States*

Low-level laser therapy (LLLT) is commonly used to treat pain; however, little is know about the effects of age on outcomes of the treatment. Participants included community dwelling adults (22 females, 9 males) with a mean age of 55 (n=31, range 29 to 77 years). Prior to participation, physical therapist examined each subject to determine appropriateness for treatment with LLLT. Following the examination, subjects received 12 sessions of LLLT using a Class 3B laser device. Intervention was administered by researchers trained in appropriate application of the intervention. The WALT guidelines and specific anatomical location of pain determined dosage of LLT. The most common site of pain or discomfort was hip and thigh pain (23%). Subjects completed the Patient-Specific functional Scale (PSFS) pre- and post-treatment and used the Numeric Pain Rating Scale (NPRS) before and after each intervention session. An analysis of the data showed that age was positively correlated (r=xx) and statistically significant ($p < 0.05$) with changes in both current and worst pain ratings and the first item on the PSFS. Age explained 13.4% of worst pain (p=0.024). Although not statistically significant, age explained 9.2% of the variability in current pain (p =0.054) and 3.9% of variability in patient identified changes in function (p = 0.147). Results suggest that older patients treated with LLLT may experience greater positive changes in pain than younger patients.

EFFECTS OF ASSISTIVE TENNIS SHOES ON GROUND REACTION FORCE FOR PATIENTS WITH PERIPHERAL ARTERY DISEASE DURING WALKING

Nathaniel Evans[1], Hafizur Rahman[2], Iraklis Pipinos[3], Jason Johanning[3], Mahdi Hassan[2], and Sara Myers[2], *1. University of Nebraska Omaha, Omaha, Nebraska, United States, 2. University of Nebraska at Omaha, Omaha, Nebraska, United States, 3. University of Nebraska Medical Center, Omaha, Nebraska, United States*

Peripheral artery disease (PAD) is caused due to buildup of atherosclerotic plaques, typically in the leg arteries, preventing adequate blood circulation and ultimately claudication. A previous study showed that the vertical ground reaction force (VGRF) curve is significantly flatter in claudicating patients, resulting in a lower and less fluctuant center of mass when ambulating. Patients with PAD also demonstrate significantly decreased propulsion forces in the anterior– posterior direction. Assistive tennis shoes (carbon fiber: CF, and spring-loaded: SL) can potentially assist push-off by substituting for muscle forces using energy stored in a carbon fiber plate or metal spring within the shoe. This study aims to examine how the CF and SL shoes impact walking performance in patients with PAD. A total of ten patients with PAD performed a progressive treadmill test using a pressure-instrumented treadmill for each shoe type: i) standard shoes, ii) CF shoes, and iii) SL shoes. We calculated the peak VGRF for three subjects to date as an average of ten stance phases for the beginning of the walking condition (pain free condition). Preliminary results from three subjects showed that patients with PAD generated a greater peak VGRF wearing CF and SL shoes compared to normal shoes during the heel contact (normal: 0.97±0.10BW, CF: 1.03±0.08BW, and SL: 1.09±0.10BW) and push-off (normal: 0.97±0.06BW, CF: 0.99±0.04BW, and SL: 1.03±0.05BW). In future, we will calculate the VGRF for the remaining patients in pain free and pain conditions and conduct statistical analysis to identify significant differences among shoe types.

OLDER DYADS USING A WEARABLE PERSONAL SLEEP MONITORING DEVICE FOR SLEEP SELF-MANAGEMENT

Cynthia Jacelon[1], Maral Torrisan[2], and Sarah Fiske[3], *1. University of Massachusetts Amherst College of Nursing, Amherst, Massachusetts, United States, 2. U. Massachusetts, Amherst, Amherst, Massachusetts, United States, 3. Elaine Maarieb College of Nursing, University of Massachusetts Amherst, Amherst, Massachusetts, United States*

Normally occurring changes in sleep patterns can affect behavior, safety, and function in older individuals. In addition, altered sleep of one partner can affect the functioning of the other. We tested a novel intervention using an off the shelf, wrist-worn actigraph as a personal sleep monitoring device (PSMD) with dyads comprised of individuals who were 70 years old or older, and slept in the same house. Aims included: 1) Establish the feasibility of sleep self-monitoring using PSMDs, as a self-management strategy. 2) Establish the feasibility of PSMD data sharing among members of the dyad to improve sleep self-management and improve sleep quality; and 3) Evaluate the usability of PSMDs and data sharing for dyads of older individuals. Over the course of a five-week trial, we used a mixed methods approach. Data were comprised of daily sleep diaries, data from the PSMD, weekly questionnaires regarding sleep patterns and function, and qualitative interviews focused on sleep, self-management within the dyad, and the usability of the PSMD. Data were analyzed using qualitative or statistical methods. The use of the PSMD increased awareness of sleep patterns at the individual and dyadic levels, but the limitations of the PSMD were frustrating. Participants valued having a graphic image of how their daily activities affected their sleep patterns. The dyadic approach was effective in improving sleep patterns for older individuals, and using over the counter activity monitoring devices provide a relatively inexpensive way to assist older adults to improve their sleep self-management.

MULTIMORBIDITY PROGRESSION AMONG MEDICARE BENEFICIARIES IN THE HEALTH AND RETIREMENT STUDY (1991–2015)

Ana Quiñones[1], Sheila Markwardt[2], Michelle Bobo[2], Heather Allore[3], Jason Newsom[4], Corey Nagel[5], Anda Botoseneanu[6], and David Dorr[2], *1. Oregon Health and Science University, Portland, Oregon, United States, 2. Oregon Health & Science University, Portland, Oregon, United States, 3. Yale University, Guilfrod, Connecticut, United States, 4. Portland State University, Portland, Oregon, United States, 5. University of Arkansas for Medical Sciences, Little Rock, Arkansas, United States, 6. University of Michigan Dearborn, Dearborn, Michigan, United States*

Older adults are at greater risk for developing and accumulating multimorbidity (2+ chronic conditions). This study describes the characteristics of older adults with multimorbidity using Medicare claims over a 24-year period. The HRS-Medicare data (1991-2015, N=17,199, age 67+ years) were used in descriptive analyses. We identified 8,800 (51%) beneficiaries who did not have multimorbidity at first observation (no multimorbidity), 6,270 (36%) with 2-4 conditions at the first observation (low multimorbidity), and 2,129 (12%) with 5+ conditions at the first observation (high multimorbidity). Older respondents (80+ years) had lower levels of multimorbidity at baseline compared with younger respondents (< 70 years); this appeared to be related to differences by birth cohort. Higher proportions of minoritized groups had high multimorbidity (15% non-Hispanic Black; 20% Hispanic; 11% non-Hispanic White). Despite only being 22% of the entire sample, persons with obese body mass index (>30) represented 41% of the high multimorbidity group. Higher incidence rates of disease accumulation were noted for Black (89/1,000 person years [py]) and Hispanic (94/1,000 py) compared with White respondents (82/1,000 py) in the high multimorbidity group. Hospitalization and ED rates increased linearly between the low and high multimorbidity groups. Functional loss was more prevalent in the high multimorbidity group compared with the no multimorbidity group; no difference was observed between no and low multimorbidity. Results highlight sociodemographic differences between Medicare fee-for-service beneficiaries with differing levels of multimorbidity, allowing new insights to guide interventions that address burdensome changes in late life.

EFFECT OF HYPERTENSION ON PREFRONTAL CORTEX ACTIVATION IN OLDER ADULTS DURING INSTRUMENTED TRAIL WALKING TASKS

Manuel Hernandez[1], and Alka Bishnoi[2], *1. University of Illinois at Urbana-Champaign, Urbana, Illinois, United States, 2. University of Illinois at Urbana-Champaign, Urbana Champaign, Illinois, United States*

Hypertension (HTN) can lead to non-amnestic cognitive impairment. However, it is unclear if this cognitive impairment affects dual task walking in older adults with HTN. The objective of this study was to evaluate the differences in prefrontal cortex (PFC) oxygenated hemoglobin (HbO2) levels during comfortable walking (CW) and an instrumented trail walking task (TWT) in older adults with HTN. We hypothesized that older adults with HTN would show decreased activation, or lower PFC HbO2 using functional near-infrared spectroscopy, during TWT in comparison to older adults without HTN. There were 15 adults in HOA group (11 females; 65±9 years old), and 9 adults in HTN group (3 females; 68±8 years old). The experimental paradigm consisted of three tasks (CW, TWT-A, TWT-B) in each of two blocks, with difficulty increasing from TWT-A to TWT-B through the inclusion of task-switching. A linear mixed effect model was conducted to investigate the effects of cohort, task, block and interaction between them on HbO2. We found that: 1) HTN adults exhibited lower HbO2 levels compared to HOA (p< 0.001), during TWTs but not CW; and 2) increased HbO2 levels were observed in TWTs relative to CW. During TWTs, HTN adults showed decreased activation compared to HOA, which shows that their ability to focus on dual task execution is limited. The hypertensive adults face difficulty in matching the attentional demands of the dual task, similar to cognitively impaired older adults, which may be partly explained by capacity sharing theory.

INFLUENCE OF TOTAL KNEE REPLACEMENT ON LEAN MASS MEASUREMENTS USING DUAL-ENERGY X-RAY ABSORPTIOMETRY

Jae Young Jang[1], Miji Kim[1], Daehyun Lee[2], Hyung Eun Shin[1], and Chang Won Won[1], *1. Kyung Hee University, Seoul, Seoul-t'ukpyolsi, Republic of Korea, 2. Kyung Hee Univerisity, Seoul, Seoul-t'ukpyolsi, Republic of Korea*

Sarcopenia and osteoarthritis often occur together. Many sarcopenic patients with osteoarthritis are managed by total knee replacement (TKR). The prevalence of TKR is increasing in older adults; however, metal implants can lead to the overestimation of lean mass (LM) in dual-energy X-ray absorptiometry (DXA). However, studies considering metal implants in DXA measurement of LM are scarce. Comparisons without and with automatic metal detection (AMD) are important for accurately measuring LM. Therefore, this study examined the effects of TKR on LM. Twenty-four subjects (mean age: 76.4±4.0 years) who underwent TKR were selected from the Korean Frailty and Aging Cohort Study. A GE Lunar iDXA (GE Healthcare Lunar, Madison, WI, USA) system was applied twice (with and without AMD). Leg LM was significantly overestimated in the right and left legs with TKR. The LMs with and without AMD were 6017.1±199.3 g and 5493.7±171.3 g, respectively (p< 0.001), in the right leg, and 5657.1±220.1 g vs. 5173.7±201.8 g, respectively (p< 0.001) in the left leg. The appendicular lean mass index (ALMI) without and with AMD was 6.5±0.6 kg/m2, 6.1±0.6 kg/m2 (p< 0.001). In addition, only one subject was classified as having low muscle mass without AMD, which increased to four based on AMD according to the Asian Working Group of Sarcopenia 2019 guidelines. The overestimated leg LM in subjects after TKR decreased with AMD. Furthermore, LM with AMD increased the prevalence of low appendicular LM in the diagnosis of sarcopenia. Therefore, metal implants should be considered to accurately measure LM using DXA.

SESSION 6750 (POSTER)

FAMILY CAREGIVING II

CARING FOR PARENTS AND IN-LAWS IN CHINA: IMPLICATIONS FOR COGNITIVE FUNCTIONING OF ADULT CHILD CAREGIVERS

Zhiyong Lin[1], and Haoshu Duan[2], *1. University of Texas at San Antonio, San Antonio, Texas, United States, 2. University of Maryland, Baltimore, Maryland, United States*

Considerable research and public discourse on family caregiving portrays it as a stressful and burdensome experience with serious negative health consequences. Yet, there is also recent evidence indicating better health status in caregivers compared to non-caregivers. Especially for cognitive health, caring for others involves cognitively stimulating activities that can help prevent cognitive decline. Although the negative consequences of eldercare on the mental and physical health of caregivers are well-documented, how it would affect their cognitive functioning is underexplored. Using three waves of nationally representative data in China, the China Health and Retirement Longitudinal Study (CHARLS, 2011, 2013, 2018), this study investigated the longitudinal association between parental caregiving and cognitive functioning among adult child caregivers, and further examined how this association was conditioned on the relationship type (parent versus in-law), caregiving frequency, and gender of adult children. Descriptive analysis indicated that women are more likely to be occasional caregivers for their own parents and regular caregivers for parents-in-law compared to men. Results from multilevel mixed-effects models showed that caring for own parents was beneficial for adult children's cognitive functioning whereas caring for parents-in-law was not significantly associated with their cognitive functioning. Both sons and daughters benefited from caring for their own parents although the beneficial effect was stronger for sons. Thus, we recommend to consider relationship types between caregivers and care-recipients when investigating informal caregiving and various health outcomes. Furthermore, we suggest more policies and programs that aim to help children-in-law who look after their parents-in-law.

CHANGES IN PATTERNS OF FORMAL AND INFORMAL HELP AND UNMET NEEDS AMONG KOREAN OLDER ADULTS

Seoyeon Lee[1], Seung-Eun Cha[2], and Kyungmin Kim[3], *1. Chonnam National University, Gwangju, Kwangju-jikhalsi, Republic of Korea, 2. The University of Suwon, Hwaseong-si, Kyonggi-do, Republic of Korea, 3. Seoul National University, Seoul, Seoul-t'ukpyolsi, Republic of Korea*

Despite the consistent expansion of social long-term care insurance (LTCI), informal care by family members is still dominant in Korea. This study aims to examine how older adults in need utilized formal and informal sources of help and how patterns of help and unmet needs changed over time, since LTCI has been introduced in 2008. Community-dwelling older adults (65+) from the Korean Longitudinal Study of Ageing (N = 2,501) reported their I/ADL limitations and who helped them—if they are in need in 2010 and 2018. We grouped older adults' sources of care into (a) no help, (b) informal help only, and (c) any formal help, and examined the patterns by wave and gender. Among older adults with I/ADL limitations, formal help use increased between waves (1% to 12%), suggesting the impact of LTCI expansion. Changes in the patterns of help and unmet need differed by gender. The proportion of older men with no help dramatically decreased (41% to 27%); more men received informal or formal help in 2018. In contrast, the proportion of older women who did not receive any help remained similar (33% to 34%); thus, although more women received formal help, less women relied on informal help in 2018. Within the context of LTCI expansion, older men may mobilize support from their family further, which contributes to lowered unmet needs. However, older women's unmet need did not decrease, while reduced use of informal help. These findings highlight the importance of considering gendered long-term care resources in Korea.

ADVERSE SOCIAL EXPERIENCES, SOCIAL SUPPORT, AND HEALTH OUTCOMES AMONG BLACK AND WHITE FAMILY CAREGIVERS

Wesley Browning[1], Ghislaine Atkins[2], Pamela Bowen[1], Michael Crowe[3], Laura Dreer[1], Nicole Ruggiano[4], and Olivio Clay[1], *1. University of Alabama at Birmingham, Birmingham, Alabama, United States, 2. University of Tampa, Tampa, Florida, United States, 3. University of Alabama-Birmingham, Birmingham, Alabama, United States, 4. University of Alabama, Tuscaloosa, Alabama, United States*

Family caregivers provide care for loved ones who have difficulty performing activities of daily living. Previous research has examined the influence of direct and indirect stressors on caregiver's health outcomes but has often neglected the role of tertiary stressors (stressors that are not caused by caregiving but influence caregivers' appraisals of stress). This study examined the impact of tertiary stressors called adverse social experiences (ASEs), including negative interaction (criticism from others, excessive demands by others, being taken advantage of, and others prying into caregivers' personal affairs), experiences of discrimination, and low physician trust on caregiver health outcomes including depressive symptoms along with mental and physical health quality of life (QoL). This study also investigated the effects of social support on health outcomes in caregivers. Linear regression models were used to analyze these relationships within a group of 56 Black and White adult caregivers (18+) recruited online via social media and listservs from

April to June 2021. Caregivers provided at least 5 hours of care weekly for recipients aged at least 45 years old. Negative interaction predicted more depressive symptoms, whereas emotional support and satisfaction with support were predictors of less depressive symptoms and better mental health QoL (p's < .05). Experiences of discrimination and physician trust did not predict health outcomes. These findings suggest researchers should further investigate the impact of ASEs, particularly negative interaction, on caregiver health. Healthcare providers of caregivers should consider how ASEs and social support may affect caregivers' health and ability to care for their relatives.

INTERSECTIONS OF SEXUAL ORIENTATION AND GENDER IN SPOUSAL CAREGIVING: A FOCUS ON COGNITIVE LABOR

Sadie Giles[1], Toni Calasanti[1], Jing Geng[2], and Brian de Vries[3], *1. Virginia Tech, Blacksburg, Virginia, United States, 2. Virginia Tech, BLACKSBURG, Virginia, United States, 3. San Francisco State University, Palm Springs, California, United States*

Our presentation adopts a lens of intersecting inequalities based on gender and sexual orientation in exploring caregiving for a spouse or partner with dementia. How the division of labor shapes caregiving approaches is sometimes examined, but how this might differ by sexual orientation has not been explored. Previous research has often examined physical tasks and, to a lesser degree, emotion work. Here, we focus on cognitive labor (Daminger, 2019): the mental labor involved in managing the household and social relationships, including anticipating needs, identifying ways to address these, making decisions, and monitoring outcomes. This theoretical backdrop informs our analysis of data garnered from in-depth interviews conducted among gay/lesbian and heterosexual older adults (N=57) who care for their spouses with dementia. However couples may have divided these cognitive steps previously, caregivers must perform them all alone, given care receivers' cognitive losses. Our analyses reveal that caregivers find being responsible for everything exhausting, but this manifests differently based on gender and sexual orientation. Heterosexual women, for instance, found making all the decisions problematic, whereas heterosexual men reported difficulty in anticipating needs. For the most part, the challenging issues for gay and lesbian caregivers were more varied, as their previous division of labor had been negotiated differently, without a reliance on traditional gender roles. Finally, we uncover a novel domain for cognitive labor: being the "memory keeper." Predominantly undertaken by women, this work involved maintaining important memories and markers of the care receiver's (and couple's) past.

FEASIBILITY OF A COMMUNITY-LED VIRTUAL SELF-CARE PROGRAM FOR AFRICAN AMERICAN FAMILY CAREGIVERS

Abiola Keller[1], Nia Norris[2], Bashir Easter[3], Andrea Garr[4], Gail Morgan[5], Ramona Dicks-Williams[6], and Colleen Galambos[7], *1. Marquette University, Milwaukee, Wisconsin, United States, 2. UW-Madison Wisconsin Alzheimer's Institute Regional Milwaukee Office, Milwaukee, Wisconsin, United States, 3. University of Wisconsin Madison, Madison, Wisconsin, United States, 4. Wisconsin Department of Health Services, Milwaukee, Wisconsin, United States, 5. UW Madison School of Medicine and Public Health, Milwaukee, Wisconsin, United States, 6. Community Member, Milwaukee, Wisconsin, United States, 7. University of Wisconsin-Milwaukee, Milwaukee, Wisconsin, United States*

As the population of older adults in the U.S. increases, the need for family caregivers will mirror this growth. Despite a greater intensity of caregiving, African American caregivers are less likely to access formal support services and engage in self-care practices. To address the self-care needs of African American family caregivers, a community-engaged approach was used to develop and implement a half-day virtual self-care program. The development of the program was guided by the Individual and Family Self-Management Theory. This study evaluates experiences of program attendees. The specific aims are to examine the acceptability and practicality of the virtual self-care program. Women who self-identified as African American and a caregiver (i.e., taking care of another adult) were personally invited to attend. All attendees were emailed an electronic survey containing Likert-type and open-ended questions. Responses were examined for patterns and key content-related categories using inductive content analysis. Eleven of the sixteen attendees responded to the survey. All eleven strongly agreed (64%) or agreed (36%) that the event met their expectations and/or needs. In addition to providing opportunity to take time to engage in self-care, the event created a virtual space for women to focus on themselves. Women spoke about three distinct ways the event met their needs: 1) learning and trying new things, 2) access to resources, and 3) having a shared experience. These findings suggest that virtual programs may be used as an additional resource to support the health of African American women who care for older adults.

EFFECTS OF PARENTING STYLE IN CHILDHOOD ON MENTAL HEALTH OUTCOMES OF CAREGIVING IN ADULTHOOD: A QUALITATIVE ANALYSIS

Abby Baumbach[1], M. Courtney Hughes[1], Lily Derain[1], and Yujun Liu[2], *1. Northern Illinois University, DeKalb, Illinois, United States, 2. Northern Illinois University, Naperville, Illinois, United States*

The life course perspective suggests that caregivers of aging parents bring their histories of relationships with aging parents, such as childhood maltreatment, to the care environment. These histories would then impact the dynamics and consequences of caregiving. However, there is a lack of research on the impact of childhood parental interactions on adult relationships with aging parents, particularly in the context of caregiving. The study aims to understand how relationships with caregivers while growing can impact an individual's role as a caregiver later in life. The qualitative study included 47 adult family caregiver survey respondents who care for their parents, with a mean age of 46.7, ranging from 20 to 79 years old. The respondents were asked to reflect on their recent experience of providing care for their loved ones and how experiences with their caregiver growing up may have influenced their current relationship dynamic. The researchers used Dedoose V.9.0.17 to perform a codebook thematic analysis. Themes from the survey analysis linking childhood to current experience included reciprocating good care, performing obligatory care, and stopping the generational transference of negative care. When focusing on specific parental genders when receiving care in childhood, levels of presence and affection stood out as important aspects of their father's caregiving. Themes associated with maternal caregiving included good relationships, strained relationships, and nurturing. Knowledge about the impact of childhood experiences can help program designers develop interventions to help lessen caregiver burdens that consider childhood care receiving experiences and the challenges and opportunities they present.

FAMILY CAREGIVERS' PSYCHOLOGICAL WELL-BEING AND PHYSICAL HEALTH IN THE CONTEXT OF THE WORK ENVIRONMENT.

Barbara Hodgdon, and Jen Wong, *The Ohio State University, Columbus, Ohio, United States*

As working family caregivers navigate work and care responsibilities, the work environment may contribute to their psychological well-being and physical health outcomes. Working caregivers who provide multi-generational care (e.g., sandwiched caregivers) experience greater vulnerability when compared to non-sandwiched caregivers (e.g., filial caregivers). This vulnerability could be mitigated by supportive work characteristics (e.g., greater decision authority and supervisor support). Informed by the life course perspective, this study compared the psychological well-being and physical health of working sandwiched and filial caregivers, and the moderating role of work characteristics (decision authority and supervisor support). Sandwiched (n=80; Mage=46.3) and filial (n=62; Mage=55.7) caregivers from the Midlife in the United States (MIDUS-II) Survey provided information about their background, caregiving, employment, well-being, and health via a set of questionnaires and phone interview. Regression analyses showed that sandwiched caregivers exhibited lower levels of generativity than filial caregivers. Moderation analyses revealed that sandwiched caregivers with greater decision authority trended toward exhibiting greater autonomy than other caregivers. Sandwiched caregivers with greater decision authority also exhibited significantly less difficulty with instrumental activities of daily living (IADLs) than other caregivers. Finally, sandwiched caregivers with greater than average supervisor support trended toward exhibiting higher level of generativity as compared to other caregivers. Results highlight the impact of sandwiched caregiving on autonomy, generativity, and IADLs in the context of decision authority and supervisor support. Findings may inform workplace programs and policies aimed at enhancing caregivers' sense of decision making and increasing supervisor support in order to promote caregivers' psychological well-being and physical health.

IMPACTS OF CAREGIVING ON WELL-BEING AMONG SPOUSAL CAREGIVERS TO OLDER ADULTS USING COARSENED EXACT MATCHING

Ruotong Liu[1], Iris Chi[2], and Shinyi Wu[2], *1. Oregon Health & Science University, Marina del Rey, California, United States, 2. University of Southern California, Los Angeles, California, United States*

Spousal caregivers to older adults may be at increased risks of negative health outcomes because they are also dealing with their own aging and health issues. Estimating the impacts of caregiving without controlling for caregivers' own aging and aging-related health decline could exaggerate the negative health consequences of caregiving, whereas focusing on caregivers only could face the risk of selection bias where healthier individuals enter and/or remain in caregiving. In this study, we used coarsened exact matching to compare outcomes in wellbeing between spousal caregivers and spousal non-caregivers. Pooled panel data from Wave 8 to Wave 13 in the Health and Retirement Study was utilized with two consecutive waves of data for each spousal caregiver. The sample included 203,162 person-wave observations from 5,162 unique individuals, among whom 3,577 were spousal caregivers. Variables used for matching were classified into three categories: care obligations, the willingness to provide care, and the ability to provide care. Outcome of interest was depressive symptoms measured by CES-D 8. A total of 2,741 (81.01%) spousal caregivers were matched with 18,043 observations of spousal non-caregivers. Regression analysis indicated that being a spousal caregiver was statistically significantly associated with a 0.27 unit increase in depressive symptoms in the subsequent wave, after controlling for other potentially confounding variables such as caregiver's race/ethnicity, length of current marriage, etc. Our results highlighted the elevated needs to address mental health among spousal caregivers, and indicated that long-term care program and policy should take into consideration the mental health among spousal caregivers.

MEANING FOCUSED COPING: IMPLICATIONS FOR FAMILY CAREGIVER BURDEN AND POSITIVE ASPECTS OF CARE

JoAnna Dieker[1], and Sara Qualls[2], *1. University of Colorado Colorado Springs, San Antonio, Texas, United States, 2. University of Colorado Colorado Springs, Colorado Springs, Colorado, United States*

The Stress Process Model (Pearlin et al., 1991) posits that different styles of coping influence both positive and negative psychological outcomes in family caregivers. Meaning-focused coping is hypothesized to promote positive psychological experiences, but presently it is unclear how meaning-focused coping is related to caregiver burden. The present study tested the associations among meaning-focused coping, indicators of burden, and positive aspects of care in adult child and spousal caregivers of older adults with dementia. An online sample of caregivers ranging in age from 30-68 (n = 219) completed a measure of meaning-focused coping (COPE-PRG; Carver et al., 1989) and the Caregiver Reaction Scale (CRS; O'Malley & Qualls, 2016) which assessed overload, role captivity, personal growth, and competence. Regression analyses indicated that meaning-focused coping predicted less role captivity and predicted greater personal growth and competence. However, meaning-focused coping did not account for significant variance in perceived overload. The findings extend prior research by demonstrating that meaning-focused coping strategies may faciliate positive aspects of care during chronically stressful experiences such as caregiving. Findings highlight that meaning-focused strategies may be more helpful for coping with role captivity (e.g., feeling unable to participate in work or family roles outside of caregiving) and less helpful for coping with subjective overload (e.g., a sense of overwhelm) in caregivers. Results inform clinical interventions that promote meaning and reduce burden in caregivers.

THE WORST PART OF THE DAY: DAILY REFLECTIONS OF DEMENTIA FAMILY CAREGIVERS

Chunhong Xiao[1], Vicki Winstead[2], and Carolyn Pickering[1], *1. The University of Alabama at Birmingham, Birmingham, Alabama, United States, 2. The University of Alabama at Birmingham, School of Nursing, Birmingham, Alabama, United States*

Family caregivers struggle with multi-dimensional demands in caring for persons living with dementia (PLWD). The challenges of caregiving combined with the requirements of daily life can impact the care of PLWD and the health and well-being of the caregivers. The purpose of this study was to describe caregivers' perceptions of the worst part of their day in the context of daily caregiving challenges. Family caregivers completed online surveys reporting on various parts of their day. The survey included an optional open-ended question: "what was the worst part of your day?" Caregivers (N=165) completed diaries for 21 days resulting in 1,773 surveys that included a response to the optional open-ended question. A subset of data was analyzed using content analysis to identify initial codes and themes; further content analysis of the complete dataset was used to confirm and refine the identified codes and themes. Final analysis revealed 6 themes describing caregivers' perceptions of the worst part of their day. These themes included days in which they had to: 1) cope with changes in their relationship with the PLWD, 2) manage their own health-related issues such as illness and lack of sleep, 3) struggle when there was a lack of help or support, 4) deal with daily life demands in the home along with the demands of caregiving, 5) cope with negative emotions such as sadness, grief, or anger over the disease process, 6) cope with physical exhaustion. The findings reflect daily stressors associated with caregiving for PLWD.

HEALTH BEHAVIORS AND MENTAL HEALTH OUTCOMES OF INFORMAL CAREGIVERS DURING THE COVID-19 PANDEMIC

Yujun Liu[1], Yuxin Zhao[2], and M. Courtney Hughes[3], *1. Northern Illinois University, Naperville, Illinois, United States, 2. Booz Allen Hamilton, Washington, District of Columbia, United States, 3. Northern Illinois University, DeKalb, Illinois, United States*

Differences exist in health behaviors and mental health outcomes between spouse and adult children caregivers and between caregivers of individuals with or without dementia. We aimed to examine the change in health behaviors and mental health outcomes of informal caregivers of older adults during the COVID-19 pandemic and explore disparities based on caregiver relationship and care recipient. Using the 2020 National Health and Aging Trends Study (NHATS) COVID-19 supplement for Family Members and Friends, our sample included adult family or friend caregivers of Medicare beneficiaries aged 65 or older in the US (N = 2,062). We used ANOVA and two-way ANCOVA to assess the effects of the pandemic, caregiver relationship type, and care recipient condition (dementia vs. non-dementia) on seven health behaviors and two mental health outcomes. We performed all post hoc analyses using Bonferroni corrections controlling the covariates age, gender, marital status, education, and self-reported health of the caregiver. Compared to before the pandemic and to spouse caregivers, adult children caregivers reported: 1) significantly less time walking and significantly more time watching TV or online programs, and 2) a significantly higher level of emotional distress and depressive symptoms. Compared to caregivers for people without dementia, those who provide care for people with dementia experienced less sleep and a higher level of depressive symptoms during the pandemic than before the pandemic. Health professionals should consider the impact of COVID-19 and the vulnerability of adult children caregivers and caregivers of individuals with dementia when designing and delivering health and wellness programs.

INFLUENCES ON CUSTODIAL GRANDCHILDREN'S RECEIVING TREATMENT FOR DISTRESS

Bert Hayslip[1], and Julian Montoro-Rodriguez[2], *1. University of North Texas, Denton, Texas, United States, 2. University of North Carolina at Chatlotte, Charlotte, North Carolina, United States*

Little work exists regarding the difficulties facing grandchildren raised by their grandparents, where previous research suggests such children to be especially at risk for psychological difficulties and that they often have limited access to potentially efficacious psychosocial interventions. The present study integrates these two perspectives in examining multiple sociodemographic, family-related, and grandchild-specific factors differentiating custodial grandchildren who were being treated for a variety of emotional and behavioral difficulties (N = 80) and those who were not (N = 157), as reported by the custodial grandparent. A MANOVA (F 23, 176 = 9.74, p < .01, eta2 = .56) indicated that custodial grandchildren who were receiving treatment came from larger grandfamilies, were older, were having a greater variety of grandparent reported psychosocial difficulties, and were experiencing more emotional, behavioral, attentional, and relationship problems. The grandparents of such grandchildren experienced more parental strain, reported less social support, were less resilient, were less satisfied with the grandparent role, and reported poorer health. They also reported being less strongly attached to the grandchild and expressed more negative affect toward him/her. However, they also reported more openness regarding a variety of difficulties that might be addressed by mental health professionals. A subsequent discriminant analysis reflecting a weighted linear combination of the above factors (X2 19 = 132.09, p < .01, Wilks' Lambda = .498) correctly classified 86.1% of cases based upon treatment status. These findings provide a basis for understanding the determinants of custodial grandchilden's receiving needed psychosocial interventions crucial to their well-being and adjustment.

POOR SLEEP COMMON AMONG HOSPICE FAMILY CAREGIVERS AND ASSOCIATED WITH WORSE CAREGIVER HEALTH

Lauren Starr[1], Karla Washington[2], Kyle Pitzer[2], George Demiris[1], and Debra Parker Oliver[2], *1. University* *of Pennsylvania, Philadelphia, Pennsylvania, United States, 2. Washington University in St. Louis, St. Louis, Missouri, United States*

Over 1.2 million hospice family caregivers in the United States are at risk for interrupted, insufficient sleep due to overnight caregiving responsibilities, anxiety or intrusive thoughts, and inadequate caregiving support. Insomnia contributes to health inequities yet is underrecognized and undertreated. The prevalence of insomnia among hospice family caregivers is not well understood. The purpose of this preliminary study was to describe insomnia prevalence among hospice family caregivers and identify factors that differentiate caregivers with sleep difficulties from caregivers without sleep difficulties. This observational study included 57 hospice family caregivers of cancer patients enrolled in a randomized clinical trial for caregivers [NCT02929108]. Results showed 49.1% of hospice family caregivers had subthreshold insomnia to severe clinical insomnia, as measured by the Insomnia Severity Index. Although social determinant of health variables did not differ based on caregiver insomnia status, caregivers with insomnia (5.0, median) self-rated their physical health significantly lower than caregivers without insomnia (8.0, median) ($P< 0.001$). Directionally, the distance a caregiver lived from a care-recipient also differed by insomnia status, with 70% of caregivers with insomnia co-residing compared to 46% of caregivers without insomnia. Overall, 78.9% of hospice family caregivers had no caregiving support; anxiety and depression were highly prevalent. Clinicians should screen hospice family caregivers for sleep disorders and seek to improve caregiver health by offering sleep interventions tailored to the specific needs of hospice family caregivers and connecting caregivers to health resources for their own wellbeing. Policy makers must expand hospice benefits to include additional caregiver support.

CHANGING FAMILY DESTINIES, DIVERGENT FAMILY CAREGIVING PATTERNS: DO BIRTH COHORTS, GENDER, RACE, AND SES MATTER?

Haoshu Duan, *University of Maryland, Baltimore, Maryland, United States*

Over the past few decades, Americans have experienced a series of demographic transitions include prolonged longevity and rise in the complexities of family structures. The Baby Boomer cohort is at the forefront of these transitions, which has profound implications on their later-life family relations and practices of family caregiving. Most caregiving literature has focused on static care experiences over a short time, while neglecting long-term care experiences. Using 10 waves of longitudinal data from HRS (2000-2018) and latent profile analysis, I identified five prominent long-term caregiving patterns: light parental caregivers (44.1%), intensive spousal caregivers (5.6%), sandwiched caregivers (5.5%), light grandchildren caregivers (38.7%), and heavy grandchildren caregivers (6.2%). Further, I conduct multinominal logistic regression to investigate how birth cohorts, gender, race, and education shaped these patterns. Results suggested that later cohorts have seen a decline in intensive spousal caregivers, light and heavy grandchildren caregivers, but an increase in light parental caregivers. Women are more likely to be sandwiched caregivers than men, and black caregivers are more likely to be intensive spousal caregivers, heavy grandchildren caregivers, and sandwiched caregivers than white. By contrast, white and more educated caregivers are more likely to be light parental caregivers, and this pattern becomes more pronounced in later cohorts. The findings suggest divergent destinies of family caregiving patterns among later cohorts. More disadvantaged groups are shouldering heavier care responsibilities than advantaged groups. Targeted care services should be implemented to ease the care burdens of the vulnerable population.

FAMILY DEPENDENCE AND ITS ASSOCIATION WITH SELF-REPORTED HEALTH AMONG OLDER ADULTS IN EASTERN NEPAL

Aman Shrestha[1], Isha Karmacharya[2], Saruna Ghimire[2], Ranju Mehta[3], and Uday Narayan Yadav[4], *1. Miami University, Cincinnati, Ohio, United States, 2. Miami University, Oxford, Ohio, United States, 3. Little Buddha College of Health Science, Kathmandu, Bagmati, Nepal, 4. The Australian National University, Canberra, Australian Capital Territory, Australia*

Historically, filial piety (caring for one's parents) has been prevalent in Nepal. The demographic transition has resulted in a burgeoning population of older adults, but limited institutional support is available to address their socio-economical and health needs. As such, the family has remained the paramount source of support to meet the health, social and economic needs of Nepali older adults. In this study, we explored the relationship between family dependency (conceptualized as the source of family support) and self-reported health among Nepali older adults. A community-based cross-sectional survey was conducted in two districts (Sunsari and Morang) of eastern Nepal. Using a multistage cluster random sampling design 847 older adults (≥ 60 years) were interviewed. Self-reported health was assessed in terms of a five-item Likert scale dichotomized into poor and good health. Two independent variables of interest were dependency on family for living and for daily activities. Binary logistic regression drew the inferences while adjusting for important confounders. About 29.4% of the participants reported poor health, 77% reported dependency on family for living and 46% reported dependency for daily activities. Those dependent on family for living had 46% higher odds of good health but the statistical significance was lost after adjusting for control variables. Likewise, those dependent on family for daily activities were three times more likely (OR: 3.22; 95%CI: 2.15 - 4.83) to report good health than their counterparts after controlling for confounders. Our findings emphasize the importance of family support for the health of older adults in Nepal.

CAREGIVER TLC: A VIRTUAL PSYCHOEDUCATIONAL PROGRAM FOR CAREGIVERS: BASELINE PRELIMINARY DATA

Julian Montoro-Rodriguez[1], Dolores Gallagher-Thompson[2], Jennifer Ramsey[3], Ann Choryan Bilbrey[4], Bruno Kajiyama[5], Kendra Jason[1], and Larry W Thompson[4], *1. University of North Carolina at Charlotte, Charlotte, North Carolina, United States, 2. Stanford University, Stanford, California, United States, 3. Case Western Reserve University, Cleveland, Ohio, United States, 4. Optimal Aging Center, Sunnyvale, California,* *United States, 5. Photozig, Inc., Moffett Field, California, United States*

Family caregivers are at increased risk for negative impacts on their psychological and physical health compared to non-caregivers. Virtual caregiving programs are beneficial as caregivers may not have time to devote to face-to-face programs and especially important to caregivers in the context of the COVID-19 pandemic. Our team at the University of North Carolina at Charlotte is testing the efficacy of the Caregiver Thrive, Learn & Connect Virtual Program adapted from the Coping with Caregiving evidence-based multicomponent intervention (Gallagher-Thompson et al., 2003). The program offers to registered caregivers six weekly sessions over Zoom teleconferencing in small groups led by trained professionals from community partners serving socio-demographically diverse caregivers. Sessions address stress management, mood management, resilience, self-care, coping strategies, and isolation. Preliminary baseline data on 42 participants indicates that caregivers are primarily female (87%), on average 64 years old, and from diverse racial backgrounds: white (69%), African American (29%) and Asian American (2%). Participants provide care to persons with memory troubles or dementia (66%) and chronic health conditions (34%). Baseline data on initial levels of caregivers' psychosocial outcomes indicated salient levels of mental health outcomes for burden (high = 49%; mild = 35%); anxiety (moderate = 16%; severe = 20%) and depression (mild levels = 35%; moderately and severe level of depression = 33%). Caregivers for chronic health conditions reported significantly higher anxiety compared to dementia caregivers. The Caregiver TLC program offers support to the targeted caregiver population seeking to improve their level of competence, mental health and social isolation.

SESSION 6760 (POSTER)

LONG-TERM CARE

STATE HOME AND COMMUNITY-BASED SERVICES AND RESIDENTIAL CARE TRANSITIONS AMONG COMMUNITY-DWELLING OLDER ADULTS

Linda Chyr[1], Chanee Fabius[2], and Emmanuel Drabo[2], *1. Elevance Health, Baltimore, Maryland, United States, 2. Johns Hopkins Bloomberg School of Public Health, Baltimore, Maryland, United States*

Medicaid home and community-based services (HCBS) provide integral health-related and personal care to support community-dwelling older adults. Growing literature suggests that states with more generous HCBS expenditures may delay or substitute costly nursing home care, but evidence is limited on the impact of HCBS spending on transitions to residential care settings like assisted living. This study determines the association of state Medicaid HCBS generosity—HCBS spending as a percent of total long-term services and supports expenditure—on the probability of incident transitions to residential care settings or nursing homes. Publicly available HCBS expenditure data was linked to a nationally representative sample of 7,197 community-dwelling older adults participating in the National Health and Aging Trends Study from 2011-2018. A discrete-time, competing risk regression model estimated the association between HCBS generosity and transitions from community to residential care settings or nursing homes, adjusting for sociodemographic, socioeconomic, and health factors. Most older adults remained in the community (93.7%). Incident transitions into residential care settings were twice as likely to occur compared to transitions to nursing homes (4.0% vs 2.3%, respectively). Older adults residing in states with higher HCBS generosity (one percentage point increase) are less likely to transition to nursing homes (relative risk ratio [RRR], 0.24; 95% Cl, 0.05-1.10; p< 0.1). Greater HCBS generosity was not associated with transitions to residential care setting. Assessing HCBS generosity on transitions elucidates important contextual factors affecting the movement of older adults across the care continuum.

WAYFINDING DESIGN IN LONG-TERM-CARE COMMUNITIES: EVALUATION OF COMPLEXITY

Rebecca Davis[1], and Margaret Calkins[2], *1. Grand Valley State University, Grand Rapids, Michigan, United States, 2. IDEAS Institute, Cleveland Hts, Ohio, United States*

Wayfinding, the ability to find one's way, is a significant problem for many older adults; especially those with cognitive impairment. Long term care communities (LTCC) are often fraught with challenges for wayfinding. Those who cannot find their way are at risk for decreased engagement and loss of independence. A critical need is to assess architectural and design features that promote effective wayfinding in an objective way. This study describes the results of a wayfinding design evaluation of 12 LTCC (4 Assisted living; 2 Independent Living; and 6 mixed residency). We measured space syntax axial integration (SSAI; a measure of the visual connectedness) and a Revised Wayfinding Checklist. The results showed low integration values in all communities, ranging from an R3 of 1.43-2.03, indicating low connectedness (and increased wayfinding complexity). The Checklist score totals ranged from 23 – 34 (M = 27.45) out of a possible total of 17 – 51. Results showed that the buildings were overall complex, all had long corridors (>100 feet), over half used multiple elevators to get to common areas; and over 60% had complex, multi-building layouts. Design wise, visibly accessible restrooms were not present; over half of the LTCC had insufficient lighting; and signage color/contrast and letter size was less than recommended. All sites had few directional signs at decision points. Thus, the review of these LTCC showed that most buildings were very complex, with low connectedness, and had room to improve design features like signage and lighting to support wayfinding ability for the residents.

LONG-TERM CARE STAFF DECISION-MAKING PROCESSES IN DETERMINING DAILY WELL-BEING OF RESIDENTS

Mary (Libbey) Bowen[1], Ju Young Shin[2], and Meredeth Rowe[3], *1. University of Delaware and Department of Veterans Affairs, Newark, Delaware, United States, 2. University of Delaware, Newark, Delaware, United States, 3. University of South Florida, Tampa, Florida, United States*

Much of the care provided to residents in long term care (LTC) comes from staff with minimal training, particularly in the area of the assessment of complex clinical presentations. This study utilized semi-structured focus group techniques with 25 clinical staff to understand how they determine whether a resident is functioning within or outside their daily "norm" and how they follow-up on these determinations. The overall finding was that each staff member develops an internally stored phenotype of each resident's norm. Three primary themes emerged: 1) the staff's phenotype becomes the 'gold standard' to determine whether there is a change and/or a cause for concern; 2) staff include sleep routines, fatigue, participation in usual activities, physical and mental status, and social interactions with others in their phenotypes. Staff reflect in what seems like a random manner through these comparisons, and, from this process, 3) a judgement emerges that helps inform clinical decision-making and potential action of the staff member. In most scenarios, staff decided there was no cause for concern. The identified weakness in this strategy was that staff rarely mentioned or used complementary and confirmatory formal assessment or referral mechanisms to ensure their judgment was correct. Thus, staff utilize complex multidimensional thinking and memory in decision-making but lack the skills or institutional structure to augment this with more formal and reliable techniques. This represents an interesting opportunity to build on existing assessment skills with additional types of assessment, technology-based information and formal referral mechanisms.

PEEKING UNDER THE COVERS: EXAMINING ETHICAL ISSUES IN ASSISTED LIVING

Kelly Turner[1], Gretchen Agans[2], Erin Donohue[3], Barqueisha Madison[2], Jason Lesandrini[2], Jennifer Morgan[3], and Candace Kemp[3], *1. Georgia State University & WellStar Health System, Atlanta, Georgia, United States, 2. Wellstar, Atlanta, Georgia, United States, 3. Georgia State University, Atlanta, Georgia, United States*

Assisted living (AL) communities comprise complex social environments composed of residents, staff, and other care partners, including external workers and residents' family and friends. Interactions among these stakeholders, especially pertaining to decisions related to resident care, frequently are fraught with value conflicts and uncertainties. Although much attention has been devoted to the ethics of aging and end-of-life in acute care settings, there is very little research on ethical issues in AL. To address this critical knowledge gap, our interdisciplinary team of gerontologists and bioethicists developed a typology of ethics issues in AL, adapting existing categorizations designed for acute care. We applied this typology to qualitative data gathered over a one-year period as part of an NIA-funded longitudinal study focused on residents with dementia living in four diverse AL communities (R01AG062310). The team coded 465 fieldnotes and interviews, analyzing data for the frequency and context of ethical issues. We found ubiquitous conflicts between residents' autonomy and care partners' obligations to maintain resident safety, as well as a high prevalence of organizational issues related to staffing and expertise. Comparing code frequency and type across the four communities, we discovered manifold ways in which facility size, organizational structure, and care practices affect the profile of value conflicts in resident care. During data analysis, we also developed new codes for ethics issues arising in AL, including, 'cognitive decline stigma' and 'uncertainty regarding professional obligations,' creating new avenues of study. We conclude our presentation by discussing implications for best practices and policy formation in AL.

INVOLVEMENT IN CARE DECISION-MAKING AND ADVERSE OUTCOME ONSET IN COMMUNITY-DWELLING CARE RECIPIENTS IN JAPAN

Ayane Komatsu, Takeshi Nakagawa, Taiji Noguchi, and Tami Saito, *National Center for Geriatrics and Gerontology, Obu, Aichi, Japan*

The involvement of older adults in care decision-making may enhance their daily life motivation and quality of life. Furthermore, it could contribute to their better prognosis in long-term care. We examined the association between decision-making involvement and the onset of adverse outcomes, such as institutionalization and death, among older adults under long-term care. This study used two-year longitudinal survey data of Japanese community-dwelling care recipients aged 65 and above. The participants were followed regarding the onset of institutionalization and deaths. The status of involvement in decision-making was assessed based on one item and the selection among the following response options: "very much involved," "fairly involved," "not very involved," "never involved," "unclarified wishes," and "absence of person supporting decision-making." A multivariable logistic regression analysis estimated the odds ratios (OR) and 95% confidence intervals (CI) for the onset of adverse outcomes, composite of institutionalization and death. A total of 707 participants with no severe cognition disabilities (MMSE>12) and no missing variables at the baseline were included and responded to the follow-up survey. At the baseline, 36.5% reported being very much involved in decision-making. The onset of adverse outcomes was observed in 17.5% of participants (institutionalization, 5.1%; death, 12.4%). Compared to those with very high involvement in decision making, those who were not involved were more likely to have adverse events, even after adjusting for covariates (OR=2.86 [95% CI: 1.21-6.76], p=0.016). Our findings show the importance of decision-making involvement in daily care regarding better prognoses in long-term care.

COMMUNICATION AND WORKFLOW ON A TYPICAL DAY IN NH VERSUS A DAY WITH A CHANGE IN RESIDENT CONDITION

Alyce Ashcraft, Donna Owen, John Culberson, and Huaxin Song, *Texas Tech University Health Sciences Center, Lubbock, Texas, United States*

A major reason technologic innovations for nursing home (NH) communication have not worked is because testing of technology fails to consider workflow of the environment. The aim of this observational study was to examine communication and workflow surrounding assessment of NH residents on a dementia care unit with suspected UTI to establish baseline data prior to introduction of technology to enhance NH staff communication. The flow of communication between CNAs, LVNs, and PCPs was recorded using a structured observation on an online survey platform. For a 3-month period, 3 days a week, an observation period from

7am to 11am was chosen to reflect one peak staff interaction time. Field notes describing the environment and what was being talked about during communication events were analyzed using content analysis. A total of 185 communication events were recorded by 3 trained observers, yielding 22 assessments for change in condition (pain, UTI, falls). The LVN was the center of 44% of communication. After the LVN assessed the resident, 43% of the time no further action was taken by the LVN; 17% of the time the PCP was texted about a change in condition. Types of change in condition was limited. Workflow surrounding LVN collection of information on days related to change in condition reflected focused communication among staff occurring away from resident rooms and nurses' station. The NH is a stable environment for provision of nursing care, thus suggesting communication technology can be accepted by staff and added into the care routine.

COLLECTIVE TRAUMA AND PERSON-CENTERED PRACTICE IN NURSING HOMES

Jennifer Morgan, Yun-Zih Chen, Waqar Ahmad, and Elisabeth Burgess, *Georgia State University, Atlanta, Georgia, United States*

Nursing home staff have experienced multilayered collective trauma. Grief from experiencing numerous resident deaths, perceived threats to their safety, stress from understaffed working conditions, financial stress, and interpersonal conflict within overwhelmed teams may impact practice. COVID-19 precautions and pandemic working conditions may have provided additional barriers to implementing person-centered care. This study (N=379) descriptively analyzes data gathered from the staff of eleven Georgia nursing homes (summer 2021) to assess the perceived impact of COVID-19 on person-centered care practice. Approximately 40% of respondents agreed that 76-100% of resident members in nursing homes were infected with COVID-19. Over 75% of staff agreed that staff experienced anxiety related to COVID 19 precautions, COVID 19 precautions made it difficult for staff to give choice to residents, and the nursing home is more short-staffed. Conversely, more than 75% of staff reported that they were satisfied with their job, they received the appropriate training and support to be successful, nursing home managers treated direct care workers with respect and they were provided with the necessary PPE. Fewer staff (60-65%) reported that there never seemed to be enough time to get everything done, that COVID 19 precautions impacted their relationships with residents, they were provided with resources for emotional support or they received recognition for working through the pandemic. Future research is needed to understand the limiting and promoting factors for person-centered care as staff experience collective trauma.

SUCCESSFUL TRANSITIONS TO LONG-TERM CARE COMMUNITIES

Daniel Koltz, and Rebecca Koltz, *Montana State University, Bozeman, Montana, United States*

Older adults who transition to independent and assisted-living communities perceive their transition experience differently. This research focused on understanding what factors were predominant for a successful transition from a long-time home to a dependent living community. A constructivist grounded theory method was used to explore the experiences of 18 older adults who had relocated within the past year. The participants of this study were aged 65-95 years and are equally represented by gender. Equal numbers of respondents transitioned into independent and assisted-living accommodations. Five factors related to a central concept of behavioral attitude were found to be key for a successful transition. When an older adult reported a successful transition, their behavioral attitude was positive about their new living environment. The five factors that contributed to their positive attitude are creating a new place, increased community integration, sense of safety and security, independence while dependent, and accepting a new life stage. The theory that emerged from the research emphasizes that when an older adult has increased awareness about the five factors associated with adapting to a dependent living community, this awareness will promote a positive behavioral attitude and increase the opportunity for success during and after a transition. Family members, LTC community administrators and social workers could all benefit from understanding these factors for a successful transition. Enhancing a positive experience for an older adult and improving their behavioral attitude toward the new transition.

FAMILY MEMBERS' COMMUNICATION WITH LONG-TERM CARE PROVIDERS AND ITS INFLUENCE ON RESIDENT WELL-BEING

Francesca Falzarano[1], Verena Cimarolli[2], and Karen Siedlecki[3], *1. Weill Cornell Medicine, Douglaston, New York, United States, 2. LeadingAge, Washington, District of Columbia, United States, 3. Fordham University, Bronx, New York, United States*

Considerable research has examined communication dynamics among family members and staff in nursing homes (NHs) and has demonstrated that better communication is associated with more optimal psychosocial outcomes in both family caregivers and formal care providers. However, the literature on how communication dynamics influence resident functioning is limited, and it has yet to be determined how communication impacts residents across other care contexts, such as Assisted Living Facilities (ALFs). Thus, using data from the National Health and Aging Trends Study and the National Study on Caregiving, the purpose of this study was to examine family perceptions of communication with formal care providers (i.e., frequency, availability, and helpfulness of communication) and its influence on resident outcomes in two samples of long-term care residents (n=337 in ALFs, n=112 in NHs) and their family caregivers, and to compare how results differ across care setting. When examining the full sample of long-term care residents, findings showed that better communication was associated with lower depressive symptoms and negative affect. When investigating differences across care settings, we found that those residing in NHs exhibited higher levels of depressive and anxiety symptoms compared to ALF residents. Further, better communication was associated with lower levels of depressive symptoms only among ALF residents. Our findings provide insights into how interpersonal dynamics between family and formal care providers influence resident functioning and underscores the importance of enhanced communication among all members of the primary care team – that is, healthcare providers, residents, and their family members.

STAFFS' PSYCHOSOCIAL WORK ENVIRONMENT IN RELATION TO RECIPIENT SATISFACTION IN HOME CARE SERVICES

Ingemar Kåreholt[1], Dan Lundgren[2], Zarina Nasar Kabir[3], and Anne-Marie Boström[3], *1. Jönköping University, Jönköping, Jonkopings Lan, Sweden, 2. Municipality of Värnamo, Värnamo, Jonkopings Lan, Sweden, 3. Karolinska Institutet, Huddinge, Stockholms Lan, Sweden*

In accordance with 'aging in place' policy, older persons in Sweden are increasingly encouraged to continue living at home and if necessary be supported by home care service (HCS). Studies have examined whether the work environment of staff has an impact on the experiences and the wellbeing of the older persons in nursing homes, but few have examined such associations in HCS. The setting was 16 HCS work units. Two surveys were sent, one to staff on psychosocial working conditions, one to care recipients on care satisfaction. For each work unit, data on individual recipient satisfaction was matched to average values on psychosocial work conditions. Outcomes analyzed with linear regressions were overall recipient satisfaction, based on one question, and indexes on: assessment of implementation of services, contact with staff, and sense of security. Index on treatment by staff was analyzed with ordered logistic regressions due to skewed distribution. We used cluster correlated standard errors (clustering on work units). Results showed that good working conditions are important for recipient satisfaction, specifically overall recipient satisfaction, treatment by staff, and sense of security. Psychosocial work factors most important were work group climate, overall job strain, sense of mastery, job control, frustrated empathy, balancing competing needs, balancing emotional involvement, and lack of recognition. Having more home help hours was associated to stronger relation between working conditions and recipient satisfaction, especially with overall recipient satisfaction and treatment by staff as outcomes.

ORGANIZATIONAL SUPPORTS ASSOCIATED WITH NURSING ASSISTANTS' JOB SATISFACTION DURING COVID-19

Natasha Bryant[1], Verena Cimarolli[1], Francesca Falzarano[2], and Robyn Stone[1], *1. LeadingAge, Washington, District of Columbia, United States, 2. Weill Cornell Medicine, Douglaston, New York, United States*

The COVID-19 pandemic has disproportionately affected nursing home residents and staff, including the nursing assistants who provide critical supports for older adults and people with disabilities. The pandemic has added significant strain to an already vulnerable nursing home workforce, which has historically experienced high levels of turnover, chronic staffing shortages, and high burnout. At the same time, it has generated awareness of the value of the direct care workforce to provide care in places for those most at risk from the disease. Job satisfaction of nursing assistants is as major driver of turnover and intent to leave the job. Research has demonstrated organizational supports and job stresses that are associated with job satisfaction and turnover. However, limited research has investigated the factors associated with job satisfaction in nursing homes during the COVID-19 pandemic. Using data from an employee engagement and management system, we examined organizational supports (e.g., supervision, appreciation, safety) and work-related stresses associated with job satisfaction among nursing assistants in nursing homes (n=402). Higher quality of supervision, feeling appreciated for the job, and feeling safe and comfortable at work were associated with higher levels of job satisfaction. Work-related job stressors –increased workload demands and understaffing – were associated with lower job satisfaction. Our findings provide insights into the importance of employer supports and reducing work-related stressors in nursing assistants' job satisfaction and practical implications for nursing home leadership regarding how to support workers

THE RELATIONSHIP BETWEEN THE FEAR OF FALLING AND QUALITY OF LIFE IN NURSING HOME RESIDENTS: THE ROLE OF ACTIVITY RESTRICTION

Dongjuan Xu[1], Yaqi Wang[2], Shanshan Zhu[2], and Kefang Wang[2], *1. Purdue University, West Lafayette, Indiana, United States, 2. Shandong University, Jinan, Shandong, China (People's Republic)*

Falls among older adults are a significant later life course event with detrimental impacts on health, quality of life (QOL), and mortality. Fear of falling (FOF) is a common problem, which can lead to physical and social activity restriction and poor QOL. However, few studies have comprehensively explored the relationships among FOF, activity restriction, and QOL among nursing home residents. This study aimed to investigate: 1) whether FOF is negatively associated with QOL; and 2) the mediating role of activity restriction in the relationship between FOF and QOL among nursing home residents in mainland China. This is a cross-sectional study. A total of 316 residents from 27 nursing homes participated in this study. The mixed-effects multivariate linear or ordinal logistic regression models were conducted. All statistical models were adjusted for resident- and facility-level variables. More than half of nursing home residents (55.4%) reported they often or always reduced their activities. As expected, FOF was directly associated with lower levels of QOL ($\beta = -0.19$, $p = 0.010$). However, the strength of this association was attenuated and no longer significant with the inclusion of activity restriction in the model. FOF was positively associated with activity restriction ($\beta = 0.33$, $p < 0.001$) and activity restriction was negatively associated with QOL (rarely/sometimes reduced activity: $\beta = -1.23$, $p = 0.386$; often/always reduced activity: $\beta = -3.85$, $p = 0.014$). Given the aging of our populations, it is important to take FOF and activity restriction into account when caring for older people.

THE VALUE PROPOSITION FOR DIVERSITY: CREATING A PIPELINE OF DIVERSITY IN THE LTSS SECTOR

Natasha Bryant, Alexandra Hennessa, Adrienne Ruffin, and Robyn Stone, *LeadingAge, Washington, District of Columbia, United States*

The long-term services and supports (LTSS) sector is a microcosm of systemic racism that exits in our society. Nationally, half of frontline professional caregivers are nonwhite, while mid- and executive-level managers and board members are predominately white. Research has identified this lack of diversity in management and leadership as a major contributor to turnover and recruitment challenges among frontline staff. We will summarize the findings from three applied research activities: 1) DEI survey of chief executive officers (CEOs) of multi-setting LTSS organizations; 2) interviews with chief diversity officers and CEOs on current workplace DEI efforts and the challenges; and 3) interviews with leaders of color who have had experience with the LTSS sector. Not-for-profit multisite organizations and life plan communities lack diversity among the senior leadership team and board members (12% are people of color). A DEI initiative is more likely to be successful if it has buy-in from the CEO and board members, aligns with the organization's strategic plan and mission, is integrated into the organizational culture, and is assessed regularly to measure its impact and identify needed adjustments. Leaders of color in aging services acknowledge the barriers – lack of diversity among leaders and residents and the microaggressions that people of color experience - that make it challenging for people of color to work in the field. They recommend increasing diversity among senior leaders, investing in enhancing DEI, and spreading awareness of the LTSS field and its career opportunities to communities of color.

AGE-RELATED DIFFERENCES IN HEALTH-RELATED QUALITY OF LIFE AMONG WESTERN CANADIAN NURSING HOME RESIDENTS

Bianca Shieu[1], Todd Schwartz[2], Matthias Hoben[3], Mark Toles[2], Anna Beeber[4], and Ruth Anderson[2], *1. University of Pittsburgh, Pittsburgh, Pennsylvania, United States, 2. UNC Chapel Hill, Chapel Hill, North Carolina, United States, 3. University of Alberta, Edmonton, Alberta, Canada, 4. Johns Hopkins University, Baltimore, Maryland, United States*

Nursing homes (NHs) typically focus on health-related quality of life (HRQoL) among residents aged 65 and over despite approximately 7% of NH residents are younger (aged 18-64). Research suggests that the needs of younger NH residents are not being met and they may have low HRQoL. However, differences in HRQoL of younger and older NH residents may not be apparent in studies that use HRQoL measures designed for research with older NH residents. We hypothesized that the younger residents would have lower HRQoL mean scores than the older (aged ≥ 65) residents using a HRQoL measure based on the HRQoL score derived from Resident Assessment Instrument – Minimum Data Set 2.0 items. The measure uses items that emphasize physical aspects of quality of life rather than social aspects. In a sample of 21,129 residents from 94 NHs in Western Canada, we performed descriptive analyses, t-test, chi-square test, and an adjusted propensity score (PS) analysis through retrospective cohort study from years 2016 to 2017. The HRQoL index score ranged from -.351 to .996 (Mean= 0.693, SD=0.265). In the PS model, the adjusted mean score for younger was higher than for older adults with a mean difference at 0.061 (95% CI 0.031, 0.091) (p<.001). Other domains such as mental health condition of quality of life must be examined in younger NH residents because it is a crucial factor influencing their daily lives, thereby we can explore a more complete set of HRQoL domains of them and redesign care for their unique needs.

REFLECTIONS OF ADULTS TRANSITIONING TO LONG-TERM CARE FACILITIES: LOOKING BACK AND LOOKING FORWARD

Pei-Fen Chang, and Gayle Hersch, *Texas Woman's University, Houston, Texas, United States*

Making a transition to a long-term care facility (LTCF) is often difficult for older adults. This study's intent was to explore ways in which life experiences and culture of older persons facilitate a successful transition to a LTCF. Eighteen participants were interviewed using a semi-structured interview guide to understand significant life events and personal factors impacting their lives. Interview data were analyzed using NVivo software to organize and manage emerging themes. The analysis revealed three related themes: person, current environments, and lifelong occupations. Within each major theme, subthemes were identified providing greater detail of how adaptive strategies are utilized to make such transitions positive. Participants were enabled to reflect upon their strengths and strategies available to adapt to these new residential settings. These perspectives are beneficial for healthcare practitioners to understand so as to personalize care and individualize the person's adjustment to a 'new' home.

PERCEPTIONS OF NURSES DELIVERING NURSING HOME VIRTUAL CARE SUPPORT: A QUALITATIVE PILOT STUDY

Justin Blackburn[1], Carol Mills[1], Yvette Tran[1], Valerie Yeager[1], Kathleen Unroe[2], and Ann Holmes[1], *1. IU Richard M. Fairbanks School of Public Health at IUPUI, Indianapolis, Indiana, United States, 2. Indiana University Center for Aging Research, Regenstrief Institute, Inc., Indianapolis, Indiana, United States*

Avoidable hospitalizations among nursing home residents result in poorer health outcomes and excess costs. Consequently, efforts to reduce avoidable hospitalizations have been a priority over the recent decade. However, many potential interventions are time-intensive, require dedicated clinical staff, and nursing homes are chronically understaffed. The Optimizing Patient Transfers, Impacting Medical Quality, and Improving Symptoms: Transforming Institutional Care (OPTIMISTIC) project was one of seven sites selected by CMS as "enhanced care & coordination providers" and was implemented from 2012 to 2020. A virtual program based on the principles of OPTIMISTIC was developed in the spring of 2020 with the goal of expanding the reach of the program's services. This qualitative study explores the perceptions and experiences of the nurses that piloted a virtual care support project in 11 nursing homes in a midwestern state, and identified the nurses' perceived facilitators of, and barriers to, the effectiveness of delivering a novel virtual care support program. A key finding from this analysis is that relationships, communication, and access to information were identified as common themes facilitating or impeding the perceived effectiveness of implementation of virtual care support programs within nursing homes, from the perspective of the nurses delivering the services. The experiences and recommendations of the program nurses provide insights into crucial elements important to the implementation of similar virtual care support models, and the role of telehealth in bridging healthcare workforce gaps.

SESSION 6770 (POSTER)

LONG-TERM CARE, PERSON-CENTERED CARE

CHRONIC DISEASE AND LIFE EXPECTANCY DISPARITIES OF OLDER ADULTS IN SINGAPORE

Xueying Guo[1], Hwee lin Wee[2], and Cynthia Chen[3], *1. national university of singapore, Singapore, Singapore, 2. National University of Singapore, Singapore, Singapore, 3. National University of Singapore, Singapore, Singapore*

Singapore is one of the countries with longest life expectancy, also one of the most rapidly ageing societies in the world. This study investigates the future demographic transitions in Singapore, focusing on the life expectancy disparities of the older adults. We developed a dynamic Markov microsimulation model based on the Singapore Multi-Ethnic Cohort study. The model was adapted to project future trends of chronic diseases, mental illnesses as well as hospitalisation costs of Singapore older people from 2020 to 2050. The prevalences of diabetes, heart disease, hypertension, stroke, disability, dementia and depression of people aged 51 and above was projected to be increasing. Overall projected life expectancy at age 51 for male is 27.8 years, and for female is 34.5 years. Moreover, for older people with secondary or upper education, the overall projected life expectancy at age 51 is 34.1 years, active life expectancy at age 51 is 28.6 years. For older people with primary or lower education, the overall life expectancy at age 51 is projected to be 27.9 years, and active life expectancy projected to be 23.9 years. Our study has significant social and economic implications for policymakers in the way that it demonstrates disparate trends in aging and costs among different education groups in Singapore.

HOME-BASED EXERCISE PROGRAM WITH MEAL DELIVERY INCREASES DAILY STEP COUNT IN HOMEBOUND OLDER ADULTS

Harmanpreet Kaur, and Jessica Lee, *McGovern Medical School at UTHealth, Houston, Texas, United States*

The United Nations projects adults aged 60 and older will reach 2.1 billion by 2050. With this trend, there will be an increase in older adults who are homebound, leading to more frailty with increased healthcare utilization and institutionalization. Improvements in frailty and homebound status may occur through increased physical activity, which has been shown in multiple randomized controlled trials to improve frailty. Our study aims to evaluate the effects of a home-based exercise program, administered through Meals on Wheels, on gait speed and frailty status in sixty-four homebound adults age 60 and older. All participants receive meal delivery for 12 weeks and half are randomized to receive an exercise kit with weekly exercise handouts. All participants are asked to wear an activity tracker with an additional longitudinal measure at 6 months. We now have 6 participants who have completed the study. Preliminary analysis was conducted on step count between the exercise and non-exercise group using two-sample t-tests. Average daily step count in the exercise group (n=3) was 2656 compared to 813 in the non-exercise group (n=3), $p < 0.00001$ during the first 12 weeks. The step count in the exercise group did decrease during the weeks after the intervention stopped, however they remained more active than the non-exercise group, 1112 vs 548, $p < 0.0001$. No adverse events were noted. As we continue to enroll participants, we are encouraged that the home-based exercise program with meal delivery appears to be a safe and effective way to increase physical activity in homebound older adults.

PERCEIVED ROLES IN MEDICATION SAFETY: PATIENTS' PERSPECTIVES

Fatoumata Jallow[1], Elisa Stehling[1], Zara Sajwani[2], Kathryn Daniel[1], Yan Xiao[1], Kimberly Fulda[3], and Anna Espinoza[3], *1. University of Texas at Arlington, Arlington, Texas, United States, 2. Children's Health, Dallas, Texas, United States, 3. University of North Texas Health Science Center, Fort Worth, Texas, United States*

Community-dwelling older adults are vulnerable to medication safety-related harms. Prevention of medication-related harms in the outpatient setting starts with thorough and thoughtful medication reconciliation at each patient encounter. Comprehensive medication reconciliation is challenging for prescribers to provide in busy time-pressured practices. Older adults currently taking five or more daily prescription medications were recruited for this qualitative study. From the participants' perspective, we explored the role of the prescriber, pharmacist, and patient in medication safety. During the COVID-19 pandemic, interviews were conducted from October 2020 to June 2021. Results from these interviews suggest that older adults recognized their role in medication safety supersedes just taking the pills as prescribed. Older adults understand that they must play an essential role in the coproduction of quality health services. Subthemes that emerged from the patient's perceived role were "taking fewer medications," "locking them up," "keeping appointments," and "reading the label." Pharmacists were expected to inform participants of any changes in their medications, such as the color, shape, or dosage, and ensure no drug interactions. Primary care providers are expected to coordinate care between all specialists treating their patients and any medication prescribed by those specialists. There was a high level of trust in the provider's knowledge, skill, and experience, along with a low level of patient engagement in decision-making around deprescribing. Among older adults, self-perceptions of their role in medication safety varied widely. Educating prescribers and pharmacists about the role expectations of this vulnerable population can help improve medication safety.

SOCIAL INTERACTION AND PSYCHOLOGICAL WELL-BEING OF PERSONS LIVING WITH DEMENTIA IN LONG-TERM CARE

Kyung Hee Lee, and Ji Yeon Lee, *Yonsei University, Seoul, Seoul-t'ukpyolsi, Republic of Korea*

Although social interaction might play a critical role to improve psychological well-being of old adults with dementia in long-term care, lack of social interaction between staff and residents has been reported. The purpose of this study was to examine whether social interaction is associated with psychological well-being of persons living with dementia during care in long-term care. We analyzed 258 videos from 30 participants with dementia. Each participant was taken nine videos at 0, 3, and 6 months at three care events (i.e., personal care, mealtime, and activity). Social interaction was assessed by quality (i.e., positive, neutral, and negative), type (i.e., verbal, nonverbal, and both), and presence of interaction (i.e., no and yes). Psychological well-being was measured by positive and negative emotional expressions. A mixed model was chosen for the data analysis since these repeatedly measured observation data were nested within subjects. Mixed models showed that positive and neutral interactions were significantly associated with positive emotional expressions of residents after controlling covariates while negative interaction was significantly associated with negative emotional expressions. There was no significance between interaction type and emotional expressions. This study highlights the importance of positive care staff interactions in dementia care. In addition, the institutional efforts to create an environment to reduce negative interactions can be of great help in promoting the psychological well-being of persons living with dementia.

HOSPITAL TRANSFERS: PERSPECTIVES OF NURSING HOME RESIDENTS AND NURSES

Alma Ahmetovic[1], Claire Drucker[2], Lesa Huber[3], Kathleen Unroe[4], and Susan Hickman[2], *1. Indiana University School of Nursing, Bloomington, Indiana, United States, 2. Indiana University School of Nursing, Indianapolis, Indiana, United States, 3. Indiana University School of Public Health, Bloomington, Indiana, United States, 4. Indiana University Center for Aging Research, Regenstrief Institute, Inc., Indianapolis, Indiana, United States*

Between 1 million and 2.2 million nursing home residents are transferred to a hospital emergency department each year. These transfers are costly, have negative health outcomes, and can increase the morbidity and mortality of residents. The purpose of this study was to examine the transfer process between the nursing home and the hospital from the perspective of nursing home residents and nurses, focusing on how decisions were made to transfer residents. Using a qualitative descriptive method, 22 participants were recruited from four nursing homes located in rural Indiana. Purposive sampling, semi-structured interviews, and conventional content analysis were used to collect and analyze narratives obtained from residents and nurses about their experiences with a recent transfer. The participants described four aspects of the transfer process: transfer decisions, transport experiences, hospital stays, and returns to the nursing home. The most common reason for transfers was an acute exacerbation of a chronic condition, and the decision to transfer was often made by a nurse. Most residents found aspects of the transfer aversive or upsetting. The return to the nursing home was typically welcomed but often challenging due to problems with mobility, medications, and cognitive changes. Participants also provided several recommendations for avoiding potentially preventable transfers including adding "in-house" diagnostic testing and treatment equipment, improving staff competencies in managing acute exacerbations, increasing staffing, improving communication among staff, and increasing staff familiarity with resident histories and preferences. The findings have several clinical and policy implications for preventing or decreasing the negative effects of hospital transfers.

EFFECTS OF DANCE INTERVENTIONS ON COGNITION IN OLDER ADULTS: A META-ANALYSIS

Tanapa Rittiwong[1], Nattaya Wongyara[2], and Joanne Schneider[1], *1. Saint Louis University, Saint Louis, Missouri, United States, 2. Saint Louis University, Saint louis, Missouri, United States*

Background: Dance interventions have been shown to improve cognition in older adults. However, no meta-analysis evaluates that effect. Objective: We examined the effects of dance on cognition in older adults and examined the moderating effects of participant, methods, and intervention characteristics.

Methods: We searched 14 databases using the search terms: dance AND cognition AND older adults. Researchers of primary studies compared dance with control groups of adults≥60 years old, measured cognition, and wrote in English. Two researchers independently coded studies and discussed to achieve consensus. Using the random-effects model, we computed effect sizes (ES) using Hedges' g with 95%CIs along with heterogeneity statistics and conducted moderator analyses.

Results: Twenty-five studies included 1,908 participants (70.9±5.2years old). Dance had a strong, positive effect on both global cognition (ES=0.52, 95%CI [0.25, 0.78], p=.000) and memory (ES=0.56, 95%CI [0.08, 1.04], p=.022) and a moderate effect on executive function (ES=0.35, 95%CI [0.06, 0.65], p=.019) and attention (ES=0.21, 95%CI [0.06, 0.36], p=.005). Several variables moderated the relationship including the country, dancing in pairs or not, or with partners vs. non-partners. Methodological quality indicators that moderated the relationship was computing a priori power and comparing participant characteristics at baseline. Weeks of dancing and minutes/session also moderated the relationship.

Conclusion: Dance can significantly improve cognition in older adults. Healthcare providers might use dance interventions as an alternative treatment to improve cognition in older adults. Future researchers should explore the effects of type of dances on cognition and measure outcome changes over time.

POLYPHARMACY, ANXIETY, AND QUALITY OF LIFE IN LONG-TERM CARE RESIDENTS

Hannah Dangerfield[1], Judith Scott[2], Jennifer Zohn[2], Daniel Segal[2], and Melissa Benton[2], *1. University of Colorado Colorado Springs, Golden, Colorado, United States, 2. University of Colorado Colorado Springs, Colorado Springs, Colorado, United States*

The prevalence of polypharmacy (≥5 medications per day) is rising among older adults. Multiple medications are increasingly prescribed to treat multiple comorbidities in this growing population. An increase in anxiety and a decline in quality of life are also seen with polypharmacy, although evidence is limited. This study investigated the relationship between anxiety and quality of life in long-term care residents with polypharmacy. Sixty-nine long-term care residents who reported polypharmacy completed a questionnaire regarding anxiety and quality of life. Anxiety was measured with the Geriatric Anxiety Scale Long-term Care (GAS-LTC), health-related quality of life was measured with two questions from the RAND-36, and medication-related quality of life was measured with the Medication-related Quality of Life Scale (MRQoLS). Mean age was 80.74 ± 7.8 years. The majority were female (72%) and white (88%). The mean GAS-LTC score was 2.75 ± 2.4, indicating relatively low overall anxiety. There were moderate-strong, negative correlations between anxiety and all quality of life measures indicating that as anxiety increased, quality of life decreased. Specifically, anxiety was negatively related to general health-related quality of life ($r = -.51$, $p < 0.001$), health-related quality of life compared to one year ago ($r = -.54$, $p < 0.001$), and medication-related quality of life ($r = -.57$, $p < 0.001$). Among this group of older adults with polypharmacy residing in long-term care, those with greater anxiety reported diminished quality of life related to both overall health and use of medications. Further studies to examine mechanism and causality are needed.

PUNCTUATED EQUILIBRIA: AN ANALYSIS OF HEALTHCARE UTILIZATION PATTERNS FOR OLDER ADULTS WITH CHRONIC DISEASE

Christopher Crowley, Amy Stuck, A. Camille McBride, and Claire Andrews, *West Health Institute, La Jolla, California, United States*

The growing population of older adults requires healthcare delivery models that are both cost effective and directed toward the higher rates of chronic conditions, frailty and functional impairment often present as one ages. Analyzing healthcare utilization patterns of older adults—especially those over the age of 75—will better inform how to re-design care delivery processes.While the presence of chronic conditions requires consistent treatment, the intensity of health services required on a day-to-day basis is highly variable. Many individuals with at-risk health status are remarkably stable, exhibiting high levels of function and low utilization of care over extended periods of time. Periodically, however, these phases are punctuated by catastrophic episodes that can lead to greater health decline, morbidity, and mortality. During cycles of health decline, a cascade of other challenges stemming from an individual's underlying risks, predispositions, and complexities can arise. This punctuated equilibrium of utilization for older adults offers insight to assess ways to improve care and lower costs. In this paper, we analyze and quantify both these states of punctuated equilibria as well as the extensive periods of stability. The associated utilization patterns are analyzed by processing Medicare claims data. Our analysis showed that over 80% of members in a group of anticipated high-risk Medicare beneficiaries over the age of 75 exhibited low utilization for 11 months out of a given year. These findings complement research exploring care redesign processes at a system level, specifically directed to high-cost episodes of care as opposed to patient-level targeting.

HEALTHY AGING TALK AROUNDS: NEAR AND FAR

Lindsay Mullins, *Franciscan Missionaries of Our Lady University, Baton Rouge, Louisiana, United States*

BackgroundLoneliness and chronic health conditions are the two most cited ailments among older adults (OAs) that deter independent living. Community-tailored health programs increase feelings of connectivity to neighbors and link OAs to healthcare resources. MethodsDesign. The Healthy Aging Talk Around program is product of CAB formation, input, and a series of talks in-person (near) and virtually (far). Using qualitative methods, data was collected to determine significant health issues for OAs and qualitative data were collected through surveys to evaluate knowledge, access, and feelings of connectivity related to series gatherings. Setting and Population. Inner-city and rural OAs in the deep south from various communities (2 FBOs, 1 Assisted Living, 2 neighborhood groups). Series was held in community and later online. Attendance ranged between 75-130 OAs. Measures. Qualitative measures included pre and post series surveys (n=110; n = 91) with questions to determine the impact of the series. Analysis. Content analysis was conducted with the qualitative data to determine the impact of the series on 1.) knowledge of health issue(s), 2.) likelihood of accessing health resources, and 3.) feelings of connectivity and isolation. ResultsThe qualitative data analysis suggested the series as relatable because information was tailored linked to local community resources. Discussion of independent living challenges fostered connectivity with neighbors. Once virtual, knowledge and access were similar, feelings of connectivity were less prevalent. ConclusionA community-tailored health program series can increase knowledge of health issues, access to resources, and create neighborly connectivity potentially influencing ability to age in place.

PERSPECTIVES OF UNDER-RESOURCED PATIENTS ABOUT THE MEDICARE ANNUAL WELLNESS VISIT

Christine Ferrone[1], Roberta Goldman[2], Joanne Wilkinson[3], Jeffrey Borkan[4], and Phillip Clark[1], *1. University of Rhode Island, Kingston, Rhode Island, United States, 2. Warren Alpert Medical School of Brown University, Pawtucket, Rhode Island, United States, 3. Alpert Medical School of Brown University, Pawtucket, Rhode Island, United States, 4. The Warren Alpert Medical School of Brown Univerity, Providence, Rhode Island, United States*

The Medicare Annual Wellness Visit (AWV) involves a personalized risk assessment and prevention plan to help prevent disease and disability among older adults. Though studies have shown that AWV uptake is suboptimal, little is known about the perspectives and experiences of patients completing it. Family medicine physicians are conducting AWVs at a Rhode Island pilot teaching clinic participating in the GWEP's Age-Friendly Health Systems Initiative. To evaluate perspectives of the clinic's under-resourced patients, 20 qualitative telephone interviews were conducted following their AWV. Interview recordings were analyzed for content and themes. Few patients recognized the term 'Annual Wellness Visit' or recognized it was significantly different from other visits: "I noticed it was a bit different, but not that different. I'm usually not covered for a visit like that by Medicare." Mental health, mobility and medications were discussed at most of the AWVs. Some patients noticed that a physician did the medication review instead of the nurse. Patients had varying experiences of how advance directives were discussed, and some thought it unnecessary since a family member knows their preferences. A few patients were dissatisfied that their physician did not focus on their chronic or acute health problems. However, most patients "trusted" their physicians to do "whatever is necessary" for them, and were glad to have had the AWV because "instead of talking about being sick all the time, talking about how to stay well". Recommendations for patient education to improve understanding and the experience of the AWV will be offered.

CAN THE PUBLIC LONG-TERM CARE INSURANCE SERVICES IN JAPAN PREVENT THE DETERIORATION OF CARE LEVELS?

Aki Sugiura[1], Reiko Kanaya[2], Yasushi Takeya[1], Hiroshi Toki[3], Ryohei Yamamoto[1], and Miyae Yamakawa[1], *1. Osaka University, Suita, Osaka, Japan, 2. Osaka University, Osaka, Osaka, Japan, 3. Health and Counseling Center, Suita, Osaka, Japan*

In Japan, the public long-term care insurance system supports a super-aged society. The long-term care service (LTCS) system is designed to prevent deterioration of care levels. We conducted a retrospective cohort study to clarify whether using LTCS prevents the deterioration of care levels. We use anonymized data of the Osaka National Health Insurance Database. We analyzed 16,469 subjects who were 65–74 years of age and certified at the mild care level from 2012 to 2015 at the time of initial certification. A baseline measurement was conducted 1 year after initial certification, and observation was continued until the subject's care level deteriorated. Statistical analysis was performed using the Kaplan-Meier method and the Cox proportional hazards model. The results revealed that the period until the deterioration of care level (which occurred in 25% of subjects) was 6 months in the service use group and 22 months in the service non-use group. Although we included sex, care level, dementia, and Parkinson's disease as variables in the statistical analysis, service users were more likely to deteriorate than non-service users (Hazard Risks: 1.89; 95% confidence interval: 1.79–2.00). It is likely that other factors, such as heart disease, may also be involved, and there may be a bias related to family caregiver factors. In conclusion, the current findings suggest that using LTCS cannot prevent the deterioration of care levels. Future studies should verify the effectiveness of LTCS by adding further variables and data regarding family caregivers and changes in outcomes.

HEALTH PROFILES OF OLDER NURSING HOME RESIDENTS BY SUICIDAL IDEATION: A LATENT CLASS ANALYSIS

Yiyang Yuan[1], Adrita Barooah[2], Deborah Mack[3], Kate Lapane[3], and Christine Ulbricht[4], *1. University of Massachusetts Chan Medical School, Burlington, Massachusetts, United States, 2. University of Massachusetts Boston, Boston, Massachusetts, United States, 3. University of Massachusetts Chan Medical School, Worcester, Massachusetts, United States, 4. National Institute of Mental Health, National Institutes of Health, Rockville, Maryland, United States*

In US nursing homes, 2% of residents have documentation of suicidal ideation (SI). Whether older residents' health profiles differ by SI is unknown. Using the 9th Patient Health Questionnaire-9 (PHQ-9) item on Minimum Data Set 3.0, we identified 15,277 older residents with and 562,184 without SI. Latent class analysis using frailty, cognitive impairment, palliative care index, pain, and remaining PHQ-9 items as indicators identified health profiles by at-admission SI and estimated the association between profiles and SI at 90 days. In residents with at-admission SI, four profiles emerged: (1) frail, intact/moderate cognitive impairment, all depressive symptoms (prevalence: 22.8%); (2) frail, moderate/severe pain, depressed mood, sleep problems, fatigue (32.2%); (3) frail, severe cognitive impairment, depressed mood, fatigue, feelings of worthlessness (22.9%); (4) prefrail, moderate/severe cognitive impairment, depressed mood (22.0%). Compared to the residents in profile 4, those in profile 1 [adjusted OR (aOR): 1.24; 95% Confidence Interval (CI):1.11-1.37] and those in profile 2 [aOR: 1.11; 95% CI: 1.01-1.22] were more likely to continue reporting SI at 90 days. In residents without at-admission SI, three profiles emerged: (1) frail, depressed mood, fatigue (33.9%); (2) frail, severe cognitive impairment (38.1%); (3) prefrail/frail (28.0%). Residents in profile 1 were more [aOR: 2.80; 95% CI: 2.60-3.00] while those in profile 2 were less [aOR: 0.79; 95% CI: 0.71-0.86] likely profile 1 residents to report SI at 90 days. Findings indicate substantial heterogeneity in the health profiles between and within older residents with and without self-reported SI.

INTERVENTIONS TARGETING LONELINESS AND ISOLATION AMONG LONG-TERM CARE RESIDENTS: A SYSTEMATIC REVIEW

Audrieanna Raciti[1], Amy Lyons[2], and Yu-Ping Chang[2], *1. Buffalo, New York Mills, New York, United States, 2. University at Buffalo, Buffalo, New York, United States*

The impact of loneliness and social isolation on health is a significant concern among people residing in long term care. Researchers have begun to design and test interventions to lessen the burden of these impacts on the individual as well as our already strained healthcare system. The purpose of this review is to synthesize types and outcomes of interventions designed to reduce loneliness and isolation among long term care residents. Six databases: CINAHL, PUBMED, Cochrane, Web of Science, PsycInfo, and Embase were searched to identify studies leveraging the use of various interventions for alleviating feelings of loneliness and isolation within long term care residents. Multiple keywords were used including loneliness, social isolation, long-term care, nursing home, treatment, and strategies. Articles were screened if they were published between 2012 and present. Twenty studies were included in this systematic review. All studies have a small sample size. Only four studies were randomized controlled trials. Interventions included laughter therapy, adaptive sports, social robotics, horticultural therapy, spirituality, electronic cognitive behavioral therapy, music therapy, virtual reality, expressive arts, telephone discussions, video conferencing, peer mentoring, and animal assisted therapy. The majority of the interventions demonstrate a significant improvement in alleviating feelings of loneliness and social isolation, while some interventions also show improvement in quality of life and physical ability. However, some studies have a high attrition rate. Future research is needed to utilize a more rigorous design with a large sample size. Participant engagement should be considered as part of the intervention activities.

"I EAT TO NOT DIE": DIET AND EXERCISE EXPERIENCES OF OLDER ADULTS LIVING ALONE

MoonKi Choi[1], and Juyeon Bae[2], *1. Kangwon National University, Chuncheon-si, Kangwon-do, Republic of Korea, 2. Yeoju Institute of Technology, Yeoju-si, Kyonggi-do, Republic of Korea*

Living alone is a critical health risk factor among older adults. Regular exercise and a balanced diet are important for maintaining an independent and healthy life. However, it can be more difficult for older adults living alone to maintain healthy exercise and dietary habits due to the lack of social support. This was a qualitative descriptive study to explore the life changes that accompany living alone, focusing on exercise and diet and the need to improve the nutrition and physical activity of older adults living alone. Thematic analyses were applied to analyze the qualitative data collected from semistructured in-depth interviews. Fifteen subjects, including 5 men and 10 women, participated in the interviews. The mean age was 77.73 ± 7.37 years, and the mean duration of living alone was 17.73 ± 12.89 years. Six main themes were developed: unavoidable difficulties of living alone (lack of someone to depend on and loneliness), just eating "to not die", exercise that is good for health but hard to do alone, conflict between maintaining independence and dependence on others, coping with available resources, and resources needed for regular exercise and a balanced diet. Living alone led to poor dietary habits, such as skipping meals or insufficient food intake. Food security should be ensured through the reinforcement of social support, financial assistance, and the operation of public cafeterias. In addition, a tailored group exercise program that can meet the need for social interaction and improve self-efficacy would help older adults living alone maintain regular exercise habits.

USE OF COMPLEMENTARY HEALTH APPROACHES AND PRESCRIPTION OPIOIDS AMONG VETERANS WITH MUSCULOSKELETAL DISORDERS

Ling Han[1], Joseph Goulet[2], Melissa Skanderson[2], Doug Redd[3], Cynthia Brandt[4], and Qing Zeng[3], *1. Yale School of Medicine, New Haven, Connecticut, United States, 2. VA Connecticut Healthcare System, West Haven, Connecticut, United States, 3. George Washington University, Washington, District of Columbia, United States, 4. Yale School of Public Health, New Haven, Connecticut, United States*

Complementary and integrative health approaches (CIH) are recommended in national guidelines for managing chronic pain and de-prescribing opioids. We followed 1,993,455 opioid-naïve Veterans with musculoskeletal disorders for two years after index diagnosis during 2005-2017. CIH exposure was defined as primary care visits for acupuncture, massage and chiropractic therapy using natural language processing and administratively coded data. Opioid prescriptions dispensed during follow-up period were abstracted from Veterans Health Administration electronic pharmacy records. Propensity score (PS) was used to match one control for each CIH recipient. Overall, 140,902 (7.1%) Veterans received CIH, with those age ≥65y the lowest prevalence (2.7%). Cox proportional hazard model revealed that time to first opioid prescriptions was longer for CIH recipients than PS-matched controls (136,148 matched pairs) and varied across age (p for interaction 0.003). The adjusted Hazard Ratio (HR) was 0.48 (95% Confidence Interval (CI): 0.45-0.51) for Veterans age ≥65y, 0.44 (95% CI: 0.43-0.45) for 50-64y and 0.47 (95% CI: 0.46-0.48) for ≤49y. Restricted mean survival time (RMST) models estimated a smaller CIH benefit for Veterans ≥65y, with an average 3.3 (95% CI: 3.2-3.5) month RMST difference, in contrast to 4.2 (95% CI: 4.1-4.3) and 3.7 (95% CI: 3.6-3.8) months for younger counterparts. Sensitivity analyses in full cohort or modeling total supply and daily dose of opioid prescriptions derived consistent results. These findings suggest potential benefits of CIH in delaying and reducing opioids prescriptions for patients with chronic pain. The observations of lower rate and smaller benefit of CIH use among older Veterans warrants further investigations.

CURRENT PRACTICE PATTERNS IN HOME HEALTH OCCUPATIONAL THERAPY

Chiung-ju Liu, Hannah Burch, Sabrina Glover, Abigail Donofrio, Gianna Oliveros, and Gianna Demeo, *University of Florida, Gainesville, Florida, United States*

Occupational therapy practitioners are essential members of the home health rehabilitation team to support patients transitioning from acute care to home. However, home health occupational therapy services have been underutilized, in part, due to limited understanding of services that the profession provides. Improving this understanding is necessary to help patients receive timely services. The purpose of the study was to describe the current practice patterns in home health occupational therapy. Fifty home health occupational therapy practitioners from 27 states completed an electronic survey between May and June 2021. The survey consisted of questions about assessment and treatment, communication with physical therapy colleagues, and the impact of the Patient-Driven Grouping Model and the coronavirus disease 2019 pandemic on service delivery. Results showed that occupational therapy assessments focused on personal care activities, mobility and balance, and cognition. The treatment content usually included training in activities of daily living, functional mobility, the application of compensatory strategies (e.g., home adaptations), and fall prevention strategies. Most respondents communicated with their physical therapy colleagues at least once a week on topics related to scheduling, changes in a patient's condition, and falls and safety concerns. Seventy percent of respondents experienced a reduction of home visits during the recent Medicare payment reform and the pandemic. These practitioners felt that some patients might be discharged prematurely because of this reduction. The survey results highlight the pertinence of occupational therapy services to support patients' independence and safety at home and the need to increase these services for home health patients.

THE ASSOCIATION BETWEEN ACCESS TO MEDICAL CARE AND RESIDENT OUTCOMES IN NURSING HOMES

Krittika Bali, *University of Alberta, Edmonton, Alberta, Canada*

The nursing home population is vulnerable and medically complex, yet little is known about models of medical service provision and associated quality outcomes. The goal of this study is to examine the association between physician (MD) and nurse practitioner (NP) accessibility and practice sensitive outcomes. This project used data from the Translating Research in Elder Care (TREC) longitudinal study and the routinely collected Resident Assessment Instrument – Minimum Data Set version 2.0 (RAI-MDS 2.0) to test the association between the availability of MDs and NPs in nursing homes (NH) and clinically-relevant resident outcomes of antipsychotic medication (APM) use without indication of psychosis, physical restraint use, hospitalization and emergency department (ED) transfers, and polypharmacy. Eight models were created using logistic regression to test the association between the access measures of daily presence of MD or NP on unit and MDs being involved in care planning and each of the four resident outcomes. The sample consisted of 10,888 residents across 320 units in 92 facilities. Staff from 277 (86%) units reported an MD or NP visited daily and 318 (99%) units reported that the MD or NP could be reached when needed. Following adjustment for multiple confounding variables, there were no associations between either measure of access and any of the resident outcomes. Although we did not find any associations between our measures of access and resident outcomes, additional research which more directly measures physician and NP activities in the NH is required.

FREQUENT USERS OF EMERGENCY MEDICAL SERVICES IN A METROPOLITAN CITY: INDIVIDUAL- AND SYSTEM-LEVEL CONSIDERATIONS

Beatrice Martinez[1], Maria Aranda[1], Iris Aguilar[2], Stephen Sanko[2], and William Vega[2], *1. University of Southern California, Los Angeles, California, United States, 2. USC, Los Angeles, California, United States*

Frequent 911 calls from older adults place a significant burden on emergency response systems. Drawing from key informant interviews, we explore factors implicated in repeated Emergency Medical Services (EMS) among older people in the City of Los Angeles and provide system and policy recommendations to mitigate overuse of EMS 911 calls. Los Angeles Fire Department (LAFD) dispatch call records documented 370,016 EMS encounters from 202,471 unique individuals over 50 from 2012 to 2016. Frequent 911 callers over the age of 50 (n=8), family members (n=6), Los Angeles Fire Department (LAFD) personnel (n=10), and community service providers (n=3) participated in in-depth, qualitative interviews to understand individual- and system-level factors that increase the likelihood of repeated calls. All interviews were audio recorded, transcribed, and analyzed thematically. Guided by Grounded Theory, two themes emerged across all interviewee groups pointing to factors that contributed to 911 calls: 1) The Nature of 911 Calls; 2) Barriers to Access. Patients and family members were aligned on a third theme: 3) Previous Encounters: Interactions with emergency care providers, while LAFD and service providers were in agreement on a fourth theme: 4) The Role of EMS Responders and Community Providers. All groups provided recommendations for the theme, 5) Change the System so that 911 calls do not serve as the default choice. Findings demonstrate the need to improve coordination between LAFD, medical and human service providers. Care coordination can support individual- and system-level supports for patients and families to address their needs and reduce repeated EMS use.

LONGITUDINAL CHANGES IN LEADERSHIP, JOB STRAIN, AND SOCIAL SUPPORT OVER FIVE YEARS IN NURSING HOMES

Annica Backman[1], Marie LINDKVIST[2], Hugo Lovheim[2], and David Edvardsson[3], *1. Umea university, Umea, Vasterbottens Lan, Sweden, 2. Umea University, Umea, Vasterbottens Lan, Sweden, 3. La Trobe University, Bundoora, Victoria, Australia*

Nursing home leadership has been described as crucial for staff job strain and social support but longitudinal data are lacking. This study aimed to explore changes in nursing home managers' leadership, staff characteristics, job strain and social support by comparing matched units in a five-year follow-up study. Repeated cross-sectional, valid and reliable, measures of leadership, person-centered care, psychosocial climate and demographic variables were collected from managers and staff n=3605 in 2014 and n=2985 staff in 2019. Descriptive statistics and regression analyses with generalized estimating equations were used. The results showed that associations between leadership and staff job strain and social support increased in strength over time. This indicates that leadership has the potential to reduce staff job strain and increase the perception of social support among staff, and the significance of leadership increases over time. It was also shown that workforce characteristics had changed with higher proportion of enrolled nurses and a smaller proportion of nurse's assistants at follow-up. An increase was also shown in staff reporting that the job required too much work effort, and perceived deteriorating collegiality and work atmosphere at follow-up.

SESSION 6780 (POSTER)

PHYSICAL FUNCTION, MOBILITY, AND FALLS

INTRACELLULAR WATER CONTENT IN LEAN MASS IS ASSOCIATED WITH MUSCLE FUNCTION AND PHYSICAL ACTIVITY AMONG OLDER ADULTS

Murad Taani[1], and Kimberly Dembinski[2], *1. University of Wisconsin-Milwaukee, Milwaukee, Wisconsin, United States, 2. Ovation Communities, Milwaukee, Wisconsin, United States*

High intracellular water (ICW) content in lean mass (LM) has been associated with better functional capacity and lower frailty risk in older adults and suggested to be a useful muscle quality indicator. However, limited research exists on the relationship of ICW to muscle function and physical activity among older adults. The purpose of this study is to examine the relationship between ICW/LM ratio and muscle function and physical activity among older adults. In a cross-sectional correlational study of older adults aged 70 years or older, a tetrapolar bioimpedance spectroscopy device (Impedimed SFB7, Australia) was used to assess both ICW and LM, and the ICW/LM ratio (mL/kg) was calculated. The Short Physical Performance Battery (SPPB) and Timed Up and

Go (TUG) tests were used to measure muscle function. The Actigraph GT3X+ accelerometer (Actigraph, Inc., FL, USA) was used to measure light and moderate-vigorous physical activity and steps per day. Multiple regression analyses were used. For 96 recruited participants (mean age 82.5 ± 7.4 years; 79 [82.3%] were female), mean ICW/LM ratio was 245.1 ± 28.1 mL/kg. The ICW/LM ratio was positively associated with SPPB score, gait speed, moderate-vigorous physical activity, and steps per day, after adjusting for age, sex, and LM. The ICW/LM ratio was negatively associated with TUG score, after adjusting for age, sex, and LM. The findings suggest that intracellular water content in lean mass may affect muscle function and physical activity among older adults. Further studies are needed to verify these findings and determine any potential cause-and-effect relationships.

BRAIN RESPONSE IN THE ELDERLY AFTER TAI CHI PRACTICE ASSESSED WITH NEUROIMAGING TECHNIQUES: A LITERATURE REVIEW

Hao (Howe) Liu[1], Yasser Salem[2], and Eric Arguello[1], *1. Allen College, Waterloo, Iowa, United States, 2. Hofstra University, Hempstead, New York, United States*

Tai Chi (TC) has been often provided to older adults by rehabilitation professionals for medical dysfunction and anti-aging healthcare. In the last 10 years, there has been an increase in the number of studies examining the effects of TC on brain as assessed by neuroimaging including near infrared spectroscopy (NIRS), and structure and functional magnetic resonating imaging (sMRI & fMRI). Thus, the purpose of this literature review is to evaluate how TC practice may affect the brain in the elderly as assessed by neuroimaging techniques. A comprehensive literature search was conducted using a variety of key words with different search engines to search from the last 10 years until January 15, 2022. Studies were included if they investigated topographic brain responses after TC practice in the elderly population. A total of 12 original studies with 15 articles met the criteria and were included for the review process. The results showed increased volume of cortical grey matter, improved neural activity, and increased neural connectivity in different brain regions, including the frontal, temporal, and occipital lobes, followed by cerebellum and thalamus. Intriguingly, the longer one practices TC, the more his/her brain areas may be altered. Such neural findings after TC practice are often associated with neurobehavioral improvements in attention, cognitive execution, memory, emotion, and risk-taking behaviors. Tai Chi is a promising exercise that is able to improve morphological capability and neurofunctional activity in the brain in the elderly. These improvements seem to be associated with time-length of TC practice.

RELATIONSHIPS OF CEREBRAL PERFUSION WITH GAIT SPEED ACROSS AGE AND SYSTOLIC BLOOD PRESSURE LEVELS

Beverly Gwen Windham[1], Michael Griswold[2], Kevin Sullivan[1], Thomas Mosley[1], Michelle Mielke[3], David Knopman[4], Ron Petersen[5], and Prashanthi Vemuri[5], *1. UMMC-The MIND Center, Jackson, Mississippi, United States, 2. The MIND Center at UMMC, Jackson, Mississippi, United States, 3. Mayo Clinic, Rochester, Minnesota, United States, 4. Department of Neurology, Mayo Clinic, Rochester, Minnesota, United States, 5. Mayo Clinic Rochester, Rochester, Minnesota, United States*

We hypothesized that poorer cerebral perfusion could impair mobility, particularly at lower systolic blood pressure (SBP). Cerebral perfusion was measured via arterial spin-labelled (ASL)-MRI in community-dwelling adults of the Mayo Clinic Study of Aging. Usual-pace gait speed was assessed over 5.6 meters on an electronic mat. Linear regression models estimated cross-sectional gait speed associations with ASL and modifying effects of age and SBP, adjusting for sex and body mass index. Results report differences in gait speed (meter/second) per standard deviation (SD) lower ASL or SBP (mean=139.1 mmHg, SD=19.7 mmHg). Among 479 participants (aged 31-94 years; mean age 67.6 years; 44% women; mean gait speed 1.17m/s), relationships of ASL with gait speed varied by age and SBP (ASL-x-age interaction: p<.007; ASL-x-SBP interaction: p<.007). At age 65, 75 or 85 years and a SBP of 120mmHg, each SD lower ASL was associated with a 0.04 m/s (0.01,0.07), 0.07 m/s (0.04,0.10), and 0.09 m/s (0.05,0.13) slower gait speed at respective ages. At age 65, 75 or 85 years with low ASL (1 SD below the mean), each SD lower SBP was associated with 0.06 (0.02,0.09) m/s, 0.03 (0.01,0.06) m/s or .01 (-0.02,0.04) m/s slower gait speed, respectively. With high ASL (mean ASL+1SD), lower SBP trended towards faster gait at older age, e.g. estimated gait speed was 0.04 m/s (0.00,0.09) faster for each SD lower SBP at age 85years. Poorer cerebral perfusion may contribute to slower gait, particularly with lower SBP. The interrelations of cerebral perfusion, SBP, and age with mobility merit further study.

ASSOCIATION OF PERSISTENT DEPRESSIVE SYMPTOMS WITH PHYSICAL ACTIVITY IN KNEE OSTEOARTHRITIS

Rhea Mehta[1], Michelle Shardell[2], Alice Ryan[3], Yu Dong[1], Brock Beamer[3], Marc Hochberg[1], and Alan Rathbun[1], *1. University of Maryland, Baltimore, Baltimore, Maryland, United States, 2. University of Maryland School of Medicine, Baltimore, Maryland, United States, 3. University of Maryland Baltimore, Baltimore, Maryland, United States*

Comorbid depression in knee osteoarthritis (OA) is associated with declines in physical activity, but how persistent depressive symptoms impact physical activity over time remains unclear. We aimed to determine how the persistence of depressive symptoms affects physical activity in knee OA. Participants (n=2,222) from the Osteoarthritis Initiative had radiographic disease (Kellgren-Lawrence grade ≥ 2) in at least one knee. The Center for Epidemiologic Studies Depression Scale (CES-D; range = 0-60) assessed depressive symptoms from baseline through the first three annual follow-up visits, and persistence was operationalized using the cumulative average severity of symptoms over time. Self-reported physical activity was measured from the first to fourth annual follow-up visit using the Physical Activity Scale for the Elderly (PASE; range = 0-793). The primary method of analysis utilized marginal structural models and included exposure by time interactions in the structural outcome model. Baseline depressive symptoms negatively impacted physical activity at the first follow-up (β = -0.7279; 95% CI: -1.1645, -0.2912), but at later time points, effect estimates were closer to the null and not statistically significant. The association between time-averaged CES-D scores from baseline through the first follow-up and physical activity at year two was -0.1410 (95% CI: -0.7105, 0.4286); and 0.2578 (95% CI: -0.3261, 0.8415) for average CES-D scores through follow-up visit two and physical activity at year three. Thus, the negative influence of persistent depressive symptoms on physical activity decreased over time. Physical activity may not consistently decline with persistent depressive symptoms in adults with knee OA.

SCALING UP A FALL PREVENTION PROGRAM IN RURAL COMMUNITIES: FEASIBILITY AND LESSONS LEARNED

Melissa O'Connor[1], Jane Strommen[2], Sean Brotherson[2], Philip Estepp[2], Rachel Grace[2], Megan Pedersen[2], Teri Undem[2], and Divya Saxena[2], *1. North Dakota State University, Moorhead, Minnesota, United States, 2. North Dakota State University, Fargo, North Dakota, United States*

In North Dakota, 28% of adults over age 65 report falling each year, resulting in substantial morbidity and mortality. Evidence-based fall prevention programs can benefit quality of life and maintenance of daily living activities, particularly for community-dwelling older adults. The Stepping On fall prevention program, a national evidence-based program, is designed to educate older adults about risk factors for falls, safety strategies, and coping behaviors. The program consists of seven weekly community-based workshops conducted in a small-group setting by two trained facilitators. The Stepping On program was introduced in North Dakota in March 2012. Since that time, 132 workshops have taken place in rural communities across the state, serving 1,502 participants. The number of workshops and participants steadily grew between 2012 and 2019. In the year 2012-13, 127 individuals participated in ten workshops. By 2019, before the program was suspended during the pandemic, 199 individuals participated in 16 workshops; 24 workshops had previously been held in 2018. The current study discusses the implementation process as the program scaled up and expanded to more locations. The feasibility and sustainability of conducting the program in isolated rural areas, challenges encountered, and lessons learned will also be discussed. It is important that residents in rural communities have access to evidence-based programs like Stepping On so they can experience the benefits.

SKELETAL MUSCLE HEALTH AND LOWER URINARY TRACT SYMPTOMS IN OLDER ADULTS

Peggy Cawthon[1], Scott Bauer[2], Candace Parker-Autry[3], Kaiwei Lu[4], Steven Cummings[5], Russell T. Hepple[6], Rebecca Scherzer[4], and Kenneth Covinsky7, *1. California Pacific Medical Center Research Institute, San Francisco, California, United States, 2. UCSF and San Francisco VA, San Francisco, California, United States, 3. Wake Forest School of Medicine, Winston-Salem, North Carolina, United States, 4. San Francisco VA, San Francisco, California, United States, 5. San Francisco Coordinating Center, San Francisco, California, United States, 6. University of Florida, Gainesville, Florida, United States, 7 University of California, San Francisco, San Francisco, California, United States*

Lower urinary tract symptoms (LUTS) are associated with increased risk of mobility limitations among older adults. Our objective was to evaluate the association of muscle (D3Cr muscle mass, MRI total thigh muscle volume, Keiser extensor power, grip strength) and physical performance (400m walk, SPPB) measures with LUTS severity and bother among adults age >70 years in the Study of Muscle, Mobility and Aging (SOMMA). We used data from the first 132 women and 103 men to complete their baseline visit where LUTS were assessed using the LURN Symptom Index-10 (SI-10) plus a global urinary bother question. We calculated Spearman correlation coefficients and chi-square tests as appropriate, stratified by sex. Among women, LURN SI-10 scores were inversely correlated with D3Cr muscle mass/body weight (ρ=-0.217, P=0.01), peak leg power/body weight (ρ=-0.179,P=0.04), and SPPB (ρ=-0.173,P=0.047), but not 400m walk, MRI thigh muscle volume, or grip strength (P>0.1 for all). 46% of women in the lowest tertile of % muscle mass versus 38% in the highest tertile reported they were at least “somewhat bothered” by urinary symptoms (P=0.04). Among men, no muscle or physical performance measures were significantly associated with LURN SI-10 or urinary bother (P>0.2 for all). In conclusion, older women with greater muscle mass, leg power, and SPPB scores had reduced LUTS severity whereas LURN SI-10 was not significantly correlated with muscle and physical performance measures in older men. Older women with higher D3Cr muscle mass were also less bothered by urinary symptoms, supporting muscle health as a novel female LUTS mechanism.

ASSOCIATIONS BETWEEN POSTURAL SWAY AND GAIT DOMAINS DURING WALKING WHILE TALKING

Oshadi Jayakody, Helena Blumen, Emmeline Ayers, Cuiling Wang, and Joe Verghese, *Albert Einstein College of Medicine, Bronx, New York, United States*

Poor gait performance during walking-while-talking (WWT) is associated with an increased falls risk. Whether this association between WWT and falls is moderated by balance is not known. To address this, we examined 1) cross-sectional associations between postural sway and gait domains during WWT and, 2) whether postural sway moderated the effects of gait domains on falls. Gait (using a computerized walkway) and postural sway in anteroposterior (AP) and mediolateral (ML) directions (using the SwayStar™ system) during WWT were assessed in 357 community-dwelling older adults (M Age 77.9 years; 55.5% female). Principal component analysis was used to derive distinct gait domains: pace (speed, step length), rhythm (swing, stance, step time) and variability (step length variability, double support time variability). Falls incidence over 12 months were ascertained using bi-monthly calls. Multiple linear regression (adjusted for age, sex, and education) was used to examine the associations between postural sway and gait domains. Poisson regression was used to examine the associations of number of falls with gait domains and postural sway. Greater AP- and ML-sway were associated with slower pace, greater rhythm, and greater variability (p< 0.005). Slower pace (not rhythm or variability) was associated with falls incidence (n=95) and the effect of pace on falls (although p>0.005) was reduced by the ML-sway (β for interaction between pace and sway -0.001 95%CI -0.002, 0.0001). These findings suggest that greater sway during WWT is associated with poorer gait performance. Interventions to maintain ML-sway during WWT may assist with reducing the effects of pace on falls risk.

ASSOCIATION BETWEEN CALF MUSCLE FATTY INFILTRATION AND PHYSICAL PERFORMANCE AMONG HEALTHY OLDER ADULTS

Miji Kim, and Chang Won Won, *Kyung Hee University, Seoul, Seoul-t'ukpyolsi, Republic of Korea*

Muscle fatty infiltration is associated with impaired physical performance. However, the association between ectopic fat, such as lower extremity fat distribution, and sex-specific differences among older adults remains to be determined. This study aimed to examine sex-specific differences in calf muscle fat infiltration and their association with physical performance among healthy older adults aged 76 to 80 years. The pilot study comprised 40 subjects (20 men; 20 women) matched by age and body mass index. The participants underwent dual-energy X-ray absorptiometry, magnetic resonance imaging (MRI), and proton magnetic resonance spectroscopy (1H-MRS) to assess body composition and lower extremity fat distribution. The tibialis anterior intramyocellular lipid (IMCL) as assessed by 1H-MRS was negatively associated with the five-times sit-to-stand test scores (rs=0.518, p=0.023) in men, while the soleus IMCL content was negatively associated with the timed up-and-go test scores (rs=0.472, p=0.048) in women. However, the soleus extramyocellular lipid (EMCL) content was positively associated with the five-times sit-to-stand test scores (rs=−0.488, p=0.040) in women, but this association was not statistically significant in men. Regarding the calf cross-sectional area (CSA) parameters assessed by MRI, calf subcutaneous fat CSA was positively associated with the usual gait speed (rs=0.447, p=0.048) in women only. To conclude, this study showed an inverse correlation between IMCL content and physical performance in healthy older individuals and calf muscle-specific IMCL based on sex differences. Furthermore, our results suggest that greater EMCL content in the soleus and calf subcutaneous fat might affect physical performance positively in older women but not older men.

EFFECTS OF RESISTANCE EXERCISE ON MOBILITY AND LIFE SATISFACTION AMONG OLDER CHINESE AMERICANS

Mei-Lan Chen, Douglas Gardenhire, Ying-Jung Wu, and Mi-Jung Lee, *Georgia State University, Atlanta, Georgia, United States*

Physical activity interventions have shown to be potentially effective for preventing mobility impairment and improving life satisfaction in older adults. However, few studies investigated the effect of resistance exercise training on mobility and life satisfaction in older Chinese Americans. The purpose of this study was to test the effect of a 12-week resistance exercise intervention (two times weekly) on mobility (balance, gait speed, and chair stand performance) and life satisfaction in a sample of community-dwelling older Chinese Americans aged 60-89 years (N = 30; mean age 77.9 ± 5.0 years). The study was a two-group randomized controlled trial (RCT). All participants were randomly assigned into either the resistance exercise group or the wait-list control group (15 participants in each group). Participants' balance, gait speed, chair stand performance, and life satisfaction were assessed at baseline and 12 weeks. Descriptive statistics and t tests were used for data analysis. The results indicated that older adults participated in the resistance exercise program had significant improvements in balance, gait speed, chair stand performance, and life satisfaction at the end of the trial. Compared to the control group, the resistance exercise group had significantly greater improvements in balance, gait speed, chair stand performance, and life satisfaction at 12 weeks follow-up. The findings suggest that resistance exercise has beneficial effects in improving mobility and life satisfaction for older adults. This resistance exercise program provides a basis for developing larger RCTs for further determining the efficacy of resistance exercise among older Chinese Americans.

SEDENTARY BEHAVIORS AND PHYSICAL ACTIVITY EXPERIENCES OF LATINX OLDER ADULTS: A THEMATIC CONTENT ANALYSIS

Suweena Bohplian[1], Kristy Liu[2], Cynthia Fritschi[1], and Ulf Bronas[1], *1. University of Illinois Chicago, Chicago, Illinois, United States, 2. University of Illinois at Chicago, Chicago, Illinois, United States*

Sedentary behavior (SB) accounts for ~7.5 % of cardiometabolic mortality globally. The burden of cardiometabolic disease is especially high among Latinx adults and increases with age. Physical activity (PA) is crucial for maintaining health, yet most Latinx older adults do not meet PA guidelines and spend much time in SB. The aim of this study was to use thematic content analysis to describe the meaning of SB; and the experiences, facilitators, and barriers to PA among Latinx adults. Individual interviews were conducted among 30 Latinx older adults aged 55 to 75 years (60.7 ± 5.7 years) and BMI 20.78 to 42.13 kg/m2 (29.8 ± 4.4 kg/m2) who were enrolled in a larger study of PA. Results showed major themes included meaning of SB, consequences of SB, barriers, and facilitators of PA. Meaning subthemes included sitting for leisure as different from sitting work and value statements about laziness. Three participants did not understand the word “sedentary behaviors”. Consequence subthemes included effects on physical (circulation, obesity, fatigue) and mental health (cognitive and psychological). Barriers to PA included COVID-19, environment (weather, safety), culture (language, no relationships with non Latinx communities), time constraints (work), and physical conditions (pain and illness). Facilitators of PA include self-motivation, family, and community support (public parks, gyms, PA program from community organizations). These findings shed deeper meaning about SB and PA among the Latinx culture. These findings will be key in developing culturally appropriate interventions to improve physical and mental health specifically for the Latinx older adult population.

PROTEIN SUPPLEMENTATION NEGATIVELY IMPACTS GLUCOSE HOMEOSTASIS IN A WEIGHT LOSS INTERVENTION IN OLDER ADULTS

John Batsis[1], Curtis Petersen[2], David Lynch[3], Hillary Spangler[1], and Summer Cook[4], *1. University of North Carolina at Chapel Hill, Chapel Hill, North Carolina, United States, 2. Dartmouth College, Hanover, New Hampshire, United States, 3. UNC, Chapel Hill, North*

Carolina, United States, 4. University of New Hampshire, Durham, New Hampshire, United States

Background: Higher dietary intake of protein has also been associated with increased risk of type 2 diabetes, yet losing weight improves glucose metabolism and homeostasis. We evaluated whether a multicomponent weight loss intervention in older persons with obesity aged 65+ years augmented with protein supplementation impacts glucose homeostasis.

Methods: A 12-week, non-randomized, parallel group intervention in 28 older rural adults with obesity (body mass index (BMI)$\geq$30kg/m2) was conducted at a community aging center of a protein and non-protein arms. Both received individualized, weekly dietitian visits with twice weekly physical therapist-led group strength training classes; aerobic exercise was prescribed outside the classes. The protein group was provided with whey protein supplementation three times weekly post-strength training. Pre/post fasting glucose, insulin, and c-peptide levels were assessed with HOMA-IR and HOMA beta-cell function calculated.

Results: Mean age was 72.9±4.4 (86% female) and 73.0±6.3 (79% female), p=0.94, with baseline BMI of 37.6±6.9 and 36.6±5.5, in the protein and non-protein groups, respectively. Mean weight-loss was -3.45±2.86kg and -5.79±3.08kg (both $p< 0.001$; Δ p=0.047). Visceral fat decreased less in the protein group (-0.02mL vs. -1.02ml;p=0.007), while appendicular lean mass did not (p=0.44). There was lower fasting glucose (protein:-4mg±13.9mg/dL vs. non-protein: 12.2±25.8, effect size:-0.40;p=.10), insulin (-1.32±4.68 vs. -7.79±10.14, ES:0.82;p=0.01), and higher c-peptide (-0.02±0.67 vs. -0.69±1.25,ES:0.66;p=0.06) at follow-up. HOMA-IR also decreased less (-0.18±0.64 vs. -1.08±1.50, ES:0.78; p=0.02) and b-cell function (-3.94±22.61 vs. -16.81±33.85; ES:0.45; p=0.09]).

Conclusions: A multicomponent obesity intervention incorporating protein supplementation led to lower degree of weight loss and mitigated the benefit on glucose homeostasis.

COGNITIVE-MOTOR GAMING IN OLDER ADULTS: FEASIBILITY OF TELEASSESSMENT AND TELEREHABILITATION ON FALL RISK

Tanvi bhatt[1], Savitha Subramaniam[1], Spyros Kitsiou[2], Lakshmi Kannan[2], and Edwina Wilson[2], *1. University of Illinois at Chicago, Chicago,, Illinois, United States, 2. University of Illinois at Chicago, Chicago, Illinois, United States*

There is limited guidance for clinically relevant tele-assessment, and access to a comprehensive physical-activity (PA) based telerehabilitation paradigm to enhance physical function, and slow progression of frailty among older adults (OA). In this we first examined the usability, safety, and feasibility of tele-assessment and telerehabilitation program on physical, and CV function. Subsequently evaluated its compliance and effectiveness. Healthy OAs (n=23,>65 years) participated a custom-designed exergaming-based tele-exercise program (EG-BTxP) delivered in home-setting for 4 weeks (3 sessions/week) consisting of 4 exercise modules: Dancing, aerobics, cognitive-motor gaming and mind-body exercises (yoga and tai-chi) in groups of 5. Pre- and post-training, a real-time online teleassessment was performed and change in lower limb strength, endurance (30-second chair stand test), static balance (one-legged stand test, Romberg test), and dynamic balance (4-step square test), aerobic endurance (2-minute step in place test) were assessed. Participants were provided with wearable sensors and education to self-monitor heart rate during exercise and report back to health coach after each module. Participants responded positively on the qualitative usability survey and there were no adverse events . All participants were able to tolerate the teleassessment and tele-intervention with a compliance of >90%. Post-training, there were improvements in 30-second chair stand test; ($p< 0.01$), one-legged stand test, Romberg test, and 4-step square test, ($p< 0.05$). Further, number of steps in the 2-minute step-in-place test increased ($p < 0.05$). These findings suggest that gaming-based tele-exercise programs could be safely implemented in community-based settings to increase compliance with participation for improved physical rehabilitation outcomes.

DAILY EXERCISE DOES NOT ALTER CEREBRAL BLOOD FLOW REGULATION DURING TILT IN OLDER ADULTS AFTER TWO WEEKS OF BEDREST

Andrew Robertson[1], Eric Hedge[2], Carmelo Mastrandrea[2], Federico Granados Unger[2], and Richard Hughson[2], *1. University of Waterloo, Waterloo, Ontario, Canada, 2. Schlegel-UW Research Institute for Aging, Waterloo, Ontario, Canada*

Bedrest is associated with cardiovascular and cerebrovascular changes that are linked to a greater prevalence of orthostatic intolerance; however, much of what we know from bedrest trials comes from young adults. How older adults respond to extended periods of activity restriction is not well understood. The current work tested the hypothesis that impaired control of cerebral blood flow in older adults following bedrest could be attenuated by regular exercise. Twenty-two older adults (55-65 years, 11 women) participated in a randomized controlled trial involving 14 days of continuous 6-degree head-down bedrest. The cohort was randomized to an exercise intervention (EX), involving daily aerobic, high-intensity interval, and resistance training, or a control group (CON), involving passive manual therapy. Cerebral blood flow velocity, cardiac output, and arterial blood pressure were measured continuously during a passive 80-degree head-up tilt protocol for up to 15 minutes. Responses in the cerebral and peripheral vascular beds were quantified by vascular resistance (cerebral: resistance area product (RAP); peripheral: total peripheral resistance (TPR)). Following bedrest, both supine RAP and TPR were elevated ($p< 0.01$), with no effect of exercise training. In addition, the number of participants who could not complete 15 minutes of tilt increased from 3 to 15 (8 EX, 7 CON). In these non-finishers, RAP dropped ~20% and TPR dropped ~15% during the final 2 minutes of tilt, with no difference between groups. These data suggest that multimodal exercise training is insufficient to prevent changes in cardiovascular and cerebrovascular regulation in older adults observed during 14-day bedrest.

HEALTH BENEFITS OF TAEKWONDO INTERVENTION IN OLDER ADULTS LIVING IN NURSING HOMES

Yongseop Kim[1], Junhyoung Kim[2], Dongchul Seo[2], and Sua Han[2], *1. Indiana University at Bloomington,*

Bloomington, Indiana, United States, 2. Indiana University, Bloomington, Indiana, United States

Physical inactivity is prevalent among nursing home residents, and it contributes to loss of lower body muscle mass, which raises the risk of falling for the older adult population. Accumulative evidence shows that engaging in leisure-time physical activity improves physical functions, mental health, and cognitive capacities and provides social benefits in older adults. Taekwondo, a form of Korean traditional martial arts, has the potential to improve the health benefits among nursing home residents in the United States. Thus, the aim of this study was to explore the health advantages for nursing home residents of participation in a Taekwondo program modified to accommodate their physical and cognitive conditions. An observational research method was incorporated to explore the health benefits of Taekwondo. 10 prospective participants (5 females, 5 males; mean age = 80 years) from the local nursing home facility participated in in-depth semi-structured interviews. The researchers employed Strauss and Corbin's (1998) grand-tour and mini-tour question strategies, as well as Creswell's (2009) five phases of data gathering and analysis. The constant comparative approach was utilized to analyze the data in this study. As a consequence of participating in Taekwondo, four key themes were recognized as health benefits: (a) supporting mental health, (b) increasing physical functions, (c) stimulating cognitive capacities, and (d) facilitating healthy social connection. The findings of this study suggest that Taekwondo might be utilized as a therapeutic intervention to improve physical activity and reduce the negative psychological effects of nursing home confinement.

OLDER ADULT PERSPECTIVES ABOUT ONLINE EXERCISE CLASSES DURING THE COVID-19 PANDEMIC AT MULTIPLE TIME POINTS

Michelle Porter, Dallas Murphy, Nicole Dunn, Ruth Barclay, Stephen Cornish, Jacquie Ripat, Kathryn Sibley, and Sandra Webber, *University of Manitoba, Winnipeg, Manitoba, Canada*

Engaging in physical activity can bring health benefits for older adults. However, during the pandemic the availability of in-person exercise classes has been sporadic. As such, online exercise programs have become more common. This research had the goal of exploring the uptake of online exercise programs by older adults in Manitoba, Canada in the first few months in the pandemic and then more than 1.5 years into the pandemic. Older adults (65 years and older) were recruited via emails from a variety of community organizations. Participants completed anonymous online surveys in summer 2020 (n=678) and fall 2021 (n=570). Less than 50% of respondents reported participating in online exercise classes during the pandemic in both surveys. For both surveys, pre-recorded classes were the most common, however, this decreased from 80% in the first survey, to 57% in the second survey. Conversely, live classes where the instructor could see the participants increased from 17% in the 2020 survey, to 47% in the 2021 survey. Additionally, platform use shifted from YouTube as the most popular in the first survey, to Zoom in the second survey. Most of the online classes originated from their local communities. Of those who participated in online exercise early and later in the pandemic, about two thirds reported that they would continue online exercise classes outside of the pandemic. A major reason for not participating was because they enjoy the social aspect of in-person classes. The perspectives of the study participants will be valuable for policymakers, programmers, and instructors.

SESSION 6790 (POSTER)

SOCIAL ISOLATION AND LONELINESS (BSS)

COMPANIONSHIP TO ADDRESS QUALITY OF LIFE AND LONELINESS AMONG OLDER ADULTS WITH SEVERE LONELINESS

Kelsey McNamara, and Ellen Rudy, *Papa Inc., Miami, Florida, United States*

Research indicates that loneliness is a powerful predictor of premature mortality. Less is known about those who experience “severe loneliness” and their responsiveness to companionship as a means to clinically improve. We sought to understand the epidemiology of a cohort of lonely older adults and the impact of companion care on severe loneliness and quality of life. Companion care was provided through Papa Inc., a national service that pairs older adults with “Papa Pals” who provide companionship and assistance with everyday tasks. Participants have free access if their Medicare Advantage plan offers it. The sample included adults ages 65+, active in Papa in 2021, and provided follow-up data (UCLA-3 Loneliness Scale; CDC's Healthy Days Measures) as of September 2021. Analysis utilized t-tests and Chi-square tests with significance set at $p< 0.05$. A total of 2650 participants were identified as lonely at baseline, 435 were successfully contacted to collect complete follow-up data. Of the follow-up cohort, 22% were classified as severely lonely at baseline reporting mean UCLA score of 8, and 15 mentally and 14 physically unhealthy days on average. Of those severely lonely, 62% were female, 11% were ages 85+. Sixty percent of severely lonely participants experienced clinical improvements and moved to a lower category of loneliness (mean change in UCLA: –3.37) and reduced their unhealthy days (–6.20 mental; –2.09 physical). This real-world evidence suggests a companionship program can improve loneliness and quality of life among severely lonely older adults. Earlier interventions to prevent chronic loneliness should be explored.

DEVELOPING A MOBILE PHONE APPLICATION TO DETECT SOCIAL ISOLATION OVER MULTIPLE TIME POINTS

Rajlaxmi Biyani[1], Anupam Joshi[2], Gretchen Tucker[3], Dana Bradley[4], and Carmen Sceppa[5], *1. University of Maryland Baltimore County, Fairfax, Virginia, United States, 2. University of Maryland Baltimore County, Baltimore, Maryland, United States, 3. University of Maryland, Baltimore, Columbia, Maryland, United States, 4. University of Maryland, Baltimore County, Baltimore, Maryland, United States, 5. Northeastern University, Boston, Massachusetts, United States*

Social isolation is an important predictor of mortality and morbidity in older persons. The increase in social isolation is often a result of major life events such as retirement, leading to the loss of social connections. The effects of the pandemic have exacerbated the loss of social connectedness. Measures to ensure social distancing have made technologies like voice and video calling, text messaging, and other phone mediated communication important resources for connecting people. Measuring social isolation often requires periodic administration of a paper survey instrument, like the Lubben Social Network Scale (LSNS). The approach was taken by Lubben for predicting a person's social isolation level typically involves looking at their general frequency of interactions with family and friends along with the specific frequencies of private, tentative discussions happening during those interactions. This paper explores the process used to develop a tool to measure social isolation continuously and automatically by using an older person's frequency and tone of telephonic conversations. We categorized a person's family and friends into three sub-categories based on the self-reported level of closeness shared with them. We then analyzed the person's conversation (content and tones). Lastly, we trained the deep learning model (Watson) using these captured tone values to determine the social isolation index of the individual. Our preliminary results indicate that we are able to correctly predict their degree of social isolation as judged by Lubben's scale using their phone conversations. This technology may be promising for the assessment and intervention of social isolation.

LONELINESS AND COGNITIVE FUNCTION IN OLDER ADULTS WITHOUT DEMENTIA: A SYSTEMATIC REVIEW

Karra Harrington[1], Shradha Vasan[2], Jee eun Kang[1], Martin Sliwinski[1], and Michelle Lim[2], *1. The Pennsylvania State University, University Park, Pennsylvania, United States, 2. Swinburne University of Technology, Hawthorn, Victoria, Australia*

Loneliness has consistently been associated with dementia risk. An important precursor to dementia is cognitive decline, which can begin decades prior to clinical diagnosis of dementia. Therefore, understanding about the relationship between loneliness and cognitive function in healthy older adults may inform our understanding of how loneliness contributes to dementia risk. The aim of this systematic review was to identify the extent to which loneliness affects cognition in older adults who do not have dementia. A systematic search of five databases (PubMed, PsycNET, Web of Science, EBSCOhost, Scopus) from inception to August 31st 2021 was completed, including search terms related to loneliness, aging, and cognition. A total of 4,302 unique articles were screened for inclusion, resulting in 16 studies that met full criteria (six cross-sectional and ten longitudinal). Three of the six (50%) cross-sectional studies reported significant negative associations between loneliness and cognitive function, while six of the ten (60%) longitudinal studies reported that loneliness was associated with greater cognitive decline over time. We did not find a significant relationship between loneliness and cognitive function in the rest of the studies. There was substantial variation across studies in the measures of loneliness and cognitive function. Furthermore, many studies relied on cognitive screening tools to identify cognitive outcomes, which may not be sensitive to subtle cognitive changes that precede dementia. Future studies should consider using validated and sensitive measures of loneliness and cognitive function, and examining these relationships prospectively, in order to, assess these relationships in a more robust way.

LONELINESS AND ACTIVITIES OF DAILY LIVING PERFORMANCE IN OLDER ADULTS: EXPLORING THE MODERATING ROLE OF COGNITION

Bianca Velez, and Cynthia Dulaney, *Xavier University, Cincinnati, Ohio, United States*

Resulting from changes in the sociodemographic landscape and the global pandemic, rates of loneliness have exponentially risen (Myers & Palmarini, 2017; Piette et al., 2020). Prior research demonstrates that loneliness is associated with an increased risk of cognitive and functional impairment (Cacioppo & Hawkley, 2009; de Jong Gierveld & van Tilburg, 1995; Holmén, et al., 1992; Wilson et al., 2007) as well as depression (Cacioppo et al., 2006; Kwon et al., 2017; Purtill, 2018). Although cognition has been studied as either a predictor or outcome of loneliness, it has yet to be examined as a moderator between loneliness and functional impairment (i.e., performance of basic and instrumental activities of daily living; ADLs, IADLs). Participants (N = 106) were community and non-community dwelling adults aged 65 years and older who completed four self-report measures assessing loneliness, ADLs/IADLs, cognitive functioning and depression. Hierarchical linear regression analyses were conducted to test the moderation model. Data revealed that cognition moderated the relationship between loneliness and IADLs. Follow-up simple slope analyses revealed that high cognition and low cognition were associated with decreased IADL performance amongst individuals with loneliness, and this association was stronger when cognition was low. The current study sheds light on the social, emotional, and physical disruptions the pandemic has caused in the lives of older adults. It highlights the need for interventions to enhance the quantity and quality of social relationships, and older adults' involvement in physical and cognitive activities to uphold functional independence in later life.

EXPECTATIONS OF RECOGNITION AND BENEFITS OF CREATIVE ACTIVITIES FOR MIDDLE AND OLDER ADULTS

Darby Mackenstadt[1], Carolyn Adams-Price[2], and Sarah Israel[1], *1. Mississippi State University, Starkville, Mississippi, United States, 2. Mississippi State University, STARKVILLE, Mississippi, United States*

Creative hobbies have been found to be beneficial for mental health, especially if an individual considers their hobby an important part of their identity (Adams-Price & Morse, 2018). Although receiving recognition from friends or family for one's creative abilities has been seen to decrease depressive symptoms for adults, these benefits may depend on expectations and type of recognition desired (Israel et al, 2020). Those who participate in creative activities as a career compared to those who participate as hobbyist may not receive the same benefits due to the stress artists endure trying to earn a living (Barker et al, 2009). This study aimed to explore the relationships between hobby recognition, hobby's impact on identity, and mental well-being. A sample of 279 primarily white (88%) female (95.3%) adults aged 40 to 84 (M = 59.9-years-old) were interviewed during the Covid-19 Pandemic. A structural equation model was developed in AMOS 28.0 to correlate these variables and do a multiple groups analysis, comparing 100 older adults (65+) and 179 middle aged adults (40-64) who all reported at least one creative hobby. Results found a negative relationship between identifying with a creative hobby and receiving recognition for the hobby, a negative relationship between mental well-being and recognition, and a positive relationship between identifying with one's hobby and mental well-being. The results suggest that recognition from others may have mixed effects on mental health but identifying with one's creative hobby may be a protective factor. Implications expectations of recognition will be discussed.

LONELINESS AND DEPRESSION: EXAMINING THE MODERATING EFFECTS OF RESILIENCE RESOURCES

Xiaoyan Zhang, and Merril Silverstein, *Syracuse University, Syracuse, New York, United States*

Loneliness is highly prevalent among older adults and can negatively influence their mental health. However, less is known about the factors that might mitigate the effects of loneliness on mental health outcomes such as depression. We propose that resilience resources may serve as potential protective factors that buffer the impact of loneliness on depressive symptoms. This study aimed to (a) test the effects of loneliness, as well as resilience factors of perceived family support and optimism, on depressive symptoms, and (b) examine resilience factors as moderators of the relationship between loneliness and depressive symptoms. Participants derived from the Health and Retirement Study (HRS), a nationally representative sample of the population aged 50 years and older. The analytic sample was selected with baseline measurements in either 2006 or 2008 and two follow-ups across four-year intervals (N= 7,336). Structural equation modeling with latent variables and interaction terms was used to investigate study aims. Results revealed that (a) loneliness was significantly related to an increase in depressive symptoms; both perceived family support and optimism significantly reduced depressive symptoms, and (b) the link between loneliness and depressive symptoms was weaker when older adults reported higher levels of perceived family support and greater optimism. This study highlights the important protective roles played by perceived family support and optimism in reducing the adverse impact of loneliness on depression. Results suggest that strengthening family support and fostering optimism might be promising avenues for improving mental health in older adults particularly among those experiencing loneliness.

IMPACT OF A SOCIAL CONNECTION PROGRAM ON OLDER ADULTS DURING THE COVID-19 PANDEMIC

Rachel Ungar[1], Rifky Tkatch[2], Yan Cheng[2],
Sandra Kraemer[3], Michael McGinn[2], and Ellen Wicker[4],
1. Optum Labs, Oak Park, Michigan, United States, 2. Optum Labs, Minnetonka, Minnesota, United States, 3. UnitedHealthcare, Minnetonka, Minnesota, United States, 4. ASI, Inc., Washington, District of Columbia, United States

Background: Research demonstrates social connections decrease loneliness and improves life satisfaction among older adults. However, the COVID-19 pandemic limited social connectedness, specifically for older adults. Thus, programs aimed to increase social connectedness among older adults are integral to their well-being. Purpose: The primary objective of this study was to determine if the telephonic Peer-to-Peer (P2P) program could improve social connectedness and reduce loneliness among older adults. A secondary objective was to improve life satisfaction and social support.

Methods: Eligible older adults (age 65+) were recruited via outbound calls and/or a mailer. Participants were mailed a T1 survey, completed intervention training, and matched into a dyad. The matched dyad engaged in weekly telephone calls for 12 weeks. Post 12 weeks, participants completed a T2 survey, and a T3 four weeks later.

Results: A total of 475 participants completed a T1, and 125 dyads (250 individuals) completed a T3. Older females were more likely to participate (77% female, 44% 75+ old). Individuals who were lonelier at baseline showed a significant improvement in loneliness throughout the program, as well as improvement in social support, life satisfaction, and subjective happiness.

Conclusion: Results from this program showed significant improvement in psychosocial well-being outcomes for lonely older adults. This program took place during the initial months of the COVID-19 pandemic and demonstrated success for lonely older adults with limited technology who may have been socially isolated during this time.

LONELINESS DURING THE COVID-19 PANDEMIC AND THE EFFECT ON PSYCHOSOCIAL FACTORS AND HEALTH OUTCOMES

Veronica Dinaj[1], Rifky Tkatch[1], Yan Cheng[1],
Julianne Holt-Lunstad[2], Carla Perissinotto3,
Sandra Kraemer[4], James Schaeffer[1], and Charlotte Yeh[5],
1. Optum Labs, Minnetonka, Minnesota, United States, 2. Brigham Young University, Provo, Utah, United States, 3 University of California, San Francisco,San Francisco, California, United States, 4. UnitedHealthcare, Minnetonka, Minnesota, United States, 5. ASI, Inc., Washington, District of Columbia, United States

Loneliness and social isolation have harmful impacts on health and well-being; thus, the social distancing mandates during the COVID-19 pandemic, meant to protect our most vulnerable populations including older adults, may have had unintended consequences. The current study aimed to assess changes in loneliness (prior to and during the pandemic) and its impact on outcomes such as perceived stress, resilience, purpose in life, quality of life and health outcomes. An annual survey on healthy aging was mailed to a randomly selected national sample (age >65 years) in 2018/2019. Respondents completed the survey again in 2020 (N=3,564) to measure the impact of COVID-19. Measures included well-being and various psychosocial factors. Health care claims data were also used to derive diagnoses for health conditions. Respondents were 52% female and 44% between 65-74 years old. Loneliness symptoms increased for one-fifth of the sample during the pandemic. Respondents lonely at both time 1 and time 2 had lower resilience, purpose in life, and quality of life and higher perceived stress compared to those only lonely at one time point or not lonely. Respondents lonely at both time points had higher rates of health conditions compared to non-lonely respondents. In conclusion, older adults experienced increased levels of loneliness during COVID-19. Those with chronic loneliness had worse outcomes than those who were not lonely or inconsistently lonely and they exhibit lower resilience and purpose and higher stress and health complications. These findings suggest that timing and early intervention for loneliness is important for older adults.

SOCIAL SUPPORT AND LONELINESS AS DETERMINANTS OF THE ONSET OF DISABILITY AMONG PUERTO RICAN OLDER ADULTS

Amilcar Matos-Moreno[1], Neil Mehta[2], Eduardo Villamor[3], Lu Wang[3], and Carlos Mendes de Leon[4], *1. The Pennsylvania State University, Bayamon, Pennsylvania, Puerto Rico, 2. UTMB, Galveston, Texas, United States, 3. University of Michigan, Ann Arbor, Michigan, United States, 4. University of Michigan, Ann arbor, Michigan, United States*

Background: The effect of loneliness and social support on health is poorly understood among older Puerto Ricans. As family size continues to decrease in Puerto Rico due to out-migration, a higher number of older adults have fewer family members to rely on, which may lead to detrimental health outcomes.Method: Using both waves (2002-03 and 2006-07) of the Puerto Rican Elderly: Health Conditions database, we examined the association between social support, living alone, and incident disability among a sample of older adults over 60 years of age residing in Puerto Rico. Disability was defined as the occurrence of difficulties with Activities of Daily Living (ADLs).

Results: 13.4% of older adults in our sample developed some form of disability. Older adults who developed a disability indicated receiving higher levels of social support (2.04 vs. 1.64) and loneliness (30.7% vs. 22.8%). Using multivariate logistic regression, we found that receiving social support increased the odds of developing a disability by 17% (OR: 1.17; CI: 1.02 – 1.35). Older adults who live alone had 58% higher odds of developing a disability (OR: 1.58; CI: 1.01 – 2.46).

Conclusion: The presence of social support and loneliness was correlated with a population prone to developing disabilities. Our findings concur with the well-established literature on psychosocial determinants in late life. However, this study represents the first attempt to understand psychosocial measures and disability in Puerto Rico. Public health organizations and healthcare systems must develop new societal mechanisms of support for older adults at risk of developing disabilities.

THE GEOGRAPHIC LAYOUTS OF OLDER EUROPEANS' SOCIAL NETWORKS AND LONELINESS IN THE COVID-19 PANDEMIC

Haosen Sun[1], and Markus Schafer[2], *1. Indiana University Bloomington, Toronto, Ontario, Canada, 2. University of Toronto, Toronto, Ontario, Canada*

Many older Europeans sustain core personal networks that are geographically dispersed. The pandemic has brought concerns about their mental health, especially during lockdown periods when travel was not permissible and casual local contact was limited. This study examines whether and how older adults' loneliness and depressed feelings vary by the prior geographic layouts of their core discussion networks. It uses a sample of community-dwelling respondents aged 50 and above (Wave 6, in 2015) from the Survey of Health, Aging, and Retirement in Europe (SHARE), with a follow-up at Wave 8 in 2020 during the height of the COVID pandemic. Latent Class Analysis and linear regression show that individuals whose networks were comprised mainly of families 5-25km and >25km away were not especially likely to feel lonely or distressed, despite typically lacking nearby confidants. We also uncover groups of people occupying more compositionally diverse networks. While these individuals were generally more likely to perceive loneliness, they tended not to attribute such feelings to the pandemic onset. The exception was individuals sustaining diverse networks comprised mainly of friends and families at intermediate distances (5-25km), who perceived heightened loneliness in the pandemic. Overall, even scattered at longer distances, family-oriented networks demonstrate good protectiveness against loneliness and depression. Meanwhile, diverse networks appeared to fall short in protectiveness under some conditions of geographic dispersion.

THE COMBINED EFFECTS OF LONELINESS AND SOCIAL ISOLATION ON MENTAL HEALTH IN A NATIONAL SAMPLE OF OLDER ADULTS

Melissa Krook, Corey Mackenzie, Verena Menec, and Jessica Cameron, *University of Manitoba, Winnipeg, Manitoba, Canada*

Social connections are important to maintain health across adulthood. Loneliness and social isolation are global issues and are linked to negative mental health outcomes worldwide, especially among older adults. Past research focuses primarily on loneliness and isolation separately, though many older people experience them simultaneously. Also, there is a paucity of research examining mechanisms through which combinations of loneliness/isolation result in poor mental health. My first objective examined how combined loneliness/isolation affect psychological distress among a group of older adults, and how grouping this sample into four groups of loneliness (yes/no) and isolation (yes/no) may help identify which group(s) are at the greatest risk for distress. My second objective explored perceived social support and relationship satisfaction as mediators of the effects of combined loneliness/solation on distress. I addressed these objectives with a cross-sectional national sample of 2,745 Canadian older adults, aged 55 to 101 years, who completed self-report measures of loneliness, social isolation, social support, relationship satisfaction, perceived physical health, and psychological distress. Those experiencing greater combined loneliness/isolation also experienced higher levels of distress. For lonely older adults, experiencing isolation simultaneously predicted clinically significant distress, but this was not true for those who were not lonely. Participants who were both lonely/isolated had the poorest mental health because they were less satisfied with their relationships, but not because they had less perceived social support. The present study has the potential to expand what we know about pathways through which combinations of loneliness/isolation may lead to poor mental health in older adults.

I HAVE TO COPE WITH IT: THE VOICES OF OLDER AFRICAN IMMIGRANTS EXPERIENCING SOCIAL ISOLATION AND LONELINESS IN THE US

Dolapo Adeniji[1], and Gifty Ashirifi[2], *1. IUPUI, Avon, Indiana, United States, 2. Indiana University, Indianapolis, Indiana, United States*

Social isolation and loneliness have been recognized as significant challenges in the world of older adults. For older African immigrants living with their families in the US, researchers have captured factors such as language barriers, cultural differences, and limited access to transportation to contribute their feelings of social isolation and loneliness. However, little is known about how they cope with these challenges. As the population of older African immigrants continues to increase in the US, it is pertinent to expand knowledge about their experiences for the purposes of social work practice and policy development. Using a qualitative approach, this study recruited and conducted in-depth interviews with 11 participants aged 63 -79. Four themes emerged from the data through a thematic analysis approach which includes a) Positive Self-talk: “I have to cope with it”, b) Technology/Social media: "if I cannot interact physically outside, then, I go through the social media”/Watch TV”, c) Intergenerational social engagement beyond caregiving: "They [grandchildren] are my immediate constituency”, and d) Digging deep through faith. Although the result of this study shows that older Africans immigrants are finding strategies to cope with social isolation and loneliness further support is needed specially to strengthen their coping skills and enhance their social network with people outside of their families.

A NEW NORMAL: EXAMINING THE LINKAGES BETWEEN SOCIAL TECHNOLOGY AND LONELINESS

Yeon Ji Ryou[1], Natasha Peterson[1], Mengya Wang[1], and Joseph Svec[2], *1. Iowa State University, Ames, Iowa, United States, 2. Iowa state university, Ames, Iowa, United States*

As the COVID-19 pandemic continues to shape social landscapes, social isolation and loneliness are major issues with mental and physical ramifications. In recent years, individuals of all ages are turning to social technology (ST) to communicate with loved ones. However, the viability of ST as a substitute to in-person interaction remains hotly debated. Moreover, few studies examined how psychosocial factors interact with ST in mental health outcomes. Using the 2020 survey data (N = 1,969) from Health and Retirement Study (HRS), this research examines whether and to what extent ST ameliorates loneliness among 65+ individuals. We identify which personality dimensions moderate the relationship between ST and loneliness using the conceptual framework of the five-factor and the unified theory of acceptance and use of technology model. Linear regression analyses are conducted to determine direct and interaction effects. Results indicate that greater ST use corresponds negatively with loneliness. We also observe that particular personality traits (e.g. extraversion) are negatively associated with loneliness, while neuroticism corresponds positively with loneliness. In the interaction between neuroticism and ST, neuroticism mitigates the association between social technology and loneliness. These findings indicate that ST can be a positive source of social connectivity but the extent may be conditioned on personality profiles. Plausibly, neurotic individuals may exacerbate behavioral propensities by technology use. As evidenced by the robust independent effects of ST and conditional nature of technology connections with neurotic profiles. These findings imply that future intervention should consider individual differences when developing mental health programs using ST.

COMMUNITY OUTCOMES FROM A PSYCHOSOCIAL INTERVENTION FOR LONELINESS AND SOCIAL ISOLATION IN OLDER ADULTS

Matthew Amick, Olivia Gartlan, Max Zubatsky, and Marla Berg-Weger, *Saint Louis University, St. Louis, Missouri, United States*

Social isolation and loneliness are quickly becoming global health epidemics, where older adults are experiencing greater chronic health conditions and other complications as a result of this trend. This prevalence is likely underreported, given that stigma and health disparities associated with social isolation and loneliness often prevent older adults from reporting this to family members and professionals. This study's aim is to determine the rates of older adult social isolation and social connections from a psychosocial group model called Circle of Friends (CoF). Circle of Friends is built on a model of group rehabilitation model, with the aim to alleviate and prevent loneliness in older adults. The group protocol consists of 6-8 older adults who self-identify as lonely or socially isolated, who meet 12 times over three months. A midwestern university conducted virtual CoF groups between 2020-2022 to underserved areas of a metropolitan city. Researchers used the UCLA Loneliness Scale and Lubben Social Support Scale to determine differences in rates of loneliness and social supports. 15 members participated in three virtual CoF groups, with over 50% of the sample reporting low socioeconomic living conditions. Preliminary findings show that group members reported a 3-point decrease in overall loneliness ($p<.05$), but no differences in frequency of social supports through friends or family. While our research group continues to collect more data on outcomes of our CoF groups, these initial results highlight the need for more community interventions and social connection resources for older adults lacking financial means for healthcare options.

COMPARING DATA-DRIVEN AND THEORY-DRIVEN APPROACHES TO CLASSIFY SOCIAL RELATIONSHIPS ACROSS THE LIFE COURSE

Elliot Friedman[1], Elizabeth Teas[2], and Kristine Marceau[1], *1. Purdue University, West Lafayette, Indiana, United States, 2. Purdue University, Lafayette, Indiana, United States*

A life course perspective on social relationships highlights the salience of specific relationships at specific times in life, but analyses that account for life course trajectories in social relationships are rare. The present study explores the properties of two analytic approaches to classifying life course relationships: 1) a priori, or theoretical, classification strategies, and 2) latent profile analysis (LPA). Including multiple dimensions of social relationships at different time points across the life course, we determined whether theoretical or LPA profiles better predict later-life functional limitations, given that functional impairment is prevalent among middle-aged and older adults. We also assessed whether the two approaches are differentially associated with a broad set of covariates. Data were from three waves of the Midlife in the United States (MIDUS) study (n = 6,909). Relationship variables (parental affection, parental discipline, social support, social strain, and positive relations with others) were from wave 1. Functional limitations were measured at wave 3. Both the LPA and theoretical approach resulted in 4 profiles (although there were qualitative differences), and both approaches differentiated covariate values in similar ways. Loglikelihood comparisons in Mplus showed that the LPA, compared to the theoretical approach, was more sensitive to detecting differences in functional limitations. Overall, the data-driven profiles differed from theory-based profiles, which may be substantively meaningful for understanding associations between life-course relationships and health. Practical implications include development of a measure for future research to apply these novel life-course social relationship groups, particularly with smaller samples not suitable for LPA.

EXAMINING THE CUMULATIVE EFFECTS OF SOCIAL ISOLATION AND LONELINESS IN OLDER ADULTS WITH HIV

Moka Yoo-Jeong, *Northeastern University, Melrose, Massachusetts, United States*

Social isolation exists when one has limited or lacks social contact with others and is distinct from loneliness, an affective state on the perception of isolation. Social isolation and loneliness are recognized as risks to well-being among older adults. Less in known about the cumulative effects of social isolation and loneliness in older persons with HIV (OPWH). Using cross-sectional data on OPWH (age ≥50) recruited from an outpatient HIV clinic in Atlanta, GA (N=146), we aimed to 1) describe the overlap between social isolation and loneliness and 2) examine the combined effects of social isolation and loneliness on quality-of-life (QoL), HIV-related stigma, depressive symptoms, and comorbidity burden. Loneliness and social isolation were assessed using the PROMIS-Social Isolation Scale and Social Network Index, respectively. Participants were grouped into four categories into 'lonely only,' 'isolated only,' 'both lonely and isolated,' or 'neither.' Bivariate and adjusted associations were conducted. Among participants (mean age=56.53), 26.7% (n=39) were considered 'lonely' only, 12.3% (n=18) 'isolated' only, 15.1% (n=22) 'both lonely and isolated,' and 45.9% (n=67) 'neither.' In bivariate analyses, individuals categorized as 'both lonely and isolated' were likely to have past homelessness and higher depressive symptoms, stigma, and comorbidity burden, and lower QoL. In adjusted models, 'both isolated and lonely' significantly predicted QoL, stigma, and depressive symptoms. Findings highlight the critical emphasis on targeting OPWH who are both isolated and lonely.

COGNITIVELY ENGAGING SOLITARY ACTIVITIES: ANOTHER LAYER OF PROTECTION AGAINST LONELINESS

Haosen Sun[1], and Markus Schafer[2], *1. Indiana University Bloomington, Toronto, Ontario, Canada, 2. University of Toronto, Toronto, Ontario, Canada*

Participating in social activities and sustaining more extensive networks are beneficial in mitigating loneliness in the aging population. However, these coping strategies are subject to multiple structural and individual constraints, including neighborhood stressors, physical limitations, and social-economic strain. The present research scrutinizes cognitively engaging solitary activities as a potential alternative to alleviate loneliness. It examines their intersections with social activities and networks and how disadvantaged groups prone to loneliness can benefit from them. We use Wave 4 and 6 of the Survey of Health, Ageing and Retirement in Europe to perform linear and logistic regressions. Results show that 78% of older Europeans perform solitary activities such as reading and playing word/number games at least weekly, a much higher rate than the 29% engaged in formal social activity. Social and personal activities do not compete but instead complement each other. Older individuals performing solitary activities report significantly lower loneliness, and this engagement compensates for low social participation and small social networks. Routine solitary activities are also protective among individuals at older ages and among those lacking a partner, additional housemates, and children. Overall, the present research highlights that solitary activities, particularly the cognitively engaging ones, are a practical layer of protection against loneliness. Future research should further examine variations in the effectiveness between solitary activities and explore the possibilities and challenges in bridging them with digital media and technologies to alleviate loneliness.

MULTIMORBIDITY AND QUALITY OF LIFE: EXAMINING THE PATHWAYS THROUGH LONELINESS, ADL, IADL, AND DEPRESSIVE SYMPTOMS

Stefan Sieber[1], Angélique Roquet[2], Charikleia Lampraki[2], and Daniela Jopp[2], *1. LIVES Centre, University of Lausanne, Lausanne, Vaud, Switzerland, 2. University of Lausanne, Lausanne, Vaud, Switzerland*

Background. Multimorbidity, defined as two or more chronic conditions, negatively affects quality of life. However, little is known about the underlying pathways leading from multimorbidity to lower quality of life (QoL). Objective. The objective of this paper was to examine multiple potential mediating factors (loneliness, Activities of Daily Living [ADL], Instrumental Activities of Daily Living [IADL], depressive symptoms) in the relationship between multimorbidity and quality of life. Furthermore, we explored moderated mediation patterns by age, gender, and education. Methods. Longitudinal data were drawn from five waves (from 2011 to 2020) of the Survey of Health, Ageing and Retirement in Europe (SHARE). We included 37,082 individuals aged 50 years and older in the analyses. The predictor (multimorbidity) and covariates were measured four and the mediators two years before the QoL outcome (CASP-12). Confounder-adjusted mediator and outcome models were fitted using mixed-effects models. The total association was decomposed into direct and indirect pathways applying causal mediation analyses with Monte-Carlo simulations. Results. Multimorbidity was associated with lower QoL four years later; 2.12%, 6.17%, and 19.90% of the association was mediated by ADL, IADL, and depressive symptoms, respectively. Mediation by loneliness was not significant. Generally, the mediation patterns were more pronounced in women and individuals with tertiary education as compared to primary and secondary. Differential mediation by age quartiles did not reveal a clear pattern. Conclusions. The results showed that depressive symptoms were the most important mediator between multimorbidity and QoL, with ADL and IADL also playing an important role.

SESSION 6800 (POSTER)

SOCIAL ISOLATION AND LONELINESS (SRPP)

CHARACTERISTICS OF NORWEGIAN OLDER ADULTS LIVING ALONE OVER THREE DECADES (1995–2019)

Milan Chang Gudjonsson[1], Mona Michelet[2], and Bjørn Heine Strand[3], *1. Norwegian Institute of Public Health, Reykjavik, Not Applicable, Iceland, 2. Vestfold Hospital Trust, Oslo, Oslo, Norway, 3. Norwegian Institute of Public Health, Oslo, Oslo, Norway*

Introduction: Among older adults who are living alone, social isolation, and physical and cognitive impairment are more common than among those who do not live alone. The proportion of older adults who live alone is expected to increase further. The current study investigated the disability and formal care service use among older adults living alone between 1995-2016 in Norway.

Methods: A total of 31,263 people aged 70+ participated in the Trøndelag Health Study (HUNT) survey 2 (1995/97), 3 (2006/08), and 4 (2017/19). The study assessed the use of formal care including practical help (PH) and home nursing (HN), and disability in personal and instrumental activities of daily living (PADL:7 items and IADL: 6 items).

Results: More than 70% of older adults living alone were women (74% in HUNT2, 77% in HUNT3, 71% in HUNT4). The use of PH service among those who were living alone decreased from 33.7% to 18.6%, while HN service use increased from 10.4% to 16.4%. The percentage of PADL disability among those who lived alone was similar (10.3% to 9.1%) between 1995-2019. However, the percentage of IADL disability has decreased from 37.6% (1995-97) to 27% (2017-19) while in all cohorts IADL disability rates were significantly higher among those who were living alone than those who were living with others.

Conclusions: Although the use of HN service among older adults who were living alone decreased during 1995-2016, those who were living alone in all cohorts had higher IADL disability rates compared to those who lived with others.

OLDER AMERICANS LIVING ALONE: AN INTERSECTIONAL ANALYSIS OF SOCIAL ISOLATION RISKS DURING THE COVID-19 PANDEMIC

Anna Bokun, Sarah Flood, and Phyllis Moen, *University of Minnesota, Minneapolis, Minnesota, United States*

More Americans aged 50-75 are living alone than ever before (about a third of adults over 60 live alone today–see Ausubel 2020; Esteve 2020), placing older adults at risk of social isolation, and especially so during COVID-19. Not only do demographers' project the rate of older adults living alone will continue to rise, but they also predict increasing racial disparities due to differential population aging rates (Verdery and Margolis 2017). We pinpoint two mediators of social isolation: employment status and living arrangements, drawing on panel data from the Current Population Survey, from January 2018 through August 2021 (N = 83,232), to investigate whether the pandemic increased disparities in vulnerabilities to social isolation across different subgroups. We use an intersectional lens to consider the experiences of population groups defined by gender, age, race/ethnicity and social class. We know that employment has important protective health benefits (Berkman, et al. 2000; Kelly, et al. 2017). Living arrangements condition social isolation, especially in terms of living alone (Cudjoe, et al. 2020). The aim of our study is twofold. First, we aim to show how the dynamics of living alone and employment participation for older adults change between the immediate pre-Covid period and Covid period, using COVID-19 as a natural experiment in precipitating change. Second, we show how demographic characteristics intersect to structure vulnerability to social isolation during the same period. Our results demonstrate the risks of social isolation are not evenly distributed, suggesting the need for policies and practices promoting social inclusion.

NOBODY KNOWS ME HERE: LONELINESS AMONG OLDER AFRICAN IMMIGRANTS

Dolapo Adeniji[1], Gifty Ashirifi[2], and Margaret Adamek[2], *1. IUPUI, Avon, Indiana, United States, 2. Indiana University, Indianapolis, Indiana, United States*

Migration in later life is often accompanied by stressors such as acculturation and disconnection from previous social networks in one's country of origin. Loneliness emerged in previous studies as one of the challenges that negatively impact older immigrants' physical and mental health. Despite the rapid growth of this population in the United States, there is limited knowledge about loneliness experiences of older African immigrants. Thus, this study explored the loneliness experiences of older African immigrants living with their adult children in the United States. In-depth interviews were conducted with nine participants aged 69-84. The tape recordings of the interviews were transcribed verbatim for thematic analysis. Findings show that loneliness was prevalent among study respondents, despite living with their adult children's family. Four major themes emerged from the study: 1) "Nowhere to go" (loneliness experience), 2) "It makes one sick if one is doing nothing" (consequences of loneliness), 3) "My grandkid makes me happy" (protective strategies) and 4) "If they ask older people to come. I will go there" (way forward in the community). Living with adult children may not prevent loneliness for older immigrant parents. Although the participants demonstrated resilience, their coping strategies were insufficient to overcome their loneliness. To address the gap in resolving loneliness, strategies are needed to increase older African immigrants' social connectedness with their peers, family, and community. Interventions that promote social interactions and embeddedness into their local community are needed to ensure a good quality of life for older African immigrants.

SOCIAL CONNECTIONS AND HEALTH AMONG OLDER ADULTS LIVING IN SUBSIDIZED HOUSING: LOCAL STAKEHOLDERS PERSPECTIVES

Avery Bullock[1], Joseph Gallo[2], Carl Latkin[2], Cynthia Boyd[2], and Thomas Cudjoe[3], *1. Johns Hopkins University School of Medicine, Baltimore, Maryland, United States, 2. Johns Hopkins University, Baltimore, Maryland, United States, 3. Johns Hopkins School of Medicine, Baltimore, Maryland, United States*

Social isolation among older adults living in the United States is a major public health problem that disproportionately affects those living below the poverty line. Though decades of epidemiological studies have provided important insights on the impact of social isolation on health, there have been limited qualitative studies on the dynamics of social connections among older adults in subsidized housing. This study aims to advance our understanding of the perspectives of local stakeholders in the field of subsidized housing on the social connections of older adults and how to enhance social connection. Semi-structured interviews were conducted between July 2021 and October 2021 with local stakeholders in Baltimore's subsidized housing community to better understand social connections among older adults. Stakeholders included, but were not limited to, the following positions: service coordinators, property managers, maintenance staff, and security guards. Interviews were imported and analyzed using NVIVO12 software and a qualitative content analytic approach. Preliminary themes identified included: barriers and facilitators of connection, engagement with family, and ideas about interventions. Mental and physical health challenges, access to and use of communications technology, and lack of transportation were barriers while food incentives, gift card giveaways, and resident champions were facilitators of social connection. Social isolation among older adults is an important concern among stakeholders in subsidized housing. To promote social connection in older adults, interventions must adopt a multi-pronged approach that addresses the barriers and leverage existing facilitators within subsidized housing communities.

LONELINESS AND PSYCHOLOGICAL WELL-BEING OF THE INSTITUTIONAL OLDER ADULTS DURING THE COVID-19 PANDEMIC

Shiau-Fang Chao[1], Hui-chuan Hsu[2], and Yun-Pei Su[2], *1. National Taiwan University, Taipei, Taipei, Taiwan (Republic of China), 2. Taipei Medical University, Taipei, Taipei, Taiwan (Republic of China)*

Purpose: Institutional residents experienced more restrictions in the lockdown of covid-19. The purpose of this study was to examine the association of loneliness and lonely literacy with mental health wellbeing during covid-19 for older institutional residents.

Methods: The participants living in the 13 long-term care institutions who were aged 65 and more and able to communicate with were invited in the survey (n=143). Mental well-being was measured by depressive symptoms and life satisfaction. Loneliness was measured by the 6-item UCLA loneliness scale. In addition, demographics, health status, active and passive coping strategies, social support from family and friends, social interaction changes after covid-19, loneliness change after covid-19, and worries about covid-19 were investigated. Linear regression and logistic regression models were conducted.

Results: The mean of the loneliness score (6~24) was 9.71 (SD=4.02). Factors related to loneliness increased during covid-19 for the institutionalized residents included having more physical function difficulties (OR=1.179), feeling more lonely (OR=1.146), and having more worries for covid-19 (OR=2.317). The residents having depressive symptoms was related to have more loneliness (OR=1.269), worse self-rate health (OR=0.320), and increased more loneliness during covid-19 (OR=3.233); while having high life satisfaction was related to less loneliness (OR=0.859), less physical difficulties (OR=0.834), higher satisfaction of family support (OR=2.835), and not increasing loneliness during covid-19 (OR=0.255).

Conclusion: Loneliness during covid-19 is related to more depressive symptoms and lower life satisfaction, especially during covid-19. Learning active coping strategy and providing proactive and helpful environment for the long-term care residents is suggested during the pandemics.

DECREASED FREQUENCY OF SMALL TALK DURING COVID-19 PANDEMIC AND MENTAL HEALTH: LONGITUDINAL SURVEYS IN JAPAN

Hiroshi Murayama[1], and Ikuko Sugawara[2], *1. Tokyo Metropolitan Institute of Gerontology, Tokyo, Tokyo, Japan, 2. Bunri University of Hospitality, Suginami-ku, Tokyo, Japan*

The coronavirus disease 2019 (COVID-19) has drastically reduced opportunities for small talk. As small talk involves socializing, such deprivation can be stressful. This study examined the association between the change in frequency of small talk before and during the pandemic and the mental health of middle-aged and older people. We conducted web-based longitudinal questionnaire surveys from March to May 2020 and from September to October 2021 among members of a Japanese social networking service. We analyzed 867 responses of people who participated in both surveys (mean age, 68.0 ± 8.0 years; men, 68.1%). This study was approved by the Research Ethics Committee of University of Tokyo. Change in small talk frequency before and during the pandemic was assessed using a single item, "Have the opportunities for small talk (including face-to-face, phone, video call, etc.) with someone other than cohabiting family members changed?" We divided the responses into "increase," "no change," and "decrease." Mental health outcomes included psychological well-being and loneliness. A total of 57.0%, 34.4%, and 8.7% reported "decrease," "no change," and "increase," respectively, from before to during the pandemic. After adjusting for potential covariates, multiple regression analyses showed that people who felt their small talk frequency decreased during the pandemic compared to pre-pandemic period had lower psychological well-being and greater loneliness than those who did not. We observed no interaction between change in small talk frequency and age/sex. Our study quantitatively revealed the importance of small talk during the pandemic in maintaining mental health.

INTERFACE OF INFORMAL AND FORMAL SUPPORT IN THE LINKAGE BETWEEN COGNITIVE DECLINE AND LONELINESS

Soobin Park[1], Sojung Park[1], Takashi Amano[2], and BoRin Kim[3], *1. Washington University in St. Louis, St. Louis, Missouri, United States, 2. Rutgers University-Newark, Newark, New Jersey, United States, 3. University of New Hampshire, Durham, New Hampshire, United States*

Older adults with cognitive impairment are at risk of higher loneliness due to increasing challenges to retain essential social skills and decreasing social networks. This study explores ways to reduce the relationship between cognitive function and loneliness. Drawing on the cognitive discrepancy theory of loneliness, we hypothesized loneliness may be reduced by improving an individual's actual level of social interaction, creating opportunities for social relationships. This study examined complex relationships among informal (frequency of social contact with family members and friends) and formal support (use of home- and community-bound services, HCBS), and loneliness, among older adults with different levels of cognitive impairment. Data came from the Health and Retirement Study (2012) (N=651) with the sample included respondents 51+ years who completed a modified Telephone Interview for Cognitive Status. Results from hierarchical regression showed older people with a lower level of cognitive function were less likely to experience loneliness (b=-.15, p<.01). Although frequent social contact with family and friends reduces loneliness (b=-.24, p<.001), it did not moderate the relationship between cognitive function and loneliness. Interestingly, the use of HSBC also turned out to be not a significant protective factor. Our findings suggest merely increasing social interaction levels with family and friends may not necessarily curb loneliness for older adults with cognitive impairment. Given the current characteristics and nature of HCBS primarily focus on providing basic physical needs of older adults, prioritizing the development of emotional comfort and recreational activities that alleviate their psychological loneliness is essential, especially amidst the pandemic.

SESSION 6810 (POSTER)

SOCIAL NETWORKS AND SUPPORTS: FRIENDS, NEIGHBORS, AND FAMILIES

BEYOND HOUSING

Marianne Raimondo, *Rhode Island College, Greenville, Rhode Island, United States*

Social isolation and loneliness in older adults are a public health challenge that has been exacerbated during the COVID pandemic. While quarantining although it was necessary to protect individuals from the virus, older adults lost their usual social supports, connectedness, and relationships. Research has shown that loneliness and social isolation have many negative effects on a person's physical and mental health. This presentation will describe an initiative of Age Friendly RI which addressed the problem of social isolation among older adults living in a congregate housing community who struggled with stress, anxiety, depression, and exacerbation of mental illness. Through a partnership between a state college and a community based mental health center, and supported with grant funding, behavioral health services and supports were embedded in the housing community. The project was multi-faceted involving community health workers and a community support professional who provided outreach and emotional support, the use of technology to help residents connect with medical providers or loved ones or enjoy music, games, movies, and students who provided outreach and taught older adults how to use technology. A social isolation scale was administered to identify residents at high risk of social isolation and targeted intervention. The evaluation of the program will be discussed in terms of the interventions implemented and the outcomes realized, including resident well-being and satisfaction. Finally, it will suggest a pathway for sustaining the integration of behavioral health services in housing to better meet the behavioral health needs of older residents beyond the pandemic.

SOCIAL RELATIONSHIPS AND COGNITIVE IMPAIRMENT IN LATER LIFE

Patricia Thomas[1], Madison Sauerteig-Rolston[2], Shawn Bauldry[2], Samuel Nemeth[2], and Kenneth Ferraro[2], *1. Purdue University--West Lafayette, West Lafayette, Indiana, United States, 2. Purdue University, West Lafayette, Indiana, United States*

With population aging and the growing population at-risk of cognitive impairment, Alzheimer's disease, and related dementias, there is a need for a better understanding of how social factors may affect cognitive impairment. Drawing from stress process theory and social integration theory, we examine the impact of positive and negative dimensions of relationship quality with friends and family on cognitive impairment in later life. We analyze Cox proportional hazards models using nationally representative panel data from the Health and Retirement Study (2006-2016, N=10,626) to examine how the quality of family and friend relationships in adulthood may influence risk of cognitive impairment. Strain with family members and with friends was significantly related to higher risk of cognitive impairment (Hazard Ratio: 1.15 [95% CI: 1.08, 1.21] and 1.20 [95% CI: 1.13, 1.28], respectively). Support from family members was beneficial, related to lower risk of cognitive impairment (HR: 0.93, CI: .89, .99); however, support from friends was related to higher risk of cognitive impairment (HR: 1.10, CI: 1.05, 1.14). Findings reveal the implications of social support and strain in different types of relationships for cognitive health.

THE STRUCTURAL AND COGNITIVE SOCIAL CAPITAL OF KOREAN OLDER ADULTS AND THEIR DEPRESSION TRAJECTORIES

Jinhyun Kim, Sun-Bi Um, Xiang Shi, and Hyunjung Park, *Pusan National University, Geumjeong-gu, Pusan-jikhalsi, Republic of Korea*

Despite the rapid increase of older population in South Korea, we do not understand the patterns of their social capital and relationships with depression trajectories in depth. This study aims to identify the patterns of social capital of Korean older adults aged 65 years and older based on latent class analyses and their depression trajectories by latent classes. For data analyses, 3,606 Korean older adults from the Korean welfare panel study data were selected. Latent class analyses were conducted by using various components of structural social capital such as number of contacts with family, friends, and neighbors and cognitive social capital such as trust, reciprocity, and satisfaction from social relationships. Results showed that three latent classes were found. We named the first class as a strong structural and cognitive group because it showed the highest levels of number of social contacts, trust and reciprocity. The second class was called as a weak structural and strong cognitive group because it showed lower levels of social contacts but higher levels of satisfaction from social relationships. The third class was called a weak structural and cognitive group because it showed the lowest levels of social contacts, trust, reciprocity, and satisfaction from social relationships. Results from latent growth curve modeling, the second class showed the lowest depressive symptoms but the third class showed the highest depressive symptoms at baseline. Only the third class showed significant rate of changes in depression. Differences in depression trajectories by three latent classes need to be further discussed.

THE MENTAL HEALTH BENEFIT OF FRIEND NETWORKS IN OLDER KOREAN AMERICANS: THE CONDITIONING EFFECT OF FAMILY TYPE

Yuri Jang[1], Nan Sook Park[2], Juyoung Park[1], David Chiriboga[2], William Haley[2], and Miyong Kim[3], *1. University of Southern California, Los Angeles, California, United States, 2. University of South Florida, Tampa, Florida, United States, 3. University of Texas at Austin, Austin, Texas, United States*

Building on the importance of family and friends as sources of social connectedness in later years of life, we conducted a contextual examination of their independent and interactive roles in predicting mental health, using a compensatory social convoy model. In a sample of older Korean Americans, we anticipated that friend networks would be a more important predictor of mental distress when strong family relationships were absent. Data were from 2,140 participants in the Study of Older Korean Americans, a multi-state survey of Korean immigrants age 60 and older (Mage = 73.4, SD = 7.97). To identify family types, latent profile analysis (LPA) was performed with 17 variables assessing family networks, positive and negative interactions with family members, and incidence of mistreatment by family. Linear regression models of mental distress then examined the direct effects of family type and networks of friends, as well as their interactions. LPA on family-related items identified three family types: close-knit, mixed, and dysfunctional. Membership in the close-knit group and a larger network of friends were associated with lower levels of mental distress. In addition, a significant interaction was found between dysfunctional family type and friend network ($B = -.35$, $SE = .08$, $p < .001$), where the positive effect of friend networks was most pronounced in the context of dysfunctional family relationships. These findings support the use of a compensatory social convoy model. Substituting for family resources, friend networks yielded compensatory mental health protection for those with dysfunctional family relations.

"STOP HASSLING ME!": HASSLES, PERCEIVED SUPPORT, AND MENTAL HEALTH OUTCOMES IN OLDER ADULTHOOD

Amy Gourley, Lucas Hamilton, Max Coleman, and Anne Krendl, *Indiana University, Bloomington, Indiana, United States*

Prior work suggests that older adults with larger social networks have better mental health, potentially due to having greater access to support from different network members. However, other research suggests that perceptions of support, which do not necessarily align with network size, predict better mental health and higher life satisfaction. It could be that, irrespective of network size, the presence of hassles – network members that are perceived as causing problems or making life difficult – is associated with lower perceptions of support, which negatively impacts mental health. We tested this possibility using social network data from 137 older adults (Mage = 74.25 years) who completed the PhenX social interview and well-validated measures of depression, perceived social support, and life satisfaction. In linear regression models controlling for other network variables, perceived support and the level of hassles independently predicted depression and life satisfaction. Testing our mediation predictions, hassles significantly mediated the effect of perceived support on depression and life satisfaction. Alternatively, perceived support only mediated the effect of hassles on life satisfaction. Taken together, these findings may indicate that the presence of hassles in one's network predicts mental health symptomology and life satisfaction, irrespective of perceptions of support or other network characteristics (e.g., network size). Thus, while perceptions of social support appear to be important predictors of life satisfaction, network characteristics better predict mental health symptomology. Future work on social engagement interventions may benefit from a targeted approach depending on the outcome of interest.

DO I GET BY WITH A LITTLE HELP FROM MY FRIENDS? FINDINGS FROM THE IOWA UNMARRIED SURVIVORS STUDY

Robert Hensley[1], Alex Bishop[2], and Peter Martin[3], *1. Southeast Community College, Lincoln, Nebraska, United States, 2. Oklahoma State University, Stillwater, Oklahoma, United States, 3. Iowa State University, Ames, Iowa, United States*

The purpose of this study was to analyze the role that selected personality variables (Neuroticism, Agreeableness, Conscientiousness, Extroversion, and Openness), social support, and coping played in loneliness of 227 (M = 78.2, SD = 8.1) participants in the Iowa Unmarried Survivors Study. This study is a sample of never married, divorced, and widowed participants. Blocked multiple regression analyses were used in this study. In the first block, age, gender, ethnicity, past schooling, current marital status, total illnesses, and childhood poverty were included. The second block contained the aforementioned personality variables, and the third block included both social support and coping. Results indicated that both Neuroticism and Extraversion were significant predictors of loneliness, $\beta = .266$, $p < .00$, $\beta = -.294$, $p < .05$, and $\beta = .27$, $p < .00$, respectively. In short, the greater the neuroticism, the higher the score in loneliness. Moreover, the lower the level of extraversion, the higher the score in loneliness. In addition, social support served as a significant predictor of loneliness, β = -.412, p < .00. The more social support in the participants' lives, the lower level of loneliness. Finally, coping predicted loneliness. In essence, the more loneliness in their lives, the greater the use of coping mechanisms utilized. This model explained 58% of the variance in loneliness scores. Navigating through late adulthood as an unmarried survivor presents a host of challenges, and these results add to our understanding of the link between personality, social support, coping, and loneliness in late life.

THE RELATIONSHIP BETWEEN SOCIAL NETWORK AND PURPOSE IN LIFE: APPLICATION OF A RANDOM INTERCEPT CROSS-LAGGED MODEL

Gina Lee, *Iowa State University, Ames, Iowa, United States*

The purpose of this study is to examine if there are reciprocal effects between social network size and purpose in life among older adults using data from the National Health and Aging Trends Study. A second aim is to assess whether there are moderated effect of gender on this relationship. The sample included 1,485 male and 2,058 female adults 65 years and older. In order to examine the reciprocal effects between social network size and purpose in life over four time points (2017, 2018, 2019, and 2020), a random intercept cross-lagged model (Model 1) was computed. Then, two multiple group RI-CLPM analyses (Model 2 and 3) were computed in order to test moderation of gender on the relationship. Model 2 estimates the cross-lagged parameters freed and model 3 estimates the cross-lagged parameters constrained. The results indicated that Model 1 fit the data well, $\chi2(9) = 26.06$, p = .002. The carry-over effects of social network and purpose in life were significant. The spill-over effect from wave 3 purpose in life on wave 4 social network was significant. The variance of the random intercepts were significant, indicating that there are stable, trait-like differences between social network and purpose in life. The results of the multiple group model revealed that there were no significant differences between the freed and constrained models, indicating that lagged effect for male and female appear to be same. Future research should explore if other factors like race or education show moderated effects.

PERSONALITY AND LONELINESS IN LATER LIFE: THE MEDIATING ROLE OF FRIENDSHIP

Emily Lim, and Jeffrey Burr, *University of Massachusetts Boston, Boston, Massachusetts, United States*

Loneliness is prevalent among American older adults and is related to poor health outcomes. Existing studies on the association between personality and loneliness are limited and no study examined the mediating role of friendship. This study investigated how personality traits are linked to loneliness, and how friendship mediated the relationship between personality and loneliness. Using three waves of the Health and Retirement Study (N=3,259), we estimated a model with personality traits in 2010 (openness to experience, extraversion, consciousness, agreeableness, and neuroticism), friendship dimensions in 2014 (number of close friends, frequency of contact with friends, positive and negative friendship qualities), and loneliness in 2018 among community-dwelling adults aged 50 years and above (M=65.54 years old, SD=8.93). Extraversion and neuroticism were negatively and positively associated with loneliness, respectively. All friendship dimensions, except negative friendship quality, were negatively associated with loneliness. Our structural equation modeling results indicated that the number of close friends negatively mediated the relationship between extraversion and loneliness. The relationships between extraversion, agreeableness, neuroticism and loneliness were negatively mediated by positive friendship quality. Negative friendship quality positively mediated the relationship between neuroticism and loneliness, and negatively mediated the consciousness-loneliness link. Friendship contact frequency negatively mediated the relationships between openness to experience, extraversion, and loneliness but positively mediated the relationship between consciousness and loneliness. These results provided insights that help us better comprehend the mechanisms leading to loneliness. Social intervention programs could be developed that tailor different personality traits and friendship dimensions to potentially reduce loneliness in later life.

THE EFFECT OF SUBJECTIVE AND OBJECTIVE RELATIONSHIPS ON THE LIFE SATISFACTION AND HEALTH OF OLDER ADULTS

Meeryoung Kim, *Daegu University, Daegu, Kyongsang-bukto, Republic of Korea*

This study examines the effects of subjective and objective relationships among older adults on life satisfaction. Human beings are social animals and must live in relationships with people. In particular, in a situation where social networks decrease in old age, objective or subjective social relationships that can receive help when needed, and satisfaction with such relationships can improve the quality of life in old age. This study used the sixth additional wave (2016) and the seventh wave (2017) of the Korean Retirement Income Study. The subjects of this study were older adults who are aged 65 and older, and the sample size was 3,423. The number of objective relationships, subjective social support, relational satisfaction, and having a spouse and children were used as independent variables. Life satisfaction and health were used as dependent variables. Demographic variables were controlled. Multiple regression was used for data analysis. The more objective relationships there were, the higher the life satisfaction and health. Subjective social support also significantly increased life satisfaction and health. Satisfaction with interpersonal relationships also significantly increased both life satisfaction and health. Having a spouse made a significant difference in affecting life satisfaction and health. The results showed that both subjective and objective relationships in old age improved the quality of life of older adults, but the presence or absence of children made no significant difference in affecting life satisfaction or health. This implies that as you get older, you may find that having a spouse becomes very important.

WITHIN- AND BETWEEN-PERSON EFFECTS OF HEALTH AND SOCIAL RELATIONSHIPS WITH FAMILY AND NEIGHBORS ON WELL-BEING

Midori Takayama[1], Yoshiko Ishioka[2], and Ikuko Sugawara[3], *1. Keio University, Yokohama, Kanagawa, Japan, 2. O.P. Jindal Global University, Sonipat, Haryana,* *India, 3. Bunri University of Hospitality, Suginami-ku, Tokyo, Japan*

Good health and positive social relationships are significant resources in well-being. However, little is known about how intrapersonal changes and interpersonal differences in health and social relationships are associated with well-being in later life. This study aimed to examine within- and between-person effects of physical health and social relationships with family, friends, and neighbors (social support and companionship) on well-being. We analyzed longitudinal data from a representative sample of older Japanese adults aged 74 to 86 years (N=1388). The results from multilevel models showed that decline in health (intrapersonal changes) was associated with lower well-being. Nevertheless, there was the interaction effect of social relationships with family and neighbors (between-person differences) in the relationship between health and well-being change. Among participants with lower social support from family and neighbors, the negative association between decline of health and well-being was stronger. Conversely, participants with higher social support reported higher well-being regardless of physical health change. Contrastingly, among participants with higher companionship with family and neighbors, participants reported higher well-being at the time of maintaining or increasing physical health. For participants with lower companionship, health change was not associated with well-being. These findings suggest social support has a preventive effect on well-being in the face of declining health, while companionship has a facilitative impact on well-being in good health. The results also suggest relationships with neighbors as well as family play an important role in well-being in very late life.

SESSION 6820 (POSTER)

SOCIAL ROLES, PHYSICAL FUNCTION, AND THE EXPERIENCE OF DEPRESSION

IMPACT OF BEHAVIORAL ACTIVATION ON COMORBID DEPRESSION AND TYPE 2 DIABETES IN LOW-INCOME ADULTS

Christopher Griffith, and Leilani Feliciano, *University of Colorado Colorado Springs, Colorado Springs, Colorado, United States*

Older age is a significant risk factor for type 2 diabetes mellitus (T2DM), and depression risk increases with comorbid illnesses such as T2DM. Older adults with depression have increased risk of developing somatic symptoms and decreased interest in activities, which impacts diabetes self-care. This makes depression an important target for treatment alongside T2DM. Behavioral activation (BA) is a therapeutic intervention shown to be effective in the treatment of moderate to severe depression. The current study examined the utility of brief BA treatment (once weekly for 4 weeks) across older adults aged 60-80, middle-aged adults aged 45-59, and younger adults aged 18-44. Fifty-six adults with diabetes participated in an in-home diabetes management program with BA to treat depression in low-income adults. Participants completed weekly measures of well-being and depressive symptoms. Two mixed-subjects analyses of variance (3 x 2 ANOVAs) found that BA was significantly effective at improving subjective well-being, $F(1, 53) = 38.24$, $p < .001$, $\eta p2 = .42$, and reducing depressive symptoms, $F(1, 38) = 27.25$, $p < .001$, $\eta p2 = .42$, but found no interaction effects between either age group and well-being or depressive symptoms ($p = .173$ and $.302$, respectively). Results indicate that BA is effective for treating depression in adults with comorbid T2DM regardless of age, making it a useful therapeutic tool for both the high number of older adults with T2DM and their younger counterparts. Further research should examine other outcomes (diabetes management) to evaluate the full extent of BA's effectiveness.

UNRAVELING THE AMBIGUITY BETWEEN COGNITION AND DEPRESSION: A LONGITUDINAL ANALYSIS OF OLDER ADULTS

Meghann Roessler[1], Mohit Manchella[2], Anmoldeep Singh[3], Max Coleman[4], Heather Francis[1], Andrew Saykin[5], Shannon Risacher[5], and Liana Apostolova[5], *1. Indiana University, Indianapolis, Indiana, United States, 2. University of Southern Indiana, Carmel, Indiana, United States, 3. Indiana University, Newburgh, Indiana, United States, 4. Indiana University, Bloomington, Indiana, United States, 5. Indiana University School of Medicine, Indianapolis, Indiana, United States*

Research on directionality of the relationship between cognitive functioning and depression is ambiguous, especially when considering implications for patients with mild cognitive impairment or Alzheimer disease (AD). Previous research suggests that depression in late life could be a preclinical manifestation of AD before other cognitive symptoms are detectable. Some research supports the hypothesis that level of depression can independently predict level of cognition. Other research suggests that depression is a risk factor for developing dementia or AD late in life. Further research on the impact of subjective cognitive decline versus objective cognitive performance in association with depressive symptoms is a critical area to explore. Using data from the Social Networks in Alzheimer Disease (SNAD) study and the Indiana Alzheimer Disease Research Center (IADRC), we conducted a preliminary longitudinal analysis of 196 focal subjects (Mage = 71.6 years, Pfemale = 63%). Interviews conducted one year apart were leveraged to elucidate the bi-directional relationship between depressive symptomology and cognition. Using a lagged dependent variable approach controlling for age, sex, race, and education, the results indicate that only executive function predicts depression at timepoint 2 (-0.31 SD, $p< 0.001$). However, depression predicts focal Cognitive Change Index (CCI) (0.06 SD, $p< 0.05$), processing speed (-0.04 SD, $p< 0.05$), and episodic memory (-0.04 SD, $p< 0.05$). Other cognitive domains examined, including attention, language, visual/spatial skills, MoCA score, and informant-rated CCI, were not significant as predictors or as outcomes. These results suggest that depression may be a more robust predictor of cognition than cognition is of depression.

DEPRESSION, DEPRESSIVE COGNITIONS, AND DEPRESSIVE SYMPTOMS IN CAREGIVING GRANDMOTHERS: A GROWTH CURVE MODEL

Christopher Burant[1], Carol Musil[2], Jaclene Zausniewski[2], and Alexandra Jeanblanc[2], *1. Case Western Reserve*

University, Parma, Ohio, United States, 2. Case Western Reserve University, Cleveland, Ohio, United States

Grandmothers caring for grandchildren have elevated levels of depressive symptoms compared to grandmothers who do not provide care. Depressive symptoms are state-like in nature and describe recent depressive symptoms. The Depressive Cognition Scale© captures changes in negative thinking patterns that often precede depressive symptoms. Depressive cognitions, according to Beck's theory of depression, are the first depressive symptoms to appear and typically lead to more serious symptoms of depression. Specifically, depressive cognitions reflect negative thinking patterns. Previously diagnosed depression may contribute to current levels of depressive cognitions and depressive symptoms. Data were collected on 342 participants in a longitudinal nationwide online research study of caregiving grandmothers. A latent growth curve model was used to track the trajectory of depressive symptoms at four time points (baseline, 2 weeks, 12 weeks, and 24 weeks). This latent growth curve model was tested to gain an understanding of how diagnosed depression and depressive cognitions impact the trajectory of depressive symptoms over time. The model fit the data well (Chi Square=24.301.; df=12; p=.019; TLI=.977; CFI=.987; RMSEA=.055). Baseline depressive cognitions strongly impacted the intercept (Standardized Beta=.65, p<.001) and the slope of depressive symptoms (Standardized Beta=-.65, p<.001), diagnosed depression predicted depressive cognitions (Standardized Beta =.32, p<.001) and the intercept of depressive symptoms (Standardized Beta=.36, p<.001). The continued impact of diagnosed depression and depressive cognitions over 24 weeks indicates the need for potential interventions to further address diagnosed depression and depressive cognitions as a way to decrease depressive symptoms in grandmother caregivers.

THE RELATIONSHIP BETWEEN EATING DIFFICULTY AND DEPRESSIVE SYMPTOMS: MODERATING EFFECTS OF EATING AND LIVING ALONE

Junyub Lim, Yeonsoo Shin, and Giyeon Kim, *Chung-Ang University, Seoul, Seoul-t'ukpyolsi, Republic of Korea*

Background and Objectives: Previous studies report that poor oral health reduces the opportunity for social interaction and increases the risk of psychological distress and that eating alone affects depressive symptoms and its connection differs by living arrangements. The present study aims to investigate the moderating effects of eating alone and living arrangements on the relationship between difficulty eating food due to poor oral health and depressive symptoms among Korean older adults.

Methods: Data were drawn from the 2020 Survey of Living Conditions and Welfare Needs of Korean Older Persons, a nationally representative survey. A total of 9,920 participants aged 65 years and older were included in analyses.

Results: Results from hierarchical regression analyses showed that difficulty eating food was positively correlated with depressive symptoms and eating alone did not moderate the relationship between difficulty eating food and depressive symptoms (b = 1.394, p < .001; b=-0.062, p > 0.05, respectively). However, the effects of eating alone significantly differed by living arrangements (b = 1.663, p < .05). In the case of older adults who live alone, eating alone significantly moderated the relationship between difficulty eating food and depressive symptoms, whereas for those living with others, eating alone did not moderate the relationship. Discussion: Social isolation can be a risk factor that worsens the mental health of older adults who have difficulty eating due to poor oral health. Practical implications for ways to reduce loneliness are discussed.

RELATIONSHIPS BETWEEN PHYSICAL/MENTAL MULTIMORBIDITY AND DEPRESSIVE SYMPTOMS AMONG OLDER BLACK AMERICANS

Seungjong Cho[1], and Tyrone Hamler[2], *1. Texas Tech University, Lubbock, Texas, United States, 2. Case Western Reserve University, Cleveland, Ohio, United States*

The purpose of this study was to identify the association between physical/mental health problems and depressive symptoms among older Black Americans (age ≥ 65) using the 2018 Health and Retirement Study (N = 812). People with multiple medical conditions face substantial emotional difficulties including depressive symptomatology. The study of depressive symptoms among older Black Americans is an emerging area of research. Several existing studies reported a higher prevalence of depressive symptoms among this population. They also experience a disproportionate burden of multimorbidity, both physically and mentally. For statistical analysis, depressive symptoms were measured with the eight-item CES-D scale (M = 1.514, SD = 1.916). Physical multimorbidity was measured by asking whether respondents had ever been diagnosed with seven diseases (high blood pressure, diabetes, cancer, lung disease, heart disease, stroke, and arthritis; M = 2.876, SD = 1.284). Mental multimorbidity was measured by asking whether they had ever been diagnosed with three diseases (clinical depression, Alzheimer's Disease, or other memory impairment including dementia; M = .228, SD = .467). Covariates included gender, marital status, and income (logged). A negative binomial regression showed that (a) higher numbers of physical health problems were associated with higher depressive symptoms (Incidence rate ratios [IRR] = 1.073, p = .048); (b) higher number of mental health problems were also related to higher depressive symptoms among older Black Americans (IRR = 2.077, p < .001). These findings underscore the importance of identifying and managing depressive symptoms among older Black Americans, who present with greater physical/mental health multimorbidity.

SESSION 6830 (POSTER)

STRESS, RESILIENCE, AND SUCCESSFUL AGING

AGING ACROSS THE LIFE COURSE: RESEARCH COLLECTIONS AVAILABLE FROM THE NATIONAL ARCHIVE OF COMPUTERIZED DATA ON AGING

James McNally, and Kathryn Lavender, *University of Michigan, Ann Arbor, Michigan, United States*

Creating and maintaining sustainable data archives can be challenging, but it offers clear advantages. Properly curated data can be used by multiple researchers, testing a variety of hypotheses and increasing the return on investment to the expensive data collection process. An internally managed archival system also provides greater control and autonomy in the equitable distribution of data resources. This process ensures all researchers will have full use of the data for original research, teaching, and new directions once the data leaves the control of the local investigator. This poster reviews the advantages of having a local strategy to preserve and share gerontological research data. Using the National Archive of Computerized Data on Aging (NACDA) as a working example, the poster offers an overview of collections at NACDA. Using our metadata tools and variable search database, NACDA can identify studies in its collections that examine aspects of aging and health among adults during their lifecourse. Many of the studies are longitudinal or repeat measure cross-sectional studies. We can also identify studies that focus on aging not maintained by NACDA are available to interested researchers. Using a strategy of archival preservation combined with a strong focus on productive research Innovation in Aging, NACDA has amassed data and metadata covering a wide array of studies worldwide that address the aging lifecourse. Because our collections are multinational, we share these data at no cost to interested users worldwide

THE MULTIDISCIPLINARY HISTORIES OF ACTIVE AGING IN POLAND

Jessica Robbins-Panko, *Wayne State University, Detroit, Michigan, United States*

In contemporary Poland, Universities of the Third Age are the most visible institutional forms of active aging. These lifelong-learning institutions that are specifically for retirees often cultivate ideals of independence through workshops and classes that teach new, and potentially transformative, skills and hobbies (Kobylarek, 2018). Universities of the Third Age in Poland emerged out of the fields of andragogy, pedagogy, and social work, fields that have regional intellectual roots in the late 19th/early 20th-century presocialist era, and are based on radically different ideals of personhood, relationality, and care than those of the contemporary postsocialist neoliberal era (Robbins, 2021). This paper analyzes 1) historical data from institutional archives of two Universities of the Third Age in Poland, and 2) secondary sources on histories of andragogy, pedagogy, and social work, to create a locally grounded intellectual history of active aging in central and eastern Europe. The Polish case offers an opportunity to think across divergent political-economic eras, in which assumptions about the value of a person to society have shifted. By tracing how the fields of andragogy, pedagogy, and social work have shaped active aging in Poland, this paper finds that 1) dichotomies of East/West, socialist/capitalist, and individual/collective are insufficient to explain the history of contemporary practices of active aging, and 2) intellectual history can reveal complex relations between political-economic change, and ideals and practices of aging. These findings have implications for advancing gerontological theories of 1) active aging in cross-cultural contexts, and 2) how active aging relates to sociopolitical change.

PSYCHOLOGICAL WELL-BEING IN OLDER ADULTS AFTER MULTIPLE SEVERE WEATHER EVENTS

Katie Cherry[1], Matthew Calamia[1], Emily Elliott[1], Luke Miller[1], Laura Sampson[2], and Sandro Galea[3], *1. Louisiana State University, Baton Rouge, Louisiana, United States, 2. Harvard T.H. Chan School of Public Health, Boston, Massachusetts, United States, 3. Boston University, Boston, Massachusetts, United States*

Catastrophic hurricanes and flooding threaten health and well-being, although the long-term consequences of these events for survivors are poorly understood. In 2005, Hurricane Katrina devastated the US Gulf Coast. Many lost homes in these storms and relocated permanently inland. In August of 2016, historic flooding in Baton Rouge, Louisiana devastated a 22-parish (county) region, resulting in widespread destruction and a second round of disaster-related losses for those who relocated to Baton Rouge after Katrina. The present research is part of a larger longitudinal study on health and well-being after multiple disasters. Cherry et al. (2021) reported that greater flood damage was associated with more symptoms of depression and post-traumatic stress during the Wave 1 immediate impact phase. Here we examined symptoms of depression, anxiety and post-traumatic stress at Wave 2, a follow-up assessment that occurred 9 (+/- 3) months after Wave 1 testing. Three flood exposure groups were compared: non-flooded (controls), single disaster (flooded in 2016) and double disaster (flooded in 2005 and again in 2016). Results indicated that symptoms of depression and post-traumatic stress, which were elevated at Wave 1 for the single and double disaster groups relative to the non-flooded controls, were reduced at Wave 2 and did not differ from the controls. Correlation analyses revealed that age was negatively associated with symptoms of post-traumatic stress, depression, and anxiety, consistent with the inoculation view of post disaster psychological reactions. Implications of these data for understanding older adults' psychological health after multiple disaster exposures are discussed.

CHALLENGES AND REWARDS EXPERIENCED IN THE VERY OLD PARENT-CHILD RELATIONSHIP: RELATIONSHIP QUALITY MATTERS

Kathrin Boerner[1], Kyungmin Kim[2], Yijung Kim[3], Elizabeth Gallagher[1], and Daniela Jopp[4], *1. University of Massachusetts Boston, Boston, Massachusetts, United States, 2. Seoul National University, Seoul, Seoul-t'ukpyolsi, Republic of Korea,*

3. The University of Texas at Austin, Austin, Texas, United States, 4. University of Lausanne, Lausanne, Vaud, Switzerland

Very old parents and their "old" children are a growing group in industrialized countries worldwide. However, little is known about the nature and implications of this relationship constellation, especially the challenges and/or rewards experienced within the relationship. We therefore examined factors associated with perceptions of challenge and reward among very old parents and their children. Using data from 114 very old parent-child dyads in the Boston Aging Together Study, we estimated Actor-Partner Interdependence Models to predict challenge, reward, and challenge/reward ratio outcomes of dyad members as a function of relationship quality, support exchanges, family norms, and personality. Relationship quality emerged as the most influential predictor, albeit more consistently for children than for parents. When children experienced the parent-child relationship as more positive, both children and parents experienced fewer challenges and more rewards (i.e., both actor and partner effect). Parents' experience of relationship quality was only associated with their own challenge perceptions (i.e., actor effect only). The roles of support exchanges, family norms, and personality were relatively minor, with few significant effects if at all. Given the importance of relationship quality for challenge and reward perceptions, support services or interventions targeting relationship quality could be a key pathway to minimizing challenges and maximizing rewards among very old parents and their children. Focusing on relationship perceptions of the child may be particularly critical in improving the experiences of both parent and child.

LIVING WITH END-STAGE LIVER DISEASE: PERSPECTIVES OF YOUNGER AND OLDER PATIENT–CARE PARTNER DYADS

Lissi Hansen, Susan Rosenkranz, and Shirin Hiatt, *Oregon Health & Science University, Portland, Oregon, United States*

The uncertain trajectory of end-stage liver disease (ESLD) leaves patients and their informal care-partners to face psychological, physical, social, and financial burdens, complicating their relationship. Knowledge is lacking on how living with ESLD affects patients and informal care-partners. The study purpose was to compare how ESLD affects relationships between younger and older patient-care-partner dyads. Patients with ESLD and informal care-partners were recruited through liver clinics at two hospital settings. They completed questionnaires including two open-ended questions about how ESLD affected their relationship (R01NR016017, NINR/NIH). Patient eligibility criteria: age >21 and MELD-Na score >15. Care-partner eligibility criteria: age ≥18 and identified as patient's primary support. Conventional content and qualitative dyadic analysis were used to analyze written responses to the two questions. Data were available for 140 patient-care-partner dyads. Patients averaged 57 years old (range, 23-83 years; 69% were male; 31% with ETOH as primary etiology). Care partners averaged 57.5 years old (range, 19-85 years; 74% were female). Older dyads were more likely to report having a closer relationship, although tempered by uncertainty and symptoms limiting activities. Younger dyads emphasized managing symptoms, financial stress, caregiving burden, and lack of intimacy among spousal/partners. Diverging and overlapping themes within dyads reflected caregiving challenges, relationship strain, and support from other relationships. Clinicians should provide information and identify helpful resources that support the patient-care-partner dyad and their ability to manage ESLD. Future longitudinal dyadic studies should examine the patient-care-partner relationship at different points in the disease progression to develop interventions that help living with ESLD.

CHANGE IN OLDER ADULTS' SELF-EFFICACY TO HANDLE DISASTERS AFTER A PREPAREDNESS PROGRAM: ROLE OF SOCIAL NETWORKS

Saida Jaboob[1], Lena Thompson[2], Abinaya Ilavarasan[2], and Sato Ashida[3], *1. University of Iowa, Coralville, Iowa, United States, 2. University of Iowa, Iowa City, Iowa, United States, 3. University of Iowa College of Public Health, Iowa City, Iowa, United States*

Social support networks provide a context within which older adults maintain their safety and well-being. Preparing for disasters and emergency situations can help older adults stay safe independent after a disaster. Self-efficacy to prepare for and handle disaster situations can influence how older adults proactively prepare and protect themselves. Fifty-four older adults 61 to 92 years of age in Eastern Iowa were interviewed before and after participating in an intervention program that helped them develop personalized disaster management plans. Participants reported seven support network members on average, ranging from one to 23. About one-third of the network members were participants' children and grandchildren, 11% were their siblings and parents, and 58% were non-family members such as friends and neighbors. Out of 549 network members identified, 245 were selected as someone participants can depend on during emergency situations; 47% were family whereas 43% were non-family members. Participants who reported higher numbers of network members whom they can depend on in emergency situations at baseline showed more increase in self-efficacy to manage disasters one-month after receiving the intervention (p=0.02). Having social support network members whom older adults feel they can turn to during emergency situations may help boost their confidence in handling and preparing for disasters through participating in a disaster preparedness program. Participants indeed identified additional members whom they could depend on in disaster situations after the intervention. Future studies may test strategies to enhance social support networks to increase confidence among older adults to prepare for and handle disasters.

MORTALITY RISK BY STATE-LEVEL POVERTY IN COLOMBIA AT DIFFERENT AGE GROUPS

Margarita Osuna[1], Eileen Crimmins[2], and Jennifer Ailshire[2], *1. University of Southern California Leonard Davis School of Gerontology, Santa Clarita, California, United States, 2. University of Southern California, Los Angeles, California, United States*

Residence in high poverty states has been associated with increased mortality risk in the United States, but less attention has been paid to the relationship between state-level poverty and mortality in younger to older adults in Latin America. Poorer states in Colombia, one of the most populous and rapidly aging countries in Latin America, tend to report less access to healthcare, education, and economic opportunities. We examine the relationship between mortality and state-level poverty in Colombia by age and gender. We use data from the 2018 Colombian Census and Vital Statistics to calculate mortality levels and male-female ratios in mortality separately for three broad age categories: young (ages 20-39), middle-aged (40-69), and older adults (70 or older). We find an association between high poverty and high mortality risk among younger men, no association for middle-aged men, and a negative association between mortality risk and poverty among older men. We did not find any evidence for an association between state-level poverty and mortality at any ages. Our results highlight that, for men at older ages, poverty had a counterintuitive association with mortality. These results may be due to selective survival older ages in Colombia or to older adults who are aging into a social safety net that includes healthcare and income benefits.

Future research should investigate the impact that unequal access to economic resources and distribution of health care resources has on women and men across age groups in Colombia.

CROSS-NATIONAL COMPARISONS OF STRESS AND WELL-BEING IN THE INTERNATIONAL FAMILY OF HEALTH AND RETIREMENT STUDIES

Yoobin Park[1], Alexandra Crosswell[1], and Drystan Phillips[2], *1. University of California, San Francisco, San Francisco, California, United States, 2. University of Southern California, Los Angeles, California, United States*

Strong evidence demonstrates the long-term influence of stress and well-being on psychological, social, and physical health outcomes across the lifespan. Because of this, stress and well-being measures have been added to nearly all of the International Family of Health and Retirement Studies. However, this newly available data has not been compared cross-nationally or within-country to unpack how culture influences these important predictors of healthy aging. Using the Gateway to Global Aging Data, which provides harmonized data from the Health and Retirement Study and its sibling nationally representative studies, levels of self-reported stress (e.g. job stress, discrimination, loneliness) and well-being (e.g. quality of life, life satisfaction) are compared across 30 countries. Data come from the following studies: HRS, ELSA, SHARE, TILDA, CHARLS, KLoSA, MHAS, and JSTAR. We used data from the latest study wave for which the relevant survey was implemented. Average age of participants across studies is 67 and 55% are women. Initial analyses show stressor specific findings such as participants in Korea reported greater work stress than participants in Japan, England, the United States, and across Europe, and the United States reported higher loneliness than China and England, but not higher than Ireland. Reporting cross-national and within-country variation in these measures will be generative in pointing to new research directions for understanding how culture influences health and aging trajectories.

YOUNGER AND OLDER ADULTS PERCEPTIONS OF STRESSORS AFTER A FLOOD

Katie Cherry[1], Marlene Friis[2], Piper Bordes[1], Matthew Calamia[1], and Emily Elliott[1], *1. Louisiana State University, Baton Rouge, Louisiana, United States, 2. Tulane University School of Medicine, New Orleans, Louisiana, United States*

In August of 2016, historic flooding in Baton Rouge, Louisiana resulted in catastrophic damages and claimed 13 lives. This study is part of a larger research program on post-flood health and well-being across the adult lifespan. Participants (n=223, age range: 18-88 years) were tested during the immediate impact phase (Wave 1) and most participated in a follow-up assessment 9 (+/- 3) months later (Wave 2). In this study, we compared participants' narrative responses to an open-ended question at Wave 2 concerning the most stressful aspect of the 2016 flood. We hypothesized that older flood survivors would report stressors related to rebuilding and financial loss more often than younger survivors based on the Conservation of Resources theory (Hobfoll, 1989). Three groups were compared: non-flooded (controls), single disaster (flooded in 2016) and double disaster (flooded in 2005 and again in 2016). To create younger and older comparison groups, age was split at the median with sample sizes that ranged from 28 to 34 younger and older participants within each flood exposure group. Content analyses of responses by independent coders blind to the purpose of the study revealed that older flood victims reported greater stressors related to rebuilding flood-damaged homes and financial stressors than did their younger counterparts. In contrast, younger flood victims were more likely to report childcare issues and being displaced from their homes as stressors compared to the older victims. Implications of these data for understanding age-related vulnerabilities after severe weather events are discussed.

SESSION 6840 (POSTER)

INTERVENTIONS (BS)

UROLITHIN A: GUT-BRAIN DIETARY INTERVENTION IN PARKINSON'S DISEASE

Jenny Hong Yu Ng, and Julie Andersen, *Buck Institute for Research on Aging, Novato, California, United States*

Gastrointestinal dysfunction is amongst the most common prodromal symptoms of Parkinson's disease (PD). Pathological alpha-synuclein has been detected in the intestines prior to disease onset, and a leaky gut is also implicated in its etiology. Thus, we hypothesized that modulation of the gut microbiome and intestinal immune milieu via early dietary intervention may act to mitigate PD pathogenesis. Urolithin A (UA) is a gut metabolite shown to ameliorate geriatric diseases by increasing mitophagy and dampening inflammation. The aim of our study is to elucidate its mechanism of action and therapeutic efficacy in PD, which to date is unclear. Preliminary flow cytometric data demonstrates that administration of a UA-diet significantly increased the proportion of colonic gamma-delta ($\gamma\delta$) T cells in nine-month-old Thy-1 α-syn mice, which are downregulated relative to non-transgenics on a non-UA control diet. PD patients have been reported to have higher levels of $\gamma\delta$ T cells in their cerebrospinal fluid and, while little is known about colonic $\gamma\delta$ Ts in the context of PD, these cells are anti-inflammatory and responsible for intestinal repair in several colitis models. Our data suggests a retention of lymphocytes involved in the targeted migration from the gut to the brain, which may contribute to gut epithelial integrity. Proportion of induced regulatory T cells in peripheral blood, which are critical for immune tolerance, also increased significantly with a UA-diet. In addition, UA-fed mice showed a slight improvement in novel object recognition. Additional analyses are underway to comprehensively evaluate the impact of UA on PD pathology.

COMBINING SCLEROSTIN AND DKK1 INHIBITORS TO IMPROVE BONE PROPERTIES IN THE AGED SKELETON

Roy Choi, and Alexander Robling, *Indiana University School of Medicine, Indianapolis, Indiana, United States*

Targeting the secreted Wnt inhibitor sclerostin has been an attractive strategy to improve skeletal health. Sclerostin antibody (romosozumab-aqqg; Evenity) was recently approved by the FDA to treat patients at increased risk of fracture. However, an increased risk of cardiovascular events was reported, resulting in issue a ‘black box warning’ requirement for romosozumab. One potential solution to lower the risk of adverse events is to reduce the medication dose. Previously, we found that dual inhibition of sclerostin and Dkk1 produced extremely potent synergistic bone anabolic effects, in both genetic and pharmacological models. While Dkk1 inhibition alone has no consistent bone-building effects, combining antibodies that target sclerostin (Scl-mAb) and Dkk1 (Dkk1-mAb) at 3:1 ratio resulted in 2-3X more bone gain as Scl-mAb alone. Further, much lower total doses of dual antibody treatment, given at optimized proportions, generated equivalent bone anabolic effects as Scl-mAb alone (at much higher doses), suggesting that a combinational strategy has obvious translational benefits. Finally, we tested whether low-dose combination therapy can maintain the same osteogenic effect as Scl-mAb in adult (6 month) and aged (20 month) mice. Outcome measures derived from radiographic, biomechanical, and histomorphometric assays revealed that a 3:1 ratio of Scl-mAb:Dkk1-mAb at 12.5mg/kg was as efficacious as 25mg/kg of Scl-mAb alone, in both age groups. Moreover, cortical porosity—a significant factor contributing to skeletal fragility in the aged skeleton—was significantly reduced by both Scl-mAb and low-dose combination treatment. In conclusion, our findings suggest that optimized low-dose combinational therapy is viable strategy for improving skeletal fragility.

ORALLY ACTIVE, CLINICALLY TRANSLATABLE SENOLYTICS RESTORE Α-KLOTHO IN MICE AND HUMANS

Yi Zhu[1], Larissa Langhi Prata[1], Erin Wissler Gerdes[1], Jair Netto[1], Tamar Pirtskhalava[1], Nino Giorgadze[2], Utkarsh Tripathi[1], and Christina Inman[1], *1. Mayo Clinic, Rochester, Minnesota, United States, 2. May Clinic, Rochester, Minnesota, United States*

Decreased α-Klotho, a geroprotective factor, and increased senescent cell burden are both associated with early onset of physical disability, cognitive impairment, and premature all-cause mortality. It has been demonstrated that eliminating senescent cells can enhance physical function, cognition, and survival in mice, as does overexpressing α-Klotho. Mice with low α-Klotho exhibit accelerated senescent cell accumulation, recombinant α-Klotho decreases senescent cell burden and restores lifespan in these mice, and senescent epidermal cells are reduced in mice overexpressing α-Klotho. Here, we tested the hypothesis that senescent cells cause decreased α-Klotho and hence that reducing senescent cells can increase α-Klotho. Senescent cell conditioned medium (CM) reduced α-Klotho in cultured non-senescent human umbilical vein endothelial cells (HUVECs), renal tubular endothelial cells, and astrocytes. These effects of senescent CM were partially attenuated by neutralizing antibodies against the senescence-associated secretory phenotype (SASP) factors, activin A and IL-1α. Transplanting senescent cells into younger mice caused decreased urine and brain α-Klotho. Genetically reducing highly p16Ink4a-expressing cells in old INK-ATTAC mice or administering the senolytics, Dasatinib plus Quercetin (D+Q) or Fisetin (F), to young mice transplanted with senescent cells, young diet-induced obese (DIO) mice, or naturally-aged mice increased urine, kidney, and/or brain α-Klotho. Treating patients with idiopathic pulmonary fibrosis (IPF), a cellular senescence-related disease, with D+Q led to increased urinary α-Klotho. Thus, targeting senescent cells causes increases in the geroprotective factor α-Klotho, potentially amplifying the beneficial effects of senolytic drugs.

OXR1 STABILIZES THE RETROMER TO EXTEND LIFESPAN AND NEURONAL HEALTH BY DIETARY RESTRICTION

Kenneth Wilson[1], Sudipta Bar[1], Eric Dammer[2], Birgit Schilling[1], Nicholas Seyfried[2], Hugo Bellen[3], Lisa Ellerby[1], and Pankaj Kapahi[1], *1. Buck Institute for Research on Aging, Novato, California, United States, 2. Emory University School of Medicine, Atlanta, Georgia, United States, 3. Baylor College of Medicine, Houston, Texas, United States*

Dietary restriction (DR) delays aging and neurodegeneration, but the mechanisms behind this remain unclear. We reared over 150 fully sequenced fly strains from the Drosophila Genetic Reference Panel under ad libitum feeding or diet-restricted conditions and measured lifespan as well as healthspan to identify new targets for DR-mediated longevity. Through genome-wide association study, we identified genetic variants associated with influencing these traits under each dietary condition. A variant in mustard (mtd, called Oxidation resistance 1, OXR1, in humans), significantly associated with DR-specific lifespan. We demonstrate that mtd/OXR1 in neurons is necessary for DR-mediated lifespan extension. Neuronal knockdown of mtd also accelerates sensory decline, arguing for a specific role of mtd/OXR1 in neuroprotection. We show that mtd is essential for stabilizing the retromer complex, which is necessary for trafficking transmembrane proteins and lipids for reuse. As a result of OXR1 deficiency, the retromer destabilizes and lysosomes become overused. Overexpression of retromer proteins or supplementation with chaperone compound R55 rescues the lifespan defects and neurodegeneration seen in mtd-deficient flies, and R55 is capable of rescuing lysosomal aggregation and OXR1-retromer co-localization in cells from humans with OXR1 deficiency. We further show through multi-omic analyses in flies and humans that mtd/OXR1 associates with accelerated transcriptomic aging and proteins involved in neurodegenerative diseases, including Alzheimer's disease (AD). Overexpression of OXR1 and retromer proteins rescued AD-associated phenotypes in a fly model of AD. Thus, mtd/OXR1 enhances protein recycling in response to DR through the retromer, improving neuronal health and lifespan through mechanisms conserved across species.

EXTENDING A HEALTHY LIFESPAN WITH 3-HYDROXYANTHRANILIC ACID

George Sutphin[1], Hope Dang[1], Raul Castro-Portuguez[1], Luis Espejo[1], Sam Freitas[1], and Jeremy Meyers[2], *1. University of Arizona, Tucson, Arizona, United States, 2. University of Washington, Tucson, Arizona, United States*

Metabolism of tryptophan by the kynurenine pathway is increasingly linked to aging. Kynurenine pathway enzymes and metabolites influence a range of molecular processes critical to healthy aging, including regulation of inflammatory and immune responses, cellular redox homeostasis, and energy production. Aberrant kynurenine metabolism occurs during normal aging and is implicated in many age-associated pathologies including chronic inflammation, atherosclerosis, neurodegeneration, and cancer. We and others previously identified three kynurenine pathway genes—kynu-1, tdo-2, and acsd-1—for which decreasing expression extends lifespan in invertebrates. More recently we discovered that knockdown of haao-1, a fourth kynurenine pathway gene encoding the enzyme 3-hydroxyanthranilic acid dioxygenase (HAAO), extends lifespan by ~30% and delays age-associated health decline in Caenorhabditis elegans. Lifespan extension is mediated by increased physiological levels of the HAAO substrate 3-hydroxyanthranilic acid (3HAA). Aging mice fed a diet supplemented with 3HAA are similarly long-lived. The mechanism of action liking 3HAA to aging is complex and partially overlaps with multiple pathways previously implicated in aging. We recently identified activation of the Nrf2/SKN-1 oxidative stress response and alterations to iron homeostasis as key players in the benefits 3HAA. Ongoing work explores the relationship between 3HAA, Nrf2/SKN-1, and iron in C. elegans and mammalian aging, age-associated immune decline, and cancer. This works provides a foundation for detailed examination of the molecular mechanisms underlying the benefits of 3HAA, and how these mechanisms interact with other anti-aging interventions. We anticipate that these findings will bolster growing interest in developing pharmacological strategies to target tryptophan metabolism to improve health aging.

LEVERAGING THE NDUFS4-/- MOUSE AS A PLATFORM FOR TESTING LONGEVITY INTERVENTIONS

Alessandro Bitto, Cara Tobey, Ayush Sharma, Anthony Grillo, and Matt Kaeberlein, *University of Washington, Seattle, Washington, United States*

Mitochondrial dysfunction is one of the hallmarks of biological aging, as well as the driving factor for mitochondrial diseases. Up to 30% of mitochondrial disorders are due to mutations affecting the activity of Complex I in the electron transport chain. Loss of the Complex I subunit Ndufs4 recapitulates symptoms of Leigh Syndrome, a pediatric mitochondrial disease, in mouse. Ndufs4-/- mice suffer developmental delays, early onset of neurological symptoms and extremely reduced lifespan. Several studies have now shown that Ndufs4-/- mice are exquisitely responsive to treatments and interventions of interest in the biology of aging, such as rapamycin, NAD+ precursors, reduced oxygen tension, alpha-keto-glutarate precursors, and the antidiabetic drug acarbose. These results point to common mechanisms underlying both aging and mitochondrial disorders. To put this hypothesis to the test, we show that Ndufs4-/- mice are responsive to a wide range of longevity interventions previously tested in worms, mice, and by the National Institute on Aging's Intervention Testing Program. These observations support the hypothesis that mitochondrial and metabolic dysfunction induced by Complex I deficiency may be a key component of biological aging as well as mitochondrial disease. Furthermore, we propose that the Ndufs4-/- mice provide an affordable testing ground for candidate longevity interventions.

DELETION OF THROMBOSPONDIN-1 PRESERVES HEMATOPOIETIC STEM CELL HEALTHSPAN DURING AGING

Pradeep Ramalingam[1], Michael Gutkin[2], Michael Poulos[2], and Jason Butler[2], *1. University of Florida, Gainesville, Florida, United States, 2. Hackensack University Medical Center, Nutley, New Jersey, United States*

Aging is associated with defects within blood stem cells, termed hematopoietic stem cells (HSC), including a loss of their self-renewal potential and a skewed differentiation towards myeloid lineages at the expense of lymphoid cells. Collectively, these HSC defects manifest as anemias, poor response to vaccines and an increased incidence of myeloid neoplasms in older adults. Unlike other somatic stem cells, aged HSCs have been shown to be refractory towards established anti-aging interventions including caloric restriction, exercise, parabiosis and plasma transfer. Thrombospondin-1 (TSP1) was initially discovered as an anti-angiogenic molecule, and recent studies have identified that TSP1 promotes age-related pathologies including chronic inflammation, reactive oxygen species (ROS) generation, and mitochondrial dysfunction. Notably, each of these TSP-1 regulated processes have been shown to critically influence HSC biology, particularly in the context of aging. However, whether TSP-1 directly regulates HSC activity remains unexplored. Here, we sought to determine whether TSP-1 is essential for HSC development, and whether blocking TSP1 signaling could ameliorate age-related HSC defects. Utilizing murine models, we demonstrate that TSP-1 is dispensable for normal HSC development and hematopoiesis. We show that deletion of TSP-1 is sufficient to preserve HSC fitness during aging, as evidenced by preservation of youthful self-renewal potential and balanced lineage reconstitution during serial HSC transplantation assays. Mechanistically, we identify that TSP-1 adversely impacts mitochondrial metabolism within HSCs, and show that loss of TSP-1 prevents the age-related decline in HSC mitochondrial membrane potential. Our findings identify TSP-1 as a pro-geronic factor that can be targeted to preserve HSC healthspan.

A FAT-PROMOTING BOTANICAL EXTRACT ARTEMISIA SCOPARIA EXERTS GEROPROTECTION IN C. ELEGANS

Bhaswati Ghosh[1], Hayden Guidry[2], Maxwell Johnston[1], and Adam Bohnert[1], *1. Louisiana State University, BATON ROUGE, Louisiana, United States, 2. Louisiana State University, Baton Rouge, Louisiana, United States*

Like other biological processes, aging is not random but subject to molecular control. Natural products that modify core metabolic parameters, including fat content, may provide entry points to extend animal lifespan and promote healthy aging. Here, we show that a botanical extract from Artemisia scoparia (SCO), which promotes fat storage and metabolic resiliency in mice, extends the lifespan of the nematode Caenorhabditis elegans by up to 40%. Notably, this lifespan extension depends significantly on SCO's effects on fat; SCO-treated worms exhibit heightened levels of unsaturated fat, and inhibiting Δ9 desaturases, which oversee biosynthesis of monounsaturated fatty acids, prevents SCO-dependent fat accumulation and lifespan extension. At an upstream signaling level, SCO prompts changes to C. elegans fat regulation by stimulating nuclear translocation of transcription factor DAF-16/FOXO, an event that requires AMP-activated protein kinase under this condition. Importantly, animals treated with SCO are not only long lived but also show improved stress resistance in late adulthood, suggesting that this fat-promoting intervention may enhance some aspects of physiological health in older age. These findings identify SCO as a natural product that can modify fat regulation for longevity benefit and add to growing evidence indicating that elevated fat can be pro-longevity in some circumstances.

FUCOIDANS ARE NOVEL SENOTHERAPEUTICS THAT ENHANCE SIRT6 AND DNA REPAIR ACTIVITY

Lei Zhang[1], Brian Hughes[2], Gregory Tombline[3], Luise Angelini[2], Matt Yousefzadeh[2], Vera Gorbunova[3], Laura Niedernhofer[2], and Paul Robbins[2], *1. University of Minnesota, Saint Paul, Minnesota, United States, 2. University of Minnesota, Minneapolis, Minnesota, United States, 3. University of Rochester, Rochester, New York, United States*

With age, senescent cells accumulate in various tissues where they contribute to loss of tissue homeostasis, aging, and age-related diseases through their inflammatory senescence-associated secretory phenotypes (SASPs). Senotherapeutics able to selectively eliminate senescent cells, termed senolytics, or suppress the detrimental SASPs, termed senomorphics, have been demonstrated to improve age-associated comorbidities and aging phenotypes. To discover novel senotherapeutics translatable to promote healthy longevity, we conducted a drug screening of diverse natural products based on the characteristic senescence-associated β-galactosidase activity. Several fucoidans from different brown seaweed were found to exhibit potent senotherapeutic activity. Fucoidans are long-chain sulfated polysaccharides found in various species of brown algae including seaweed. The best senomorphic fucoidan was able to suppress senescence in cultured senescent fibroblasts, in ex vivo human tissue explants, and in vivo in mouse models of natural and accelerated aging. Specifically, fucoidan reduced markers of cellular senescence and SASP in senescent mouse and human cells. Acute treatment of the fucoidan in naturally aged mice reduced tissue senescence, especially in the kidney and lung. Chronic treatment of the fucoidan in Ercc1-/Δ progeria mice attenuated composite aging symptoms and extended healthspan. Interestingly, preliminary mechanistic studies demonstrated that fucoidan can improve non-homologous end-joining-directed DNA damage repair and increase the mono-ADP-ribosylation activity of SIRT6, suggesting a relationship between cellular senescence, DNA repair, and SIRT6 signaling pathways. Collectively, fucoidans were identified as novel senotherapeutics with translational potential for reducing cellular senescence, ameliorating age-associated phenotypes, and extending healthspan as well as able improve DNA repair pathways through modulation of SIRT6 activity.

EFFECT OF L-VALINE TREATMENT ON SIRTUIN (SIRT1 AND SIRT2) ISOFORMS

Shakshi Sharma, Xiaomin Zhang, Gohar Azhar, and Jeanne Wei, *University of Arkansas for Medical Sciences (UAMS), Little Rock, Arkansas, United States*

L-valine is one of the essential branched-chain amino acids (BCAAs) required for synthesis of proteins in human body. It promotes muscle growth and tissue repair and is important for immune function. Recent data indicate that BCAAs can activate sirtuins expression and elevate mitochondrial biogenesis and fatty acid oxidation in both adipocytes and myotubes thereby increasing life span. Sirtuins are a conserved family of proteins, play a critical role in maintaining metabolic health by deacetylating many target proteins in numerous tissues, and regulate mitochondrial function and the aging process. Due to multiple effect of sirtuins on aging, we sought to determine whether the addition of valine might enhance sirtuin gene expression. We utilized the C2C12 skeletal muscle cell line grown on physiological normal glucose (100mg/dL) media. The cells were treated with two different concentrations of valine (0.5 and 1.0mM) for different time intervals (18 and 24). Gene expression of sirtuin 1 (SIRT1) and sirtuin 2 (SIRT2) isoforms were determined by RT-PCR. The results showed increased expression of the sirtuin gene isoforms after treatment with valine. Relative expression varies with in different isoforms of SIRT1 (v1 and v2) and SIRT2 (v1, v2 and v3). Among all, SIRT1 v1 and SIRT2 v1 showed maximum expression as compared to the other isoforms used in the study. Our study showed that adequate supplementation of L-valine enhanced sirtuin gene expression, which may promote healthy muscles and healthy aging.

LOSS OF HYPOXIA SIGNALING IMPAIRS RESPONSE TO AEROBIC EXERCISE IN AGED MICE

Indranil Sinha[1], Yori Endo[2], and Mehran Karvar[1], *1. Brigham and Women's Hospital, Boston, Massachusetts, United States, 2. Harvard Medical School, Boston, Massachusetts, United States*

To assess the differential effects of exercise with age, Young (Y, 10-12 weeks) and Old (O, 23-25 months) mice were subjected to regimented treadmill running or no regimented exercise. Y, trained mice experienced a significant increase in maximal distance running, maximal speed of running, and lean muscle mass in comparison to age-matched, untrained controls. O mice did not improve significantly in any of these measures following training. Transcriptome analysis of gastrocnemius from Y mice demonstrated differential regulation of 120 genes with exercise. None of these genes were similarly regulated in the O group. Genes most upregulated following exercise in Y mice were direct targets of the hypoxia signaling pathway. Immunoblotting demonstrated that aryl hydrocarbon receptor nuclear translocator (ARNT), a critical regulator of hypoxia signaling, increased 3-fold with exercise in Y mice, but this increase was absent in O mice following exercise. To assess whether this loss of ARNT in O muscle impaired the exercise response, we generated a mouse with inducible, skeletal muscle-specific knockout of ARNT (ARNT muscle (m) KO). Following regimented exercise, ARNT mKO mice did not improve maximal distance running, maximal running speed, or lean muscle mass in comparison to untrained ARNT mKO mice. Littermate, age-matched ARNT wild type mice increased significantly in all of these measures following training. Administration of ML228, an ARNT agonist, increased maximal running distance and speed in response to exercise training in O mice. These results suggest that restoration of ARNT and hypoxia signaling may restore the physiologic response to exercise in aging.

LATE BREAKING ABSTRACTS

SESSION 1470 (BIOLOGICAL SCIENCES INVITED SYMPOSIUM)

LATE BREAKING SESSION: BIOLOGICAL SCIENCE PROGRAM

Chair: Viviana Perez

ALTERED SUPER ENHANCER – PROMOTER INTERACTIONS MEDIATED BY YY1 UNDERLIE AGE-INDUCED TRANSCRIPTOME

Weiwei Dang, Luyang Sun, and Brenna McCauley, *Baylor College of Medicine, Houston, Texas, United States*

Significant changes in transcriptome during aging have been observed in various tissues and cell types, even at the single-cell level. However, the molecular mechanisms that underlie these changes remain poorly understood. Using an ex vivo mesenchymal stem cells (MSC) replicative aging model and Hi-C technology, we discovered that, rather than large-scale changes in chromosome conformation, alterations to super enhancer – promoter looping interactions had the best positive correlation with age-associated transcriptome. Furthermore, we found evidence that these age-induced transcriptomic changes are mediated by YY1, a key regulator of promoter-enhancer looping. This work, for the first time, unveiled a molecular mechanism elucidating the changes in transcription during aging.

INTERMITTENT KETOGENIC DIETS EXTEND LIFESPAN AND ATTENUATE INFLAMMAGING IN MALE MICE

Zeyu Zhou, Kyoungmi Kim, Jon Ramsey, and Jennifer Rutkowsky, *University of California, Davis, Davis, California, United States*

A ketogenic diet (KD) has been shown to increase functional lifespan in male mice when fed isocalorically to a control diet (CD). However, it is not clear if intermittent ketogenic diets (IKD) that induce brief and recurring periods of ketosis would be as effective at prolonging lifespan. In the present study, 12-month-old C57BL/6JN male mice were fed an intermittent single day KD (KD fed on Mon, Wed and Fri each week, IK1) or 2-day KD (KD fed on 2 consecutive days each week, IK2). These two IKD regimes were selected to mimic the widely used alternate-day or 5:2 intermittent fasting approaches, without the caloric deficit. Our results showed that lifespan was significantly increased in both IK1 and IK2 groups, with IK1 showing a 13.6% and IK2 showing a 7.9% increase in median lifespan compared to the CD ($p < 0.01$). At 27 months of age, levels of circulating proinflammatory cytokines were significantly decreased in IK1 and IK2 mice compared to control mice. Also, levels of proinflammatory cytokines were significantly elevated in 27-month-old control mice compared to 12-month-old mice, while levels in IK1 and IK2 mice were not significantly altered with aging, and these effects were still persistent during days the animals were fed the CD. Unlike the continuous KD, health span measures were not altered in IK1 or IK2 mice at 26 months of age. In summary, IKDs that produce shorts episodes of ketosis can be effective at extending longevity in mice, possibly by attenuating systemic inflammation with aging.

SINGLE-CELL ANALYSIS OF SKELETAL MUSCLE MACROPHAGES REVEALS AGE-ASSOCIATED FUNCTIONAL SUBPOPULATIONS

Chang-Yi Cui, Linda Krasniewski, Papiya Chakraborty, Krystyna Mazan-Mamczarz, Luigi Ferrucci, and Myriam Gorospe, *National Institute on Aging, Baltimore, Maryland, United States*

Tissue-resident macrophages represent a group of highly responsive innate immune cells that acquire diverse functions by polarizing towards distinct subpopulations. The subpopulations of macrophages that reside in skeletal muscle (SKM) and their changes during aging are poorly characterized. By single-cell transcriptomic analysis with unsupervised clustering, we found eleven distinct macrophage clusters in male mouse SKM with enriched gene expression programs linked to reparative, proinflammatory, phagocytotic, proliferative, and senescence-associated functions. Using a complementary classification, membrane markers LYVE1 and MHCII identified four macrophage subgroups: LYVE1-/MHCIIhi (M1-like, classically activated), LYVE1+/MHCIIlo (M2-like, alternatively activated), and two new subgroups, LYVE1+/MHCIIhi and LYVE1-/MHCIIlo. Notably, one new subgroup, LYVE1+/MHCIIhi, had traits of both M2 and M1 macrophages, while the other new subgroup, LYVE1-/MHCIIlo, displayed strong phagocytotic capacity. Flow cytometric analysis validated the presence of the four macrophage subgroups in SKM, and found that LYVE1- macrophages were more abundant than LYVE1+ macrophages in old SKM. A striking increase in proinflammatory markers (S100a8 and S100a9 mRNAs) and senescence-related markers (Gpnmb and Spp1 mRNAs) was evident in macrophage clusters from older mice. In sum, we have identified dynamically polarized SKM macrophages and propose that specific macrophage subpopulations contribute to the proinflammatory and senescent traits of old SKM.

REGENERATION OF AGING LUNG TISSUE: A NOVEL WAY OF REOPENING THE PLASTICITY WINDOW OF POSTNATAL ALVEOLAR TYPE II CELLS

Hannah Hausman,[1] Hannah Golding,[2] Amitoj Sawhney,[3] and Douglas Brownfield[3], *1. St. Catherine University, St. Paul, Minnesota, United States, 2. University of Colorado Boulder, Boulder, Colorado, United States, 3. Mayo Clinic, Rochester, Minnesota, United States*

Prevalence of chronic lung diseases, such as pulmonary fibrosis and chronic obstructive pulmonary disease, have been found to increase with age. Pulmonary disease can occur from failure to maintain alveolar type (AT) 1 and alveolar type 2 cells located in the epithelium of the lung. It is currently known that AT2 cells are the facultative stem cells of the lung, and can transform into AT1 cells which make up the structure of the alveoli. This process happens throughout embryonic development, but AT2 cells can also replenish AT1 cell populations post lung injury. This research investigates whether this process that normally occurs during development can also occur in mature AT2 cells, and studies this question using genetically engineered mouse models at a postnatal stage. Using a double inhibition mechanism, we attempted to increase cellular proliferation by administering an agonist and conducted cellular lineage tracing with an SpcCreER lox system via tamoxifen-induced GFP expression. Through lineage labeling, we saw AT1 cells arising from AT2 cells that became plastic, mirroring the plasticity observed in development. Further research is needed to determine if this agonist can be used to epigenetically unlock mature AT2 cells. This result would provide a mechanism to temporarily induce plasticity in a patient's own AT2 cells in an attempt to regenerate their lungs in disease.

THE ROLE OF THE ENDOPLASMIC RETICULUM UNFOLDED PROTEIN STRESS RESPONSES IN A C. ELEGANS MODEL OF QUIESCENCE

Arianna Pankey, *Howard University, Washington, District of Columbia, United States*

Cells devote extraordinary energy to translate and fold approximately 20,000 proteins encoded by the human genome. About one third of these proteins are transmembrane proteins—correctly folded in the endoplasmic reticulum (ER). The ER Unfolded Protein Response (UPRER) is a response to disturbances at the ER. As an organism ages, cells lose the ability to activate the UPRER. Our lab uses C. elegans—a microscopic roundworm—as a model organism to determine how loss of ER function can contribute to aging. The UPRER plays a key role in maintenance of functional quiescence. Quiescent cells exist in a reversible state of dormancy and can receive specific environmental cues to proliferate. The developmental state known as L1 arrest resembles the same features as quiescent cells. IRE-1 is required for worms to exit their quiescent state after starvation. Understanding the genetic pathways that are best at suppressing ire-1 terminal L1 arrest could indicate ways to improve functional quiescence. We forced the worms into an L1 arrest state; The unfolded protein response in the endoplasmic reticulum maintains functional quiescence within the cell. The worm's ability to develop once they exit this quiescent stage effectively, indicated the ability of the worm to maintain protein homeostasis despite non-ideal conditions. It was found that all tested mutations were unable to demonstrate improvement in ability to maintain development when arrested long-term. Our data indicates that our worms were counted prematurely. In the future, we will allow for a longer growth period as well as larger quantities of food.

SESSION 3481 (PAPER)

LATE BREAKING: COMMUNITY-BASED PARTICIPATORY RESEARCH APPROACHES I

COGNITION AND HEALTH: PRELIMINARY RESULTS OF A MUSIC CREATIVITY INTERVENTION FOR ADULTS AT RISK OF MCI

E. Lim Lydia Wu-Chung,[1] Anthony Brandt,[1] Melia Bonomo,[1] Bryan Denny,[1] Christof Karmonik,[2] Jefferson Frazier,[3] Karl Blench,[1] and Christopher Fagundes[1], *1. Rice University, Houston, Texas, United States, 2. Houston Methodist Research Institute, Houston, Texas, United States, 3. Houston Methodist Hospital, Houston, Texas, United States*

As the number of people with dementia is projected to rise to 13.8 million by 2050, there is a growing need to develop interventions that prevent or slow down disease progression in at-risk individuals. Older adults are particularly vulnerable, given that increasing age is the strongest predictor of dementia. Music interventions are promising, non-pharmaceutical treatment options for slowing down cognitive decline and enhancing psychological health. However, more music-related clinical trials are needed to evaluate treatment efficacy and to identify biobehavioral mechanisms of change. Project Chroma is a Stage 1 semi-randomized clinical trial, developed to assess the effects of a novel, music creativity curriculum on cognitive, socio-emotional, neurobiological, and immunological outcomes. In this study of 58 older adults with or without MCI, we demonstrate that Project Chroma has good feasibility and acceptability: participation, retention and satisfaction rates were comparable to other similarly designed clinical trials. Preliminary analyses revealed that participants in the music condition, relative to those in the control condition, showed marked improvements in cognitive functioning. Slight changes in socioemotional well-being were observed, which may be attributed to a minimally distressed sample. This study contributes to a growing literature substantiating music interventions as effective options for curtailing cognitive decline. Forthcoming work will examine the effects of music creativity on neural and immune outcomes.

USABILITY AND ACCEPTABILITY OF A PEER-DELIVERED TECHNOLOGY BASED MENTAL HEALTH INTERVENTION FOR FAMILY CAREGIVERS

Caroline Collins-Pisano,[1] Amanda Leggett,[2] and Karen Fortuna[3], *1. University of Colorado, Colorado Springs, Hanover, New Hampshire, United States, 2. Wayne State University, Ypsilanti, Michigan, United States, 3. Dartmouth College, Hanover, New Hampshire, United States*

Family caregivers of people with dementia are critical to the quality of life of care recipients and the sustainability of healthcare systems but face increased risk of emotional distress and negative health outcomes. The purpose of this study was to examine the usability, acceptability, and preliminary effectiveness of a technology-based and caregiver-delivered peer support program, "Caregiver Remote Education and Support" (CARES) smartphone application and to identify barriers and facilitators to the ethical use of former caregivers as technology-based interventionists. Nine family caregivers of people with dementia received the CARES intervention and three former family caregivers of people with dementia were trained to deliver the CARES system. Quantitative data were collected at baseline and at the end of the two-week field usability study. Qualitative data were also collected at the end of the two-week field usability study. The pilot study demonstrated that a two-week, peer- delivered and technology supported mental health intervention designed to improve burden, stress, and strain levels was experienced by former and current family caregivers as usable, acceptable, and ethical. CARES was associated with non-statistically significant improvements in burden, stress, and strain levels. This pre/post field usability study demonstrated it is possible to train former family caregivers of people with dementia to use technology to deliver a mental health intervention to current caregivers. Future studies would benefit from a longer trial, a larger sample size, a randomized controlled design, and a control of covariables such as stages of dementia, years providing care, and the severity of dementia symptoms.

USING COMMUNITY-BASED PARTICIPATORY RESEARCH TO PROMOTE MENTAL HEALTH LITERACY IN OLDER CHINESE

Jessie Ho-Yin Yau, Edwin Lok Yan Wong, Hotinpo Sky Kanagawa, Nicole HL Wong, Tianyin Liu, Gloria H.Y. Wong, and Terry Lum, *1. The University of Hong Kong, Hong Kong, Hong Kong*

Whilst traditional mental health literacy programmes utilized a top-down approach, no bottom-up community-based participatory research (CBPR) model had been used to promote mental health literacy among older adults. Moreover, the existing CBPR model was developed in the West and might not be applicable in Chinese communities given different socio-cultural contexts. This research aimed to fill the gap by implementing a CBPR project to promote mental health literacy among older adults and developing a CBPR model in Chinese context. A year-long CBPR project was conducted in five Hong Kong districts from May 2021 to August 2022. A district advisory group was formed in each district, which comprised 50 community older adults, 2 NGO social workers, and 2 researchers. Each district had their own promotional activities that were initiated and designed by older adults, including street booths, art workshops, videos and photos to promote mental health and introduce relevant information and resources. Researchers recorded field observations in each district activity and conducted focus group discussions with stakeholders. Collected data suggested that specific elements are important for a CBPR model in Chinese context, including participant empowerment, technical support, stakeholder expectation management and potential community contribution. Following the implementation of district promotional activities, a territory-wide advisory group was formed to promote mental health literacy on a territory level in the coming year. This is the first large-scale CBPR project that promoted mental health literacy among older adults in Chinese context. Implications for future research and practice will be discussed.

CAUSAL INFERENCE IN PSYCHOPATHOLOGY OF DEPRESSIVE SYMPTOMS IN MIDDLE-AGED AND OLDER ADULTS

Zheng Zhu,[1] Xiang Qi,[1] Yaolin Pei,[1] Jing Wang,[2] and Bei Wu[1], *1. New York University, New York, New York, United States, 2. The University of North Carolina at Chapel Hill, Chapel Hill, North Carolina, United States*

Most previous research studied depression as a holistic conception and ignored the complex relationships between depressive symptoms. How depressive symptoms interact with each other is still unknown. The aims of this study were to develop symptom networks of middle-aged and older adults and to explore the core symptom in the symptom networks. This study used three-wave data from the China Health and Retirement Longitudinal Study (CHARLS) in 2013 (T1), 2015 (T2), and 2018 (T3). Depressive symptoms were measured by the 10-item Epidemiological Research Center for Depression Scale (CES-D). A multilevel vector autoregression model (VAR) was used to identify 10 depressive symptoms dynamically interacting with each other over time. A total of 3558 participants were included in the final analysis. The strongest direct effects were “D10: felt fearful” -> “D6: felt everything I did was an effort” (β=0.14). “D10: felt fearful” reported the largest value of out-predictability (r=0.064) and out-strength (r=0.635). “D3: felt depressed” reported the largest value of in-predictability (r=0.077) and in-strength (r=0.545). Substantial heterogeneity in the network may stem from an individual’s gender and living region. “Felt fearful” was the strongest predictor compared to the other nine depressive symptoms based on node centrality. It was also the most crucial bridge node between negative symptoms cluster and positive affects cluster. Network density and the sum of all absolute strength centrality should also be incorporated into clinical practice as key indicators of emotional vulnerability, particularly in male middle-aged and older adults.

SESSION 3482 (PAPER)

LATE BREAKING: INNOVATIONS IN CLINICAL PRACTICE I

CHARACTERISTICS OF HOSPITALS AND PROVIDER MARKETS ASSOCIATED WITH INCREASES IN HOME HEALTH CARE USE

Elizabeth Watts,[1] Taylor Bucy,[1] John McHugh,[2] and Dori Cross[1], *1. University of Minnesota School of Public Health, Minneapolis, Minnesota, United States, 2. Columbia University Mailman School of Public Health, New York, New York, United States*

Many older adults require post-acute care from a nursing home or home health agency following hospitalization. Recent trends show providers are increasingly relying on home health agencies rather than institutionalized settings, with home health volume surpassing skilled nursing facility (SNF) volume since 2017. Using MedPAR patient encounter data from 2016–2019 and provider data from CMS, we analyze changes in the profile of patients receiving home health over time, showing that individuals discharged to home health are increasing in complexity based on hospital length of stay, comorbidities, and use of critical care services. Mixed effects models additionally suggest that grouping patients at the hospital and market level helps to account for unexplained variation in whether a patient is likely to receive home health versus SNF services. Examining the characteristics of hospitals and provider markets with increasing rates of home health referrals over time, we found that hospitals with increasing rates of discharge to home health were more likely to be for-profit facilities in urban areas with higher operating margins. However, this increase was not consistently tied to a corresponding decrease in rates of discharge to SNF, suggesting that hospitals are experiencing a combination of both patient-shifting across post-acute settings as well as an overall increase in baseline complexity of hospitalized patients over this time period. These results have implications for understanding the how policies currently being considered to improve value in the post-acute sector filter through heterogeneous market structures and complex organizational environments to impact patient care decisions.

BRAIN ACTIVITY DURING DUAL-TASK STANDING IN OLDER ADULTS WITH MILD COGNITIVE IMPAIRMENT

Melike Kahya,[1] Natalia Gouskova,[2] On-Yee Lo,[3] Junhong Zhou,[4] Davide Cappon,[3] Alvaro Pascual-Leone,[2] Lewis Lipsitz,[5] and Brad Manor[6], *1. Marcus Institute for Aging Research, Harvard Medical School, Boston, Massachusetts, United States, 2. Hebrew SeniorLife, Roslindale, Massachusetts, United States, 3. Marcus Institute for Aging Research, Boston, Massachusetts, United States, 4. Harvard Medical School/Hebrew SeniorLife, Roslindale, Massachusetts, United States, 5. Hebrew SeniorLife, Brookline, Massachusetts, United States, 6. Hebrew SeniorLife/Harvard Medical School, Roslindale, Massachusetts, United States*

Performance of a cognitive task while standing disrupts balance in older adults. This disruption is exaggerated in those with mild cognitive impairment (MCI). Moreover, older adults with MCI who exhibit greater dual-task 'cost' are more likely to develop falls and dementia. EEG studies suggest that cognitive-motor dual-tasking is associated with brain activity fluctuations originating from central brain regions at specific frequencies, particularly in the alpha-band (8–13 Hz). We hypothesized that older adults with MCI would demonstrate decreased EEG alpha power during dual-task standing compared to healthy controls, and that decreased alpha power would be associated with elevated dual-task cost. We recorded postural sway and EEG in 14 participants with MCI [Montreal Cognitive Assessment (MoCA) < 25] and 16 healthy older adults [MoCA>25] as they completed trials of standing with and without serial subtractions. Postural sway metrics were derived, and from EEG we calculated absolute alpha-, theta-, and beta-band powers within a-priori defined regions-of-interest: the left and right anterior, central, and posterior regions. Repeated Measures ANOVA demonstrated that participants with MCI exhibited decreased alpha power in the central regions during dual-task standing compared to healthy controls ($p= 0.01$). No significant difference was observed for theta and beta-band powers between participants with MCI and healthy controls. In those with MCI, lower alpha power during dual-task standing correlated with increased dual-task cost to postural sway path (worse balance) ($r=-0.4$, $p=0.03$). These results provide preliminary evidence that specific patterns of brain activity during dual-tasking are disrupted in MCI and this is associated with elevated dual-task costs.

UNMET TRANSITIONAL CARE NEEDS OF OLDER ADULTS DISCHARGED FROM HOME HEALTH CARE: A QUALITATIVE NEEDS ASSESSMENT

Ayomide Bankole,[1] Tyra Girdwood,[2] Jennifer Leeman,[1] Jennifer Womack,[3] and Mark Toles[1], *1. University of North Carolina-Chapel Hill, Chapel Hill, North Carolina, United States, 2. Duke University, Durham, North Carolina, United States, 3. Appalachian State University, Boone, North Carolina, United States*

Transitional care is widely recognized as a set of time-limited services to support older adults during transfers between settings and providers of care; however, little is known about services that prepare older adults and their caregivers for transitions from Home Health Care (HHC) to independent self-care at home. The objective of this study was to describe HHC patients and clinician perceptions of unmet needs after HHC discharge and recommendations to address them in future research. A multiple case-study design was used in a single large HHC organization in North Carolina. Data were collected using chart reviews of HHC records and semi-structured interviews with paired patients (or caregivers as proxy) and HHC clinicians (Nf17 pairs). A transitional care intervention model was used as a conceptual framework to guide framework analysis of interview transcripts. Most patients were White (65%) and female (53%) with mean age of 83 years. Clinicians were Registered nurses and Physical therapists. Across cases, 17 patient and clinicians pairs described three unmet needs: (1)skills for symptom management; (2)community-based support for transportation, food, social engagement, and health services; (3)in-home support to assist with safety, and activities of daily living. HHC patients recommended new services while clinicians emphasized the need for resources to improve their capacity to prepare patients for discharge. These findings will inform an innovative adaptation of transitional care and other supports to prepare older adults and caregivers for transitions from HHC to independent self-care at home. Future research should explore adding transitional care services to address these needs.

TESTING A DYADIC SLEEP INTERVENTION FOR PERSONS LIVING WITH COGNITIVE IMPAIRMENT AND THEIR CARE PARTNERS

Glenna Brewster, *Emory University, Lithonia, Georgia, United States*

Sleep disturbance is prevalent among persons living with cognitive impairment (PLWCI) and their care partners, suggesting that dyadic sleep disturbance is an interdependent phenomenon. There is also interdependence in the dyadic sleep disturbance. Despite the pervasiveness of shared sleep disturbance among these dyads and its negative impact on dyadic health outcomes, there are remarkably few interventions for sleep disturbance in which both members of the dyad participate. This study examines sleep outcomes of PLWCI-care partner dyads with insomnia symptoms. Dyads were simultaneously participating in a cognitive behavioral therapy for insomnia intervention. The Epworth Sleepiness Scale and the Insomnia Severity Index assessed daytime sleepiness and insomnia, respectively, at baseline and immediately post-intervention. We compared pre- and post-intervention ESS and ISI scores. For the 14 participants ($n=7$ dyads), care partners were spouses, on average 71.6 years, female (100%) and highly educated (18.85 years). The PLWCI were on average 73.85 years with 18.28 years of education. Daytime sleepiness improved for four and worsened for two care partners. It improved for three and worsened for three PLwCI. Insomnia improved for five care partners and four PLwCI. Two dyads experienced congruent improvement of daytime sleepiness. Four dyads reported congruent improvement of insomnia symptoms. A behavioral sleep intervention simultaneously engaging both the PLWCI and the care partners resulted in a reduction in insomnia and daytime sleepiness symptoms for most of the participants. This study provides preliminary evidence that PLwCI-care partner dyads with sleep disturbance can work together to improve their sleep outcomes.

LATE BREAKING: QUALITY IMPROVEMENT INNOVATIONS DURING THE COVID-19 PANDEMIC I

Alisha Johnson, *University of Missouri, Columbia, Missouri, United States*

THE INFLUENCE OF TREATMENT DELAY INCREASE RISKS OF CANCER MORTALITY AMONG OLDER ADULTS: A POPULATION-BASED STUDY

Jansen Cambia,[1] Edmund Cedric Orlina,[2] and Jason Jiashuan Liu[1], *1. National Yang Ming Chiao Tung University, National Yang Ming Chiao Tung University, Taipei, Taiwan (Republic of China), 2. Department of Health - Rizal Cancer Registry, Department of Health - Rizal Cancer Registry, Rizal, Philippines*

Treatment delays during the ongoing COVID-19 pandemic has worsened oncologic outcomes, such as increasing early mortality among older adults. We investigated the association of treatment delay on the 2-year and 5-year risk of all-cause mortality, and stratified among age ≤60 and age >60 years. This was a retrospective study of cancer patients using the Department of Health-Rizal Cancer Registry (DOH-RCR) from 1971–2012. We employed Poisson regression analysis to compare the risk of death among patients with different treatment delay lengths, defined as interval from diagnosis to treatment of ≤30 days, 31–60 days, and >60 days. We included 16,472 cancer patients. After adjusting for confounding, the 2-year risk of death was significantly higher among patient with treatment delay of >60 days by IRR=1.27 [95% CI=1.2–1.3] and 5-year risk by IRR=1.21 [95% CI=1.2–1.3], compared to delay of less than 60 days. Consistent findings were observed by age-groups, revealing that delay of >60 days puts age≤60 and age>60 years at higher risk of 5-year mortality, by IRR=1.21 [95% CI=1.2–1.3] and IRR=1.20 [95% CI=1.1–1.3], respectively. Treatment delay was associated with overall cancer mortality for cancer diagnoses at any age range. However, further investigation is needed to understand the predictors of longer treatment delay, which may provide consolation to balanced care during the current pandemic.

CARDIOVASCULAR CONSEQUENCES OF COVID-19 INFECTION IN OLDER ADULTS WITH A HISTORY OF HEART FAILURE

Claudia Beatriz Marcano Ocasio,[1] Andrew Crawford,[2] Mary Parianos,[3] Marina Stukova,[4] Alan Wong,[2] Ali Vaeli Zadeh,[5] Elias Collado,[5] and Joshua Larned[6], *1. Holy Cross Hospital - - Fort Lauderdale, F, Ford Lauderdale, Florida, United States, 2. Holy Cross Health-University of Miami, Fort Lauderdale, Florida, United States, 3. University of Miami, Fort Lauderdale, Florida, United States, 4. University of Miami at Holy Cross, Fort Lauderdale, Florida, United States, 5. Holy Cross Health-Jim Moran Cardiovascular Research Institute, Fort Lauderdale, Florida, United States, 6. Holy Cross Health-University of Miami, Miami, Florida, United States*

Background: COVID-19 frequently affects the cardiovascular system. Advanced age and pre-existing heart failure HF are considered risk factors for a poor prognosis. However, the cardiovascular consequences of COVID-19 in older adults with a history of HF have not been clearly depicted. Methods: A retrospective review was conducted using the PearlDiver database (PearlDiver Technologies, Fort Wayne, IN). Using ICD codes, patients aged 65–75 and Elixhauser Comorbidity Score(ECI)>4 with a history of HF admitted for COVID-19 were identified. This cohort was propensity score matched with a group of patients without HF by age, gender, other cardiovascular diseases, and ECI. Records from both groups were reviewed for new onset of cardiovascular-related conditions, including myocardial infarction(MI), arrhythmias, and hypertension, within one year following the admission. Pearson's chi-squared test was used to compare groups. The strength of association was reported using Risk Ratios (RR). A p-value < 0.05 was deemed significant. Results: 4,014 members in each group were identified. A history of HF was associated with an increased risk of MI(RR=1.18, CI95% =1.005–1.37, p=0.04), and arrhythmias (RR=1.17, CI95% =1.08–1.26, p < 0.00001). No differences present in risk of myocarditis(RR=0.05, CI95%=0.12–1.99, p=50) across groups. Conclusion: Older adults with a history of HF are more likely to experience MI and arrhythmias over a year after hospitalization for COVID-19.

SUPPORT AND UTILIZATION OF ADVANCED PRACTICE NURSES IN LONG-TERM CARE TO MAXIMIZE OUTCOMES AND EMERGENCY RESPONSE

Alisha Johnson[1] and Tracie Harrison[2], *1. University of Missouri, Columbia, Missouri, United States, 2. University of Arkansas for Medical Sciences, Little Rock, Arkansas, United States*

Incorporation of Advanced Practice Registered Nurses (APRNs) into Long-Term Care (LTC) results in sustained positive outcomes and has potential to help guide LTC facilities in times of emergency such as the COVID-19 pandemic. To optimally utilize the role of an APRN in the care of older adults and people with disabilities requires understanding the needs of LTC while balancing the personal characteristics of APRNs transitioning into practice (TTP). Findings from an ethnographic dataset (participant observations, interviews, field notes) of a cohort of 9 APRNs embedded full-time into 5 LTC settings over their first year of practice (overlapping with the first 3 ½ months of the COVID-19 pandemic) were integrated to glean lessons about LTC and APRN characteristics associated with successful APRN transition and utilization during stable and emergent care. Guided by a complexity science sensitizing framework focused on emergent and holistic systems, findings lead to multiple conclusions. The ability to influence positive outcomes in routine and emergent situations must be modeled. APRNs require meaningful mentoring relationships and acceptance by administrators and practitioners to develop successful TTP. Successful TTP included their embrace of role as resident caretaker, their participation in facility quality improvement, and their positive impact in an emergency response. Utilization and transition were enabled by facilities with organized characteristics versus inhibited by chaotic ones, which was exacerbated by the pandemic. Personal role fulfillment drove many APRNs to push through adversity. Administrators must address and honor concerns and attempts at self-care during times of doubt.

EXPLORING INTERSECTIONS OF NURSING HOME CULTURE, IMPROVEMENT, AND DOCUMENTATION-RELATED ATTITUDES

Hannah Baker, *Concordia University Wisconsin, West Bend, Wisconsin, United States*

Documentation of patient care and characteristics is an important part of nursing home (NH) operations, affecting financial aspects, quality improvement (QI) efforts, inter-provider communication, and potential for medical errors. However, relationships among NH culture, QI, and documentation-related attitudes are unclear. This study explored Wisconsin NH staff and administrator perspectives on these variables (n = 10 in 8 NHs), using interviews structured on a composite of Schein's organizational culture typology and Shortell's Quality Improvement Implementation Survey concepts. Interview questions related to perspectives and emotions about NHs' documentation quality, OC, QI efforts, and nursing staff turnover. Verbatim transcription, member checks, and team-based transcript coding and analysis ensured good data quality. Thematic analysis was used to construct a "storyline" and refine the original theoretical model. Sample data fit the model well, supporting the perception of pairwise relationships between NH OC, QI, and documentation. One of Schein's culture types was not represented in the sample. Attitudes and perceived influences on documentation-related quality were mostly negative. This research contributes to knowledge on long-term care and could point future research toward (1) similar work in dissimilar NHs to replicate results, (2) closer examination of staffing variability, (3) quantitative work on effects of education and auditing on documentation-related attitudes, and (4) strategies to improve attitudes without increasing staff stress levels.

SESSION 4020 (PAPER)

LATE BREAKING: INNOVATIONS IN CLINICAL PRACTICE II

MULTI-CASE STUDY OF A NOVEL HEALTHCARE DELIVERY MODEL TO SUPPORT AGING IN PLACE IN RURAL, REMOTE, AND SMALL URBAN AREAS

Wendy Hulko,[1] Noeman MIrza,[2] Kathy Rush,[3]
Dawn Hemingway,[4] Sarah de Leeuw,[4] Katrina Plamondon,[3]
Emily Bartle,[1] and Lilly Chisholm[1], *1. Thompson Rivers University, Kamloops, British Columbia, Canada, 2. University of Windsor, Windsor, Ontario, Canada, 3. University of British Columbia, Kelowna, British Columbia, Canada, 4. University of Northern British Columbia, Prince George, British Columbia, Canada*

Aging in place has long been a policy objective in Canadian healthcare, with accompanying concerns about older adults in rural and remote regions, and growing interest in small urban areas as distinct from large urban ones. As one of the six health authorities in British Columbia (BC), Interior Health (IH) developed and implemented an innovative healthcare delivery model to support aging in place for older adults, while addressing system issues of cost containment and resource allocation. By transferring funds from acute care to primary care, IH created Seniors Health and Wellness Centres (SHWCs) in two small urban areas (Kelowna and Kamloops) and a third one with two rural sites (Salmon Arm and Revelstoke). Our multi-case study aimed to compare how the SHWCs are meeting their objectives, and addressing the priorities of rural and small urban older adults and their social determinants of health (SDoH). We used mixed methods of data collection and analysis, including key informant interviews (n=9), service user questionnaires (n=10), document analysis (n=19), and secondary data analysis of service usage (n=2343) to answer research questions (RQs) on the outcomes and impacts of IH's restructuring. The results show the outcomes (RQ1) to be three SHWCs which vary considerably in their design and usage, including access, quality, and continuity of care. Our findings on the impacts (RQ2) indicate the SHWCs are meeting their cost reduction aims while concentrating on some SDoH (income & dis/ability) and neglecting others (gender, racism, rurality), and progressing slowly in addressing certain priorities of older adults.

UNDERSTANDING OLDER ADULTS' ATTITUDES TOWARD MOBILE AND WEARABLE TECHNOLOGIES TO SUPPORT HEALTH AND COGNITION

Ibukun Fowe and Walter Boot, *Florida State University, Tallahassee, Florida, United States*

Technologies that facilitate remote patient monitoring, virtual care, and telehealth are becoming increasingly prevalent, accelerated due to the challenges providing healthcare during the COVID-19 pandemic and the need for more efficient and effective methods to care for the expanding older adult population. Despite the potential benefits of these technologies, their promise can be hampered by low rates of acceptance and adoption among older adults. We assessed older adults' ($N = 92$) attitudes towards the use of wearable and mobile technologies for 1) predicting cognitive decline, 2) assisting with adherence to health activities, and 3) collection of self-report data to understand current health status and predict future problems. Participants generally rated hypothetical technology solutions as useful ($M = 4.2$, $SD = 0.70$, 1 = Strongly Disagree, 5 = Strongly Agree), were interested in learning more about these technologies ($M = 3.81$, $SD = 0.86$), and indicated willingness to adopt these technologies themselves ($M = 3.83$, $SD = 0.93$); however, participants did indicate some privacy concerns ($M = 2.92$, $SD = 1.02$. General technology attitudes and previous experience using mobile devices were the best predictors of acceptance and willingness to adopt these technologies ($r = 0.50$, $p < .001$; $r = 0.22$, $p < .05$, respectively). These findings suggest generally positive attitudes and highlight potential targets for intervention to increase the uptake of these technologies, maximizing their benefits.

CAN MONITORING OLDER ADULTS' TECHNOLOGY USE PATTERNS HELP DETECT COGNITIVE DECLINE?

Shelia Cotten, Reza Ghaiumy Anarsky, and Amy Schuster, *Clemson University, Clemson, South Carolina, United States*

Approximately six million U.S. older adults are diagnosed with Alzheimer's Disease (AD), and this number is expected to more than double by mid-century. Monitoring older adults' cognitive functioning is essential for the early detection of cognitive diseases, such as AD, which can increase treatment efficacy and slow AD's progression. Cognitive functioning tests, however, have limitations as administrating them can be costly and time-consuming. This study aimed to determine whether technology use patterns could be used as an indicator of cognitive functioning. We utilized six waves (from 2015 to 2020) of data from the National Health and Aging Trends Study to assess whether stopping the use of different types of technology (using the Internet, computers or tablets, or sending texts and emails) are associated with cognitive functioning (memory, orientation, and executive functioning). We controlled for age, gender, marital status, race, education, activities of daily living, and overall health. Our analyses showed that stopping the use of going online, computers, tablets, and sending texts and emails were related to cognitive decline. These results suggest that practitioners should incorporate assessments of their patient's online activity and use as it may be an innovative approach that is economical and efficient to identify individuals at risk of cognitive decline.

TECHNOLOGY TO PROTECT HIPS IN SERIOUS FALLS - PRELIMINARY EVIDENCE

REBECCA TARBERT,[1] and Richard Stefanacci[2], *1. Active Protective Technologies, Inc, Allentown, Pennsylvania, United States, 2. Jefferson College of Population Health, Philadelphia, Rhode Island, United States*

Major injuries from falling in the older adult population is a tragic outcome that is growing in number. There is limited evidence of methodology to avoid major injuries from falls for those most at risk. Hip fractures are a catastrophic outcome from falls that incur cost to the individual, family and healthcare system. A study is currently underway in older adult living settings designed to demonstrate the efficacy and safety of a wearable smartbelt that deploys a protective airbag around the hips prior to landing on the ground as a mitigation for fall-related major hip injuries. The smartbelt technology includes embedded sensors and WiFi connection for data sharing. The primary endpoint of the study is to examine the efficacy and safety of the smartbelt in a population of older adults with high-risk profile of falls and major hip injuries. The study will be a comparative analysis of rate of major hip injuries from falls between a retrospective control group and a selected intervention group wearing the smartbelt for 6 months with all subjects continuing to receive standard of care for fall injury mitigation. Implementation methodology of clinical study performance in the care settings and integration into plan of care will be outlined. Outcomes from the enrolled subjects to date in the study will be shared including fall risk factors, fall events and injuries from falls reported.

PERCEPTIONS OF OLDER ADULTS AND CAREGIVERS OF AN AUTOMATED ROBOT TO FACILITATE AGING IN PLACE

Donna Case,[1] Nathan Velazquez,[1] and Tatjana Savich[2], *1. University of Michigan Flint, Flint, Michigan, United States, 2. Quality Care Rehab & Autism Center, Shelby Township, Michigan, United States*

This study explored the perceptions of forty older adults 55+ and caregivers of the usefulness of the Labrador Retriever (https://labradorsystems.com/) in facilitating aging in place. Participants consisted of older adults who are enrolled in a PACE program or reside at The Village of Oakland Woods in southeastern Michigan as well as providers and board members of organizations that provide support to these older adults. Participants viewed an in-person demonstration of the Labrador Retriever before verbally completing a thirteen question survey with answers input by research team members. The questions were a combination of multiple choice questions such as "Having seen the Labrador demonstration, do you think the Labrador Retriever System could help you in your setting?" followed by open ended questions such as "Having seen the Labrador Retriever, how might this system help you in your setting?". A total of 9 qualitative themes related to the potential uses of the Labrador Retriever System were identified as: Medications, Aging in Place, Safety and Fall Prevention, Carrying Items (i.e. laundry, food, cleaning supplies), Hydration, Independence, Reducing Caregiver Burden, Nutrition, and Cognitive Issues. These themes are consistent with the barriers to aging in place identified in the literature.

SESSION 4021 (PAPER)

LATE BREAKING: MOTIVATING PATIENTS FOR HEALTH BEHAVIOR CHANGE I

MOTIVATIONAL INTERVIEWING TO MODIFY SORTING AND DISCARDING BEHAVIORS IN HOARDING DISORDER

Caitlyn Nix and Mary Dozier, *Mississippi State University, Mississippi State, Mississippi, United States*

The act of sorting and discarding possessions is the fundamental health behavior that underlies clutter, a core symptom and signifier of hoarding disorder. In older adults, excessive clutter can cause hazardous conditions in the home that increase the risk of being unable to age in place safely. Current evidence-based treatments for hoarding require lengthy treatment dosages and primarily target fears surrounding sorting/discarding. Because not all older adults with hoarding disorder experience a fear-response when sorting/discarding, other targets for hoarding treatment must be evaluated in this population, including directly targeting motivation for behavior change. The current pilot study investigated motivation to sort and discard items as a treatment target for hoarding disorder in older adults. The rationale for this treatment study was that targeting motivation to engage in regular sorting/discarding of household clutter would result in decreased hoarding severity by creating a sustainable change in behavior. Fifteen participants (age 50 and up, M = 62) engaged in six in-home sessions of a novel intervention that combined intensive motivational interviewing with sorting practice (i.e., spending time engaging in the target behavior of sorting and discarding items in the home). This presentation will discuss the applications of motivational interviewing for hoarding disorder in older adults, including skills related to engaging, focusing, evoking, and planning. Our initial treatment outcomes suggest that motivation is a worthwhile treatment target for hoarding disorder.

THE EFFECT OF OBESITY ON COVID-19 OUTCOMES AMONG HOSPITALIZED OLDER ADULTS

Mary Parianos,[1] Ali Vaeli Zadeh,[2] Ricardo Criado Carrero,[3] Claudia Marcano,[1] Andrew Crawford,[4] Elias Collado,[2] and Joshua Larned[4], *1. University of Miami, Fort Lauderdale, Florida, United States, 2. Holy Cross Health-Jim Moran Cardiovascular Research Institute, Fort Lauderdale, Florida, United States, 3. University of Miami/Holy Cross Hospital, Fort Lauderdale, Florida, United States, 4. Holy Cross Health-University of Miami, Fort Lauderdale, Florida, United States*

Background: According to the CDC, approximately 30% of hospitalizations for COVID-19 infection between the onset of the pandemic and November 2020 were attributed to obesity. However, there is limited data on how obesity affects the overall outcome of COVID-19 in hospitalized older adults. Methods: A retrospective study was conducted using the PearlDiver database (PearlDiver Technologies, Fort Wayne, IN). Using ICD-10 codes, a cohort of patients aged 65–75 and Elixhauser Comorbidity Index (ECI) >4 with a history of obesity admitted for COVID-19 was identified. This cohort was matched with a group of patients with no history of obesity, considering age, gender, and ECI. Records from both groups were reviewed for multiple outcomes over 30 days following admission. Pearson's chi-squared was used to compare groups. The strength of association was reported using Risk Ratios (RR). A p-value < 0.05 was deemed significant. Results: There were 151,429 members in each group. Obese individuals had a higher risk of 30-day all-cause readmission (RR=1.10, CI95% 1.07–1.11, $p < 0.0001$), ICU admission (RR=1.11, CI95% 1.08–1.15, $p < 0.0001$), acute thromboembolic events (RR=1.14, CI95% 1.07–1.2, $p < 0.001$), and deep venous thrombosis (RR=1.21, CI95% 1.12–1.32, $p < 0.00001$). There was no difference in length of hospitalization. Conclusion: Obesity is a modifiable risk factor that negatively affects COVID-19 outcomes in the older population. Given the prevalence of obesity in our population, primary and secondary obesity prevention is more important than ever.

UNDERSTANDING MOTIVATIONS FOR PARTICIPATING IN EVIDENCE-BASED FALL PREVENTION PROGRAMS ON ZOOM

Andy Rapoport and Margaret Danilovich, *CJE SeniorLife, Chicago, Illinois, United States*

The pivot to remote delivery of NCOA evidence-based programs has increased participant reach due to eliminating geographic or transportation barriers. Despite the convenience of participation in one's own home, challenges for helping patients adhere to behavior change remain. This paper will present data from one community-based organization's NCOA evidence-based falls prevention program implementation of Bingocize, Tai Chi, Otago, and SAIL on Zoom. Across all programs, only 36% of people who registered for workshops attended the first session. Participants, on average, only attended 27% of the sessions in a given workshop. To explore the barriers and facilitators to attendance in order to encourage patients to change health behavior, we used a mixed-methods approach to evaluate reasons for suboptimal adherence among n=735 participants across the 4 programs. We performed sub-group analysis to examine barriers and facilitators by the self-reported attendance rate. We conducted semi-structured interviews with n=14 participants, focusing on those who had less than 50% attendance for the workshop they registered for, and also received n=234 survey responses. For participants who attended >50% of workshop sessions, class enjoyment was the most cited facilitator of attendance. However, for those who attended < 50% of workshop sessions, email reminders were the most cited attendance facilitator. Results from this project provide critical information about specific barriers that different sub-groups of older adults face regarding participation in NCOA evidence-based programs to develop strategies to help motivate patients for health behavior change.

ENGAGING OLDER ADULTS IN HEALTH PROMOTION: PILOT STUDY OF TEAM GAMEPLAY OF AN EDUCATIONAL EXERGAME IN A SENIOR CENTER

Laurie Ruggiero,[1] Elizabeth Orsega-Smith,[1] Amy Nichols,[1] Joshua Varghese,[2] Nancy Getchell,[1] Rachel DeLauder,[1] Reza Koiler,[1] and Roghayeh Barmaki[1], *1. University of Delaware, Newark, Delaware, United States, 2. Wilmington University, Williamstown, New Jersey, United States*

Digital health games offer one innovative approach to engage older adults to support healthy aging. Multiple reviews have described the positive impact of health games. Limited research has examined multi-focus health games implemented in senior centers. Informed by healthy aging theory and community-engaged methods, our multi-disciplinary team developed/refined an educational exergame with a combined focus on educating about healthy lifestyle behaviors (i.e., physical activity, healthy eating), stimulating cognitive functioning, and engaging movement to support healthy aging. A pilot study (Nf13; mean age = 78, 100% female) examined team gameplay (4 sessions in two weeks) in a senior center. Teams (2–3 members) worked together to answer knowledge, trivia, and cognitive challenge questions and competed for the highest score. A post-gameplay survey asked about acceptability, usability (i.e., adapted System Usability Scale), and perceived game impact. Preliminary results suggest team gameplay was engaging and nearly all (>90%) agreed/strongly agreed that they enjoyed playing with others (i.e., on teams); were comfortable doing the physical movements during gameplay; were satisfied with game educational, trivia, and cognitive questions; enjoyed the social part of team gameplay; would recommend the game to others; and the game increased their knowledge and motivation regarding physical activity and healthy eating. The System Usability Scale was above 70, on average, suggesting above average usability for the game. Findings support use of this educational exergame as an innovative way to engage older adults in health promotion. Presentation will describe game development/refinement, senior center pilot, and implications for future research and senior center translation.

DEPLOYING IN-HOME SENSORS TO COMMUNITY-DWELLING OLDER ADULTS: ADOPTION OF TECHNOLOGY AND LESSONS LEARNED

Erin Robinson, Gashaye Melaku Tefera, Geunhye Park, Marjorie Skubic, Noah Marchal, Mihail Popescu, James Keller, and Rantz Marilyn, *University of Missouri, Columbia, Missouri, United States*

In-home, sensor technologies can promote chronic disease self-management and independence among older adults. However, the translation of these technologies from assistive living/long-term care to community-dwelling older adults is lacking. This study aimed to tailor such technologies for private use by older adults, and gather feedback about adoption/interpretation of sensor-generated health information to make informed health decisions. Participants (Nf33; 72.7% female) aged 60+ (Mean=79.5) had three types of sensors installed: 1) depth sensors that track gait parameters and falls; 2) passive infrared motion sensors that track room activity; and 3) hydraulic bed mats that track sleep, respiration, and heart rate. Participants were also offered a Garmin smartwatch/fitness tracker. A health app was developed for participants to retrieve their sensor-generated health information via an Amazon Echo Show device with touch display and voice-activated capabilities, and a web-based interface. Data were collected over two years, and feedback was solicited during four quarterly interviews and one exit interview. Thematic analysis revealed participants used the Echo Show to retrieve their health information, set medication/health appointment reminders, and for non-health related purposes (e.g. music, weather). Regular retrieval of health information was low, partly due to technology skills, lack of interest, health issues, and technical/internet issues. Despite this, participants reported a sense of security in having the sensors installed and valued the depth sensor's fall detection abilities. This study yielded many additional findings that will be presented, such as participant recommendations to facilitate greater adoption. Implications can inform technological solutions for older adult health self-management and aging-in-place.

SESSION 4022 (PAPER)

LATE BREAKING: APPLYING REFRAMING AGING IN YOUR WORK I

THE RELATIONSHIP BETWEEN CHILDHOOD ADVERSITY AND MENTAL HEALTH IN OLDER ADULTS

James Lian, Kaarin Anstey, and Kim Kiely, *University of New South Wales, Sydney, New South Wales, Australia*

Background: There is a need to understand how early adversity is linked with mental health in older adults. The aim of this study was to 1) explore the optimal way to operationalise a scale of adverse childhood experiences (ACEs) and 2) examine the association between ACEs with depression and anxiety in older adulthood. Methods: Data were from Wave 1 of the Personality and Total Health (PATH) Through Life Project (N = 7485, 51% women). Older adults aged 60–65 reported their childhood experiences of domestic adversity on a 17-item scale (e.g., physical abuse, neglect, poverty). Depression and anxiety were assessed using four validated screening instruments (GDS, GAS, MCS-12, PHQ-9). Three approaches to scoring the ACE scale were compared: i) cumulative risk, ii) factor analysis, and iii) latent class analysis (LCA). Confirmatory factor analysis (CFA) of the dimensional model of adversity and psychopathology was examined. Linear regression models estimated associations between ACEs and mental health, adjusting for age, race, education, and gender. Results: Childhood adversity was associated with late life depression and anxiety using the cumulative risk approach. CFA examined latent factors of threat and deprivation in our dataset, which were highly correlated, leading to problems with multicollinearity when estimating associations. Finally, LCA revealed six classes of ACEs: high adversity, low adversity, low affection, authoritarian upbringing, high parental dysfunction, and moderate parental dysfunction. High adversity and high parental dysfunction were associated with higher levels of depression and anxiety symptoms compared to other latent classes.

TRENDS IN MENTAL ILLNESS ACROSS ASSISTED LIVING SETTINGS: RESIDENT AND COMMUNITY FACTORS

Bryant Carlson,[1] Sarah Dys,[2] Ozcan Tunalilar,[2] and Paula Carder[2], *1. Oregon Health & Science University - Portland State University School of Public Health, Portland, Oregon, United States, 2. Portland State University, Portland, Oregon, United States*

Although rates of serious mental illness (SMI), depression, and anxiety are becoming more common among assisted living (AL) and residential care (RC) residents, few studies have investigated resident and community-level factors to ensure that the settings and resources are adequate to meet residents' mental health needs. Using a representative sample of Oregon AL/RC residents (n = 1,013), this study uses descriptive cross-sectional analysis to examine intrastate variation in the prevalence of SMI, depression, and anxiety related to: (1) resident-level characteristics (e.g., mental illness comorbidity, psychotropic medication use, and Medicaid status); (2) community-level characteristics (e.g., facility type and urban/rural geographic designation); and (3) health services utilization (e.g., emergency room visits and hospital admission). Results indicate that 12% of AL/RC residents had an SMI diagnosis, nearly half of whom also had depression and anxiety, and 80% were Medicaid eligible. One in six residents with SMI received at least three psychotropic medications in the last week. Residents with SMI were also more likely to live in RC facilities than AL facilities, in facilities with Medicaid contracts, and in urban rather than rural settings. Compared to residents without SMI, a larger share of residents with SMI utilized hospital emergency rooms (32% vs. 18%) and were admitted to the hospital overnight (15% vs. 9%). Findings underscore characteristics associated with potentially higher needs among AL/RC residents with SMI compared to their counterparts, with implications for the high quality provision of mental health services and quality of life and care in these settings.

INTERGENERATIONAL CONNECTIONS: TURNING POINTS IN COLLEGE STUDENT ATTITUDES ABOUT OLDER ADULTS AND AGING

Wendy Watson,[1] Sandra Faulkner,[1] Madison Pollino,[1] Jaclyn Shatterly,[2] and Charlie Stelle[1], *1. Bowling Green State University, Bowling Green, Ohio, United States, 2. University of Alabama, Tuscaloosa, Alabama, United States*

Intergenerational Connections was a semester-long community-based engagement project in which thirty-four undergraduate students enrolled in a relational communication course met via Zoom with older adults in a long-term care facility for four dialogues about close relationships. The project used a Critical Interpersonal and Family Communication Pedagogy approach to have students critically engage with stereotypes and expectations about older adults through class readings, discussion, and interaction. The students wrote reflections after each dialogue and a final reflection expressing their expectations and experiences of interacting with an older adult. We analyzed the reflections using a turning point analysis and found two turning points related to Perceptions of Aging and Developmental Changes and Understanding and Expectations of Relationships. Students recognized stereotypes they held about older adults and aging and how engaging with an older adult dispelled many of those assumptions. Students were surprised by how much they had in common with their older adult partner. They learned about relationships through their dialogues with their partner and found many “words of wisdom” they wanted to incorporate into their relationships. In their final papers, students reflected on being advocates for older adults and how this project helped them understand that they can have conversations with older adults and not be afraid that they will not be able to connect. This paper will discuss how this community engagement project served to reframe aging for these young adults, and students’ recognition of the role that older adults play and the value that their involvement brings to society.

UNCOVERING THE POSITIVE ASPECTS OF CAREGIVING: A PROFILE OF CAREGIVERS’ DEMOGRAPHIC AND CARE CONTEXTS

Yeonjung Lee,[1] and Alex Bierman[2], *1. Chung-Ang University, Seoul, Seoul-t’ukpyolsi, Republic of Korea, 2. University of Calgary, Calgary, Alberta, Canada*

Burden and benefits of caregiving experiences can coexist. The objective of this research is to describe and compare the predictors of the two intertwined caregiving experiences. This study examines how the variations in caregiving experiences can be explained in terms of both positive and negative aspects of caregiving, respectively by demographic characteristics and care related contexts. The Caregiving, Aging, and Financial Experiences study is a national survey intended to examine social conditions and well-being among a representative sample of 4,010 Canadians between age 65 and 85. Within the sample, 1,641 informal caregivers are the focus of the current analysis. Scales of positive and negative caregiving experiences are employed. Findings based on principal axis factor analysis shows that there is clear separate factor loadings between the positive and negative caregiving experiences. Subsequent seemingly unrelated regression analysis shows that there are similarities as well as differences in predictors between the two caregiving experiences. Lastly, the variance explained differs markedly between the two measures, with over 26% of the variance in negative caregiving accounted for by demographic and caregiving factors, but less than 4% of the variance in positive caregiving. This study demonstrates that positive aspects of caregiving is not simply the flip-side of negative caregiving. Standard predictors do not sufficiently explain positive caregiving as well as negative caregiving. Consequently, greater attention to factors that account for positive aspects of caregiving is warranted for an inclusive understanding of caregiving experiences.

LOVE OR OBLIGATION TO “SEE THEM THROUGH:” BURDENS AND GAINS IN CAREGIVING FOR CENTENARIANS

Eric Ngai Yin Shum,[1] Bobo Hi Po Lau,[1] Peter Martin,[2] Joey Chung Yue Siu,[3] Karen Siu Lan Cheung,[4] Cecilia Lai Wan Chan,[4] Grace Man Yee Chan,[5] and James Ka Hay Luk[6], *1. Hong Kong Shue Yan University, Hong Kong, Hong Kong, 2. Iowa State University, Ames, Iowa, United States, 3. Caritas Institute of Higher Education, Hong Kong, Hong Kong, Hong Kong, 4. The University of Hong Kong, Hong Kong, Hong Kong, 5. The Hong Kong Council of Service, Hong Kong, Hong Kong, 6. TWGHs Fung Yiu King Hospital (FYKH), Hospital Authority, Hong Kong, Hong Kong*

In Hong Kong, the population of centenarians increased from about 3,000 in 2011 to over 10,000 in 2021. The growth of this population has led to challenges concerning how far family caregivers, who are usually older adults themselves, could care for their spouse or parents. In 2021, we launched the 2nd Hong Kong Centenarian Study and included the voices of family caregivers. Notwithstanding the increased difficulties of caregiving during COVID outbreaks, our interviews with 120 caregivers revealed low to moderate scores of caregiving burden and gains (measured by 4-items from the Zarit Burden Scale and 5-items from the Positive Aspects of Caregiving Scale). Female and older (aged 70 or above) caregivers reported more emotional distress, burden, and poorer self-rated health, while younger caregivers (less than 70 years old) sustained a wider social network. Financial stress was related to smaller social network size and more emotional distress. When being asked what sustained their motivation to care for their spouse or for their parents, “filial obligation to see them through” and “repaying for love” were answered as key motivators. Caregivers also derived pride and satisfaction from contributing to the remarkable longevity of their loved ones or from witnessing their loved ones recovering from life-threatening traumas (e.g., falls, hospitalization), but felt helpless when faced with escalating care needs due to their own deteriorating physical health and capacities. “Double-old caregiving” will become more common, and society will need to overhaul the care system to support these motivated families who have escalated care needs.

SESSION 4023 (PAPER)

LATE BREAKING: COMMUNITY-BASED PARTICIPATORY RESEARCH APPROACHES II

AI AND AGING: IDENTIFYING IMPORTANT LIVING ACTIVITIES FOR HEALTHY AGING IN SINGAPORE LONGITUDINAL AGING COHORT

Xin Zhong,[1] Feng Yang,[2] Wangyang Hu,[3] Xinyi Gwee,[3] Denise CHUA Qian Ling,[3] and Tze Pin Ng[3], *1. A*STAR Singapore, Singapore, Singapore, 2. Institute of High Performance Computing, Singapore, Singapore, 3. National University of Singapore, Singapore, Singapore*

Population aging in Singapore has encouraged the development of ambient smart communities to support healthy aging. Poor understanding of the living activities that address both clinical and biological concerns may plague efficient aging service designs and community health programs. We have designed a new computational workflow to identify important living activities for older adults in Singapore. We investigated innovatively three pillars of human life aspects: activities, clinical health, and biological health to identify living activities that are significantly associated with both clinical health and biological health. Cross-sectional data analyses were performed on 1356 community-living Chinese older adults of 65–80 years old in the Singapore Longitudinal Aging Study II (SLASII) cohort. 7 out of 29 living activities were found significantly associated with clinically healthy aging and showed improved prediction accuracy towards health status in machining learning schemes. Furthermore, biological age has been computed by screening and modeling 66 biomarkers. 15 out of the 29 living activities were found significantly associated with biologically healthy aging. Checking the overlapping living activities, we have found that physical exercise and cognitive-simulating activities are the most important activities for healthy aging: such as jogging regularly and reading, writing, and doing puzzles often. We regroup participants into active and non-active groups according to these two activities. The Keplan-Meier survival analysis showed statistically significant differences in survival time between the active and non-active groups ($p < 0.001$) in an 8-year longitudinal study. The workflow, results and biomarkers may provide references for future health program design improvement.

NEEDS FOR SUPPORTING PEOPLE AGING WITH HIV: RESULTS FROM A CBPR COMMUNITY-NEEDS ASSESSMENT

Andy Rapoport, Rick Guasco, Teresa Musolino, Melanie Reese, Kenneth Teasley, and Margaret Danilovich, *CJE SeniorLife, Chicago, Illinois, United States*

Nearly half of people living with HIV in the U.S. are over age 50 and are navigating age-related changes while managing the complexities and challenges of HIV. People aging with HIV are an emerging community—it is imperative to understand the key issues faced by this community so to improve health outcomes and eliminate health disparities. This paper presents a CBPR approach by the SHARE board (a community advisory group comprised of older people living with HIV) and academic researchers. SHARE members conducted a mixed-methods needs assessment using a semi-structured interview guide they had developed, as well as a survey to determine community priorities for research, healthcare, and social services for people aging with HIV. SHARE members conducted 32 semi-structured interviews with individuals from across the country. From the 216 survey responses (mean age 55 years), 35% were Black, 30% were Hispanic, 50% were male, and 43% had been living with HIV for 11–15 years. 44% were fearful that long-term HIV medications will adversely affect them with aging. Triangulating interviews and surveys, financial strains and caregiving were primary age-related concerns. Affording medication and transportation were primary barriers to accessing healthcare. Most respondents had experienced stigma due to both age and HIV status. Respondents felt the most important areas for future research were optimizing management of multiple co-morbidities including HIV, and cognitive changes with HIV. Results from this community-led needs assessment identified key areas for interventions and research to address conditions disproportionately affecting the health of those aging with HIV.

OVERCOMING OLDER ADULT RESISTANCE TO TECHNOLOGY TO SUPPORT DIGITAL HEALTH LITERACY: A CBPR APPROACH

Paul Freddolino,[1] Fei Sun,[1] Ha-Neul Kim,[1] Dona Wishart,[2] Eileen Godek,[3] and Megan Bentley[1], *1. Michigan State University, East Lansing, Michigan, United States, 2. Administration, Otsego, Michigan, United States, 3. Otsego County Commission on Aging, Otsego, Michigan, United States*

Overall low digital use by older adults creates a barrier to tools that enable them access to basic and specialty healthcare through telehealth and address their isolation and loneliness. In particular, older adults with low-income, like low-income isolated Home Delivered Meal (HDM) program recipients, can be most vulnerable to this barrier. A university team and a local Commission on Aging jointly secured funding to pilot the Virtual Table (VT) model which builds on relationships between HDM drivers and meal recipients to overcome lack of interest and skepticism of technology like the internet and video chatting. For the pilot, 25 recipients were recruited to learn basic technology skills (e.g., email, video chat) from trusted peer tutors through weekly one-to-one sessions, in-person or by video, leading to knowledge and skills to support telehealth utilization. Twenty recipients (80%) are completing the pilot. Results to date show increased technology use and comfort, together with confidence to use telehealth. Participants valued the interactions with tutors as well as what they learned. Feedback from tutors, agency staff, and participants has been used to refine the pilot during implementation. Building on the lessons learned and feedback, the goal for the next stage of collaboration is developing a set of effective tools to implement VT in several diverse communities. Four VT ‘graduates’ will be actively involved as co-producers of these revised tools. In addition, older adult home-delivered-meal (HDM) recipients, agency staff, tutors, and other older adult volunteers will directly participate in ongoing evaluation of the new resources.

INTERPROFESSIONAL COLLABORATIVE RESEARCH ASSESSING OLDER ADULT TECHNOLOGY USE (OR NONUSE)

Donna Case, Sheryl Groden, MIchelle Sahli, and Wendy Tremaine, *University of Michigan-Flint, Flint, Michigan, United States*

This interprofessional study conducted by faculty in Occupational Therapy, Social Work and Public Health explored older adult technology use (or nonuse) by 216 Genesee County Michigan residents. Three professional lenses informed survey development, implementation and data analysis. Occupational therapy emphasized accessibility, how physical or cognitive impairments hinder technology use, and role of technology to complete daily living activities. Social work focused on technology use to facilitate social connectivity, decrease risks for mental health problems, and resource access. Public health explored if technology use or nonuse impacts health. Results indicated that 14% of participants want to learn to obtain transportation (social, health) via the internet, 13% stated they wanted to learn how to use technology to access medical records, 12.5% to attend on-line appointments, 11% reported they would engage in additional technology-based social activities (e.g. communicating with family/friends), 10% to order/refill medications, and 9% of older adults surveyed had difficulty accessing technology due to a physical, cognitive or sensory impairment. Researchers found the questions provided an integrated view of factors influencing older adult use or nonuse of technology and provided a guide for designing collaborative interventions to facilitate older adult access and use of technology to result in positive holistic health outcomes.

SESSION 4681 (PAPER)

LATE BREAKING: COMMUNITY-BASED PARTICIPATORY RESEARCH APPROACHES III

USING HUMAN CENTERED DESIGN TO DEVELOP TWO NEW MEASURES OF LIVING WELL WITH DEMENTIA

Sheila Molony,[1] Sam Fazio,[2] Sheryl Zimmerman,[3] Ricci Sanchez,[2] Joe Montminy,[2] Cindy Barrere,[1] Rachel Montesano,[1] and Kimberly Van Haitsma[4], *1. Quinnipiac University, Hamden, Connecticut, United States, 2. Alzheimer's Association, Chicago, Illinois, United States, 3. University of North Carolina, Chapel Hill, North Carolina, United States, 4. Pennsylvania State University, University Park, Pennsylvania, United States*

Background: New measures are needed that can provide a holistic approach to capturing salient outcomes contributing to quality of life in dementia. Purpose: To use human centered design to develop, prototype and evaluate new positive psychosocial measures for persons living with dementia Methods: This project used a conceptual framework of human centered design to obtain and analyze data from multiple sources, including individual and focus group interviews, observations in the field and related methods to enhance empathy for the lived experience of dementia, and to design prototypes for two new measures. Results: Qualitative analysis of interview data, integration of data from the theoretical and empirical literature and human centered design techniques including brainstorming and ideation were used to define constructs and create prototypes for a new Living Well with Dementia Inventory and Good Day-Bad Day assessment tool. Results of qualitative analysis, item development, and initial validity assessment will be presented. Conclusion: Human centered design is a useful method for development of person-centered measures. This method may complement traditional methods of instrument development and CBPR.

IT'S A FAMILY AFFAIR: COMMUNITY-BASED RESEARCH PARTNERSHIP TO CREATE A FAMILY-CENTERED DEMENTIA CAREGIVER PROGRAM

Rachel O'Conor,[1] Dianne Oladejo,[1] Sarah Filec,[1] Janice Knox,[2] Angel Griffin,[2] Joyce Chapman,[3] and Tonya Roberson[4], *1. Northwestern University, Chicago, Illinois, United States, 2. Helping Communities Help Themselves, Chicago, Illinois, United States, 3. Far South Chicago Coalition, Chicago, Illinois, United States, 4. Governors State University, Chicago, Illinois, United States*

People in the Black community are two times more likely to develop dementia than white people. This racial disparity is due to both social and structural factors which shape access to power, resources and exposure to health-damaging conditions by race. Due to the significant cognitive changes that occur, Black families assume substantial caregiving responsibilities to support family members, yet few caregiving programs offer culturally tailored support and training to the preferences and familial care norms of Black caregivers. In response, individuals from two community-based organizations (CBOs) and an academic medical center partnered to develop a culturally tailored, community-based, family-centered dementia caregiving research program for individuals living in far south Chicago. A team of stakeholders identified by the CBOs convened in the Fall 2021 to discuss the need for the proposed program, and together a key informant interview guide was designed. We have conducted 16 of 30 interviews and preliminary analyses of the interviews has revealed that caregivers are largely caring for parents or grandparents and are sharing caregiving responsibilities with other family members. Caregivers endorsed a need for the program; preferred a hybrid format and the need to include content related to 1) education on dementia, 2) emotional coping, and 3) linkage to medical and community-based resources. Anticipated barriers to participation included, time, location, and care for their family member while they participated. Our stakeholder team will continue to conduct key informant interviews, review and interpret data findings, and collectively develop a community-based family-centered caregiving program.

AFRICAN-AMERICAN ALZHEIMER'S CAREGIVER TRAINING AND SUPPORT PROJECT 2 PILOT STUDY: OUTCOMES ANALYSIS

Robert Glueckauf,[1] Nik Lampe,[2] Michelle Kazmer,[3] Alexandra Nowakowski,[4] Yuxia Wang,[1] Naomi Thelusma,[1] Dominique Williams,[1] and Cordy McGill-Scarlett[1], *1. Florida State University College of Medicine, Tallahassee, Florida, United States, 2. Vanderbilt University, Nashville, Tennessee, United States, 3. Florida State University, Tallahassee, Florida, United States, 4. Florida State University College of Medicine - Orlando Regional Campus, Orlando, Florida, United States*

The purpose of this study was to conduct an initial evaluation of the quantitative and qualitative outcomes of the African-American Alzheimer's Caregiver Training and Support Project 2 (ACTS2). Quantitative objectives focused on assessing changes in caregiver depression and health status, as well as the severity of caregiving and self-care problems from pre- to post-intervention. Secondary quantitative analyses examined post-treatment changes in social support and caregiver burden. Qualitative objectives included examining caregivers' perceptions of the effectiveness of in-session training activities, quality of relationships among participants and their facilitator, and appraisals of spiritual elements of the program. Nine African American family caregivers of older adults with dementia completed the ACTS2 lay pastoral care facilitator-led, telephone cognitive-behavioral intervention. The twelve-week training program included 7 skills-building groups and 5 individual problem-solving sessions. Significant improvements were found on the majority of dependent measures, including caregiver depression, health status, problem severity, and social support. Qualitative analysis highlighted the value caregivers placed on relationships with their co-participants and group facilitators, the role of spirituality within the program, and the importance of goal setting in improving caregiver distress and self-care. Convergence was found between quantitative and qualitative findings, particularly improvements in the domains of caregiver distress, health status, and social support. Overall, the findings of the pilot study were promising. Replication using a randomized controlled design with a larger sample size is needed to test the reliability of the findings. Benefits of tailoring intervention to caregivers' sociocultural preferences and spiritual values are also addressed.

REMOTELY MEASURED IN-HOME DISTANCE FROM CARE RECIPIENT PREDICTS DEMENTIA CAREGIVERS' LONELINESS

Kuan-Hua Chen,[1] Yuxuan Chen,[2] Darius Tran Levan,[1] Claire Yee,[1] Jennifer Merrilees,[3] Julian A. Scheffer,[1] Samson Chen,[4] and Robert W. Levenson[1], *1. University of California, Berkeley, Berkeley, California, United States, 2. Stanford University, Stanford, California, United States, 3. University of California, San Francisco, San Francisco, California, United States, 4. Tracmo, Inc., Taipei, Taipei, Taiwan (Republic of China)*

Caregivers (CGs) of a family member with dementia often experience increased loneliness, which can result from reduced social interactions and increased physical distancing associated with care recipient's (CR) disease progression. Through a university-industry collaboration, we developed new technology for measuring physical distance remotely. CGs and CRs wore watches that monitored their location in the home using low-energy Bluetooth technology that enabled long battery life (up to four months). Using measures of proximity of the watches to three plug-in Bluetooth receivers located in the home, we assessed CG-CR physical distance on a second-by-second basis over a six-month period. Participants were 27 CRs diagnosed with dementia or mild cognitive impairment and their co-residing familial CGs. CG loneliness was measured by questionnaire at the beginning and end of the study. Both watches and receivers were remotely installed (by CGs). Results indicated that CG-CR physical distance increased from the first three months to the last three months of the study ($t = 20.67$, $p < 0.001$). In addition, greater increases in CG-CR physical distance over the six-month period were associated with greater increases in CG loneliness ($r = 0.46$, $p = 0.03$). These results advance our understanding of how increases in physical distancing between CGs and CRs contribute to increased CG loneliness (a well-established risk factor for depression and other mental health symptoms). The study also underscores the value of remote technologies that allow for in-home long-term monitoring for research on interpersonal distance and other social behaviors in CG-CR and other aging dyads.

SESSION 4682 (PAPER)

LATE BREAKING: MOTIVATING PATIENTS FOR HEALTH BEHAVIOR CHANGE II

DEVELOPMENT AND APPLICATION THE QUESTIONNAIRE FOR MEDICAL CHECKUP OF OLD-OLD (QMCOO) - TAIWAN VERSION

Jui-Ying Hung, *Chaoyang University of Technology, The National Center for Geriatrics and Gerontology, Wufeng, Taichung, Taiwan (Republic of China)*

In 2022, population over the age of 65 is currently about 3.8 million (accounting for about 16% of the total population) as an "aged society" in Taiwan. According to the report about the frailty of the elderly increases with age, especially 75 - 79 years old, are the most obvious functional decline (The Ministry of Health and Welfare, 2022). This trend that also happened in 2005, the interim report of the 3rd national health promotion measures showed an increased prevalence of diabetes mellitus and obesity in Japan. In response to this, Dr. Satake and Dr. Arai (2020) develop the questionnaire for Medical Checkup of Old-Old (QMCOO) suited measure frailty to people aged ≧75 years better and composed of 15 questions regarding the following 10 domains: health condition, mental health, eating behavior, oral function, body weight loss, physical function and falls, cognition function, smoking, social participation and social support implemented in April 2020. This study authorized by Dr. Satake et, al in August 2022, aims to translate the QMCOO in Chinese version and through expert discussions to confirm that there are no difference between the original version in Japanese/English, and the apply query specification for QMCOO in Taiwan. This study recruited 300 older adults in Taichung city to answer all the questions in QMCOO and analysis the diagnostic frailty distributed status compared to the data measure in the Kihon Checklist in the same time. This finding the cutoff scores 2/3 for the QMCOO might be effective in diagnosing frailty in Taiwan.

LONGITUDINAL ASSOCIATIONS BETWEEN FALLS AND DEPRESSIVE SYMPTOMS AMONG CHINESE OLDER ADULTS

Nie Zuoting,[1] Eunjin Lee Tracy,[2] Yan Du,[3] Sha Li,[1] and Rumei Yang[1], *1. Nanjing Medical University School of Nursing, Nanjing, Jiangsu, China (People's Republic), 2. University of Pittsburgh School of Medicine, Pittsburgh, Pennsylvania, United States, 3. UT Health San Antonio, San Antonio, Texas, United States*

Falls and depressive symptoms are prevalent and costly to Chinese older adults. Although falls and depressive symptoms are frequently interrelated, previous studies were mainly based on cross-sectional data, and the nature of interrelationships between them were not well understood. In this study, we aimed to examine the longitudinal bidirectional relationship between falls and depressive symptoms among Chinese older adults, and whether this bidirectional relationship is different for males and females, given that females are found to suffer from falls and depressive symptoms significantly more than males. Older adults aged 60 years+ who completed all three waves of data from the China Health and Retirement Longitudinal Study on falls and depressive symptoms between 2011 (wave 1), 2013 (wave 2), and 2015 (wave 3) were included in the current analysis (Nf2,203). Data were analyzed using random intercept multilevel models that adjusted for demographic information (e.g., age, education, and marital status). Overall, there is a relatively stable rates of comorbid falls and depression (about 10%) over time among Chinese older adults. Significant bidirectional associations at between-person and within-person levels were observed between depressive symptoms and falls over time, with greater depressive symptoms associated with higher risk for falls and vice versa. However, such associations were not different between males and females. Taken together, these findings indicate the importance of addressing both depression and falls at the same time to prevent falls in the clinical practice for both males and females.

MOTIVATING CHANGE IN OLDER ADULTS: MOTIVATIONAL CIGARETTE SMOKING CESSATION MESSAGE TESTING

Adrienne Johnson, and Jesse Kaye, *University of Wisconsin School of Medicine and Public Health - Center for Tobacco Research and Intervention, Madison, Wisconsin, United States*

Cigarette smoking remains the leading preventable cause of death and disability in the U.S., resulting in ~480,000 deaths annually. Older adults who smoke bear a disproportionate weight of the health consequences of smoking, including cancer, mortality, and the greatest health-related fear of older adults: dementia. Compared to younger adults, older adults who smoke are half as likely to make a quit attempt, but more likely to stay quit using evidence-based treatments. Research suggests the increased risk of dementia among people who currently smoke may motivate adults ages >50 to quit smoking, particularly if given a clear/actionable strategy. Research also suggests Fear-based messages may perform differently than Hope-based messages. 820 adults (ages 50–80) without dementia who smoke, completed an online survey evaluating time-matched messages (randomly assigned between-subjects: Control Nf266, Fear of dementia Nf274, Hope from quitting Nf280) on motivation and intentions to quit smoking. Participants' demographics were Mage=61.1 years (SD=7.4), 48.0% cisgender women, 66.6% White, 23.3% Black. Mann-Whitney U Tests were use to examine change scores for each variable due to non-normal distributions. Compared to control message (water ad), the Fear message showed greater increase in motivation to quit U(Ncontrol=266, Nfear=274)=30391, z=-3.33, p=.001. The Hope message did not differ from the control or Fear message (p's>.05). Intention to quit did not differ between messages (p's>.05). A Fear-based message highlighting that smoking increases the risk of developing dementia, motivated quitting more than a control message. Future work should examine the feasibility, acceptability, and behavioral impact of this motivational message in healthcare settings.

THE IMPACTS OF LIFESTYLE ON DEPRESSION AND LIFE SATISFACTION AMONG CHINESE OLDER ADULTS: A 7-YEAR FOLLOW-UP STUDY

Man-Man Peng, *Beijing Normal University, Zhuhai, Guangdong, China (People's Republic)*

This study aims to explore the long-term effects of lifestyle-related factors and physical health on life satisfaction among older adults by transitions in mental health conditions. Using data derived from the China Health and Retirement Longitudinal Study (CHARLS), the analytic sample included 643 older adults. Linear regression analyses were used to examine the cross-sectional and longitudinal associations of lifestyle-related factors and physical health with depression risk and life satisfaction in older adults. In this study, sleep duration and multimorbidity was found to be significantly related to baseline and follow-up depressive symptoms in older adults. Compared to non-drinkers, current drinkers reported more severe depressive symptoms. More depressive symptoms were associated with worse impairment in physical function or Activities of Daily Living (IADLs). Among older adults remaining no depressive symptoms at baseline and follow-up, current drinkers tended to have lower life satisfaction than non-drinker. Shorter sleep duration showed a longitudinal correlation with lower life satisfaction. In the subgroups of emerging depression, past drinkers tended to have lower life satisfaction than non-drinkers, and baseline multimorbidity significantly predicted lower subsequent life satisfaction. In conclusion, our findings identified drinking and shorter sleep duration as the lifestyle-related detrimental factors of late-life depression and life satisfaction in Chinese community-dwelling older adults. Other physical-health-related risk factors of depression included worse impairment in physical function or IADLs, and multimorbidity. Our findings have implications for future psychosocial interventions targeted at alleviating depressive symptoms and promoting life satisfaction of the older adults based on their long-term mental and physical health conditions.

SESSION 4683 (PAPER)

LATE BREAKING: INNOVATIONS IN CLINICAL PRACTICE III

VALIDATION OF GLIM CRITERIA ON MALNUTRITION IN CHINESE OLDER INPATIENTS

Tong Ji,[1] Yun Li,[2] Pan Liu,[2] Yaxin Zhang,[2] Yu Song,[2] and Lina Ma[2], *1. Capital Medical University Xuanwu Hospital, Beijing, Beijing, China (People's Republic), 2. Xuanwu Hospital Capital Medical University, Beijing, Beijing, China (People's Republic)*

Backgrounds: Malnutrition is a nutritional disorder that has a high incidence and can lead to multiple poor prognoses, such as frailty. Early identification and correct evaluation of malnutrition are essential for improving clinical outcomes. Objective: Therefore, we aimed to explore the applicability and effectiveness of the Global Leadership Initiative on Malnutrition (GLIM) criterion for identifying undernutrition in older inpatients. Methods: In total, 223 participants aged ≥60 years were involved. Nutrition was evaluateded employing MNA-FF and GLIM criteria, which adopts a two-step procedure. The first step was to use three different methods for nutritional risk screening: NRS-2002, MNA-SF, and MUST. The second step is to diagnose undernutrition. The Clinical Frailty Scale was used to assess frailty. Sensitivity, specificity, Youden index, kappa values, and positive and negative predictive values were measured to test the validity of the GLIM criteria. Logistic regression models were used to assess whether there was a correlation between malnutrition and frailty. Results: We found that 32.3–49.8% of inpatients were at risk of malnutrition based on the GLIM diagnosis using the three different screening tools, 19.3–27.8% of patients were malnourished. The GLIM criteria with MNA-SF as the diagnostic validation and MNA-FF as a reference showed high consistency ($k = 0.629$; $p < 0.001$), sensitivity (90.5%), and specificity (86.4%). Logistic regression analysis showed that malnutrition, using MNA-SF with the GLIM criteria, was relevant to higher likelihood of frailty (OR=1.887; 95% CI: 1.184–2.589). Conclusions: The GLIM criteria with the MNA-SF may be a more reliable malnutrition assessment process in elderly inpatients.

EFFECT OF CHANGE IN BODY SIZE ON MORTALITY IN THE INITIALLY HEALTHY COMMUNITY-DWELLING OLDER ADULTS

Sultana Monira Hussain,[1] Anne Newman,[2] Lawrence Beilin,[3] Andrew Tonkin,[1] Robyn Woods,[1] Johannes Neumann,[4] Mark Nelson,[5] and John McNeil[1], *1. Monash University, Melbourne, Victoria, Australia, 2. University of Pittsburgh, Pittsburgh, Pennsylvania, United States, 3. The University of Western Australia, Perth, Western Australia, Australia, 4. University Heart & Vascular Center Hamburg, Hamburg, Hamburg, Germany, 5. Menzies Research Institute, University of Tasmania, Hobart, Tasmania, Australia*

Utilising data from the ASPirin in Reducing Events in the Elderly trial participants [aged >70-years (Australians), >65-years (US)], we estimated percent change in body size (BMI: body mass index, WC: waist circumference) from baseline and the second annual visits. Both BMI and WC changes were categorised as 1) change within 5% (stable), 2) decrease by 5–10%, 3) decrease by >10%, 4) increase by 5–10%, and 5) increase by >10%. Mortality events were classified according to the underlying cause by adjudicators. Hazard ratios were calculated to compare mortality between body size change categories. Amongst 16,773 participants, 1,269 mortality were observed over an average 4.4±1.7 years. In men compared to stable BMI, a 5–10% decrease in BMI had a 35% higher (HR 1.35, 95% CI 1.08–1.67), and a >10% decrease in BMI had a 3.84-fold higher (HR 2.99, 95% CI 2.44–3.68) risk in all-cause mortality. A decrease in BMI was associated with a higher cause-specific (cancer, cardiovascular disease [CVD], and non-cancer non-CVD) mortality. A decrease in BMI was associated with higher mortality risk in women, however, the magnitude of association was weaker than men. A decrease in WC was predictive of mortality but with a much weaker relationship than a decrease in BMI. Weight gain was not predictive of mortality except for non-cancer non-CVD mortality in women. Physicians should be aware of the ominous consequence of weight loss, especially amongst older men. The risk extends beyond an increased risk of cancer, extending to CVD and a range of other life-limiting conditions.

REVISITING ELECTRONIC FRAILTY INDEX BY ADDING A LAB-BASED MARKER OF NUTRITION: A HEART FAILURE COHORT

Seulgi Kim,[1] Ariela Orkaby,[2] Catherine Park,[3] Molly Horstman,[3] Salim Virani,[1] Orna Intrator,[4] Aanand Naik,[3] and Javad Razjouyan[3], *1. Baylor College of Medicine, Houston, Texas, United States, 2. VA Boston, Boston, Massachusetts, United States, 3. Veterans Affairs, Houston, Texas, United States, 4. Veterans Health Administration, Rochester, New York, United States*

Malnutrition is associated with worse prognosis and increased risk for adverse outcomes in patients hospitalized with heart failure (HF). The objective is to assess the utility of adding the Prognostic Nutritional Index (PNI), a validated measure of nutritional status, to the Veterans Health Administration frailty index (VA-FI) in predicting time to death in patients hospitalized with HF. We conducted a retrospective cohort study of veterans age ≥50 years hospitalized with HF as their primary diagnosis. PNI was calculated using lab values in the year prior to hospitalization with the following equation: 10 x serum albumin (g/dL) + 0.005 x total lymphocyte count (mm3). VA-FI identified five groups: robust (≤0.1), prefrail (0.1–0.2), frail (0.2–0.3), moderately frail (0.3–0.4), and severely frail (>0.4). PNI was added to VA-FI (VA-FI-Nutrition) using the same cutoffs. We identified changes in frailty status using VA-FI versus VA-FI-Nutrition by summarizing the count by each class and reported the hazard ratio (HR) for all-cause mortality in each VA-FI category based on the new VA-FI-Nutrition groups. VA-FI-Nutrition identified patients within each VA-FI class that belong to the next frailty strata: robust (20.2%), prefrail (18.3%), frail (16.7%) and moderately frail (16.7%). We observed higher mortality rates among those whose frailty class changed based on VA-FI-Nutrition compared to VA-FI: robust (HR, 1.65, 95%CI:1.38, 1.97), prefrail (HR, 1.52, 95%CI: 1.41, 1.65), frail (HR, 1.42, 95%CI: 1.33, 1.52), and moderately frail (HR, 1.33, 95%CI: 1.24, 1.43). Adding PNI to VA-FI provides a more accurate mortality assessment and may be utilized to triage high-risk patients.

SESSION 4684 (PAPER)

LATE BREAKING: APPLYING REFRAMING AGING IN YOUR WORK II

A THEORETICAL EXAMINATION INTO THE CONNECTIONS BETWEEN LINKED LIVES AND LATER LIFE DISABILITIES

Akwasi Adjei Gyimah, and Samuel Van Vleet, *Miami University, Oxford, Ohio, United States*

As people age, they find themselves living similar lives to those around them. This concept is often referred to as linked lives. Linked lives explains that individual lives are often interdependent. This is due to various elements such as social and historical influences. These influences can imprint networks of shared relationships. Researchers have found that the first point of socialization as humans are social relationships with family and friends. However, while the connections of linked lives are often attributed to early life course trajectories, little research has evaluated the interdependency that is created with disabilities in later life. Life course disability research is a key factor of gerontology because a majority of older adults encounter disabilities within later life. This attributed disability can often forge bound and interdependence within people and their own social networks. This paper theoretically examines different perspectives of disabilities research and how it relates to the fundamental principles of linked lives. This paper highlights the gap in the current gerontological understanding of the later life links among older adults with disabilities. This theory paper provides the needed information for gerontologist focusing on older people with disabilities to be able to evaluate allocations needed for providing adequate social support and services tailored towards the needs of these interdependent lives.

THE DETERMINANTS OF LIFE SATISFACTION AMONG MONGOLIAN OLDER ADULTS

Saranchuluun Otgon,[1] Khorolsuren Lkhagvasuren,[1] Yerkebulan Mukhtar,[1] Anujin Baatar,[2] Casati Fabio,[3] Agnieszka Czajka,[4] and Sugarmaa Myagmarjav[1], *1. Mongolian National University of Medical Sciences, Ulaanbaatar, Ulaanbaatar, Mongolia, 2. The International University of Ulaanbaatar, Ulaanbaatar, Ulaanbaatar, Mongolia, 3. University of Trento, Trentino-Alto Adige, Italy, 4. Polish-Japanese Academy of Information Technology, Warsaw, Kujawsko-Pomorskie, Poland*

Background: As the average life expectancy and the proportion of the elderly population increases, approaches that limit their policies, programs, and activities to health issues are changing worldwide. International organizations, such as the WHO, United Nations, have pledged their member countries to update their policies on the elderly population and increase their psychological and social participation over the next 20 years. We determined social demographic factors of life satisfaction among Mongolian older adults. Methods: A cross-sectional study recruited three hundred four older adults recruited by geriatric doctors and seniors' association units in urban and rural areas of Mongolia. The questionnaire included life satisfaction, social network, loneliness, social participation, self-rated health, and demographics. We used multiple linear regression analyses. Result: Life Satisfaction of the older adults living in urban is higher than those living in rural area ($\beta = 0.954$, $p = 0.001$). Good self-rate of health ($\beta = 1.013$ $p = 0.001$), voluntary work ($\beta = 0.847$ $p = 0.001$), and employment increase life satisfaction levels. Life satisfaction scores increased by 0.3 points for male older adults with a 1-point increase in education, 0.9 points for women living in cities ($\beta = 0.929$ $p = 0.002$), and 0.8 points for volunteering ($\beta=0.790$ $p=0.006$) respectively. However, when the loneliness score increases by one, the satisfaction score decreases by 0.3 points ($\beta = -0.353$ $p = 0.013$). Conclusions: The level of satisfaction of the Mongolian older adults is associated with self-rate of health, education level, loneliness, social activities, and living areas.

THE QUALITY IN QUALITATIVE: AN EXAMINATION OF RETIREMENT INTERVIEWS

Michelle Silver, *University of Toronto, Toronto, Ontario, Canada*

Qualitative interviews are a dynamic and complex way to understand life experiences. Retirement is an ever-evolving, dynamic, and complex social construct we associate with the end of one's career. Exploring what retirement means to different people in the context of critical gerontological theories of successful aging can contribute to a better understanding of the implications of this important transition at the individual and societal level. However, sifting through participants stories is not always a straightforward endeavor, particularly in the case when participants have complex and dynamic stories. This paper examines the value of qualitative research methods in unpacking complex personal narratives. As the landscape surrounding mature workers' experiences continues to change, this paper extends policy debates about retirement, as well as scholarly conversations about the richness and complexity of qualitative research.

FEELING VS BEING CONNECTED: DIFFERENTIATING LONELINESS AND ISOLATION IN NEAR- AND CENTENARIANS

Lian Ying Chun Pat,[1] Bobo Hi Po Lau,[1] Peter Martin,[2] Joey Chung Yue Siu,[3] Karen Siu Lan Cheung,[4] Cecilia Lai Wan Chan,[4] Grace Man Yee Chan,[5] and James Ka Hay Luk[6], *1. Hong Kong Shue Yan University, Hong Kong, Hong Kong, 2. Iowa State University, Ames, Iowa, United States, 3. Caritas Institute of Higher Education, Hong Kong, Hong Kong, Hong Kong, 4. The University of Hong Kong, Hong Kong, Hong Kong, 5. The Hong Kong Council of Service, Hong Kong, Hong Kong, 6. TWGHs Fung Yiu King Hospital (FYKH), Hospital Authority, Hong Kong, Hong Kong*

While gerotranscendence theories postulate that older adults tend to orient themselves toward solitude, activity theories highlight the importance of continuing social and meaningful engagement for well-being across lifespan. The distinction between loneliness and social isolation is particularly observable in older adults of advanced age who are often facing accelerated decline in physical and functional health, therefore restricting their opportunities to interact with others.

This has been particularly disturbing during the previous two years under COVID. This study utilized data from the 2nd Hong Kong Centenarian Study which interviewed 120 family caregivers of older adults aged 95 or above in 2021–2022 when the city experienced almost an entire year of the outbreak. Using family or friend proxy information as well as caregiver ratings of whether older adults expressed feelings of social isolation and loneliness, we found that 10.7% of older adults reported high levels of loneliness and isolation; 26.7% feeling low in both; 11.5% were isolated but not lonely, and 38.2% were lonely but not isolated. Loneliness ratings were more strongly associated with psychological well-being (Patient Health Questionnaire-4), autonomy, happiness, perceived usefulness, worries, and death anxiety than did isolation, with the latter negatively correlated with optimism. Participants rated in the low isolation/loneliness group were least (death) anxious than the other three groups. Our findings underscore the divergence of isolation and loneliness for adults of advanced age and call for psychological support for oldest-old adults who continue to face social isolation, especially when society gradually recovers from COVID.

COMPARING SUCCESSFUL AGING OF NEAR-CENTENARIANS AND CENTENARIANS: FINDINGS FROM 2011 AND 2021/22

Eric Ngai Yin Shum,[1] Bobo Hi Po Lau,[1]
Karen Siu Lan Cheung,[2] Grace Man Yee Chan,[3]
Joseph Shiu Kwong Kwan,[4] James Ka Hay Luk,[5]
Peter Martin,[6] and Cecilia Lai Wan Chan[2], *1. Hong Kong Shue Yan University, Hong Kong, Hong Kong, 2. The University of Hong Kong, Hong Kong, Hong Kong, 3. The Hong Kong Council of Service, Hong Kong, Hong Kong, 4. Imperial College London, London, England, United Kingdom, 5. TWGHs Fung Yiu King Hospital (FYKH), Hospital Authority, Hong Kong, Hong Kong, 6. Iowa State University, Ames, Iowa, United States*

Successful aging (SA) was proposed by Robert J Havighurst in 1961 to capture how older adults add “lives onto (their) years.” While there is a consensus regarding the multidimensionality of the concept, the set of criteria that should be applied to older adults of advanced age remain controversial. Notwithstanding their inevitable decline in physical health, adults of advanced age may still enjoy good psychosocial well-being. In this light, we compared the proportion of “successful agers” in two cohorts of adults aged 95 or above who lived with their families in 2011 (N=77) and 2021/22 (N=120) in Hong Kong using two models – Model A: i: Good subjective health, ii: more well-off than average, iii: as happy as young (Cho et al., 2012) and Model B: i: Weekly social activities, ii: absence of dementia, iii: intact sight and hearing ability, iv: intact mobility (Nosraty et al, 2012). Both models have been applied in adults aged 90 or above. In the 2011 cohort, 13.0% and 16.9% of our sample fulfilled the SA criteria of Model A & B respectively. The percentages fell to 1.7% and 13.7% respectively in the 2021/22 cohort. The decrease is due to less participants fulfilling the financial criterion of Model A, as well as the criteria on intact sight and hearing ability and the absence of dementia of Model B. COVID presents multidimensional challenges for adults of advanced age. Examining the dimensions that are most impacted will help orient recovery works along the direction of SA.

SESSION 5082 (PAPER)

LATE BREAKING: COMMUNITY-BASED PARTICIPATORY RESEARCH APPROACHES IV

A CLINICAL TRIAL USING METHYLATION AGE TO EVALUATE CURRENT ANTIAGING PRACTICES

Josh Mitteldorf, *DataBETA Project, Philadelphia, Pennsylvania, United States*

Recent advances in the technology of “aging clocks” based on DNA methylation suggest that it may be possible to measure changes in the rate of human aging over periods as short as a year or two. To the extent that methylation (and other biomarkers) are valid surrogates for biological age, the testing of antiaging interventions has thus become radically cheaper, faster, and more practical. Together with colleagues at McGill University, I have initiated a clinical trial to evaluate some of the most popular antiaging strategies currently deployed by “early adopters” in the lay community of personal health activists. We are recruiting 5000 subjects, age 45–65, and interviewing them in detail about their diet, drugs and supplements, exercise, social, and other practices that plausibly contribute to modulate the rate of aging. They agree to submit saliva samples for analysis of methylation age at the beginning and end of a 2-year test period. Primary endpoint is the difference in methylation age over the course of 2 years. Results will be viewed as an exploratory study to identify synergistic combinations of age-retarding treatments. All data (redacted for privacy) will be open sourced, available to the scientific community and to the public.

CHANGES IN GENERAL SELF-EFFICACY FOLLOWING THE WITS WELLNESS PROGRAM: PRELIMINARY FINDINGS FROM THE 12-WEEK RCT

Neha Gothe,[1] Molly Hofer,[2] Chelsey Byers,[3] Laura Payne,[1] and Julie Bobitt[4], *1. University of Illinois at Urbana Champaign, Urbana, Illinois, United States, 2. University of Illinois Extension, Chicago, Illinois, United States, 3. University of Illinois Extension, Champaign, Illinois, United States, 4. University of Illinois at Chicago, Chicago, Illinois, United States*

Self-efficacy among older adults has been associated with better sleep, increased vitality, decreased pain and discomfort as well as overall satisfaction with life. Interventions designed to increase general self-efficacy can therefore have wide-ranging effects on individual’s health as well as reduce the burden on healthcare systems. In this abstract we present preliminary data examining the impact of Wits Wellness on general self-efficacy among participants. Middle aged and older adults, N=285 (Mean age 65.58 yrs, males=28) were randomized to either a Wits Wellness group or a Waitlist Control for 12-weeks. The 12-week wellness program addresses multiple factors including physical activity, stress, sleep, social isolation and diet with the goal of empowering older adults to make healthier lifestyle choices. At baseline and end of the 12-week trial, the 10-item PROMIS general self-efficacy scale was used to assess global self-efficacy which reflects a problem-solving approach despite perceived obstacles and challenges. Older participants aged 65 and above, who attended 8 or more weeks (Nf123, n=63 in Wits Wellness group) of the program demonstrated significant increases in their general self-efficacy. Results showed a significant group*time effect favoring the Wits Wellness intervention (F(1,120)=4.10, p=.045, partial eta2=.03). The intervention was most effective in boosting confidence among the older adults within the trial (>65 yrs.). These findings demonstrate preliminary efficacy of the Wits Wellness program and are significant as general self-efficacy is considered an important moderator of healthy adaptation to illness which is critical in old age. Funded by the Midwest Roybal Center grant P30AG022849.

SESSION 5083 (PAPER)

LATE BREAKING: INNOVATIONS IN CLINICAL PRACTICE IV

AN OLDER ADULT FRACTURE PROGRAM EMPLOYING AGE-FRIENDLY CARE CAN BE IMPLEMENTED AT YOUR HOSPITAL AND IMPROVE OUTCOMES

Kathleen Breda, Michelle Keller, Hiroshi Gotanda, Karma McKelvey, Carol Lin, and Sonja Rosen, *Cedars-Sinai Medical Center, Los Angeles, California, United States*

Older adult fractures are expected to increase dramatically over the next several decades, with hip fractures reaching an estimated 6.26 million worldwide by 2050. A combined approach to the care of older adult fracture patients was first reported in the early 1990s, emphasizing geriatric and orthopedic co-management. Early studies showed significant improvements in complications, function, and discharge rates to nursing homes. Subsequent studies demonstrated shorter time-to-surgery, lengths of stay (LOS), lower readmission rates, reduced in-hospital mortality, and lower cost of care. The studies are from large academic centers whose physicians are employed faculty or have dedicated geriatric units. Less studied is whether similar models could be implemented in community health systems/mixed practice settings like Cedars-Sinai. Cedars-Sinai's older adult fracture program integrates inpatient and outpatient care and uses best practices of the 4Ms Framework of an Age-Friendly Health System, including What Matters Most, Mentation, Medications, and Mobility. The program was designed through the consensus of interprofessional champions and empirical evidence. Results showed enrolled patients with all fracture types had significantly lower LOS (marginal effect [ME]: -2.12, 95%CI: -2.61, -1.63), LOS index (ME: -0.33, 95%CI: -0.42, -0.25), and total direct costs (ME: -$5316.4, 95%CI: -6806.31, -3826.5). There was no significant difference in time-to-surgery. Of the 746 enrolled patients, 170 (23%) had a post-discharge visit with a participating geriatrician within 6 months. Findings indicate a systematic approach to improving care for older adults with fractures improves inpatient outcomes in a mixed practice setting. Future studies will examine the effectiveness of Cedar-Sinai's outpatient program.

PROFILE OF OKLAHOMA CLIENTS REFERRED TO ADULT PROTECTIVE SERVICES FOR ALLEGED SELF-NEGLECT

Samantha Tuft, Farida Ejaz, Miriam Rose, and Courtney Reynolds, *Benjamin Rose Institute on Aging, Cleveland, Ohio, United States*

Self-neglect is the most commonly reported allegation of abuse to Adult Protective Service (APS) agencies nationwide. Researchers collaborated with Oklahoma APS to understand characteristics of allegedly self-neglecting clients who were reported to APS (focus of this paper), and to subsequently refer a random sub-sample to home-and community-based services and track outcomes. Clients (n = 188) were interviewed by phone; data were collected on demographic and background characteristics, physical and mental health, social support, social isolation, and the impact of COVID-19 on them. Most clients were white, 18% were American Indian, and 14% were African American. Their ages ranged from 18–92 years, 63% were women, most were low-income ($12,000-$15,000 annually), and 60% lived alone. Many used public benefits such as Medicare (75%), Social Security, and Medicaid. Based on PHQ scores, about a third had moderate to severe symptoms of depression; and 27% scored similarly on anxiety. More than a third saw family and friends less often during the pandemic. APS administrative data was also obtained on these clients and preliminary analyses indicated that the 188 study participants had a total of 205 allegations of self-neglect prior to the study, with 76% of the allegations needing a referral for community services. During the intervention phase, however, only 31 clients had any type of abuse allegations with 24 being for self-neglect. About half needed community services. It is possible that services they were referred to prior and during the study was related to the decline in self-neglect allegations during the study period.

PLASMA HIGH DENSITY LIPOPROTEIN CHOLESTEROL AND RISK OF FRACTURES IN OLDER ADULTS

Sultana Monira Hussain,[1] Peter Ebeling,[1] Anna Barker,[1] Lawrence Beilin,[2] Andrew Tonkin,[1] and John McNeil[1], *1. Monash University, Melbourne, Victoria, Australia, 2. The University of Western Australia, Perth, Western Australia, Australia*

The ASPirin in Reducing Events in the Elderly trial participants (ASPREE, aged >70-years Australians), for whom high-density lipoprotein cholesterol (HDL-C) levels were measured were included. Fractures included were confirmed by medical imaging and included both traumatic and pathological fractures. Fractures were confirmed by an expert review panel. Cox proportional hazards regression was used to calculate hazard ratio (HR) and 95% confidence interval (CI) for associations with fractures. Of the 16262 participants who had a plasma HDL-C measurement at baseline 1,659 experienced at least one episode of fracture over a median of 3.98 years (interquartile range, 0.02, 7.0 years). In the fully adjusted model, each mmol/L increment in HDL-C was associated with a 34% (HR 1.34, 95% CI 1.20–1.50) higher risk of fractures. The results remained similar when these analyses were stratified by sex. Sensitivity analyses demonstrated that these associations persisted when the analyses were repeated including only: 1) nontraumatic fractures, 2) participants not on osteoporotic medications, 3) participants who were never-smokers and reported that they did not drink alcohol, and 4) participants who walked outside less than 30 minutes and reported no participation in moderate/vigorous physical activity. No association was observed between non-HDL-C and fractures. This prospective observational study suggests that higher levels of HDL-C are associated with higher fracture risk. This association was independent of the common risk factors of fractures.

POTENTIALLY INAPPROPRIATE MEDICATION USE INCREASES RISK OF INCIDENT DISABILITY IN HEALTHY OLDER ADULTS

Jessica Lockery,[1] Taya Collyer,[2] Robyn Woods,[2] Suzanne Orchard,[2] Anne Murray,[3] and Michael Ernst[4], *1. RMIT University, Melbourne, Victoria, Australia, 2. Monash University, Melbourne, Victoria, Australia, 3. Hennepin Healthcare, Minneapolis, Minnesota, United States, 4. The University of Iowa, Iowa City, Iowa, United States*

Background: Efforts to minimize medication risks among older adults include avoidance of potentially inappropriate medications (PIMs). However, most PIMs research has focussed on aged or inpatient care, creating an evidence gap for community-dwelling older adults. To address this, we investigated the impact of PIMs use in the ASPREE clinical trial. Methods: ASPREE enrolled 19,114 community-dwelling participants aged 70+ years (65+ if US minorities) without a history of major cardiovascular disease, cognitive impairment, and significant physical disability. PIMs was defined according to a modified 2019 AGS Beers Criteria. Cox proportional-hazards regression models were used to estimate the association between baseline PIMs exposure, and disability-free survival, death, disability, and hospitalization, with adjustment for comorbidities including frailty. Results: At baseline, 7396 (39% of total) participants were prescribed at least one PIM. Compared with those unexposed, participants on a PIM at baseline were at an increased risk of persistent physical disability (Adjusted HR 1.47, 95%CI 1.21, 1.80) and hospitalization (Adjusted HR 1.26, 95%CI 1.20, 1.32), but had similar rates of disability free survival and death. These effects did not vary by polypharmacy status. PIMs exposure was associated with higher risk of disability followed by hospitalization (Adjusted HR 1.92, 95%CI 1.25, 2.96) as well as vice versa (Adjusted HR 1.54, 95%CI 1.15, 2.05). Conclusions: PIMs exposure is associated with increased risk of incident disability and hospitalization. Increased risk of disability prior to hospitalization suggests that PIMs use may start the disability cascade, emphasizing the importance of caution when prescribing PIMs for community-dwelling older adults.

A STEPPED WEDGE CLUSTER RANDOMIZED TRIAL OF THE STRIDE SUPERVISED WALKING PROGRAM IN VA HOSPITALS

Susan Hastings, Karen Stechuchak, Cynthia Coffman, Ashley Choate, Courtney Van Houtven, Virginia Wang, Cassie Meyer, and Caitlin Kappler, *Durham VA Health Care System, Durham, North Carolina, United States*

In trials, hospital walking programs improved functional ability after discharge, but little evidence exists on their effectiveness under routine practice conditions or their implementation across health systems. We conducted a Type III hybrid implementation-effectiveness, stepped-wedge cluster randomized trial (SW-CRT) in 8 Veterans Affairs hospitals examining a hospital-based walking program known as STRIDE. Based on the SW-CRT design, hospitals were randomized to a sequence (timeline) for STRIDE, and additionally randomized 1:1 to receive implementation support according to the Replicating Effective Programs (REP) framework only or REP plus additional team-based communication training known as CONNECT. The study was powered to examine impact of STRIDE on discharge destination to home vs other (primary outcome); hospital length of stay (LOS) was a secondary outcome. Patient-hospitalizations in pre-STRIDE time periods (n=8167) were similar to post-STRIDE time periods (n=9070) (e.g., mean age 73, 97% male, 28–30% Black race). In adjusted models, odds of discharge to home were higher among eligible patients hospitalized in post-STRIDE time periods (OR 1.6; 95% CI 1.3–2) compared to pre-STRIDE. Findings were robust to 3 sets of sensitivity analyses. There was no difference in LOS (IRR 1.01; 95% CI 0.94,1.09). Hospitals randomized to CONNECT had higher program reach (mean 13% vs 3%) but lower daily fidelity (mean 25.7% vs 37.5%). Despite limited direct program reach, implementation of a hospital walking program was associated with higher odds of discharge to home. Implementation strategies like CONNECT that enhance teamwork and communication may improve patient access to clinical programs being implemented in new settings.

SESSION 5084 (PAPER)

LATE BREAKING: APPLYING REFRAMING AGING IN YOUR WORK IV

SURVIVAL OF THE FITTEST OR FRAILEST? COMPARING THE HEALTH OF CENTENARIANS OVER A 10-YEAR PERIOD

Lian Ying Chun Pat,[1] Bobo Hi Po Lau,[1] Karen Siu Lan Cheung,[2] Grace Man Yee Chan,[3] Joseph Shiu Kwong Kwan,[4] James Ka Hay Luk,[5] Peter Martin,[6] and Cecilia Lai Wan Chan[2], *1. Hong Kong Shue Yan University, Hong Kong, Hong Kong, 2. The University of Hong Kong, Hong Kong, Hong Kong, 3. The Hong Kong Council of Service, Hong Kong, Hong Kong, 4. Imperial College London, London, England, United Kingdom, 5. TWGHs Fung Yiu King Hospital (FYKH), Hospital Authority, Hong Kong, Hong Kong, 6. Iowa State University, Ames, Iowa, United States*

The first centenarian study in Hong Kong was conducted in 2011 and examined the multidimensional health of adults aged 95 or older. The 2011 study found that, among a population of about 3,000 centenarians, a significant proportion enjoyed a high degree of autonomy in their daily functions in relatively good health. The study has been repeated in 2021/22 (i.e., born in 1926 or before) when the city had more than 11,000 centenarians. Comparison of the two samples (2011: Nf77; 2021/22: Nf120) who lived with their family shows a significant difference in functional health, but not as much for physical health, favouring the 2011 cohort. More than 75% of the 2011 cohort demonstrated autonomy in activities of daily living (Bathing: 77.9%, dressing: 85.7%, toileting: 90.9%, indoor transfer: 89.6%; continence:75.3% and feeding: 94.8%). Only about half of the 2021/22 cohort were autonomous in these areas (40.0%, 44.3%, 54.7%, 42.5%, 63.2%, 46.7%, respectively). The number of chronic illnesses between the two cohorts were comparable (Mean(SD): 2011: 2.7 (1.6); 2021: 3.26 (1.60), yet dementia and frailty were more prevalent in the 2021 cohort (dementia: 44%; frailty: 9.1%) then the 2011 cohort (41.0%; 23.4%). Our findings alert metropolitans worldwide to the fast-increasing population of adults of advanced age with significant personal care and health needs in the community. Existing care for older adults has to be reframed and overhauled to provide comprehensive home- and personal-care support which will be essential for realizing ageing-in-place for adults in advanced age, especially after social distancing policies in COVID-19.

FRAILTY INDEX AT THE BEGINNING OF ELDERHOOD AND HEALTHCARE COSTS AND UTILIZATION OVER 10 YEARS

Jieun Jang and Dae Kim, *Hebrew SeniorLife, Harvard Medical School, Boston, Massachusetts, United States*

Background: We assessed whether the frailty index measured at the beginning of elderhood can predict healthcare costs over 10 years in a nationwide Korean population. Methods: This retrospective cohort study included 215,887 individuals who underwent a standardized comprehensive geriatric assessment at the age of 66 years as part of the National Screening Program for Transitional Ages in 2007–2009 and participants were followed up until December 31, 2019, from the Korean National Health Insurance database. Frailty status was defined based on a 39-item frailty index: robust (< 0.15), pre-frail (0.15 to < 0.25), frail (≥0.25). Generalized linear model was used to examine any changes in healthcare cost among pre-frail group, frail group following 10 years from the age of 66 years, relative to changes in healthcare cost of the robust group. This study constructed an interaction term between the frail group and age. Results: Frailty status at age 66 years was associated with an increased annual total healthcare cost per NHI beneficiary (robust * age vs frail * age: $\beta = 89.5$, SE = 4.0, $P < .0001$), annual inpatient healthcare cost per NHI beneficiary (robust * age vs frail * age: $\beta = 70.3$, SE = 4.1, $P < .0001$) over 10 years, but not significant in annual outpatient cost per NHI beneficiary after adjusting for frailty category, demographic factor, socioeconomic factor, and time fixed effect. Conclusions: The frailty index at the age of 66 years was associated with an accelerated increase in healthcare costs over 10 years.

A PSYCHOMETRICALLY ROBUST LONGITUDINAL RESEARCH MEASURE OF FRAILTY: FIVE DIMENSIONS ACROSS AGE AND TIME

Stacey Voll,[1] Graciela Muniz Terrera,[2] and Scott Hofer[1], *1. University of Victoria, Victoria, British Columbia, Canada, 2. Ohio University, Athens, Ohio, United States*

The research construct of frailty in aging requires a measure with sound psychometric properties, that is stable across longitudinal points of observation. Using Exploratory Factor Analysis and Longitudinal Mixed Methods, we developed a five-factor research measures of frailty that is robust across time. Standardized regression scores for each factor allow us to estimate the change in severity of dysfunction as individuals age. We propose a system for developing research tools for the concept of frailty in large longitudinal data sets, and present our findings of five factors of frailty for females and males from the English Longitudinal Study on Ageing.

DEVELOPING A NOVEL FRAILTY INDEX TO STUDY FRAILTY OF SEXUAL AND GENDER MINORITY OLDER ADULTS IN THE ALL OF US DATABASE

Chelsea Wong,[1] Michael Wilczek,[2] Jordon Bosse,[3] Louisa Smith,[3] Justin Manjourides,[3] Ariela Orkaby,[4] and Brianne Olivieri-Mui[3], *1. Harvard Multicampus Geriatric Medicine Fellowship Program, Brookline, Massachusetts, United States, 2. Northeastern University, Gray, Maine, United States, 3. Northeastern University, Boston, Massachusetts, United States, 4. VA Boston, Boston, Massachusetts, United States*

Prevalence of frailty among older sexual and gender minority adults (OSGM) is unknown despite disparities in mental health, medical comorbidities, and physical function. The NIH-funded All of Us Program was launched May 2018 aiming to enroll 1 million US participants focusing on those underrepresented in biomedical research, including OSGM. Using validated methods, we developed an All of Us deficit accumulation frailty index (AoU-FI) consisting of 33-items using baseline survey responses of adults aged 50+. Deficit domains include comorbidities, physical functioning, mental health, cognition, and sensory impairment. AoU-FI was valid if ≤20% of items were missing and ≤70% were comorbidities. OSGM self-identified or had discordance between gender and sex responses. OSGM (n=5,678) and non-OSGM (n=66,325), were similar in age (mean (IQR) = 66.7 (60–73) vs 66.9 (60–74)) but were more diverse (White 78% vs 82%, Black 7.5% vs. 6.5%, Hispanic/Latino 6.9% vs. 5.9%). AoU-FI had an expected gamma distribution across groups. OSGM frailty had a narrower range (0–0.67 vs. 0–0.75) and higher mean of 0.19 (sd=0.11) vs 0.17 (sd=0.1) compared to non-OSGM. To our knowledge, this is the first study of frailty among OSGM. Findings suggest OSGM experience worse frailty, highlighting the need to understand disparities in frailty, identify interventions, and develop policies to support OSGM. Additionally, our novel AoU-FI creates opportunities to apply frailty to diverse participants and types of data from digital health to genomics within the All of Us database.

REFRAMING STUDENT EXPERIENCES AND ATTITUDES TOWARDS WORKING WITH OLDER ADULTS

Iveris Martinez, *California State University, Long Beach, Long Beach, California, United States*

We are experiencing a shortage of trained health and social service providers to meet the needs of an aging society. However, few students have positive opportunities to work with older adults in their training. If they interact with older adults it is usually in end-of-life and nursing home care settings. We therefore need to find creative ways to motivate students in these fields to choose to work with older adults. We recruited students from health and social services programs to implement four health promotion projects at an older adult low-income residential community. We asked students (Nf22) to reflect on their experiences, and analyzed responses using a grounded theory approach. Myths regarding working with older adults included that they were mean, difficult, not technologically savvy, nor physically active. Initially nervous and uncertain about working with older adult prior to their experience, students gained confidence and had fun. They reported rewarding experiences, built relationships, and learned the benefits of prevention programs for older adults, and reconsidering their career trajectories to focus on working with older adults. Encouraging positive student experiences working with older adults can help prepare to develop the health and human services workforce for an aging society.

SESSION 5171 (PAPER)

LATE BREAKING: MOTIVATING PATIENTS FOR HEALTH BEHAVIOR CHANGE III

YOU DON'T KNOW WHAT YOU DON'T KNOW: BLACK/LATINX CANCER SURVIVORS' KNOWLEDGE AND USE OF SURVIVORSHIP CARE PLAN

Candidus Nwakasi, Cristy Romero, Kateri Sinkler, and Abigail Pawlowicz, *Providence College, Providence, Rhode Island, United States*

Compared to Whites, Black and Latinx cancer survivors and their families experience disproportionate adverse effects of cancer and cancer therapy. This is due to extreme psychosocial, physical, emotional, and financial challenges they experience, thus, highlighting racial/ethnic disparity in cancer survivorship. A cancer survivorship care plan (SCP) is important for improving cancer health and quality of life, but the effectiveness of SCP as a tool to address the disproportionately persistent poor health and quality of life of Blacks/Latinx compared to Whites deserve critical attention. This study is part of a larger study on evaluating cancer survivorship in Rhode Island. We explored knowledge and use of SCP among Blacks and Latinx cancer survivors in Rhode Island. The study employed a qualitative descriptive method. Semi-structured interviews in English and Spanish were conducted with a purposive sample of 12 cancer survivors, 8 Latinx and 3 Blacks (Mage = 62 years). Their responses were transcribed and analyzed for themes. The 3 major themes identified were: 1) invisibility of survivors; 2) understanding the needs of cancer survivors; and 3) issues of empowerment. Our findings draw attention to the need for tailored interventions targeting Black/Latinx cancer survivors. One of such interventions include designing programs to increase the accessibility of SCP to help improve quality of life of cancer survivors from disadvantaged population groups.

THE IMPACT OF A DIGITAL CANCER SURVIVORSHIP PATIENT ENGAGEMENT TOOLKIT ON OLDER CANCER SURVIVORS' HEALTH OUTCOMES

Eun-Shim Nahm,[1] Mary McQuaige,[2] Katarina Steacy,[2] Nancy Corbit,[2] Shijun Zhu,[1] and Hohyun Seong[1], *1. University of Maryland School of Nursing, Baltimore, Maryland, United States, 2. University of Maryland Marlene and Stewart Greenbaum Comprehensive Cancer Center, Baltimore, Maryland, United States*

Cancer is a disease that predominantly affects older adults. The median age at diagnosis is 66 years and 62% of the 15.5 million American cancer survivors are age ≥65 years. Provision of supportive care after treatment is critical to this group due to their complex care needs; however, limited resources are available to them. As increasing numbers of older survivors adopt technology, digital health programs have significant potential to help them improve their health and communicate with their providers. Previously, we developed/tested a digital Cancer Survivorship Patient Engagement Toolkit program for older adults, CaS-PET Silver. The aim was to examine the preliminary impact of CaS-PET Silver on older survivors' health outcomes. This was a 2-armed RCT with two observations (baseline, 8 weeks) on a sample of 60 survivors age ≥65 years (mean age, 70.1±3.8), who were treated with curative intent within 12 months from enrollment (02/2020-01/2022, COVID-19 pandemic). Outcomes included health-related quality of life (HRQoL), self-efficacy for coping with cancer, symptom burden, health behaviors, and patient-provider communication. Data were analyzed using descriptive statistics, linear mixed models, and content analysis. The majority of participants were black (68.3%, n=41) and female (56.6%, n=34). At 8 weeks, CaS-PET Silver group showed significantly improved physical HRQoL ($p < .001$, ES=0.64) and symptom burden (p=.053, ES= -0.41). Self-efficacy (ES=0.56), mental HRQoL (ES=0.26), and communication (ES=0.40) showed a tendency to improve. Most participants reported benefits from the program on health management (mean, 19.41±2.6 [3–21]). Further research is needed with larger, diverse older cancer populations.

THE RELATION OF AGE TO OUTCOMES IN THE DIABETES LIFESTYLE CHANGE PROGRAM CONDUCTED BY VIRGINIA COOPERATIVE EXTENSION

Azin Pourkhalili,[1] Carlin Rafie,[2] Arash Sarshar,[1] and Lynn Margheim[1], *1. Virginia Tech, Blacksburg, Virginia, United States, 2. Virginia Tech/Virginia Cooperative Extension, Blacksburg, Virginia, United States*

The National Diabetes Prevention Program established by the Centers for Disease Control and Prevention promotes the implementation of an evidence-based lifestyle change program (LCP) to prevent or delay the onset of diabetes. The LCP is a 12-month program with 26 lessons covering topics on healthy diets, increasing physical activity, managing stress, and coping with triggers, among others. It includes weekly goal setting, food, and physical activity tracking, and group support. The goals of the program are 5–7% sustained weight loss and 150 minutes of physical activity weekly. Little is known about the real-world effectiveness of the LCP in different age groups, particularly in older adults. The aim of this study was to evaluate the effects of age on LCP outcomes (weight loss, average physical activity, program attendance) conducted by Virginia Cooperative Extension from 2017 - 2022. Among 191 participants enrolled in the

LCP, 141 (73%) completed eight or more sessions and 56% were above 60 years of age. Results show there was a significant direct relationship (coefficient=0.05, p=0.001) between age and weight loss percentage. Participants older than 60 had significantly (p=0.03) higher average physical activity (215 min per week) compared to those under 60 years old (161 min per week). In addition, participants above 60 had significantly (p=0.03) higher attendance (22 sessions) compared to those under 60 years of age (19 sessions). These findings suggest that targeting different age groups and intervention delivery methods can improve program outcomes.

DIABETES MELLITUS AND HARD BRAKING EVENTS IN OLDER DRIVERS

Difei Liu,[1] Stanford Chihuri,[2] Thelma Mielenz,[2] Linda Hill,[3] Carolyn DiGuiseppi,[4] David Strogatz,[5] and Guohua Li[5], *1. Columbia University Medical Center, New York, New York, United States, 2. Columbia University, New York, New York, United States, 3. University of California San Diego, La Jolla, California, United States, 4. University of Colorado Anschutz Medical Campus, Aurora, Colorado, United States, 5. Bassett Research Institute, Cooperstown, New York, United States*

There are an estimated 37 million people with diabetes mellitus (DM) in the United States, including 16 million older adults. DM can impair patients' driving safety due to diabetic peripheral neuropathy, hypoglycemia, or hyperglycemia, and eye diseases. However, few studies have examined the association between DM and driving safety based on naturalistic driving data. Data for this study came from the Longitudinal Research on Aging Drivers (LongROAD) project, a multisite naturalistic driving study of 2990 drivers aged 65–79 years at baseline. Driving data for the study participants were recorded by in-vehicle recording devices for up to 44 months. We used multivariable negative binomial modeling to estimate the incidence rate ratios (IRRs) and 95% confidence intervals (CIs) of hard braking events (i.e., proxies for unsafe driving behavior defined as maneuvers with deceleration rates ≥ 0.4 g) associated with DM. Of the 2856 study participants eligible for this study, 482 (16.9%) reported having DM at baseline. The overall incidence rate of hard braking events was 1.16 per 1000 miles. Adjusted for age, race/ethnicity, marital status, education level, annual household income, urbanicity, history of stroke, and number of medications, drivers with DM had a 10% increased rate of hard braking events compared to drivers without DM (adjusted IRR 1.10; 95% CI: 1.08, 1.12). Results of this study indicates that DM is associated with a significantly increased rate of hard braking events in older drivers, suggesting less safe driving. Driving safety should be incorporated into DM management and care programs.

SESSION 5172 (PAPER)

LATE BREAKING: APPLYING REFRAMING AGING IN YOUR WORK V

APPLYING REFRAMING AGING GUIDELINES WHEN REVIEWING FOR NON-AGING JOURNALS

Zainab Suntai, *Baylor University, Waco, Texas, United States*

The Reframing Aging initiative began in 2012 with the aim of changing the way in which the public views aging, and one of the key tenets of the initiative centers around language that perpetuates negative views of aging. Despite widespread knowledge about the initiative, recent publications in high-tier journals point to a gap in adopting the Reframing Aging initiatives outside of aging journals. Terms that project a negative view of older adults are still used in manuscript titles and within abstracts and bodies of research publications in non-aging journals. As researchers who publish aging-related work, members of organizations such as the Gerontological Society of America are often solicited as reviewers for their expertise in the field of aging. While many researchers in aging may review for aging-related journals, such expertise is often needed in non-aging journals. As such, it is critical for aging researchers to continue to advance the Reframing Aging initiative when conducting reviews of manuscripts that do not adhere to the guidelines. This presentation will provide explicit examples of such publications and review specific steps that reviewers can take in addressing the Reframing Aging initiative in future reviews.

MEASURING AGE-FRIENDLINESS OF TRANSPORTATION, MOBILITY COMMUNITY CHARACTERISTICS: A SCOPING REVIEW

Kellia Hansmann,[1] David Deemer,[2] Carolyn McAndrews,[3] and Stephanie Robert[3], *1. William S Middleton Memorial Veterans Hospital, Madison, Wisconsin, United States, 2. University of Wisconsin School of Medicine and Public Health, Madison, Wisconsin, United States, 3. University of Wisconsin Madison, Madison, Wisconsin, United States*

Age-friendly community initiatives seek to identify and develop infrastructure and services that promote active aging. Inclusive characteristics of transportation and outdoor spaces can improve everyone's mobility around their communities but are particularly important to adults who are transitioning to non-driving. In this study, we aimed to identify and describe age-friendly community indicators that evaluate characteristics most associated with community-level mobility, specifically transportation and outdoor spaces. We conducted a scoping review of peer-reviewed and gray literature to find records describing the development of age-friendly community indicators and then to identify indices with measures of transportation and outdoor spaces resources. We searched PubMed, Scopus, Ebsco, and Web of Science in August 2022 for literature published since 2005. Our search resulted in 1,012 unique records; screening for relevance by title and abstract resulted in 33 records that received full text reviews. We identified 9 final indicators for inclusion and reviewed records to describe the source of the indices, development methodology, and specific indicators used to measure transportation and outdoor spaces. Included indicators were sponsored by governmental or non-profit public health organizations (n=4) and academic researchers (n=5), including one academic partnership with a for-profit insurance company. Most indices (n=6) described measures drawn from subjective data collected during community assessments. Age-friendly indicators were not developed specifically for investigating older adults' transition to non-driving, a missing focus that represents a significant gap. Aligning indicators with this common life transition will facilitate research into the interventions promoting mobility at the community level for all.

AN AGE-FRIENDLY COURSE ADOPTING THE 4M GERIATRIC MODEL IN A PRIMARY CARE NURSE PRACTITIONER PROGRAM

Ophelia Empleo-Frazier,[1] Ami Marshall,[1] Margaret Doyle,[2] Andrea Rink,[3] Noelle Gallant,[4] Barry Wu,[3] and Richard Marottoli[2], *1. Yale University School of Nursing, Orange, Connecticut, United States, 2. Yale University, New Haven, Connecticut, United States, 3. Yale University School of Medicine, New Haven, Connecticut, United States, 4. Yale New Haven Health System, New Haven, Connecticut, United States*

Training nurse practitioners to assume an expanded role in management of geriatric patients is key to addressing the care needs of a growing older adult population. To that end, the Yale School of Nursing revised geriatric coursework required of family nurse practitioner (FNP) and adult geriatric nurse practitioners (AGNP) to ensure the curriculum was sufficiently in-depth, engaging, and inclusive. Revisions included a new course, "Advanced Primary Care of the Older Adult" which focuses on the role of the nurse practitioner in the assessment, diagnosis, and management of primary geriatric syndromes. The 4M model (Medications, Mentation, Mobility, and what Matters most) provided the framework. Additionally, faculty added expert speakers, interactive dementia animated videos, book and movie discussions and a geriatric telehealth simulation component. Content was guided by training needs data collected from prior nurse practitioner students. At the end of each course, students were surveyed to assess attitudes towards geriatric care and satisfaction with the course. We compared survey responses pre (academic year 2019–2020, Nf18, response rate=53%) and post (academic years 2020–2021 and 2021–2022, Nf28, response rate=44%) rollout. In multivariate regression analyses adjusted for differences in age, gender, race, program (AGNP and FNP) and previous geriatric experience, we found significant improvement in measures of both confidence in providing geriatric care and satisfaction with course content. Analysis of qualitative data confirmed student satisfaction with the new course. Future work will include expansion and more rigorous evaluation of the program, including measures of student knowledge of best practices and increasing survey participation rates.

DEVELOPMENT OF OPEN EDUCATIONAL RESOURCES FOR AN AGING AND MENTAL HEALTH COURSE

Madison Ambrose, Jocelyn McGee, Sinai Wood, and Chris Zakrzewski, *Baylor University, Waco, Texas, United States*

The financial pressures associated with a gerontological education are significant given the rising costs associated with education. This fact is particularly relevant for economically vulnerable university students. One source of stress is the cost of textbooks and other required course materials. Indeed textbook prices have increased at a rate faster than other educational expenses. Additionally, the perspectives of diverse and underrepresented scholars are often not as readily available in some textbooks. In this presentation, our process of adapting an undergraduate Aging and Mental Health course to reduce cost and also showcase diverse perspectives is described in detail. The goals of this project were to: 1) adapt a preexisting course to include low- and no-cost content through the integration of open educational resources (OER); 2) provide the most up-to-date evidence based information for content and skills development in the area of aging and mental health; and 3) highlight the perspectives of diverse or traditionally underrepresented scholars in this field of study. We will also share the process of developing an interactive Pressbooks webbook from a strengths-based perspective wholistic perspective.

AN AGE-FRIENDLY NURSING HOME PROJECT ECHO IN RURAL COMMUNITIES

Lee Jennings, Teri Round, Diana Sturdevant, and Keith Kleszynski, *University of Oklahoma Health Sciences Center, Oklahoma City, Oklahoma, United States*

We launched an Age-Friendly Nursing Home Project ECHO in October 2021 focused on the 4Ms (mobility, medications, mentation, what matters most) with emphasis on dementia and QI in long-term care. One-hour virtual sessions included a short expert presentation and case discussion, were offered twice weekly, and recordings were posted online. Topics included person-centered care, advance care planning, LGBTQIA+ care, fall prevention, medication reduction, dementia resident activities, oral health, skin integrity, staff retention, COVID-19, PDSA cycles, root cause analysis, team huddles, among others. 235 individuals from 80 nursing homes, 19 ALFs, 6 continuing care communities, and 10 VA-affiliated sites in 5 states (OK, AR, KS, MO, CO) participated in the first four 6-week ECHO series; 27% attended ≥2 series. Most attendees were nursing home administrators (46%), directors of nursing (20%), nursing assistants (12%), or activity directors (11%). Most were female (91%) and worked in rural settings (77%). 237 attended an additional COVID-19 update session. 152 participants (65%) completed an evaluation. 91% rated the program as valuable (score≥8/10); 99% would recommend to others; 57% discussed topics with colleagues; 59% reviewed materials after sessions; 25% implemented new QI processes; and 25% made a change to resident care. Suggestions for future sessions included: active shooter training, antibiotic stewardship, team building, staff-resident communication, dementia training for non-clinical staff, weight loss, capacity determination, and family caregiver support. An age-friendly nursing home Project ECHO was well-received by health professionals in long-term care. ECHO can successfully expand the reach of training in long-term care, especially in rural areas.

SESSION 5173 (PAPER)

LATE BREAKING: INNOVATIONS IN CLINICAL PRACTICE V

YES, AND...ENHANCING DEMENTIA CARE COMPETENCY THROUGH IMPROVISATIONAL THEATRE TECHNIQUES

Candace Kemp,[1] Jennifer Craft Morgan,[1] Andrea Hill,[1] Emerald Pullon,[1] Elisabeth Burgess,[1] Molly Perkins,[2] and Alexis Bender[3], *1. Georgia State University, Atlanta, Georgia, United States, 2. Emory University School of Medicine, Atlanta, Georgia, United States, 3. Emory University, Atlanta, Georgia, United States*

As the number of persons living with dementia escalates globally, innovations in clinical practice are needed to promote care interactions that lead to positive outcomes for care recipients and their care partners, including family, friends, direct care workers, and other care providers. Our ongoing NIH-funded study, focused on meaningful engagement and quality of life, points to the potential benefits of training care partners to use improvisational (improv) theatre skills in the context of dementia care. We present analysis of data derived from two one-year-long waves of qualitative data collection involving persons with dementia (n=59), their formal and informal care partners (n=165), and participant observation (over 12,000 hours) in six diverse assisted living communities. We identified a minority of care partners who, relative to others, had greater success engaging residents and eliciting positive responses. They also experienced less frustration during care encounters. In interactions with persons with dementia, these individuals routinely extended and accepted invitations to communicate and demonstrated an ability to be in the moment and meet people where they were. They accepted uncertainty about interactions and recognized the need to be flexible. These approaches parallel key improv tenets, which are teachable. We argue that improv training for care partners would enhance care competency and led to positive outcomes for care recipients and providers. Findings contribute to a small, but growing innovative body of literature from a variety of disciplines, including health care, that demonstrates the benefits of improv training in a myriad scenarios and settings, including in dementia care.

PREVALENCE, BURDEN, AND LOCATION OF CEREBRAL MICROINFARCTS AND THEIR ASSOCIATION WITH LATE-LIFE BLOOD PRESSURE

Mo-Kyung Sin,[1] Yan Cheng,[2] Ali Ahmed,[3] Jeffrey Roseman,[4] and Edward Zamrini[5], *1. Seattle University, Seattle, Washington, United States, 2. George Washington University, Washington, District of Columbia, United States, 3. Washington DC Veterans Medical Center, Washington DC, District of Columbia, United States, 4. University of Alabama at Birmingham, Birmingham, Alabama, United States, 5. Irvine Clinical Research, Irvine, California, United States*

Little is known about the relationship of late-life blood pressure (BP) profiles (level, trend and variability) with the presence, number and regional distribution (cortical vs subcortical) of cerebral microinfarcts. We examined these associations in older adults (age ≥65) using the Adult Changes in Thought (ACT) data. 551 participants (94.6% ≥80 years, 58.6% women, 94.2% white) had complete data on microinfarcts and 4 BP measures. Late-life BP, defined by the four BP values before death (2 year-time gap between measures), was treated using 3 different approaches: (1) categories (based on mean of 4 values); (2) trend (based on the difference between values 1 and 4); and (3) variability (based on standard deviation of the mean of the changes in 4 BP values from 1 to 4). Multivariable-adjusted logistic regression models were used to examine the associations of the late-life BP with microinfarcts, adjusting for relevant covariates. Each of the 5 systolic BP categories between 120 and 169 mmHg (reference: 110–119 mmHg) had significant twice higher odds (4 times for SBP ≥170) of presence and number of microinfarcts, which was only significant for subcortical region. Similar higher odds were observed for systolic BP trend (increase/decrease/no change), which was significant for both cortical and subcortical microinfarcts. Systolic BP variability had no significant association with microinfarcts. Similar associations were observed with diastolic BP. In conclusion, the presence (especially for subcortical regions) and number of microinfarcts were more likely to be in those with higher mean BP and those whose BP changed over the study.

CARDIOVASCULAR DISEASES PREDICT ALZHEIMER'S DISEASE ONSET IN NON-DEPRESSED ADULTS

Ginny Natale, and Sean Clouston, *Stony Brook University, Stony Brook, New York, United States*

We examined the mediating or moderating effect of stroke on the effect of cardiovascular disease (CVD) and the onset of Alzheimer's disease (AD) in a nationally-representative sample of older Americans with and without clinical depression. Diagnosis of CVD was adjudicated with the established Health and Retirement Study (1992–2016) methodology and included self-reported coronary heart disease, angina, heart failure, myocardial infarction, or other heart conditions. Probable-AD and probable-Stroke were identified inferentially using a validated pattern recognition algorithm. Analyses were stratified by a validated cutoff of the Center for Epidemiologic Studies Depression Scale (CES-D.) Participants (Nf17,154) were observed an average of 8 times over the span of 20 years (Obs=138,510). 12% of all AD cases are preventable by eliminating CVD in older adults in the US, compared to the 31% of all AD cases are preventable by eliminating stroke in the population. In non-depressed adults, risks for accelerated AD onset included: CVD, stroke, age, diabetes, and current smoking. Non-depressed females had delayed AD onset than males. The interaction of CVD x Stroke accelerated AD onset by 1.79 times (95%C.I. =1.63–1.97) in non-depressed adults. CVD was not a significant risk of AD onset in depressed adults. We conclude that 1)reducing the incidence of CVD and strokes in the US would drastically reduce the number of new cases of AD; and 2) stroke compounds the CVD hazards of accelerated AD onset; and 3) clinical depression is a key modulator of the effect of the risk factors of accelerated AD onset.

HOPE PARTIALLY MEDIATES STRESS AND PERCEIVED BURDEN IN FAMILY CAREGIVERS OF PERSONS LIVING WITH A DEMENTIA

Jocelyn McGee, Dennis Myers, Rebecca Meraz, Clay Polson, Weiming Ke, and Angela McClellan, *Baylor University, Waco, Texas, United States*

Recent research suggests that hope may positively impact perceived burden in family caregivers of persons living with a dementia. However, there are few studies that have examined hope, as a multidimensional construct, on perceived burden. The purpose of this study was to investigate the relationship between objective and subjective stressors, hope and perceived burden in a sample of caregivers using taking into consideration multiple hope dimensions—specifically hope-agency and hope-pathway. Hierarchical multiple regression and mediation analyses were utilized in a sample of one-hundred and fifty-five family caregivers. Multiple regression analysis revealed that low hope-agency predicted high levels of perceived burden after controlling for known burden correlates. Hope-pathway did not impact perceive burden. Objective stress on perceived burden was partially mediated by hope-agency. The multi-dimensional aspects of hope should be taken into consideration when assessing this population. Hope-related psychosocial interventions aimed at bolstering multiple aspects of hope among family caregivers of persons with a dementia should be further developed and assessed in clinical intervention research.

DATA-DRIVEN IMPROVEMENTS TO DEMENTIA DISEASE DETECTION STRATEGIES IN AN FQHC SETTING

Theresa M Sivers-Teixeira,[1] Patrick Tabon,[2] Jessie Yuan,[3] Erin Thayer,[4] Sonali Matta,[3] and Bonnie Olsen[4], *1. University of Southern California, Alhambra, California, United States, 2. University of Southern California School of Pharmacy, Los Angeles, California, United States, 3. Eisner Health, Los Angeles, California, United States, 4. Keck School of Medicine of University of Southern California, Alhambra, California, United States*

Despite higher prevalence of dementing illnesses in Latina/o populations, detection is lower compared to white populations, compounding racial/ethnic and economic disparities. Undetected illness compromises effective delivery of primary care and impedes linkages to much needed services. Development of robust detection and culturally sensitive management of cognitive impairment is critical for adequate care of this population. The Geriatric Workforce Enhancement Program at the University of Southern California (USC) partnered with Eisner Health, a Federally Qualified Health Center, serving a primarily immigrant, Spanish-speaking, uneducated, urban older adult population, to help achieve their goal of becoming an Age-Friendly Health System to prioritize identification and management of cognitive impairment. Over 14 months, a sustainable clinic workflow was developed and implemented to detect, evaluate, diagnose, and develop care plans for patients and their care partners. Staff and provider education was delivered through didactics, workshops, case reviews, and at-elbow training. Additional efforts focused on EHR optimization and alignment of existing clinical resources. Frequency data was extracted using i2iTracks software reflecting pre and post-implementation. Results show a higher percentage of patients diagnosed with cognitive impairment in the post-implementation period (7.35%) compared to pre-implementation (4.05%). Detailed data tracking the volume of patients engaged at each step of the workflow supports meaningful analysis of barriers and opportunities for optimization, such as how and where additional resources and efforts will yield the greatest effects. Data-driven strategies such as these, strengthen efficiency and effectiveness of the collaborative process and result in sustainable outcomes for this underserved population.

SESSION 9000 (POSTER)

LATE BREAKING POSTER SESSION I

A QUALITY INITIATIVE TO INCREASE HOSPICE REFERRALS FOR STARS PATIENTS DURING THE SECOND COVID SURGE

Perihan El Shanawany,[1] Chris Nouryan,[2] Chris Choi,[3] Ann Flynn,[3] and Edith Burns[4], *1. Northwell Health, Plainview, New York, United States, 2. Zucker School of Medicine at Hofstra Northwell, Uniondale, New York, United States, 3. Northwell Health, Uniondale, New York, United States, 4. Zucker School of Medicine at Hofstra Northwell, Manhasset, New York, United States*

Background: CMS uses the Overall Hospital Quality Star Rating program to stratify hospitals based on specific quality criteria (e.g., 30-day readmissions of older adults with pneumonia). “STARS patients” experience more readmissions, longer LOS and often have more complex discharge plans. During the second surge of COVID we implemented a program to increase hospice referrals through early identification and implementation of goals of care (GOC) conversations. Methods: Electronic Medical Records reviewed for STARS patients from pre- (1/2019-7/2020) and post (3/2021–2/2022) program implementation. Location: 2 community-based hospitals. Data collected: demographics, hospital outcomes, discharge disposition. Data compared with Student’s t tests and Chi square. Results: 459 patients, 177 pre-program and 282 post-program were included. Groups were similar in age (83.0 vs 83.6), LACE score (13.0 vs 12.8), principal diagnoses (PNA: 41.5% vs 46.0%, HF/COPD/AMI: 58.5% vs 54.0%), and mortality (3.5 vs. 4.0%). LOS increased 4.9 days vs. 6.1 days ($p < 0.01$), readmission rates unchanged: 12.6% vs 13.0% ($p=0.90$). GOC conversations increased, 48.6% to 75.0% ($p < 0.01$), DNR from 24% to 44% ($p < 0.01$), and comfort measures from 0.5% to 5% ($p < 0.01$). Hospice referrals increased from 0.5% to 11.2% ($p < 0.01$). Discussion: Early identification of STARS patients increased GOC conversations, DNR, comfort measures and hospice referral. Patients across time periods were similar in age, LACE and admitting diagnoses. LOS increased by a day, likely reflecting time needed to arrange discharge disposition. Increased hospice at end-of-life is associated with better quality care and patient/family satisfaction. This program may be adapted to larger, academic medical centers within the health system.

65 &THRIVE: TRANSFORMING OLDER ADULT CARE IN THE EMERGENCY DEPARTMENT

Tracey Vien,[1] and Stella Bobroff[2], *1. Kaiser Permanente Med Group/Southern California, Los Angeles, California, United States, 2. Kaiser Permanente, Los Angeles, California, United States*

Kaiser Permanente Los Angeles Medical Center’s (LAMC) Utilization Management Department expanded our geriatric initiative throughout the hospital with emphasis in the

Emergency Department (ED). The ED is the first point of patient contact in the hospital, early identification and initiation of interventions needed for potential discharge barriers will assist in timely discharges. LAMC obtained Geriatric ED Accreditation (GEDA) Level 2 this year, the first in the Los Angeles County to achieve this title. This was done by implementing ten new policies with quality improvement (QI) metrics, conducting age sensitivity trainings for our staff, and enhancing our ED rooms to be geriatric friendly. Two of the ten interventions in our ED include 1) volunteers to provide support to our geriatric patients prevent functional decline, prevent delirium and readmission rates, and 2) palliative care consults initiated in the ED prevent suffering and promote the best possible quality of life for patients who are facing a serious illness. Between 2020 and 2021, there has been a 15% increase for the census of 65+ patients. 21% increase of number of older adults with ED readmissions, and a 13% increase in number of older adults staying in the ED for more than 8 hours. With the increasing older adult population, we see a rise in our admission and readmissions of older adults in our ED. This indicates a need for geriatric specialized care and Kaiser plans to obtain GEDA for all Southern California Hospitals.

INITIAL EXPERIENCE OF THE FIRST HELPLINE DEVOTED TO SUPPORTING CONCERNED PERSONS IN THE LIVES OF ELDER ABUSE VICTIMS

E-Shien Chang,[1] Lisa Rachmuth,[1] Yuichi Seki,[1] Sandy Regenbogen-Weiss,[1] Serena Ross,[1] Lina Irias,[1] Mark Lachs,[1] and Tony Rosen[2], *1. Weill Cornell Medicine, New York, New York, United States, 2. Weill Cornell Medical College / NewYork-Presbyterian Hospital, Pelham, New York, United States*

Elder abuse is common and can deeply impact older adults who experience it. Little is known, however, about another group that may be profoundly affected: non-abusing family members, friends, and neighbors, referred to as “concerned persons”. We describe the initial experience of the first telephone helpline in the U.S. devoted to supporting these concerned persons. The New York City Elder Abuse Center developed a Concerned Persons Helpline to assist concerned persons and alleged victims in New York State. Using this frontline call data, we examined characteristics of concerned persons, circumstances surrounding alleged abuse, and interventions offered. Overall, the helpline received 864 total calls (16.6 calls per week) over a one-year period between 10/1/20 to 9/31/21. An initial subset of 149 logged calls were used for this exploratory analysis. Concerned persons most commonly reported that an older adult in their life was suffering from financial exploitation (28.9% of all callers), followed by caregiver neglect (26.2%), with 42.2% reporting polyvictimization. Relationship of callers to alleged victims was most commonly non-abusing adult child (37.6%), followed by other relatives (13.4%), friends (12.8%), and neighbors (10.0%). An adult child was also the most commonly reported perpetrator (36.9%). A large proportion of alleged victims suffered from cognitive impairment and/or physical disabilities (55.7%). Intervention provided included referrals to social services, civil and legal services, victim assistance programs, and caregiver counseling programs. Developing resources to support concerned persons should continue to be a research and practice priority in elder abuse.

GLOBAL ELDER ABUSE: A MEGA-MAP OF SYSTEMATIC REVIEWS

Lilly Estenson,[1] Kelly Marnfeldt,[1] Yongjie Yon,[2] Christopher Mikton,[3] and Kathleen Wilber[1], *1. University of Southern California, Los Angeles, California, United States, 2. World Health Organization, Copenhagen, Hovedstaden, Denmark, 3. World Health Organization, Geneva, Geneve, Switzerland*

Elder abuse is an increasingly prevalent public health problem that requires a global political and evidence-based response. To make global evidence on elder abuse easier to locate and analyze, we constructed a mega-map – an interactive map that systematically identifies and overviews existing systematic reviews – on elder abuse prevalence, consequences, risk and protective factors, and interventions. Following Campbell Collaboration methodological guidelines, we conducted a comprehensive database and grey literature search of the global elder abuse literature (n=2,776) to identify systematic reviews that examine one or more of these four abuse domains among adults age 60+ (n=111). We then coded the reviews to identify key characteristics, including the types of abuse, settings, World Health Organization (WHO) geographic regions, and demographic subgroups represented in each review, that can be filtered in the mega-map. We also adapted the Joanna Briggs Institute Critical Appraisal Checklist for Systematic Review and Research Syntheses to appraise the quality of each review. We found that the focus of existing evidence syntheses is most commonly interventions (n=59), followed by prevalence (n=52), risk factors (n=51), consequences (n=31), and protective factors (n=16). The majority of published elder abuse studies have been conducted in the European, Western Pacific, and Region of the Americas WHO geographic regions. Few reviews examine systemic abuse and system-level interventions. Future studies on elder abuse should address these gaps in research on protective factors and systemic aspects of elder abuse, and build evidence about elder abuse in the African, South-East Asian, and Eastern Mediterranean WHO geographic regions.

EXPLORING FRONTLINE PERSONNELS’ PERCEPTIONS OF SUPPORT, KNOWLEDGE, AND RESOURCES FOR ELDER ABUSE

Sarah Marrs, Courtney O’Hara, Catherine MacDonald, Miranda Yelvington, and Tracey Gendron, *Virginia Commonwealth University, Richmond, Virginia, United States*

In Virginia, the number of both reported and substantiated cases of abuse in later life have grown steadily over the last several years (DARS, 2021; O’Connor, 2019). Unfortunately, the resources provided to combat elder abuse have not maintained the same steady increase; in many cases, funding to agencies that work to prevent abuse in later life has even been reduced (DARS, 2021). To better understand the gap that exists between need and available resources in Virginia, we conducted an exploratory sequential mixed methods study [QUAL → quan] (Creswell & Plano Clark, 2018). In the qualitative strand, we conducted a series of interviews and focus groups with professionals who often are called upon to respond/intervene when elder abuse is suspected: aging and victim services (n = 9), healthcare providers (n = 7), law enforcement (n = 8). Three themes emerged from the qualitative data: increasing capacity, prevention/coordination, and ageism. Findings from the qualitative strand were then used to guide implementation of the quantitative strand. These participants (N = 2,891) worked in a variety of frontline settings with older adults or in aging services, mostly in health care, law enforcement, social services. Project findings point to a need for increased resources for and training on elder abuse, a shift from reaction to prevention of abuse, improved care coordination and case management, and a need to reduce harmful ageist beliefs. Moreover, our findings highlight the effect structural and societal ageism at the policy level perpetuates the prevalence of abuse in later life.

ENGAGING IN CQI TO ENHANCE ADULT PROTECTIVE SERVICES INTAKE AND SCREENING: A QUALITATIVE ANALYSIS

Joan Davitt,[1] Jocelyn Brown,[2] Peiyuan Zhang,[2] Erin Barry-Dutro,[2] and Greg Sesek[3], *1. University of Maryland, School of Social Work, Baltimore, Maryland, United States, 2. University of Maryland, Baltimore, Baltimore, Maryland, United States, 3. Department of Human Services, Baltimore, Maryland, United States*

This qualitative evaluation study was part of a larger Continuous Quality Improvement initiative implemented by the Maryland Department of Human Services Office of Adult Services to improve the Adult Protective Services (APS) screening and intake process statewide. Researchers conducted two 90-minute focus groups via Zoom with 21 intake and screening staff from 14 counties in Maryland in the summer of 2022. Focus group participants were mostly White and African American women with an average of 6.5 years working in adult services. Interviews focused on understanding challenges in APS intake/screening and strategies to overcome those challenges. Each interview was recorded and transcribed verbatim and three researchers used open and axial coding to identify themes. The key challenge expressed by all participants was the difficulty obtaining adequate information from referral sources, in order to discern whether the adult was vulnerable and if the alleged abuse/neglect/exploitation was being committed by a trusted caregiver or fiduciary as defined by state law. Inadequate referral information results in supervisors/screeners making time-consuming follow-up calls to obtain additional information or cases inappropriately screened in for investigation. This challenge was exacerbated by intake workers inexperienced in APS, understaffing, unclear policies and screening tools for APS, and community partners' and the public's unfamiliarity with APS services and policy. Strategies to overcome these challenges included additional staff training, public education, additional resources for APS, clearer policies, and improving the APS screening tool. Quality improvement strategies developed from this study that are relevant to APS systems nationwide will be discussed.

ELDER ABUSE SCREENING PRACTICES IN THE VETERANS HEALTH ADMINISTRATION: RESULTS FROM A NATIONWIDE EVALUATION

Lena Makaroun,[1] Jaime Halaszynski,[2] Kathrine Smith,[3] Melissa Dichter,[4] Ann-Marie Rosland,[5] Carolyn Thorpe,[6] and Tony Rosen[7], *1. VA Pittsburgh Healthcare System/University of Pittsburgh, Pittsburgh, Pennsylvania, United States, 2. VA Butler Health Care System, Butler, Pennsylvania, United States, 3. VA Fargo Health Care System, Fargo, North Dakota, United States, 4. Temple University College of Public Health, Philadelphia, Pennsylvania, United States, 5. University of Pittsburgh/VA Pittsburgh Healthcare System, Pittsburgh, Pennsylvania, United States, 6. UNC Eshelman School of Pharmacy, Chapel Hill, North Carolina, United States, 7. Weill Cornell Medical College / NewYork-Presbyterian Hospital, Pelham, New York, United States*

Elder abuse (EA) is common and has devastating health consequences yet is rarely detected by healthcare professionals. Veterans are at high risk for EA, and the Veterans Health Administration (VHA) has experience screening for complex psychosocial phenomena including intimate partner violence. While the VHA has national policy regarding mandatory reporting of EA cases, little is known about the extent to which VHA sites currently screen for EA in a standardized fashion and what approaches are used. To address this knowledge gap, we conducted a national survey of all 170 parent station VHA medical centers from January to August of 2021. Surveys were distributed electronically to the Social Work Chief at each site, as social work is responsible for interpersonal violence response in VHA. The survey assessed the presence and characteristics of EA-specific screening practices as well as general abuse/neglect screening conducted with patients of all ages, including older adults. Follow up emails were sent to sites who reported conducting screening requesting additional details not included in the initial survey. Overall, 138 sites (81%) responded to the survey. Among respondents, 3% reported screening older adults for EA using a previously published tool, while 2% reported screening for EA with an unstudied or locally-developed tool. Forty-three percent reported doing general abuse/neglect screening using unstudied questions/tools for patients of all ages, and 41% reported no EA screening at their site. The wide variability in current EA screening practices in VHA presents an important opportunity to standardize and improve EA detection practices.

EARLY OUTCOMES OF A NATIONAL CONSORTIUM TO ADVANCE FAMILY CAREGIVERS IN NURSING EDUCATION

Hui Zhao,[1] Lindsay Mullins,[2] Andra Davis,[3] Kathryn Sexson,[4] and Sara Hart[5], *1. James Madison University, Harrisonburg, Virginia, United States, 2. Franciscan Missionaries of Our Lady University, Baton Rouge, Louisiana, United States, 3. University of Portland, Portland, Oregon, United States, 4. UC Davis, Sacramento, California, United States, 5. University of Utah, Salt Lake City, Utah, United States*

Family caregivers (FCGs) hold primary responsibility in caring for people with chronic illness often with little training and insufficient resources Standardized guidance for supporting FCGs currently does not exist. Given this fact, it is an urgent call to healthcare professionals, particularly nurses as the key members of the healthcare team, to

promote education for FCGs. In April 2022, experts in the field of family caregiving from UC Davis and University of Utah schools of nursing, convened educators and champions of FCGs from across the country and formed the Family Caregiving Nursing Education Consortium to advance the inclusion of FCGs in nursing education in order to address the lack of standardized nursing competencies for family caregiving. The consortium consists of members from nine diverse universities representing member expertise in pediatrics, geriatrics, palliative care, disabilities, mental health, and underserved communities in order to address a broader range of health issues through the lifespan. Preliminary data were reviewed and identified as a framework, including Family Caregiver Competencies for Interprofessional Education (4 domains) developed by the school of nursing at UC Davis and the AACN Essentials (10 competency categories). Members mapped the family caregiving competencies to the AACN Essentials (2021) during monthly meetings. Though current work presented an early-stage outcome, it marched through crucial steps, including institutional environmental scans, needs assessments, and toolkit development, as building blocks that not only advanced the inclusion of family caregiving education in nursing curricula but also provided foundation to guide the next stage of work.

AGEISM: AGING KNOWLEDGE AND PERSPECTIVES OF THE AGING NUTRITION NETWORK

Savannah Schultz,[1] Sarah Francis,[1] and Alexandra Bauman[2], *1. Iowa State University, Ames, Iowa, United States, 2. Iowa Department on Aging, Des Moines, Iowa, United States*

Addressing ageism is essential to support older adult well-being. The Nutrition and Aging Resource Center (NRCNA) (1) examined the general characteristics, aging perceptions, and preferred training modalities of national aging nutrition network providers and (2) measured the impact an ageism webinar had on topic familiarity, knowledge, and behavioral intent. Frequencies were run to analyze the characteristics, aging perceptions, and behavioral intent while Wilcoxon signed rank tests measured outcome changes. Ageism was assessed via the W.H.O. Ageism Quiz (AQ) while aging perceptions were measured with the Facts on Aging Quiz (FAQ) and Expectations Regarding Aging (ERA). Respondents (n=1910) were primarily female (63%), non-Hispanic (90%), and white (87%) with an average age of 50 years. At least one-half had moderate ageism and aging perspective scores [Mean scores: AQ = 4.9±1.9 (max 8); FAQ =5.9±1.8 (max 10); ERA = 54.4±18.7 (max 100)]. The most preferred continuing education format was live webinars (44.3%). In response, a one-hour webinar about unconscious aging bias was offered in June 2022. A retrospective evaluation was used to assess the webinar impact (n=130 responses). A significant increase in subject matter familiarity (Z= -8.8, $p < 0.0001$) and knowledge (Z= -8.5, $p < 0.0001$) was noted. Further, analyses revealed positive attitudes (beneficial, good idea), perceived behavior control, indirect social norms (client support), and intent to reflect on past interactions with an older adult(s) to see how age-related biases might have influenced those interactions. These results illustrate the need for and the impact of ageism awareness training among those who work with the aging population.

AGE-INCLUSIVE PRINCIPLES ON CAMPUS: EMBRACING DIVERSITY ACROSS THE LIFESPAN

Kelly Munly,[1] and Lauren Jacobson[2], *1. Penn State - Altoona, Altoona, Pennsylvania, United States, 2. Penn State Altoona, Altoona, Pennsylvania, United States*

In this poster, researchers based at a Mid-Atlantic university campus provide an understanding of their evaluative steps informing an adaptation of the Diversity Circles program to include a multigenerational component, supporting diversity across the lifespan. Project methods and analysis have been informed by critical theoretical frameworks, including feminist gerontology, that illuminate the invisibility of age, even in the context of intersectional work. Pilot feedback from five participants from a condensed program in an Adult Development and Aging course informed the interview approach. Post-program semi-structured interviews, with program participants, including students and older adults (n=7), and community stakeholders (n=18), provided feedback on diversity needs at the campus and in the surrounding community, as well as on program content and experience and opportunity for further curriculum integration of concepts of age-friendliness, ageism, and age-awareness. Stakeholders interviewed included community practicum liaisons, university advising and student affairs staff, faculty and staff previously engaging in diversity-related activities, university administrators, university personnel attending to enrollment matters, and staff and faculty interested in student-centered curriculum design. Semi-structured interviews were chosen for data collection because of their capacity to provide saturated data from a small, purposeful sample. Focused codes emergent from the interviews included both a) suggestions for curriculum adaptation and modification as well as the value of existing content and b) issues of age-friendliness and ageism more generally. The research team looks toward incorporating suggestions within their findings in an expansion of the program on their campus, and disseminating findings for the benefit of other campuses' programs.

'IT RESTORED A BIT OF THEIR HUMANITY": BRIDGING THE GAP THROUGH HANDS-ON INTERGENERATIONAL LEARNING

Katherine Meszaros, and Renee Beard, *College of the Holy Cross, Worcester, Massachusetts, United States*

The Covid-19 pandemic laid bare many of the social inequities and vulnerabilities within the American nursing home industry. Intergenerational learning is thought to be an effective approach to debunking ageism and addressing social isolation, especially in institutional care settings. This study used a mixed method approach to explore the benefits of intergenerational learning, here between college-aged students and nursing home residents. We analyzed qualitative observational data, including 56 hours of participant observation during TimeSlips™ sessions with 32 students and 30 residents at a nursing home in Worcester, Massachusetts. A content analysis of 68 student reflections on the classroom community-based learning (CBL) experience was also performed. This poster reports on the findings from the students who participated in the intergenerational learning project in 2020–2022. A series of common themes emerged. Many students began their experience as skeptics, but retrospectively reported that it was transformative. Personal interactions with elders revealed to students the shared humanity that had with older generations, which then forced them to confront their own ageism and ableism. Intergenerational learning also encouraged students to reflect on their lives, ask what type of person they want to be, what world they would like to live in, and gain new life lessons and perspectives on now to age meaningfully. The value of intergenerational learning far exceeds providing nursing home residents with social stimulation. It can be just as formative to the personal philosophies and outlooks of college-aged students. Intergenerational learning provides tangible and intangible "in-the-moment" benefits to those who participate.

A PILOT STUDY OF AN INTERGENERATIONAL BOOK CLUB: LESSONS LEARNED FOR IMPROVING FEASIBILITY

Katelyn Frey, Jennifer Sublett, Jennifer Stanley, and Harvey Stearns, *The University of Akron, Akron, Ohio, United States*

Intergenerational book clubs have been successful in reducing ageist attitudes of younger adults (YA) while increasing feelings of social connectedness among older adults (OA; Lohman et al., 2003). We implemented both in-person (Nf11: YA=4, OA=7) and virtual (Nf8: YA=5, OA=3) modalities for an intergenerational book club to increase intergenerational interactions on campus, considering aging researchers' claim of heightened ageism and exacerbated loneliness following the beginning of the COVID-19 pandemic (Ayalon et al., 2020; Brooke & Jackson, 2020). Both groups met thrice over twelve weeks and completed measures on ageist attitudes (α=.83), engagement with the group (α=.91), and social connectedness (α=.91) each time. There was attrition in both groups (final meeting: Nf9 (in-person) and Nf3 (virtual)). To better understand overall motivations to participate and what factors may have contributed to attrition, we utilized content analysis with participants' feedback to examine their motivation for joining, what they enjoyed most after participating, and what they would improve. Participants were motivated to join because they enjoyed reading; comparatively, they enjoyed group discussions and hearing different perspectives. Future recommendations include meeting more often, increasing the number and size of groups, and scheduling meetings closer together. The majority wished to continue participating. The data suggest future expansion of intergenerational book clubs on campus are desired to support age-friendly interactions and needed to further examine if these interactions can curb ageism and increase social connectedness among diverse age groups. Discussion will include recommendations regarding measures, lessons learned for an optimal protocol, and next steps.

THE RELATIONSHIP BETWEEN AGE DISCRIMINATION AND QUALITY OF LIFE OF DEPENDENT COMMUNITY DWELLING OLDER PERSONS

Felipe Sandoval Garrido, *University of Tsukuba, TSukuba, Ibaraki, Japan*

The objective of this study is to examine the age discrimination suffered by dependent older adults and its effects on their quality of life, using a large representative cohort study. Dependency is defined as having difficulties with activities of daily living, both basic (ADL) and instrumental (IADL). To identify perceived ageism, we used data collected by the English Longitudinal Study of Ageing (ELSA) in 2010–2011 (wave 5) that asked respondents about being discriminated because of their age. Quality of life was measured using the CASP-19 scale. We performed both cross-sectional and longitudinal analyses using the subsequent 2012–2013 (wave 6) and 2018–2019 (wave 9) follow-ups. Multivariable logistic regression analysis was used to estimate the odds ratios of experiencing perceived age discrimination. The results show that a quarter (22%) of all respondents experienced age discrimination. Those suffering from dependency and age discrimination had independently significant lower quality of life scores. Perceived age discrimination was cross-sectionally associated with being male, white, in poor physical and mental health, highly educated, with lower wealth. Longitudinally, with being male (odds ratio -OR-: 1.5), highly educated (OR: 1.3), and poor mental health (OR: 1.7). However, quality of life change was not statistically significant among dependent older persons in subsequent waves. Understanding ageism is important to create policies for future interventions. The present results reinforce the idea of previously documented groups at risk of age discrimination in order to protect them, but also the complex panorama of bio-psychosocial determinants involved in tackling it.

OLDER, ENTITLED, & EXTREMELY OUT-OF-TOUCH: DOES "OK, BOOMER" SIGNIFY THE EMERGENCE OF A NEW OLDER ADULT STEREOTYPE?

Katelyn Frey, and Toni Bisconti, *University of Akron, Akron, Ohio, United States*

"OK, Boomer" is a phrase used online by younger adults to dismiss an older person for their perceived out-of-touch or offensive beliefs (Lorenz, 2019). An initial study utilizing content analysis techniques with a younger adult sample (N = 316) explored how two theoretical frameworks from the age stereotype literature, the Stereotype Content Model (Fiske et al., 2002) and Hummert et al.'s (1994) age stereotype categories, could explain this phenomenon and the enduring online references to "Boomers." We found that neither theory adequately captured how younger adults view the titular "Boomer;" the low-competence/low-warmth quadrant of the Stereotype Content Model was the only quadrant with support (N = 32), albeit not a large amount, whereas the age stereotype category data revealed that "Boomers" partially overlapped with elements of the "Shrew/Curmudgeon," the "Severely Impaired," and the "John Wayne Conservative" to varying degrees. This necessitated a second study that used an open-ended, interpretative phenomenological analysis approach to better understand younger adults' perceived age-related stereotypes of "Boomers." Results identified seven unique characteristics ascribed to "Boomers" and older people in general: closed-minded, argumentative, out-of-touch, offensive, critical, nostalgic, and/or conservative, all of which seem to possess a decidedly hostile ageist undertone. Future work should examine exactly how synonymous "Boomers" are with older adulthood, the potential underlying hostile and/or benevolent ageism associated with using this phrase, and how derogatory age-based internet jargon influences age stereotype development and intergenerational relations given the heightened ageism following the COVID-19 pandemic.

NOT ONE AND THE SAME: VARIED EXPERIENCES OF BENEVOLENT AGEISM IN OLDER ADULTHOOD

Jennifer Sublett and Toni Bisconti, *University of Akron, Akron, Ohio, United States*

Prior work has explored benevolent and hostile attitudes toward older adults (Chasteen & Cary, 2015) and their paternalistic, mixed incompetent-warm perceptions within the Stereotype Content Model (SCM; Fiske et al., 2002); however, older adults' perspectives of these attitudes have not received similar attention. This study assessed older adults' experiences with benevolent and hostile ageism using an adapted version of the Ambivalent Ageism Scale (AAS; Cary et al., 2017; α=.85) and using a mean split, examined if there are differences among the younger- and older-older adults. Within a sample of older adults (Nf202) that ranged in age from 65–90 (M=71.6), we found that when comparing those aged 65–70 and 71 and above, those who were older (M=1.76, SD=.44) reported more experiences with benevolent ageism than their younger counterparts (M=1.56, SD=.42), t(200)=3.30, p =.001). These groups did not significantly differ in hostile ageism, t(200)= -.05, p = .96. When participants were asked why they have been treated thusly as described by the AAS items, 18% of the participants believed it was due to their age, in comparison to those who attributed it to personality (41%), gender (9%), or unknown factors (11%). Benevolent ageism is clearly not a monolithic experience for older adults as those who are older report more patronization, and not all participants felt age was the defining reason for their treatment. Further work should assess how these experiences are qualitatively different across diverse age groups of older adults, as ageism reduction interventions may need to be tailored appropriately.

CHALLENGING AGEISM IN HEALTHCARE THROUGH INTERPROFESSIONAL EDUCATION

Min Kyoung Park,[1] and Diane Martin[2], *1. University of Maryland, Baltimore County, Ellicott City, Maryland, United States, 2. University of Maryland, Baltimore, Baltimore, Maryland, United States*

Broadly defined as prejudice, discrimination, or stereotyping of older adults, ageism is prevalent in the healthcare system. It is implicated in the over- or under-diagnosis and/or treatments provided to older persons, resulting in decreased quality of life and increased costs of care. In Fall 2021, we developed a virtual interprofessional education (IPE) activity to increase professional health and social care trainees' awareness of ageism and to biases they may hold. During the asynchronous portion of the training, participants complete the Harvard Implicit Association Test (age), watch a video, and respond to related threads on Blackboard, which provides an opportunity to discuss experiences prior to participating in a synchronous training activity incorporating a presentation on ageism in healthcare. To date, 98 trainees have provided qualitative data on the impact of the ageism training components. Overwhelmingly, trainees indicated the value of information provided; many of whom responded that the test revealed their own biases. Participants commented that the training was an opportunity to open their eyes to ageism and that it made them more aware of the importance of understanding older adults' capabilities and limitations in a respectful way. More than half (55.86%) of threaded discussions noted that the ageism training helped them to realize their biases against older adults and understand older people's challenges. Quantitative data from pre/post IPE surveys indicated increased interest in working with older adults. Responses illustrate the need to and value of incorporating anti-ageism content into educational programs of our future health and social care workforce.

ASSOCIATIONS BETWEEN ATTITUDES TOWARDS AGING AND CLINICAL DECISIONS AMONGST INTERNAL MEDICINE RESIDENTS

Brent Schell,[1] Megan Carr,[2] Jesse Katz,[1] and Maryam Hasan[1], *1. Baystate Medical Center, Springfield, Massachusetts, United States, 2. High Point University, High Point, North Carolina, United States*

It has been shown that physicians-in-training can develop negative attitudes towards caring for older patients. Little is known about how these attitudes develop throughout training or if they are associated with ageist clinical decisions. In this pilot study, Internal Medicine (IM) residents completed the Expectations Regarding Aging (ERA-12) survey, a validated instrument that assesses expectations regarding physical health, mental health, and cognitive function in older adults. Residents then completed a survey that included simulated clinical scenarios as part of an educational intervention on Ageism. Of the 72 residents invited to participate, 48 residents (67%) completed the ERA-12 survey. Responses were obtained from all training levels including 24 PGY-1 (50%), 10 PGY-2 (21%), and 14 PGY-3 (29%). When grouped by training year, there were no statistically significant differences found with regards to total ERA-12 scores or expectations regarding physical health, cognitive function, or mental health of older adults. When grouped by responses to clinical scenarios, residents with more biased clinical responses were associated with lower total ERA scores (73 vs. 91, p = 0.015). Those with lower total ERA scores indicated they were inclined to initiate CODE STATUS discussions earlier with older adults and were less inclined to consider coexisting depression. Despite limitations in sample size and the subjective nature of simulated clinical scenarios, this pilot study suggests a possible association between expectations regarding aging and clinical decision-making. More research is needed to assess the strength of this association and if it can be modified through educational initiatives.

THE EFFECTS OF NEIGHBORHOOD DEPRIVATION AND PERCEIVED NEIGHBORHOOD PROBLEMS ON DEPRESSIVE SYMPTOMS

Jean Choi,[1] Elizabeth Muñoz,[1] Robin Corley,[2] Sally Wadsworth,[2] and Chandra Reynolds[3], *1. The*

University of Texas at Austin, Austin, Texas, United States, 2. University of Colorado Boulder, Boulder, Colorado, United States, 3. University of California, Riverside, Riverside, California, United States

The progression of detrimental mental health outcomes may begin before old age, and investigating correlates earlier in the lifespan may provide insights into prevention efforts. Neighborhoods have been linked with mental health in adulthood, but there is variation in measurement across studies. Studies have examined the independent associations between either of objective or subjective measures of neighborhoods, but few to none have examined both of these in one study. We assessed the effects of both objective (Area Deprivation Index; ADI) and subjective, or perceived, neighborhood characteristics on depressive symptoms among early midlife adults, using data from the Colorado Adoption/Twin Study of Lifespan behavioral development and cognitive aging (Nf1166, Mage=33.51 (5.07)). Participants completed self-report assessments of perceptions of their neighborhoods (e.g., perceived safety, disorder). Addresses were geocoded and linked with 2010 Census data, and we created a standardized ADI composite. To account for subject non-independence, we fitted multilevel linear regressions, controlling for relevant confounding variables. Results showed that higher ADI was linked with greater depressive symptoms (d = .04), but the effect of ADI was no longer significant and was reduced by about 30% after accounting for subjective neighborhood domains. Perceived neighborhood disorder had the largest effect (d = .19) and remained the sole predictor of depressive symptoms when all perceived domains were included in one model. Findings suggest that residents' subjective interpretations of their neighborhood surroundings may be shaped by the broader structural contexts in which they live in, revealing a potential pathway through which objective neighborhoods affect depression.

SUPPORTING AGING IN PLACE WITH MOBILITY IMPAIRMENTS THROUGH ANNOTATED TELEPRESENCE TECHNOLOGY

Ben Thompson, Maribeth Gandy, Kala Jordan, and Laura Levy, *Georgia Institute of Technology, Atlanta, Georgia, United States*

Most smarthome and smartphone technologies are designed with younger adults in mind, even though many older adults can benefit greatly from their use. Through our examination of how to make these technologies more accessible to adults aging in place with mobility impairments, we have found remote troubleshooting to be a possible solution to many problems. However, we have found most current teleconferencing solutions to be lacking in the limited perspectives of a single webcam, as well as from a lack of ability to point out specific items and locations within a camera view. As such, Our team developed a prototype system that used multiple desk space and room space views, as well as on screen annotations, to facilitate remote troubleshooting and social interactions through a teleconferencing service. This prototype was then evaluated with adults aging in place with mobility impairments, as well as accessibility experts, in order to see what parts of the system could be utilized for troubleshooting, as well as to see where the system was lacking. The studies tested the system's ability to be used for troubleshooting, as well as their uses in games and social interactions. We have gathered positive feedback for these prototypes in the areas of troubleshooting, socialization, games, and for use in other accessibility studies. From these results, we have begun development of a mobile deployment kit for use of our teleconferencing solution in other accessibility studies.

SUBSIDIZED SENIOR HOUSINGS (SSH) FOR LOW-INCOME OLDER ADULTS IN THE U.S.: A SCOPING REVIEW

Sojung Park,[1] Soobin Park,[2] Takashi Amano,[3] Jihye Baek,[4] BoRin Kim,[5] and Byeongju Ryu[4], *1. Washington University in Saint Louis, Saint Louis, Missouri, United States, 2. Washington University in St. Louis, Saint Louis, Missouri, United States, 3. Rutgers University-Newark, Newark, New Jersey, United States, 4. Washington University in St. Louis, St. Louis, Missouri, United States, 5. University of New Hampshire, Durham, New Hampshire, United States*

Subsidized senior housing (SSH) has been advocated as a key component of a community-based, long-term care policy for low-income older adults that links housing with health and social services to support aging-in-place (AIP). Relative to the accumulating evidence on for-profit housing models, SSH remained understudied. Guided by the Person-Environmental fit perspective, this scoping review described and synthesized existing literature on SSH to identify strengths and gaps in the literature. With a five-step scoping review method, we focused on the empirical studies published from 2010 in the U.S using four electronic databases and additional manual searching. Sixty-six articles met the inclusion criteria. Study participants were predominantly non-Hispanic White and female; most studies were quantitative surveys with a cross-sectional design. Five areas of outcomes emerged: (1) Health and well-being (45%), (2) Healthcare use and health behavior (24%), (3) Social Relations (11%), (4) Housing Relocation (12%), and (5) Technology (8%). In examining the study outcomes, the existing articles primarily focus on the personal (29%) and environmental (71%) dimensions, including 9% of the articles investigating both dimensions. For each dimension, the majority of the research tends to highlight residents' health conditions and characteristics of supports and service programs in the housing. The largest proportion of the literature studied the relationship between residents' health and the outcomes related to health and well-being. Future research needs to examine subpopulations of older residents in SSH (e.g., racial/ethnic minority, LGBTQIA, and others) as well as the current and future role of technology in SSH and community partnership.

PERSONALITY PROFILE OF RURAL-DWELLING OLDER ADULTS IN AN ONGOING HOARDING TREATMENT STUDY

Caitlyn Nix and Mary Dozier, *Mississippi State University, Mississippi State, Mississippi, United States*

Symptoms of hoarding disorder, such as significant household clutter, difficulty discarding, and excessive acquisition tend to increase in later life. With many challenges involved in aging in place, older adults may be particularly vulnerable to adverse events occurring while living with excessive clutter (e.g., fall risk, sanitation issues). Therefore, understanding what factors predict hoarding symptom severity is an essential step towards increasing older adults' ability to age in place while experiencing hoarding symptoms. Personality traits have been demonstrated to predict hoarding symptoms in a wide range of ages. However, a sample of older adults in this clinical population has not been evaluated. The IPIP-NEO-60 is a shortened version of a widely used open-source personality measure that utilizes the five-factor model of personality (Neuroticism, Extraversion, Openness, Agreeableness, and Conscientiousness). We used this measure to evaluate the personality profiles of rural-dwelling older adults (age 50 and up, M = 63) enrolled in an ongoing treatment study for hoarding disorder (n = 14). Compared to normative data from 910 adults aged 50 and up and matched for gender, most participants scored in the average range for Neuroticism, Extraversion, and Openness, with a nearly even split between high, low, and average scores for Agreeableness. Half of participants scored in the low range for Conscientiousness. Given the considerable proportion of participants demonstrating low Conscientiousness in this sample, screening a larger sample for beyond-average facet scores within this factor (e.g., self-efficacy, cautiousness) may assist clinicians in selecting impactful treatment targets for hoarding disorder in older adults.

MACHINE LEARNING TO PREDICT HOMEBOUND STATUS IN OLDER ADULTS USING CANADIAN LONGITUDINAL STUDY ON AGING DATASET

Shehroz Khan, Can (Shirley) Cui, and Andrea Iaboni,
Toronto Rehabilitation Institute, Toronto, Ontario, Canada

Individuals who are unable to leave their home or with great difficulty are considered homebound or semi-homebound. Homebound status is strongly associated with disability, social isolation, healthcare use and costs, and mortality. Most homebound older adults have multiple chronic conditions and poor health. There is not enough information about homebounded older adults in Canada. The Comprehensive cohort of the Canadian Longitudinal Study on Aging (CLSA) presents an excellent opportunity to study the complex factors associated with homebound status and the interplay between physical, social, psychological, and environmental determinants over time. This is a population-level study which makes use of provincial healthcare registration data to sample older adults across the country. We obtained the first wave of CLSA dataset containing samples from 21667 individuals over 3223 variables. We developed a definition of 'homeboundedness' in using life-space index variables present in the CLSA datatset. The dataset contained numerical, categorical and missing values. After preprocessing, we selected 1101 Homebound and 20521 Non-Homebound individuals, and 1771 variables. We showed that Random Forest classifier (with missing values) provided an AUC ROC and PR of 0.89 and 0.49. The missing value imputation did not improve the results significantly. Using feature hashing, we converted the dataset to numerical values; the AUCs improved to 0.96 and 0.71 at the cost of losing interpretation. In future, we will consult clinical experts in choosing the relevant features and use analytical methods to select features and compare. We will also test these predictive models on the next wave of this dataset.

GEOGRAPHIC AVAILABILITY OF SUBSIDIZED SENIOR HOUSING AND NEIGHBORHOOD DISPARITIES IN MISSOURI

Byeongju Ryu,[1] Jihye Baek,[1] Sojung Park,[2] Yung Chun,[1] Takashi Amano,[3] and BoRin Kim[4], *1. Washington University in St. Louis, St. Louis, Missouri, United States, 2. Washington University in Saint Louis, Saint Louis, Missouri, United States, 3. Rutgers University-Newark, Newark, New Jersey, United States, 4. University of New Hampshire, Durham, New Hampshire, United States*

Subsidized senior housing (SSH) provides an affordable option to low-income older adults for economic stability and aging-in-place. To date, limited attention has been given to the geographic availability of SSH and its relation to neighborhood characteristics (e.g., socioeconomic characteristics and availability of supportive services). The current study aims to describe (1) the availability of government-subsidized senior housing (SSH-availability) in Missouri and examine (2) to what extent the housing availability is associated with county-level neighborhood characteristics. First, SSH-availability in each county was measured with the number of subsidized units for older adults divided by the eligible population (i.e., aged 65 or over, income below poverty level, and spending 30% or more of income on housing). The Geographic Information System (GIS) was used to examine the distribution of SSH in Missouri. Second, based on existing literature, we used principal component analysis with multiple indicators to create two neighborhood characteristics (i.e., socioeconomic deprivation and health and social service indices). Non-parametric bivariate analyses (Kruskal-Wallis tests) were conducted with the availability quartiles and each index. Our findings showed that in 66 counties (57% of entire counties in Missouri), SSH-availability was below 20%. Bivariate analyses showed SSH-availability was significantly associated with both neighborhood characteristics: counties with higher SSH-availability were more likely to be socioeconomically deprived and face a lack of health and social services. The current study suggests the government should address the geographic disparities in SSH for low-income older adults. Also, more supportive services are needed around SSH to facilitate aging-in-place of vulnerable older adults.

COMMUNITY-DWELLING OLDER ADULTS' PERCEPTIONS OF SMART HOME SURVEILLANCE: AN INTEGRATIVE REVIEW

Shehroz Khan,[1] Jessica Campbell,[2] Jacob Buchan,[3] Andria Bianchi,[1] Jesse Hoey,[4] and Charlene Chu[3], *1. Toronto Rehabilitation Institute, Toronto, Ontario, Canada, 2. University of Victoria, Victoria, British Columbia, Canada, 3. University of Toronto, Toronto, Ontario, Canada, 4. University of Waterloo, Waterloo, Ontario, Canada*

Background: Many older adults wish to use smart homes for aging in place, health monitoring, and enhanced safety. However, concerns over privacy and security remain pressing. User perception studies can help to inform policy and design solutions. Aim: To explore community-dwelling older adults' (50+) perceptions of smart home surveillance. Methods: As part of a larger scoping review of smart home user perception based on four non-mutually exclusive categories: privacy, safety, purpose of data collection, and risk, we found

68 results. 15 studies focused on older adults exclusively and were included in this review. Results: The included studies mainly focused on smart speakers, motion sensors, or home monitoring systems. 13 studies (87%) discussed user privacy concerns in terms of data collection and access. Nine studies (60%) reported that users were enthusiastic about the potential for home safety, improved health outcomes and independent living with smart homes. Seven risk awareness studies (47%) featured a range of perspectives on sharing sensitive information due to the possibility of data breaches and third-party misuse, with some reporting a willingness to trade privacy for enhanced safety. Finally, four studies (27%) explored user knowledge of data collection purposes. While many were uncertain of the details, users were generally more comfortable sharing smart home data with healthcare professionals than others. Conclusion: This review has helped us in creating a user perception survey that is currently in the fielding stage. Given Canada's increasing aging population and technological advances, privacy regulators and designers should focus on older adults' concerns.

RISK FACTORS FOR HAZARDOUS DRINKING AMONG DEMENTIA FAMILY CAREGIVERS

Jessica Hernandez Chilatra, Wesley Browning, Danny Wang, and Carolyn Pickering, *The University of Alabama at Birmingham, Birmingham, Alabama, United States*

Little is known about alcohol use disorder (AUD) among family caregivers of people living with dementia, even though it is suspected as a contributing cause for caregiving outcomes such as elder mistreatment. This study examines the frequency of and potential risk factors for hazardous drinking (one dimension of AUD, measured by the Alcohol Use Disorders Identification Test AUDIT-C) among a sample of dementia family caregivers (Nf165). We used data from the first wave of an ongoing longitudinal study on daily dementia caregiving experiences. We computed binary logistic regression models using SPSS version 28 to identify potential risk factors. Among our sample, 20% of caregivers identified as positive for hazardous drinking. Caregivers with greater difficulty regulating their emotions (OR= 1.046, P=0.005, [95%CI] = 1.014–1.079) had significantly greater odds for hazardous drinking, as well as those with a history of physical neglect in childhood (OR=1.176, P=0.01, [95%CI] =1.037–1.334) and those who seek social support as a coping mechanism (OR=1.119, P=0.01, [95%CI] = 1.027–1.220). Additionally, the higher number of ADLs their relative needs assistance with the lower the odds (OR=0.775, p=0.01, [95%CI] =0.64–0.94) of hazardous drinking. Demographic factors such as gender and age were not associated with hazardous drinking, though the sample was predominantly female (90%). Findings show that dementia family caregivers experience hazardous drinking at a rate higher than the general population (6–16%) suggesting family caregivers are at a uniquely higher risk for AUD. Furthermore, the potential risk factors could inform future screening efforts to identify family caregivers experiencing hazardous drinking.

AI-ASSISTED METHODS FOR ASSESSING AFFECT AND BEHAVIORAL SYMPTOMS IN DEMENTIA: A SYSTEMATIC REVIEW

Ying-Ling Jao,[1] Yo-Jen Liao,[2] Fengpei Yuan,[3] Ziming Liu,[3] Xiaopeng Zhao,[3] Wen Liu,[4] Diane Berish,[1] and James Wang[1], *1. Pennsylvania State University, University Park, Pennsylvania, United States, 2. Pennsylvania State University, State College, Pennsylvania, United States, 3. University of Tennessee, Knoxville, Tennessee, United States, 4. University of Iowa, Iowa City, Iowa, United States*

Negative affect and neurobehavioral symptoms occur in most people with dementia and significantly impact their health outcomes and sense of wellbeing. Detecting these symptoms in this population is challenging due to associated cognitive impairment and communication difficulties. Innovative technology and artificial intelligence (AI)-assisted tools are emerging for assessing affect and neurobehavioral symptoms in individuals with dementia. This review synthesizes research evidence to identify existing AI-assisted measurement tools and evaluate their accuracy in assessing affect and symptoms in people with mild cognitive impairment and dementia. PubMed, CINAHL, Scopus, and Web of Science databases were searched. Eight articles were identified. Multiple machine learning (ML) models were developed to assess affect, apathy, anxiety, depression, agitation, and wandering. One ML model detected positive and negative affect via facial expression with an overall accuracy of 86%. One ML model detected apathy based on speech and achieved an area under curve (AUC) accuracy of 0.77–0.88. Another speech-based ML model, based on paralinguistic markers, predicted apathy, anxiety, and depression by ≥0.3 points. Another model detected wandering based on activity monitoring data and showed 98% sensitivity and specificity. Furthermore, multiple ML models were developed to detect agitation using multi-modal sensors with AUC ranging from 0.50–0.82. Findings suggest that AI-assisted tools are a promising approach to detecting affect and neurobehavioral symptoms, yet the evidence is limited. More research is needed to develop comprehensive, accurate models to detect neurobehavior symptoms. The results have significant implications for supporting research and clinical practice to promote quality of care for people with dementia.

ADULT INFECTIONS ARE ASSOCIATED WITH HIGHER RISK OF ALZHEIMER'S DISEASE BUT LOWER RISK OF CANCER

Svetlana Ukraintseva, Vladimir Popov, Hongzhe Duan, Arseniy Yashkin, Igor Akushevich, Konstantin Arbeev, and Anatoliy Yashin, *Duke University, Durham, North Carolina, United States*

Growing evidence suggests that infections may promote Alzheimer's disease (AD). Chronic infections have also been linked to several cancers. However, there is evidence that acute febrile infections may treat some cancers, suggesting that anti-pathogen immune response could help fight off transformed cells. To explore potentially ambivalent role of infections in cancer and AD, we estimated associations between history of infection and subsequent risks of AD, cancer (all sites combined), and all-cause mortality, in sample of 270K participants of the UK Biobank. We found that prior infection is associated with 29% higher risk of AD (RR=1.29, 95% CI[1.02,1.63], both sexes). In contrast, the overall cancer risk was 49% lower in people with history of infection, compared to individuals without such history (RR=0.49, 95% CI[0.46,0.52], both sexes). History of infections was also associated with 7% reduced total survival at ages 70+ (RR=0.93, 95% CI[0.92,0.94]); however, the negative effect was less evident at younger ages. Results of our study suggest that infections may antagonistically influence chances of AD and cancer. They also show that impact of infections on survival depends on age and is more detrimental at older ages, which may reflect general decline in immune resilience due to aging, as well as the fact that cancer becomes a major contributor to mortality risk at younger ages than AD. Understanding the trade-offs between major diseases is essential for optimizing disease prevention and pro-longevity interventions, since measures aiming to prevent one disease may sometimes increase risks of other major conditions and/or all-cause mortality.

A THEORETICAL FRAMEWORK FOR UTI PREVENTION AND MANAGEMENT IN COMMUNITY-DWELLING OLDER PERSONS WITH DEMENTIA

Kuan-Ching Wu,[1] and Oleg Zaslavsky[2], *1. University of Washington, Seattle, Washington, United States, 2. Unversity of Washington, Seattle, Washington, United States*

UTI admission rates are 3.4 times higher among persons with dementia (PWD) than among those without dementia. The hospitalizations often result in adverse health complications such as the increased risk of delirium, cognitive decline, and higher mortality. To date, several UTI guidelines exist for specific populations, including women, children, people with catheters, and long-term care patients; however, there has been little focus on non-pharmacological prevention and management in PWD. The goal of this work is to propose a theoretical framework for UTI prevention and management in community-dwelling older PWD with the following three aims: 1) identify factors and outcomes of UTIs in community-dwelling older PWD; 2) generate a conceptual framework informed by Bronfenbrenner's 1977 ecological model; 3) integrate preventive measures to the adapted framework. We conducted a scoping literature review utilizing the following keywords and concepts: risk factors, UTI management and prevention, community-dwelling older adults, and dementia. The UTIP framework was generated with four levels of risk factors (individual, interpersonal, community, and national) and four domains of affected outcomes (PWD, caregivers, PWD and their caregivers, and community/national). Additionally, seven themes of preventive measures emerged: physical activity and mobility, behavioral therapy, personal hygiene, phytotherapy, dietary, compound, and hormone. Finally, a table of care management opportunities was proposed according to dementia severity and caregivers' involvement. In conclusion, the UTIP framework synthesizes exciting and is flexible to accommodate new evidence. As such, the framework is informative for programs, practices, and policies to lower the risks of preventable admission in PWD.

A DEMENTIA IMMERSION SIMULATION EXPERIENCE AS A TRAINING TOOL FOR HEALTH CARE PROFESSIONALS

Sandra Sanchez-Reilly,[1] Paula Reilly,[2] Elizabeth Reilly,[2] Isabella Silva,[2] Lyda Arevalo,[2] and Gabriela Zaragoza[3], *1. South Texas Veterans Health Care System and the University of Texas Health Science Center at San Antonio, San Antonio, Texas, United States, 2. South Texas Veterans Health Care System, San Antonio, Texas, United States, 3. UTHSCSA, San Antonio, Texas, United States*

Background:Dementia, a progressive, devastating and incurable disease affects millions of older Americans and their caregivers. Effective dementia-training programs for caregivers and healthcare professionals (HP) can lead to improved patient outcomes. Simulation-educational experiences are innovative with long-lasting impact. Currently, there are no simulation hands-on experiences focused on dementia care to train HP or hired caregivers (HC). Objective: To evaluate the educational effectiveness of a Dementia Immersion Simulation Experience (DISE) intervention among HP and HC. Methods: DISE is a face-to-face 2-hour intervention that includes virtual reality, hands-on simulation with multiple sensory experiences, group debriefing led by dementia-caregiving expert. Program evaluation and pre/post knowledge assessments were administered. Results: Nf110. HP, Nf72; HC, Nf25. Pre/post mean score of knowledge assessment (scale 0–12) for all was 8.3/9.7 ($p < 0.0001$). Participants were also grouped by whether they were "well-informed" (achieving 10 or better on knowledge assessment) or had "knowledge gap" (9 or fewer). 25% were well-informed on dementia before DISE; 63% after DISE ($p < 0.0001$). DISE program evaluation showed 98% participants highly rated experience across all categories. Evaluation scores further support an effective program. Furthermore, number of clinical referrals seeking expertise from a dementia specialist/team increased by 50% two months post-intervention. Conclusion: DISE is a successful tool to teach, support and empower HP and HC, effectively changing care provided to individuals with dementia by using hands-on simulation training. Further studies are needed to evaluate the effectiveness of DISE in improving behavioral symptoms, training family caregivers, and decreasing other dementia-related undesirable outcomes such as nursing home placement.

A COMPREHENSIVE ALZHEIMER'S AND DEMENTIA CARE PROGRAM (ADCP) FOR PATIENTS AND CAREGIVERS

Madieska Ramirez,[1] Prabhash Kakarla,[2] Marzena Gieniusz,[1] Jessica Alvarez,[1] Chris Nouryan,[3] and Edith Burns[4], *1. Hofstra-Northwell, New Hyde Park, New York, United States, 2. Hofstra University, New Hyde Park, New York, United States, 3. Zucker School of Medicine at Hofstra Northwell, Uniondale, New York, United States, 4. Zucker School of Medicine at Hofstra Northwell, Manhasset, New York, United States*

Background: Alzheimer's and related dementias (ADRD) are progressive and associated with behavioral and psychological symptoms (BPSD) contributing to caregiver stress. We report initial impact of implementing UCLA-designed ADCP to support ADRD patients and caregivers. The program centralizes care, utilizing a nurse dementia-care specialist. Methods: Prospective repeated measures of ADRD patient/caregiver dyads from 3/2021–7/2022. Measures: BPSD, ADL/IADL, cognition, and caregiver burden, distress and depression. Results: Total of 154 patient/caregiver dyads enrolled to-date. 42 have been enrolled for one-year: 23 with complete data, 5 pending follow-up, 14 disenrolled (2 expired, 3 to hospice, 2 moved, 7 lost contact). For 23 patients with baseline and follow up, Neuropsychiatric Inventory Questionnaire decreased from 16.3 to 13.1 (p=0.170), Patient Health Questionnaire-9 (PHQ-9) for caregivers decreased (3.5 to 2.2, p=0.044), Montreal Cognitive Assessment decreased from 11.3 to 8.4 (p=0.045), and Dementia Burden Scale (DBS) showed nonsignificant decrease, 20.6 to 18.4 (p=0.312). Cornell Scale for Depression in Dementia was unchanged, 5.67 to 5.14 (p=0.380), and ADL and IADL decreased one year after enrollment, from 4.05 to 2.36 ($p < 0.01$) and 1.38 to 0.238 ($p < 0.01$) respectively. Conclusion: Although attrition rate was high for the small sample (1/3 of dyads enrolled in the program for a year), there were improvements in some metrics for both patients and caregivers, despite the expected decline in cognitive function and ADL/IADL. As data is accrued, we anticipate it will identify patients and support resources that will be most beneficial.

WHAT MOTIVATES PARTICIPATION IN ALZHEIMER'S PREVENTION RESEARCH: A MIXED-METHODS STUDY

Lizbeth Vera Murillo,[1] Maria Vander Meulen,[1] Monique Villamor,[1] Angel Collie,[1] Sarah Cline,[1] Jody Nicholson,[1] and Jerri Edwards[2], *1. University of North Florida, Jacksonville, Florida, United States, 2. University of South Florida, Tampa, Florida, United States*

6.5 million Americans aged 65 and older are currently living with Alzheimer's disease or related dementias (ADRD; Alzheimer's Association, 2022). By 2060, it is estimated that this number will increase to 13.9 million (Matthews et al., 2018). Therefore, it is imperative to gain insight into participants' personal motivations and expectations of research to advance community participation. The Preventing Alzheimer's with Cognitive Training (PACT) study is a National Institute of Health, National Institute on Aging-funded, multi-site clinical trial examining the prevention of mild cognitive impairment and ADRD through computer-based cognitive training. Across 5 locations, data were collected from 2,360 cognitively normal participants (M=73.03 years, range=65–97, SD=5.04). The current project explores individuals' motivations and expectations of cognitive training (CT) utilizing a mixed-method approach by coding qualitative open-ended questions about motivation to participate and comparing how motivational themes aligned with expectations about CT from the Expectations Assessment Scale (EAS; Rabipour et al., 2018). Six themes for participant motivation emerged: direct experience with the disease (26.9%), concern about brain health and aging (23.9%), general personal interest (17.9%), general interest in research (20.1%), referral to the study (5.8%), and altruism (5.4%). After completing the initial training session, motivation themes did not differentiate satisfaction with (p=.06) or perceived success of (p=.11) the CT program. Understanding participants' motivations can further expand and optimize recruitment and retention strategies in AD prevention research. Future research will focus on how these themes influence adherence and retention and relate to participant demographic characteristics (i.e., education, gender, race, and ethnicity).

USER PERSONAS TO GUIDE TECHNOLOGY INTERVENTION DESIGN TO SUPPORT CAREGIVER-ASSISTED MEDICATION MANAGEMENT

Anna LINDEN,[1] Priya Loganathar,[1] Richard Holden,[2] Malaz Boustani,[3] Noll Campbell,[4] Aaron Ganci,[5] and Nicole Werner[2], *1. University of Wisconsin-Madison, Madison, Wisconsin, United States, 2. Indiana University School of Public Health-Bloomington, Bloomington, Indiana, United States, 3. Indiana University School of Medicine, IU Center for Aging Research, Indianapolis, Indiana, United States, 4. Purdue University, Indianapolis, Indiana, United States, 5. IUPUI, Indianapolis, Indiana, United States*

Informal caregivers often help manage medications for people with ADRD. Caregiver-assisted medication management has the potential to optimize outcomes for caregivers and people with ADRD, but is often associated with suboptimal outcomes. We used the user-centered design persona method to represent the needs of ADRD caregivers who manage medications for people with ADRD to guide future design decisions for technology interventions. Data were collected through virtual contextual inquiry in which caregivers (Nf24) sent daily multimedia text messages depicting medication management activities for seven days each, followed by an interview that used the messages as prompts to understand medication management needs. We applied the persona development method to the data to identify distinct caregiver personas, i.e., evidence-derived groups of prospective users of a future intervention. We used team-based affinity diagramming to organize information about participants based on intragroup (dis)similarities, to create meaningful clusters representing intervention-relevant attributes. We then used group consensus discussion to create personas based on attribute clusters. The six identified attributes differentiating personas were: 1. medication acquisition, 2. medication organization, 3. medication administration, 4. monitoring symptoms, 5. care network, 6. technology preferences. Three personas were identified based on differences on those attributes: Regimented Ruth (independent, proactive, tech savvy, controls all medications), Intuitive Ian (collaborative, uses own judgment, some technology, provides some medication autonomy), Passive Pamela (reactive, easy going, technology novice, provides full medication autonomy). These personas can be used to guide technology intervention design by evaluating how well intervention designs support each of them.

UNIQUE TRANSKINGDOM MICROBIOME SIGNATURES LINKED WITH COGNITIVE DECLINE IN OLDER ADULTS OF MIAGB CONSORTIUM COHORT

Diptaraj Chaudhari,[1] Shalini Jain,[1] Hariom Yadav,[1] Michal Masternak,[2] Peter Holland,[3] Marc Agronin,[4] and MiaGB Consortium Team[1], *1. University of South Florida, Tampa, Florida, United States, 2. University of Central Florida, Orlando, Florida, United States, 3. Florida Atlantic University, Boca Raton, Florida, United States, 4. Miami Jewish Health, Miami, Florida, United States*

The prevalence of age-related cognitive disorders is increasing. Effective prevention and treatment interventions are unavailable due to a poor understanding of aging biology. Multiple emerging evidence indicates that the gut microbiome is linked with age-related disorders; however, their clinical importance in differentiating and predicting the risk of cognitive decline or dementia is largely elusive. Utilizing samples and data of a large, multi-site clinical study across the state of Florida called Microbiome in aging Gut and Brain (MiaGB) Consortium, our whole genome microbiome sequencing revealed that the viral and archaeal population was significantly reduced in the gut of older adults with dementia (n=8) compared to those with mild cognitive impairment (MCI) (n=25) and normal cognition (n=59). Whereas the fungi were exclusively detected in the controls only. Alpha diversity of the participants with MCI and dementia was lower than the cognitively healthy controls. The abundance of Actinobacteria and Verrucomicrobia phyla was higher, and Firmicutes phylum was lower in the participants with dementia. Bacteriophages Lactobacillus prophage Lj771 and Microbacterium phage Min1 were exclusively detected in the gut of the participants with dementia. The study also identifies key metabolic pathways altered in the controls versus the cognitive impairment state. Our biomarker discovery analyses also revealed that these unique microbiome signatures and pathways might have predictive power for cognitive decline and dementia risk and offer new targets for future therapeutic interventions.

UNDERSTANDING DEMENTIA DISCOURSE DURING ALZHEIMER'S AWARENESS MONTH IN CANADA: FIRST INSIGHTS FROM A TWITTER STUDY

Juanita-Dawne Bacsu,[1] Megan E. O'Connell,[2] Allison Cammer,[2] Mehrnoosh Azizi,[2] Soheila Ahmadi,[2] Karl Grewal,[2] Shoshana Green,[2] and Corinne Berger[2], *1. Thompson Rivers University, Kamloops, British Columbia, Canada, 2. University of Saskatchewan, Saskatoon, Saskatchewan, Canada*

Twitter has become a key platform for public health campaigns, ranging from mental health awareness week to diabetes awareness month. However, there is a paucity of knowledge about how Twitter is being used to support health campaigns, particularly for Alzheimer's Awareness Month. This presentation aims to: 1) identify how Twitter was used to share dementia discourse during Canada's Alzheimer's Awareness Month in January; and 2) explore actions to enhance dementia awareness using Twitter for future Alzheimer's Awareness Month campaigns. Tweets were collected from Twitter using the Twint application in Python from January 1 to January 31, 2022. Filters were used to exclude irrelevant tweets (5,820), and the remaining 1,289 tweets were exported to Excel. Tweets were divided among eleven coders and analyzed using inductive thematic analysis. Analysis revealed four main themes: dementia education and advocacy; fundraising and promotion; sharing experiences of dementia; and opportunities for future actions such as collaborative partnerships and educational tweets to correct stigmatizing language and dementia stereotypes. Increased educational content, collaborative partnerships, and evidence-informed research are essential to enhancing dementia awareness strategies on Twitter during Alzheimer's Awareness Month in Canada. Further research is needed to develop, implement, and evaluate methods to improve dementia awareness on Twitter during Alzheimer's Awareness Month and beyond.

TRENDS IN OSTEOPOROSIS DRUG USE AMONG MEDICARE BENEFICIARIES WITH & WITHOUT ALZHEIMER'S DISEASE/RELATED DEMENTIAS

Peyton Armstrong,[1] Yong-Fang Kuo,[2] Jordan Westra,[1] and Mukaila Raji[2], *1. UTMB, Galveston, Texas, United States, 2. University of Texas Medical Branch at Galveston, Galveston, Texas, United States*

Background: Osteoporotic fractures are a leading cause of disability and premature death in the elderly. Patients with Alzheimer's and related dementia (ADRD) have high rates of osteoporosis (OP) and substantial risk of osteoporotic fractures. Yet research is sparse on trends and predictors of OP medication use in ADRD. Methods: Medicare beneficiaries with OP aged ≥67 years with Medicare parts A/B/D without HMO from 2016–2018. Outcome was receipt of OP medications in 2018. A multivariable logistic regression assessed association between ADRD and OP drug prescribing, adjusted for age, sex, race, region, Medicare entitlement, dual Medicaid eligibility, chronic conditions, number of provider visits/hospitalizations, and nursing home (NH) resident status. Age/ADRD and NH residency/ADRD interactions were tested. Results: Sample consisted of 47,871 people with OP and ADRD and 201,840 with OP without ADRD. OP drug use was 38.6% in ADRD patients vs. 52.7% in non-ADRD. After adjustment for demographics, chronic conditions, previous hospitalizations/physician visits, the OR for OP drug in ADRD vs. Non-ADRD was 0.85 (95% CI: 0.83–0.87). NH residents had lower odds for OP medication (OR: 0.61, 95% CI: 0.58–0.64). There were significant interactions between ADRD/age and between ADRD/NH residency. The OR for OP drug use associated with ADRD was 0.88 (95% CI: 0.86–0.90) among community-dwelling elders and 0.66 (95% CI: 0.64–0.69) among NH residents. Conclusions: ADRD patients received OP drugs at lower rates than non-ADRD counterparts. More research is needed on prescribing or deprescribing OP drugs in context of ADRD severity, patient preferences, remaining life expectancy and time-to-benefit from OP drugs.

THE WHATMATTERS APP: CO-DESIGNING PERSON-CENTERED CARE FOR PEOPLE WITH DEMENTIA IN CARE SETTINGS

Lillian Hung,[1] Ellen Guo,[2] Mariko Sakamoto,[1] Karen Lok Yi Wong,[1] Candy Tran,[3] Jim Mann,[4] Annette Berndt,[4] and Eva Egeberg[5], *1. University of British Columbia, Vancouver, British Columbia, Canada, 2. The University of British Columbia, University Endowment Lands, British Columbia, Canada, 3. School of Nursing University of British Columbia, University Endowment Lands, British Columbia, Canada, 4. Community Engagement Advisory Network, Vancouver, British Columbia, Canada, 5. Emily Carr University, Vancouver, British Columbia, Canada*

The purpose of our study is to provide comfort through digital resources (e.g., music and visual materials) for patients/residents with dementia in hospitals and long-term care. By working with users (patients/residents, families, and staff) and using a co-design approach, we have developed a mobile app prototype called "WhatMatters" to equip staff with a useful digital tool for delivering person-centered care in hospitals and long-term care homes. Using user experience co-design methods, we conducted a series of virtual

co-design workshops with acute and long-term care staff (n=10), clinical experts (n=3), residents (n=3), and patient and family partners (n=7) to understand: (a) what "comfort" means, (b) how care needs are communicated and provided for, and (c) how a mobile app may be used to support psychosocial needs of people living with dementia in hospital and long-term care settings. Thematic analysis has identified three themes to inform the development of the mobile app WhatMatters: (a) familiarity brings comfort, (b) sharing of information between staff and families allows for continuity of care and person-centered care, and (c) accessible and curated content can evoke memories and create a comforting space. Our study conclusions are: It is feasible and necessary to work with users (including clinical staff, patient, and family partners) and relevant stakeholders to co-design a mobile app, a useful tool to support the delivery of person-centered care in care settings.

THE ROLE OF SLEEP DISTURBANCE IN COGNITIVE OUTCOMES AMONG LONELY ADULTS IN THE HEALTH AND RETIREMENT STUDY

Adrienne Grudzien, *Florida International University, Miami, Florida, United States*

Both sleep disturbance and loneliness have been linked to poorer cognitive performance and increased risk of dementia in older adults. Loneliness is believed to influence cognitive functioning directly and indirectly through the HPA axis dysfunction, which increases systemic inflammation through endocrine, immune system, and genetic pathways which produce a range of negative effects on brain tissue. Higher levels of HPA axis activity associated with lonely feelings may lead to poorer sleep quality, which decreases beta-amyloid and tau clearance, as well as memory consolidation, which may further disrupt sleep through alterations in brain tissue. Despite the growing body of research, little is known about how sleep disturbance and loneliness, both modifiable risk factors, interact to effect cognition and dementia risk over time. Secondary analysis of the 2006, 2010, 2014, and 2018 waves of the Health and Retirement Study was completed using data from 1,092 participants (mean age: 66.24; SE: .1366). Mixed effects regression modeling was used to evaluate the role of sleep disturbance in the relation between loneliness (R-UCLA loneliness scale, 11 item) and four cognitive performance measures: Immediate and Delayed Word Recall, Serial 7s, and Backward Count, and cognitive status category (cognitively normal, cognitively impaired, and dementia) across a 12-year period. Sleep disturbance moderated the relation between loneliness and Immediate Word Recall (p=.048) and Serial 7s (p=.032) outcomes even after controlling for demographic covariates and depression. Findings suggest that sleep disturbance may exacerbate the negative physiological effects of loneliness on episodic memory and executive functioning in older adults.

THE RELATIONSHIP BETWEEN SOCIOECONOMIC DISADVANTAGE AND DEMENTIA CAREGIVER BURDEN

Alexis Beverly,[1] Christina Baucco,[1] Seho Park,[2] Matthew Schroeder,[3] Shelley Johns,[2] Katherine Judge,[4] and NIcole Fowler[5], *1. Regenstrief Institute, Indianapolis, Indiana, United States, 2. Indiana University School of Medicine, Indianapolis, Indiana, United States, 3. Regenstrief Institute, Inc., Indianapolis, Indiana, United States, 4. Cleveland State University, Cleveland, Ohio, United States, 5. Indiana University School of Medicine, IU Center for Aging Research, Indianapolis, Indiana, United States*

More than 16 million people provide unpaid care to someone with Alzheimer's disease or a related dementia (ADRD) in the United States. These caregivers frequently report experiencing psychological and physical burden. Prior research shows that socioeconomic disadvantaged neighborhoods have higher rates of ADRD, but little is known about caregiver burden. We hypothesized more socioeconomic disadvantage is associated with higher caregiver burden. We performed a secondary analysis using baseline data on dementia caregivers (n=132) enrolled in the Indiana University Telephone Acceptance and Commitment Therapy for Caregivers (TACTICs) pilot trials. Mean (SD) caregiver age was 61.6 (11.6) years; 83.3% women; 78.8% white; 19.7% black. Seventy-two percent of the caregivers lived with the care recipient and 50.8% reported moderate dementia severity. A linear regression model examined the relationship between caregiver's national Area Deprivation Index (ADI) score (ranging from 1–100 with higher scores indicating greater socioeconomic disadvantage) and caregiver burden. The following covariates were included: age, sex, race, education, shared residence with care-recipient, health status, anxiety, depression, and dementia severity of care recipient. Higher ADI was associated with lower caregiver burden (β=-0.222, $p < 0.001$). Caregiver burden has a significant negative relationship with ADI and dementia severity (p<-.001 and 0.046, respectively) and positive relationship with anxiety (p=0.014) controlling other covariates in the model. Although we found no support for the hypothesis, further research should examine these factors with how caregiver's ADI may impact other psychosocial wellbeing outcomes. Discussion will highlight the need for caregivers to have access to resources that can aid them through their experience.

THE IMPACTS OF NURSING HOME COVID-19 SOCIAL ISOLATION POLICIES ON RESIDENTS LIVING WITH DEMENTIA

Bill Buron,[1] Tim Killian,[2] and Cassy Eng[1], *1. The University of Tulsa, Tulsa, Oklahoma, United States, 2. University of Arkansas, Fayetteville, Arkansas, United States*

Using reports from 31 nursing home activity directors (AD) from across the United States, we examined responses to COVID-19 social isolation policies/practices in relation to AD's perceptions of the impact on residents living with dementia (RLWD). AD's perceptions are particularly valuable because they are generally responsible for bolstering social connectedness. We approached this study from the sociological perspective of personhood (Buron, 2008; Kitwood, 1997) that suggests social isolation may threaten personhood status, lead to increased agitation, and other behaviors as mechanisms to preserve self. Most ADs reported that social isolation protocols began in March 2020 and were still ongoing through the beginning of 2022. Over 90% reported a 50% or more reduction in family member/guest visits, with over 30% reporting a 90% or more reduction in visits. Systemic content analyses were applied to open-ended responses. These patterns suggested ADs had concerns about (1) poor quality care as a result of a) a reduced workforce leading to caregiver burnout, and b) less accountability of caregivers (to families/visitors in their absence) for resident care, and (2) increasing signs of depression and negative behaviors among RLWD. Some ADs felt that Isolation policies disrupted routines of RLWD, leading to confusion and a greater progression of their dementia. Some ADs felt the need to "fill-in" as an attempt to make up for the loss of interactions with family members. The results of this study indicate a need to consider future pandemic policies and potential impacts on residents living with dementia in nursing home settings.

THE IMPACT OF 12 WEEKS OF ADAPTED DANCE ON BALANCE, GAIT, AND LOWER EXTREMITY FUNCTION AMONG PERSONS WITH DEMENTIA

Keara Quijano,[1] and Crystal Bennett[2], *1. University of West Florida, Milton, Florida, United States, 2. University of West Florida, Lillian, Alabama, United States*

Person's living with dementia commonly experience difficulty with mobility. Difficulties with these activities can lead to an increased fall risk, resulting in an increased loss of independence. Dance engages various parts of the brain including the cerebellum that is primarily involved in coordinating balance, posture, body positioning, and voluntary movement. An aim of this study was to assess whether 12 weeks of adapted dance improves balance, usual walking speed, and lower extremity function among persons living with dementia. An experimental design was used to randomly assign persons with dementia to either a 12-week adapted dance or social stimulation group. The convenience sample consisted of 12 participants, ages ranging from 62–97 years. The adapted dance is low impact where one foot is always in contact with the floor and is appropriate for older adults with cognitive and physical limitations. At baseline and at 12 weeks, measures of balance, gait, and lower extremity function were assessed. From baseline to posttest, the dance group had greater increased times for maintaining tandem balance (+47.5%) and faster times for usual gait speeds (+15.1%); compared with the social stimulation group tandem balance time (+0.98%) and usual gait speed times (+10.5%). A limitation of this study is the small sample size.

THE EFFICACY OF MUSIC AND DEMENTIA EDUCATION PROJECT ON HEALTH CARE PROFESSIONAL STUDENTS: PRELIMINARY OUTCOMES

Jiaming Shi,[1] Fei Sun,[1] Jen Hirsch,[1] Dan Cohen,[2] and Ha-Neul Kim[1], *1. Michigan State University, East Lansing, Michigan, United States, 2. Right to Music, New York City, New York, United States*

This study aims to improve dementia literacy and competence to use music in practice with people with dementia among students in health professional fields. The eight-week curriculum was developed by a gerontology social worker and a subject matter expert on personalized music use for people with dementia. Two focus groups were completed in Spring of 2022 with people living with dementia and care partners to refine the curriculum and include information that those with lived experience felt was important for future health care professionals to know. The study used 2 single group designed cohorts of students who received the 8-week educational intervention over Zoom. Each cohort included 2 persons living with dementia (PWD) as co-trainers. Pre- and post- surveys included a modified Alzheimer's Disease Knowledge Scale and Dementia Attitude Scale. Participants (n=17) included Social Work = 8, Nursing = 2, Psychology =3, and Others =4. Total of 11 student participants completed both pre-test and post-test surveys. Paired t-tests were used to compare pre-post differences. At post-test, participants reported increased dementia knowledge (M=2.45, p=.0027); increased dementia attitudes (M=13.18, p=.0057); and improved competency on using music with PWD (M=.97, p=.0045) compared to the baseline scores. The 8-week intervention showed a statistically positive impact on dementia attitudes and competency of music use. The findings of this study laid the groundwork for future studies on training current service professionals and comparing their practice after the training to non-trained professionals to measure the impact of the training in intervention.

THE COMPARISON OF DUAL TASK TIME AMONG APOE CARRIERS AGAINST NON-APOE CARRIERS IN AGING ADULTS

Cody Diehl,[1] Anthony Campitelli,[1] Megan Jones,[1] Joshua Gills,[2] Sally Paulson,[3] Jordan Glenn,[4] Kelsey Bryk,[5] and Michelle Gray[1], *1. University of Arkansas, Fayetteville, Arkansas, United States, 2. Rutgers University-Newark, Jersey City, New Jersey, United States, 3. St. Elizabeth Healthcare, Cincinnati, Ohio, United States, 4. Neurotrack Technologies, Redwood City, California, United States, 5. Neurotrack Technologies, Inc., Redwoods City, California, United States*

No single variable has been identified as the sole factor for predicting an individuals' declining health status. In order to predict mental or physical decline in older adults, researchers have designed tasks that include both a physical and mental or cognitive demand known as dual task (DT). The purpose of implementing dual task is to assess the possible changes in accuracy when a second task gets compounded with a given single task. Our study consists of males and females aged from 45 to 75 years who have risk factors for dementia. Each subject was randomly assigned to either a health coaching (HC), or health education (HE) control group. The HC group received coaching to address the lifestyle areas known to be linked to AD risk, such as diet, exercise, sleep, stress, cognitive training, and social interaction. Blood markers of each individual have been assessed to determine carrier status of Apolipoprotein E 4 (APOE4) due to the correlation between the allele and increased risk of Alzheimer's. To be included in the study, the participants must have at least 2 positive risk factors for AD as determined by the Australian National University-Alzheimer Disease Risk Index (ANU-ADRI). Among non-APOE carriers, a 2x3 (group x time) mixed ANOVA revealed a significant interaction effect wherein the HC group improved DTC score more than the HE group from time 1 to time 3, F (2, 362) =1.253, P=0.017. No significant interaction was noted for APOE carriers.

THE ASSOCIATION OF LIFESTYLE AND SOCIAL ENGAGEMENT WITH DEMENTIA: A NATIONWIDE POPULATION-BASED COHORT STUDY

Jiyoon Jang, Sang Hwa Lee, and Eunhee Cho, *College of Nursing, Yonsei University, Seoul, Seoul-t'ukpyolsi, Republic of Korea*

As the aging population increases, the number of people with dementia is expected to rise rapidly, resulting in a growing burden on families and society. Delaying and preventing the clinical onset of dementia are significant public health goals. Unhealthy lifestyles and social disengagement have been identified to be modifiable risk factors for all-cause dementia. However, this has not been fully examined in the Korean population. Therefore, this study aimed to determine the association of lifestyle and social engagement with dementia incidence, based on the Korean Longitudinal Study on Aging (KLoSA) database with recently added dementia-related variables (diagnosis, medication administration, and treatment). The study included 5,071 participants; cases are patients diagnosed with dementia from 2010 to 2020 and controls are older adults without dementia. Logistic regression analysis was used to examine the relationship of dementia with lifestyle factors (alcohol consumption, smoking, exercising) and social engagement. Among the lifestyle factors, the current smoking status was associated with an increased risk of dementia (OR = 2.359, $p < .05$) after controlling the health-related covariates and general characteristics. Furthermore, increased participation in social activities was significantly related with a decreased risk of dementia (OR = 0.575, $p < .01$). This study highlighted the importance of non-smoking and social engagement in reducing the risk of dementia in later life. Therefore, implementation of interventions that focus on these leading risk factors can significantly reduce the burden of dementia in Korea.

SUPPORTING DEMENTIA CAREGIVERS DURING COVID-19 WITH CAREHEROES IT: USAGE PATTERNS AND OUTCOMES

Nicole Ruggiano,[1] Ellen Brown,[2] C. Victoria Framil,[2] Shannon Hurley,[3] Lisa Roberts,[2] Peter Clarke,[2] Sai Chaithra Allala,[2] and Jane Daquin[1], *1. University of Alabama, Tuscaloosa, Alabama, United States, 2. Florida International University, Miami, Florida, United States, 3. Florida State University, Tallahassee, Florida, United States*

Caregivers of people with dementia often experience negative physical and mental health outcomes due to the complex challenges posed by dementia symptoms and navigating care systems. The COVID-19 pandemic posed even greater hurdles for caregivers as many health care and support services transferred to virtual formats and required increased use of information technologies (IT). This research examined usage data and psychosocial outcomes of dementia caregivers who used a new mobile-enabled web-based app that was offered as an adjunct to clinical care at two memory clinics (Birmingham, AL; Miami, FL) during the pandemic. This app, called CareHeroes: (1) allows caregivers to self-assess their emotional and mental health; (2) offers a secure platform for tracking and communicating patient-related information among caregivers and providers; and (3) offers caregiver education. CareHeroes is also available in Spanish. Effort was made to recruit digitally underserved populations of caregivers (e.g., rural dwelling, underserved racial/ethnic groups). This presentation will review caregiver outcomes (e.g., burden, depression, user data) at baseline and 3-month follow-up. Among the 22 caregivers who enrolled in the study, 17 completed baseline and 3-month follow-up interviews. Over a 14-month period, participants logged onto CareHeroes 131 times, which varied by month. Caregivers most often used CareHeroes to complete assessment tools. Findings indicate that depression and burden were lower at 3-month follow-up compared to baseline, though this reduction was not statistically significant. The presentation will also review challenges of integrating a new technology intervention designed to promote telehealth during the COVID-19 pandemic.

R1P DISPERSION IN WHITE MATTER CORRELATES WITH COGNITIVE IMPAIRMENT IN OLDER ADULTS

Fatemeh Adelnia, Taylor Davis, Lealani Mae Acosta, Amanda Puckett, Feng Wang, Zhongliang Zu, Kevin Harkins, and John Gore, *Vanderbilt University Medical Center, Nashville, Tennessee, United States*

Alzheimer's disease is the most frequent form of dementia in older adults and has a total estimated worldwide cost that rises to $2 trillion by 2030. Much previous neuroimaging research in AD has focused on the roles of amyloid and tau proteins using PET, but there have also been several studies that have implicated microvascular changes as an early indicator of damage related to later dementia. Here, we developed and refined a non-invasive 3D-R1ρ dispersion imaging technique using different locking fields to quantify microvasculature changes within brain tissues in persons with mild cognitive impairment (MCI) compared to healthy controls. The fractional difference in R1ρ comparing different locking fields provides a unique way of characterizing changes in the geometry and structure of microvasculature. After providing informed consent, 40 adults aged 62 to 82 years (n=17MCI) underwent cognitive assessments and MRI scan at 3T. We found the fractional change in R1ρ of the whole brain white matter is significantly greater in persons with MCI, and the correlation remained significant (ß=-0.4, p-value=0.01) after introducing age (ß=0.2, p-value=0.2) and sex (ß=-0.1, p-value=0.5) as covariates. The white matter hypertonicity lesion volume measured from conventional MRI was also correlated with the health status (p-value < 0.05); however, the size of the regression coefficient was substantially smaller (53% lower), and it was no longer significant (p-value=0.14) after adjusting for age and sex. This work establishes a new non-invasive method that can potentially characterize changes in microvasculature anatomy with the progression of cognitive impairment regardless of an age effect.

PRIMARY CARE PROVIDER PERSPECTIVES ON LANGUAGE AND COMMUNICATION BARRIERS IN DEMENTIA DIAGNOSIS AND CARE

Alma Hernandez de Jesus,[1] Melissa Ma,[2] Daniel Dohan,[3] Cecilia Alagappan,[4] Katherine Rankin,[5] and Alissa Sideman[2], *1. UCSF, San Francisco, California, United*

States, 2. University of California, San Francisco, San Francisco, California, United States, 3. UC San Francisco, San Francisco, California, United States, 4. University of California San Francisco, Memory and Aging Center, San Francisco, California, United States, 5. University of California San Francisco, San Francisco, California, United States

Dementia diagnosis and care relies on extensive communication between a doctor, patient, and oftentimes a family caregiver. Communication is important for recognizing when there is a cognitive concern, gaining an understanding of the patient's history of cognitive decline, engaging in cognitive testing, and providing quality care post-diagnosis. We conducted a qualitative study of 35 primary care clinicians and primary care nurse practitioners working in safety net settings in California to understand facilitators and barriers to dementia diagnosis and care. Using thematic analysis, we identified similar themes to those that have been explored extensively related to language and communication in doctor-patient relationship. Topics ranging from challenges that emerge when there is language discordance, difficulties finding and using interpreters, and challenges related to communicating medical topics in a patient's native language. Specifically related to dementia, we found that language challenges emerge due to inadequate translation or availability of cognitive testing and post-diagnostic resources in multiple languages. However, we also identified unique challenges related to communication, including hearing loss, communicating about trauma during the diagnostic history interview, navigating the logistics of care, including communicating with specialists, building trust and rapport when there is language discordance, and cultural miscommunication even when the spoken language is the same. These issues affect historically marginalized individuals and communities, especially when dementia and cognitive impairment are present. We suggest new approaches and policies to enhance communication and better ways of working with patients who are hard of hearing.

PREDICTING DYADIC RELATIONSHIP STRAIN IN INDIVIDUALS WITH DEMENTIA

Amanda MacNeil,[1] Katherine Judge,[2] and David Bass[3], *1. Cleveland State University, Fairview Park, Ohio, United States, 2. Cleveland State University, Cleveland, Ohio, United States, 3. The Benjamin Rose Institute on Aging, Cleveland, Ohio, United States*

Recent literature has addressed the perceptions of individuals with dementia to understand how they experience their illness, with evidence suggesting these perceptions are impactful. Few studies, however, have used a conceptual model to explore different aspects of the illness. One aspect to consider is dyadic relationship strain, or feelings of tension, manipulation, and stress between the individual and caregiver. Little work has addressed this strain from the perspective of the individual with dementia who may have different feelings about the quality of the relationship. Cognition and function are two hallmark symptoms in dementia, however little work has addressed how the perception of these two areas impacts the illness experience. Perceptions of difficulties in these two areas may impact dyadic relationship strain as they necessitate increased care and changes in the relationship. Guided by the Stress Process Model for Individuals with Dementia, this study assessed potential predictors of dyadic relationship strain, finding personal activities of daily living (PADLs) to be impactful. In a multiple regression, PADLS (b=.319, p = 02) predicted strain above and beyond two measures of cognition: objective cognitive impairment (b =-.011, p =.93) and perceived memory difficulty (b=.003, p=.311) suggesting that perceived function is impactful for dyadic relationship strain. Because PADLS include more hands-on assistance, the perception of difficulty may create more feelings of embarrassment or stress and impact the perception of relationship strain. Future intervention work may target perceptions of function to improve the dyadic relationship by using techniques such as open communication about difficulties.

POSITIVE EMOTION EXPRESSION AND ADAPTIVE COPING BEHAVIORS FOR ADULT CHILDREN OF PARENTS WITH MEMORY LOSS

Dustin Gad, Amanda Piechota, and Joan Monin, *Yale School of Public Health, New Haven, Connecticut, United States*

The broaden-and-build theory suggests that experiences of positive emotion may lead to enhanced utilization of adaptive coping strategies, and a decrease in maladaptive coping strategies (Gloria & Steinhardt, 2016). This relationship between positive emotion and adaptive coping has yet to be studied directly in a sample of adult child caregivers of a parent with memory loss. As part of a larger study investigating relationship dynamics between adult children and their parents with memory loss, adult children 18 years of age and older (n= 67) responded to self-report surveys and engaged in a 6 minute, video recorded, positive interaction session, playing "name that tune" with each other. The session was observationally coded by two coders for "enjoyment/enthusiasm/fun" (k= .516), "laughter" (k= .631), and "positive affect displayed towards partner" (k=.464), using a reliable and valid support-seeking and caregiving behavior coding system (Collins & Feeney, 2000). Spearman's rank correlations between these behavior codes and the self-reported Brief COPE Inventory (BCI) scores suggested positive correlations between "laughter" and the emotional support subscale of the BCI (rs=.259, p= .034), and between "positive affect displayed towards partner" and the venting subscale of the BCI (rs= .256, p= .036). These findings suggest that the expression of positive emotions in the caregiving process might yield important psychological benefits to the caregiver, through increased utilization of specific coping mechanisms. More research in this area is needed to determine whether positive emotion expression is associated with the use of adaptive coping more so than maladaptive coping mechanisms in this population.

PERCEIVED SOCIAL ISOLATION IS CORRELATED WITH BRAIN STRUCTURE AND COGNITIVE TRAJECTORY IN ALZHEIMER'S DISEASE

Ye Zhang,[1] Yasuko Tatewaki,[2] Yingxu Liu,[2] Naoki Tomita,[2] Yumi Takano,[2] Taizen Nakase,[2] Tatsushi Mutoh,[2] and Yasuyuki Taki[2], *1. Tohoku University, Sendai, Miyagi, Japan, 2. Institute of Development, Aging and Cancer, Tohoku University, Sendai, Miyagi, Japan*

Perceived social isolation was associated with future cognitive decline and increase risk of Alzheimer's disease (AD). However, the impacts of perceived social isolation depending on different clinical stages of AD have not been elucidated. This study was to investigate the influence of perceived social isolation, or loneliness on brain structure and future cognitive trajectories in patients who are living with or are at risk for AD. 176 patients (mean age of 78 years, 39 subjective cognitive decline [SCD], 53 mild cognitive impairment [MCI], 84 AD) underwent structural MRI and neuropsychological testing. Loneliness was measured by one binary item question "Do you often feel lonely?". Voxel-based morphometry was conducted to evaluate regional gray matter volume (rGMV) difference associated with loneliness in each group. Subgroup analysis was performed in 51 patients with AD (n=23) and pre-dementia status (SCD-MCI, n=28) using the longitudinal scores of Alzheimer's Disease Assessment Scale-cognitive component-Japanese version (ADAS-Jcog). Whole brain VBM analysis comparing lonely to non-lonely patients revealed loneliness was associated with decreased rGMV in bilateral thalamus in SCD patients, and in the left middle occipital gyrus and the cerebellar vermal lobules I-V in MCI patients. Annual change of ADAS-Jcog in patients who reported loneliness was significantly greater comparing to these non-lonely in SCD-MCI group, but not in AD group. Our results indicate that perceived social isolation, or loneliness, might be a comorbid symptom of patients with SCD or MCI, which make them more vulnerable to the neuropathology of future AD progression.

PARTNERING WITH DEMENTIA CAREGIVERS TO DEVELOP AND REFINE THE ENACT INTERVENTION

Jacqueline Eaton,[1] Sarah Neller,[2]
Moroni Fernandez Cajavilca,[3] Julene Johnson,[4] and
Lee Ellington[5], *1. University of Utah, Salt Lake City, Utah, United States, 2. University of Tennessee, Knoxville, Tennessee, United States, 3. University of Utah, Bronx, New York, United States, 4. University of California, San Francisco, San Francisco, California, United States, 5. University of Utah and Huntsman Cancer Institute, Salt Lake City, Utah, United States*

The behavioral symptoms of dementia negatively affect family caregivers. Several interventions have been developed to support caregiver needs, and evidence suggests improved outcomes when interventions actively engage caregivers. However, the strategies to implement active engagement techniques have not been sufficiently studied. Enhancing Active Caregiver Training (EnACT) is an arts-based intervention aimed at actively engaging dementia caregivers as they view and interact with participant-informed vignettes that portray caregiving experiences. We conducted a series of three iterative focus groups with dementia caregivers (n=9) to identify scenarios and refine activities for inclusion within the EnACT intervention. We analyzed the data in three cycles, using structural, descriptive, and pattern coding. From the first focus group, we coded 182 items as what went well, illustrating how caregivers resonated with video content, applied scenarios to individual experiences, and appreciated the "informative" vignettes that facilitated learning, processing, and awareness of the realities of caregiving. We coded 42 items as needing to change, including considerations for caregiver impact, confusing components, accessibility, and missing content. Participants identified eight specific vignettes that resonated and focused on the topics of respite, behavioral symptoms, validation, burnout, and communication. Intervention revisions were made based on focus group feedback, including: 1) selecting video vignettes for intervention use and 2) creating an index of vignette topics to facilitate multiple discussion pathways to align with dementia caregiver training and support groups. Partnering with dementia caregivers has the potential to make intervention activities engaging and applicable to participant needs.

NUMBER OF CHILDREN AND RISK OF ALZHEIMER'S DISEASE AND DEMENTIA: EVIDENCE FROM THE UK BIOBANK

Yan Zhang, and Jason Fletcher, *University of Wisconsin-Madison, Madison, Wisconsin, United States*

This study uses a large-scale dataset of half a million respondents aged 39–73 from the UK Biobank to examine how parity (i.e., number of children) may influence parents' risk of Alzheimer's Disease and dementia (AD/D). We use respondents' (i.e., children's) reports of their parents' dementia status as the outcome variable. 38,040 respondents in the sample reported that their mother had AD/D, and 20,304 respondents reported their fathers had AD/D. Fixed effects logistic regression models suggest that compared to parents who had one child, high parity (> 4 kids) is associated with a lower risk of AD/D for both mothers and fathers. Moreover, as the parity increases, the protective effects become larger. This study advances prior dementia literature with two contributions. Methodologically, largely representative AD/D cases can increase the power of analysis. Also, children's reported AD/D cases are very likely through the observation of parents' entire life span, which can reduce misclassification of AD/D status and measurement errors from selective samples or self-reported cases. Empirically, this study provides important evidence suggesting protective effects of high parity on the risk of AD/D for both fathers and mothers. It implies that parity, as one of the life course contexts, may link to the risk of dementia in later life. More future work is needed to explore potential mechanisms.

LONELINESS IS INVERSELY ASSOCIATED WITH EXERCISE AND SLEEP APNEA IN OLDER WOMEN AT RISK FOR ALZHEIMER'S DISEASE

Madina Danish,[1] Alyx Shepherd,[2] Kitty Lui,[2]
Atul Malhotra,[2] Sheri Hartman,[2] Ellen Lee,[2]
Erin Sundermann,[2] and Sarah Banks[2], *1. University of California San Diego, San Diego, California, United States, 2. University of California, San Diego, San Diego, California, United States*

Background: Modifiable risk factors (MRF) for Alzheimer's disease (AD) include sedentary behavior, sleep apnea, and loneliness; however, how these MRFs influence one another is unclear. We examined correlations among loneliness, physical activity and sleep apnea among older women at higher risk for AD. Methods: Data were collected as part of the Women: Inflammation and Tau Study, which recruits women age 65–85 with higher AD genetic risk and mild impairment on the Montreal Cognitive Assessment. Participants completed the UCLA Loneliness Scale and home sleep tests to derive the Apnea Hypopnea Index (AHI), a measure of sleep apnea severity. Women wore ActiGraph accelerometers for one week to measure average Moderate-Vigorous Activity per day (MVPA). We used Spearman correlation to examine the relationships among AHI, MVPA and Loneliness Scale score. Results: Preliminary data were available for 12 women (mean age=72.4 [SD=2.8], 100% non-Hispanic White). MVPA ranged from 0.3–52.8 minutes (mean=9.38 [SD=14.1]; AHI ranged from 1.5–28.3 (mean=14.0 [SD=9.0] and Loneliness Scale score ranged from 0–34 (mean=9.8 [SD=x]). Significant, positive associations were observed between AHI and Loneliness (rho=.80, p=.006) and a moderate relationship at trend level was notable between higher MVPA and less Loneliness (rho=-9.53, p=.07). AHI did not relate to MVPA. Conclusion: Results suggest that loneliness independently relate to both sleep apnea severity and sedentary behavior in older women. Combined interventions that target loneliness in addition to physical activity and sleep may be important in women at-risk for AD.

LIGHT THERAPY FOR SLEEP DISTURBANCE OF NURSING FACILITY RESIDENTS WITH DEMENTIA: A SYSTEMATIC REVIEW

Wenxin Bian,[1] Mark Toles,[2] and Rose Mary Xavier[1], *1. University of North Carolina at Chapel Hill, Chapel Hill, North Carolina, United States, 2. UNC Chapel Hill, Chapel Hill, North Carolina, United States*

Background: Bright light therapy has shown promise in addressing sleep problems in nursing facility residents with dementia. However, recent studies yielded conflicting outcomes and few studies focused on nursing facilities. The purpose of this systematic review was to describe effectiveness of light interventions in nursing facility residents with dementia. Method: We searched PubMed, CINAHL, EMBASE, PsychINFO, and Scopus using key terms “sleep”, “dementia” and “residential facilities”, and synthesized data with thematic analysis and vote-counting. Results: Of eight studies that met inclusion criteria, six were randomized controlled trials and 2 were quasi-experimental. Sample size ranged from 11 to 77 residents. Studies tested 3 light therapies: timed bright light (n=6), timed regular light (n=1), and variable 24hour light (n=1). Light delivery method, light exposure, and adherence to therapy protocols were not consistently reported. All studies indicated light therapy improved some resident outcomes, such as sleep efficacy and total sleep time; however, 88% of studies did not report sampling strategies or a statistical power analysis and 22% had small sample size (n < 15). Conclusion: Insufficient evidence is available to recommend light therapies for nursing facility residents with dementia. Adequately statistically powered studies that are rigorously designed with representative samples are needed for robust estimation of the effects of light therapy on sleep. Future studies must account for the unique characteristics of nursing facility residents with dementia that impact their adherence to light therapy.

LIFE-COURSE MULTI-DISCIPLINARY PREDICTORS OF DEMENTIA AMONG OLDER ADULTS

Sayaka Kuwayama,[1] Kevin González,[1] Freddie Márquez,[1] Hector González,[1] and Wassim Tarraf[2], *1. University of California San Diego, La Jolla, California, United States, 2. Wayne State University, Detroit, Michigan, United States*

The incidence of dementia is rapidly increasing. Identifying risk factors for dementia may help improve risk assessment, increase awareness for risk reduction, and identify potential targets for interventions. We use a life-course multi-disciplinary modeling framework to examine leading predictors of incident dementia (ID). We use the Health and Retirement Study (HRS) to measure 57 exposures across 7 different domains: (1) demographic, (2) adverse childhood socioeconomic and psychosocial, (3) adverse adulthood experiences, (4) adult socioeconomic status, (5) health behaviors, (6) social connections, and (7) adult psychological conditions. Our outcome is ID (over 8-years) operationalized using Langa-Weir classification for adults aged 65+ years who meet criteria for cognitively normal at the baseline when all exposures are measured (Nf 1,622 in testing set and Nf1,460 in validation set). We compare standard methods (Logistic regression) with machine learning (ML) approaches (Lasso, Random Forest) in identifying highly predictive exposures across the risk domains of interest. Standard methods identified lower education, childhood financial duress, and pessimism as among the leading factors associated with ID. Psychological factors explained the highest variance for ID, followed by adult socioeconomic and adverse childhood factors. However, ML techniques differed in their identification of (1) predictors and (2) factors predictive importance. The findings emphasize the importance of upstream risk factors and the long-reach of childhood experiences on cognitive health. The ML approaches highlight the importance of life-course multidisciplinary frameworks for improving dementia risk assessment. Further investigations are needed to identify how complex interactions of life-course risk factors can be addressed through interventions.

INTERNATIONAL LONG-TERM CARE HOME QUALITY ASSURANCE: HOW DO EUROPEAN MEASURES ADDRESS DEMENTIA?

Michael Lepore,[1] Franziska Zúñiga,[2] Jos Schols,[3] Klaus Wingenfeld,[4] Theo van Achterberg,[5] and Briana Murray[1], *1. University of Maryland School of Nursing, Baltimore, Maryland, United States, 2. University of Basel, Basel, Basel-Stadt, Switzerland, 3. Maastricht University, Maastricht, Limburg, Netherlands, 4. University of Bielefeld, Bielefeld, Nordrhein-Westfalen, Germany, 5. KU Leuven, Leuven, Vlaams-Brabant, Belgium*

Alzheimer’s Disease and related dementias (ADRD) are prevalent conditions in long-term care homes (LTCHs) with about 50% of LTCH residents living with ADRD in many countries. Despite the prevalence of ADRD in LTCHs, a recent examination of LTCH quality assurance programs in four countries revealed a small percentage of LTCH quality measures across those countries addressed ADRD, most commonly as a risk adjuster, and once each as an inclusion or exclusion criterion. To better understand how quality assurance programs address ADRD internationally, we examined LTCH quality measures in four European countries—The Netherlands, Switzerland, Germany, and Belgium—following procedures previously used to examine international LTCH quality assurance measures. 73 measures were examined across 4 quality assurance programs. 26% of the measures addressed ADRD. The programs addressed ADRD in starkly different ways: in The Netherlands and Belgium no measures addressed ADRD; in Germany the majority (13/15) of measures addressed ADRD as an exclusion or inclusion criterion; and in Switzerland all the measures addressed ADRD through risk adjustment. Although limited to examining measures from LTCH quality assurance programs in four European countries, this study adds evidence that ADRD tends not to be addressed by LTCH quality measures, but when ADRD is addressed, it tends to be through risk adjustment. LTCH regulators, policymakers, and providers can use this information to assess options for addressing ADRD in quality assurance programs. Future research is needed to assess how standard indicators of quality differ across quality assurance regimes and how to address dementia beyond risk adjustment.

INCORPORATING SPIRITUALITY INTO COGNITIVE STIMULATION THERAPY GROUPS FOR PERSONS WITH DEMENTIA

Ebow Nketsiah,[1] Max Zubatsky,[1] and Marla Berg-Weger[2], *1. Saint Louis University, St. Louis, Missouri, United States, 2. Saint Louis University - St Louis, MO, Saint Louis, Missouri, United States*

With the rise in Dementia-Related Disorders globally, few non-pharmacological approaches have been developed to effectively target cognitive impairment and memory loss. Cognitive Stimulation Therapy (CST) has shown effectiveness in improving cognition and quality of life of older adults with dementia. To date, no studies have incorporated spirituality into CST for improving the cognition and quality of life of older adults with dementia. This study's aim is to evaluate the effectiveness of CST with a spirituality component compared to the traditional CST group intervention. Our team grouped participants (Nf34) into either spiritual or traditional groups based on their location of residence and level of cognition. Preliminary results showed that spiritual-themed groups improved in mental health status, mobility, and depression. The spiritual groups had a mean difference of 1.85-points improvement on mental status exam as compared to 0.2-point reduction for the traditional groups. In addition, the spiritual groups had a mean difference of 4.80-points improvement in mobility and 0.6-point improvement on depression as compared to a 5.25-points reduction in mobility and a 2.13-points reduction on depression of the traditional groups respectively. Compared to the traditional CST group, there were no significant differences noted regarding cognition and memory recall. Incorporating spirtiuality and other faith-based themes in groups may provide additional benefit for individuals with memory loss. Both healthcare and long-term care facilities may benefit from incorporating group interventions such as CST into their routine care with older adults.

IMPLEMENTING VISUAL VIDEOS AND IMAGES WITH PEOPLE WITH DEMENTIA IN CARE SETTINGS: A SCOPING REVIEW

Karen Lok Yi Wong,[1] Mario Bayani,[2] Jim Mann,[2] Annette Berndt,[2] Lily Wong,[2] Carly Wang,[1] Diane Pan,[1] and Lillian Hung[1], *1. University of British Columbia, Vancouver, British Columbia, Canada, 2. Community Engagement Advisory Network, Vancouver, British Columbia, Canada*

There is limited literature on using visual videos and images with people with dementia in care settings. We conducted a scoping review on this topic to fill this literature gap. Our scoping review adopted the Joanna Briggs Institute scoping review methodology. We eventually included eleven papers for the review and conducted the content analysis. We found the facilitators for implementing visual videos and images with people with dementia in care settings: 1. Matching people's interests 2. Being congruent with people's cognitive abilities 3. Support from families and staff 4. Using in a group setting. We also found the barriers: 1. Staff is unwilling to support 2. Lack of resources 3. Not congruent with the cognitive or other abilities of the people. We found benefits of using visual videos and images with this population: 1. Encourage expression 2. Facilitate discussions with other people 3. Improve well-being. We also found drawbacks: the potential of arousing negative emotions and memories. We suggest future research should include the voices of people with dementia, staff should be trained to support the people in case negative memories and emotions are aroused, and there should be consideration of using visual videos and images to tackle isolation and loneliness in care settings. With these findings, this scoping review should shed light on implementing visual videos and images in care settings.

HEALTH EXP ERIENCES OF SEXUAL AND GENDER MINORITY PEOPLE LIVING WITH DEMENTIA AND THEIR CAREGIVERS: A SCOPING REVIEW

Melissa Harris,[1] and Jennifer May[2], *1. Duke University, Durham, North Carolina, United States, 2. Duke, Durham, North Carolina, United States*

People living with dementia and older adults who identify as sexual and gender minority (SGM - lesbian, gay, bisexual, transgender, queer individuals) both represent minoritized groups of older adults, but little is known about the health experiences of older adults who are at the intersection of having dementia and also identify as SGM. This review explored the extent and nature of research focused on health and healthcare experiences of SGM people with dementia and/or their informal caregivers. A scoping review framework was used given the exploratory nature of the project's purpose. Health librarians comprehensively searched four databases (MEDLINE, CINAHL, PsycINFO, AgeLine) to identify relevant studies. A total of 8,137 unique titles and abstracts were reviewed by 2 independent reviewers. Forty citations were determined relevant and reviewed by full text. Eight studies met inclusion criteria and were analyzed thematically. Study methods were quantitative cross-sectional (n=2), qualitative exploratory (n=4), and a mixed methods case study (n=1). Studies were published from 2010–2022. Sample sizes ranged from 1 to 415 (M=113, SD=116). Four studies focused on caregivers, 2 on persons with dementia, and 1 on dyads. Themes emerged pertaining to caregiver health and well-being, identity, relationships, disclosure, discrimination, and safety. Findings highlight the significance of inclusive care that addresses intersecting psychosocial and health-related identities (e.g., cognitive status, SGM status, race/ethnicity, substance abuse history, multimorbidity) and that protects the rights of families of choice. More research is needed to better understand how sociopolitical structure influences dynamics between cognitive health and SGM status among older adults.

GERIATRICIAN PERSPECTIVES ON THE MANAGEMENT OF MILD COGNITIVE IMPAIRMENT/ MILD ALZHEIMER'S DISEASE

Ganesh Gopalakrishna,[1] Jeremy Pruzin,[1] Susan Alford,[2] Carol Hamersky,[2] Anup Sabharwal,[2] and Stephen Brunton[3], *1. Banner Alzheimer's Institute, Phoenix, Arizona, United States, 2. Novo Nordisk, Inc., Plainsboro, New Jersey, United States, 3. Primary Care Education Consortium, Winnsboro, South Carolina, United States*

Mild cognitive impairment (MCI) and Alzheimer's disease (AD) dementia are characterized by cognitive impairment and in AD a progressive functional impairment. This study sought to understand the role of geriatricians in treating patients with MCI/mild AD dementia. An anonymous, online survey was conducted in the US with 301 healthcare professionals (HCPs), including 75 primary care providers who practice as board certified geriatricians, and treat ≥10 patients per month with MCI/mild AD dementia. Geriatricians reported that among their patients with MCI/mild AD dementia, they initially make this diagnosis 70% of the time. Geriatricians reported that the topics commonly discussed with patients at the time of diagnosis are treatment options (85%), care management strategies (81%) and disease progression (80%). When referring patients to other specialties for treatment, geriatricians most often referred to neurologists (41%). Most (83%) geriatricians considered themselves the coordinator of care for patients with MCI/mild AD dementia; however, only 5% of non-geriatrician HCP respondents view geriatricians as such. Geriatricians reported prescribing/recommending treatments for ongoing management of MCI/mild AD dementia, with the most common being mental exercises (76%), acetylcholinesterase inhibitors (75%), social interaction (73%), medications to manage comorbidities (72%), and lifestyle improvements (72%). Most (76%) geriatricians have received advanced formal training in MCI/mild AD dementia care with the majority (84%) expressing that they feel very confident in managing patients with MCI/mild AD dementia. Geriatricians are specialists that are well trained and confident in diagnosing, treating, and managing patients with MCI/mild AD dementia.

GAIT AND/OR BALANCE DISTURBANCES AND THE ONSET OF ALZHEIMER'S DISEASE IN MILD COGNITIVE IMPAIRMENT

Sangwoo Ahn, *University of Tennessee at Knoxville, Knoxville, Tennessee, United States*

Physical frailty is one of the fundamental hallmarks of aging. Older adults with mild cognitive impairment (MCI) are more likely to exhibit some characteristics of physical frailty such as worse gait and/or balance. Gait and/or balance disturbances may precede cognitive decline among cognitively healthy older adults. The purpose of this longitudinal observational study was to identify the temporal relationship between gait and/or balance disturbances and the onset of Alzheimer's disease (AD) because it has not been well characterized among older adults with MCI. Data of 2,692 older adults with MCI (ages 74.5 ± 7.1 years, women making up 47% of the sample) were from the National Alzheimer's Coordinating Center's Uniform Data Set. Risk of incident AD by baseline gait and/or balance disturbances was examined by Cox regression models over 4.0 ± 3.0 years, adjusting for demographic characteristics, medical conditions, and study site where the data were collected. The presence of gait and/or balance disturbances predicted 38% to 55% (hazard ratios [HR] 1.38 to 1.55) increased risk of AD. Findings remained robust in sub-group analyses by sex and there were no noticeable changes compared with the original analyses. Thus, regardless of sex, gait and/or balance disturbances predicted the onset of AD among older adults with MCI. Health care providers may need to (1) catch a warning of possible cognitive decline by a frequent assessment of gait and/or balance disturbances and (2) provide effective strategies to improve gait and/or balance disturbances to potentially delay the onset of AD.

EXPLORATION OF CARE CONTENTS AFFECTING STRESS VARIABILITY IN FAMILY CAREGIVERS OF OLDER PEOPLE WITH DEMENTIA

Sonoko Kabaya, Chieko Greiner, Masahide Nakamura, Yuko Yamaguchi, and Zhang Xuanrong, *Kobe University, Kobe City, Hyogo, Japan*

Support for family caregivers (FCs) caring for older people with dementia in the home settings is a common issue in developed countries. Previous studies have reported that the increase in the burden of FCs not only causes health problems, but also makes it difficult to continue care at home and causes serious problems such as abuse. However, it is not clear how FCs' stress, which leads to increased burden, fluctuates within a day through daily care activities. The aim of this study was to explore care activities that influence the increase in FCs' stress. We recruited one dyad of an older adult with dementia over the age of 65 and a FC. Data collection was performed for consecutive 7 days throughout 24 hours. We adopted hamon® developed by Mitsufuji Corp. Japan to measure Heart Rate Variability (HRV)-based stress. Moreover, we asked a FC to talk with Virtual Agent on a laptop freely to understand when and what kind of care activities were done and how FC's feelings were. Kruskal-Wallis's test and Bonferroni's multiple comparison test were used to compare differences in stress in the care contents. Results showed that sleeping care, which is composed of such as assistance in using the toilet and changing clothes, gives more stress to FC, compared with morning care which includes such as assistance in changing clothes, eating breakfast, and taking medicine (p=0.042). this finding is beneficial for considering how to reduce FC's stress on daily care activities.

EXAMINING THE HEALTH EQUITY OF PEOPLE WITH DEMENTIA DURING THE COVID-19 PANDEMIC: FIRST INSIGHTS FROM A TWITTER STUDY

Juanita-Dawne Bacsu,[1] Megan E. O'Connell,[2] Allison Cammer,[2] Soheila Ahmadi,[2] Corinne Berger,[2] Mehrnoosh Azizi,[2] Rory Gowda-Sookochoff,[2] and Karl Grewal[2], *1. Thompson Rivers University, Kamloops,* *British Columbia, Canada, 2. University of Saskatchewan, Saskatoon, Saskatchewan, Canada*

The COVID-19 pandemic has deepened issues of health inequity and social injustice against people with dementia. Despite having one of the highest mortality rates, little research focuses on the COVID-19 impact of people with dementia. This presentation aims to: 1) explore the COVID-19 experiences and key factors of health inequity among people with dementia during the pandemic; and 2) identify actions to improve the health equity of people with dementia in the pandemic. We collected 6,243 relevant tweets using the Twint application in Python from September 8, 2020, to December 8, 2021. Tweets were divided among eleven coders and analyzed using thematic analysis. Analysis identified three primary themes: structural inequities (e.g., restricted access to health and support services, ageism, social isolation, vaccination barriers, and inadequate staffing in care facilities); frustration and despair due to loss (e.g., loss of cognitive abilities, loss of time with loved ones, and loss of life); and resiliency and hope for the future (e.g., lifting of restrictions and COVID-19 vaccine). There is an urgent need for policymakers to improve the health equity of people with dementia in the pandemic. Tackling COVID-19 inequities requires revisiting infection control policies to improve access to health and support services, recognizing the essential role of family care partners, and providing resources to help support people with dementia during the pandemic. Moreover, it is essential that COVID-19 policy responses are informed by evidence-informed research and authentic partnerships that embrace the insight and lived experiences of people with dementia.

ENGAGING OLDER ADULTS WITH ALZHEIMER'S DISEASE IN EXERCISE: IMPACT ON CAREGIVERS

Tai Sims,[1] Kristine Talley,[2] Joseph Gaugler,[2] Cynthia Peden-McAlpine,[2] Laura Kirk,[2] and Fang Yu[3], *1. Minnesota State University, Mankato, Mankato, Minnesota, United States, 2. University of Minnesota, Minneapolis, Minnesota, United States, 3. Arizona State University, Phoenix, Arizona, United States*

Informal caregivers provide the bulk of care for persons with Alzheimer's dementia (PWAD) living at home, resulting in increased burden, and deteriorations in wellbeing and health. The stress process model hypothesizes characteristics of PWAD influence caregiver outcomes. Few studies have identified if engaging PWAD in exercise influences caregiver outcomes. This ancillary mixed methods study of a RCT evaluated the impact of a 6-month, moderate-intensity aerobic exercise intervention for community-dwelling PWAD on family caregiver burden, wellbeing and general health. Quantitative data was collected at baseline, 3, 6, 9 and 12 months using Zarit Burden Interview, Caregiver Strain Index, Caregiver Wellbeing Scale, and 36-item Short Form Health Survey. Qualitative data was collected at 6 and 9 months using semi-structured interviews. The convergent mixed methods design included ANCOVA analyses of quantitative and content analysis of qualitative data. Participants were 25 (17 intervention, 8 control) caregivers aged 34–86 years who were primarily white, females that lived with care-recipient. Based on group assignment, quantitative and qualitative results provided mixed insight on influence of intervention on burden and wellbeing, and found no influence on general health. Quantitative findings indicated caregiver characteristics of relationship with care-recipient, gender and education influenced wellbeing, and relationship with care-recipient, co-residence and education influenced general health; and caregiver characteristics did not influence burden. Qualitative findings suggest improved burden and wellbeing were consequences of respite and social support, rather than the exercise intervention. This study provides insight that integrating family caregiver components into community-based exercise programs may benefit PWAD and their family caregivers.

ENGAGING A DIVERSE PATIENT AND CARE PARTNER COUNCIL TO REFINE DEMENTIA CARE DIGITAL HEALTH TOOLS

Jessica Cassidy,[1] Mary Fisher,[2] Evelyn Romeo,[3] Samantha Holden,[3] Melanie Caffrey,[4] Donald Nease,[3] and Hillary Lum[2], *1. University of Texas at Arlington, Arlington, Texas, United States, 2. University of Colorado Anschutz Medical Campus, Aurora, 3. UC Health Anschutz, Aurora, Colorado, United States, 4. Colorado Springs, Colorado, United States*

Digital health tools have potential to reduce health disparities for persons with dementia and their family care partners (i.e., dementia dyads). We aimed to promote digital health equity through engaging stakeholders to identify priorities and suggestions for refinements to digital health tools. We convened a council, "Memory Research Partners in Caring and Technology" comprised of three dementia dyads, two care partners, and 10 community members with experience as research partners. The council met six times over seven months. Methods of engagement included: a) delivering preparatory educational materials and hosting guest speakers; b) World Café participatory methods and small group discussions using Google jamboards; and c) individual consultations with partners for additional input. Data was analyzed using rapid qualitative analysis and member checking with research partners. We evaluated engagement methods with a research partner survey and analyzed responses using descriptive statistics. Research partners identified key priorities for equitable refinement of digital health tools, including: 1) Communicating with dementia dyads based on their preferences; 2) Creating user-friendly patient portals; 3) Ensuring digital health tools offer dementia dyads convenience; 4) Providing technology supports; and 5) Facilitating connection to community resources. Stakeholder feedback regarding project engagement indicated majority strongly agreed their input was accurately heard (69%); communication and scheduling was accommodating (77%); they contributed to the research project (69%); and they gained new knowledge on digital tools (54%) and dementia (85%). Research partner insights and ongoing member checking will inform future next steps towards improving dementia care coordination and communication using digital tools.

EMOTIONAL FUNCTIONING IN PEOPLE WITH DEMENTIA AND CAREGIVER AFFECT DURING DYADIC INTERACTIONS

Hannah Cozad,[1] Yuxuan Chen,[2] Casey Brown,[3] Julian A. Scheffer,[3] Kuan-Hua Chen,[3] and Robert W. Levenson[3], *1. Georgetown University, Oakland,* *California, United States, 2. Stanford University, Stanford, California, United States, 3. University of California, Berkeley, Berkeley, California, United States*

Dementia caregivers can experience negative affect when interacting with their care recipients. However, few studies have examined the specific factors that predict caregiver negative affect in this dyadic context. We hypothesized that deficits in care recipients' emotional functioning would be associated with increased intensity of caregivers' negative affect during interactions with their care recipient. Caregivers (Nf100) reported on two aspects of their care recipients' emotional functioning: (1) emotion recognition (the ability to recognize other people's emotions), and (2) negative emotional reactivity (the ability to generate negative emotional responses). Dyads then visited the laboratory and engaged in a 10-minute conversation about an area of conflict in their relationship. Caregivers then watched recordings of their conversation while rating the valence and intensity of their experienced affect using a rating dial. We used these ratings to quantify changes in caregivers' emotional valence across the course of the conversation. Caregivers of care recipients with greater deficits in emotion recognition demonstrated greater increases in negative affect across the conversation. In contrast, care recipients' negative emotional reactivity was not related to changes in the valence of caregivers' affect across the conversation. Findings remained significant even after accounting for caregiver baseline valence ratings, biological sex, and age, as well as the care recipients' diagnosis and level of cognitive impairment. Results reveal the important role that care recipients' deficits in emotion recognition play in caregivers' emotional lives. Caregivers' negative affect may be more likely to increase when their care recipient has deficits in emotion recognition.

DEVELOPMENT AND IMPLEMENTATION OF THE COGDRISK DEMENTIA RISK ASSESSMENT TOOL AND INTERACTIVE WEBSITE

Scherazad Kootar, Ruth Peters, Md Hamidul Huque, Ranmalee Eramudugolla, and Kaarin Anstey, *University of New South Wales, Sydney, New South Wales, Australia*

We developed a comprehensive risk assessment tool for dementia – Cognitive Health and Dementia Risk Assessment (CogDrisk) and a version specifically for Alzheimer's disease called CogDrisk-AD that could be applicable in low and high-resource settings. This tool incorporates risk and protective factors identified through systematic synthesis of observational studies that report risk ratios. Risk and protective factors included in the tool were selected on the strength of evidence as well as the availability of measures that are practicable in a range of clinical and research contexts. Seventeen risk/protective factors were identified for inclusion in the dementia algorithm to estimate the risk of dementia while sixteen factors were identified for the AD model, with an overlap in the majority of the factors. CogDrisk and the CogDrisk-AD were predictive of dementia and AD when validated across four high-quality international cohort studies. To enable the CogDrisk tool to be implemented in practice our team has developed an interactive website where individuals 18 years and above can complete the CogDrisk questionnaire, obtain a personalised risk profile, and receive feedback on their risk profile. The website was developed with the capacity to collect and store data. We anticipate that the tool can be used by members of the public, in clinical settings and as a screening or outcome measure for clinical trials.

DESCRIBING THE EVOLUTION OF MEDICATION USE OVER TIME IN PEOPLE LIVING WITH DEMENTIA USING NETWORK ANALYSIS

Abby Emdin,[1] Alexa Boblitz,[2] Laura Maclagan,[2] Jennifer Bethell,[3] Jennifer Watt,[1] Daniel Harris,[1] Colleen Maxwell,[4] and Susan Bronskill[1], *1. University of Toronto, Toronto, Ontario, Canada, 2. ICES, Toronto, Ontario, Canada, 3. Toronto Rehabilitation Institute, Toronto, Ontario, Canada, 4. University of Waterloo, Kitchner, Ontario, Canada*

Prescribing for community-dwelling older adults living with dementia is complex. Multiple medications may be used to manage symptoms associated with dementia and/or co-existing chronic conditions, and can lead to problematic polypharmacy. Our objective was to use network analysis, a data science method, to provide a comprehensive description of co-prescribed medications in persons with dementia and describe whether these patterns change over time. We created a population-based cohort of community-dwelling older adults (aged 67+ years) in Ontario, Canada, newly diagnosed with dementia (between April 2014 and January 2019), from health administrative data, and developed medication networks at one year prior to, at, and for up to five years following dementia diagnosis. Among 136,292 individuals newly diagnosed with dementia, the mean age was 82.2 years and 59% were female. The most common medication subclasses dispensed at diagnosis were primarily cardiovascular medications: statins (45.6%), proton pump inhibitors (27.3%), beta-blockers (27.0%), calcium blockers (25.1%), and ACE inhibitors (24.6%). Similar proportions of medication subclasses were found at five years after diagnosis, except cholinesterase inhibitors (34.0% at five years were dispensed cholinesterase inhibitors compared to 16.9% at diagnosis). The most frequent co-prescribed medication pairs at diagnosis included statins and beta-blockers (16.0%), proton pump inhibitors (16.0%), and ace inhibitors (15.4%), respectively. Co-prescription was similar at five years, but also included higher frequency of co-prescribing with cholinesterase inhibitors (e.g., 19.4% were prescribed cholinesterase inhibitors and statins). Network diagrams demonstrate the complexity of prescribing in this population and highlight concurrent prescribing which may require careful monitoring or deprescribing.

DEMENTIA-FRIENDLY IN THE CONTEXT OF HOSPITALIZATION: A CONCEPT ANALYSIS

Ellen Munsterman, Pamela Cacchione, Nancy Hodgson, and G. Adriana Perez, *University of Pennsylvania, Philadelphia, Pennsylvania, United States*

Persons living with dementia experience more and longer hospitalizations when compared to those without dementia. In response, initiatives to address the hospital experience for individuals with dementia and their families are becoming more common. The term "dementia-friendly" attached to terms such as "hospital", "ward", "initiative", "program", etc. is being used to describe this response.

Literature has begun to summarize current knowledge of dementia-friendly initiatives and define characteristics of dementia friendly hospitals, however, a formal definition of the concept of "dementia-friendly" is lacking. A concept analysis was completed using the 8-step Walker and Avant method including: selecting the concept and aim, identifying use of the concept in the literature, determining defining attributes, antecedents, consequences, and empirical referents, and developing cases that further distinguish the concept. The goal of this analysis was to clarify the definition of dementia-friendly in the context of hospitalization. Attributes of dementia-friendly in the hospital include dementia-specific staff education, use of person-centered care practices, environmental modification, and nursing-specific factors such as attitude, time to spend with patients and adapting responses based on patient need. Antecedents include recognition of the impact of hospitalization on older people with dementia. Consequences include enhanced staff knowledge and patient outcomes including decreased length of stay and decreased use of antipsychotic medication. Based on the above analysis, a conceptual definition for dementia-friendly in the context of hospitalization is proposed. This definition highlights the identified antecedents and attributes with a focus on the essential role of nursing in delivering dementia-friendly care.

CROSS-CULTURAL COMPARISON OF A LATENT DEMENTIA INDEX IN MEXICO AND THE UNITED STATES

Joseph Saenz, and Christopher Beam, *University of Southern California, Los Angeles, California, United States*

Latent variable models have recently been used to extract latent dementia index scores using cognitive and functional ability data. Yet, no cross-cultural comparisons have been conducted. This analysis tests metric measurement invariance of a latent dementia indicator (LDI) among older adults in Mexico and the US using different statistical criteria. We then test whether demographic risk factors relate with the LDI similarly depending on criteria used to test measurement invariance. Data included the MexCog (Mexico, n=2,265) and Harmonized Cognitive Assessment Protocol (US HCAP, n=3,347). The LDI is a latent variable measured using 13 cognitive and 10 functional common items. Measurement invariance was tested in multiple group confirmatory factor analyses using both nested chi-square difference tests and comparisons of comparative fit indices (CFI). Covariances between demographic risk factors (age and education) and the LDI were compared across models achieved using different measurement invariance criteria. Full metric invariance of the LDI was achieved using CFI comparisons but not with chi-square comparisons, which required nine loadings to be freely estimated across studies to achieve partial metric invariance. Regardless of criteria used to test measurement invariance, age and education correlated with the LDI in both studies in expected directions with similar parameter estimates regardless of approach used to test measurement invariance. The LDI may be a valid tool to compare associations between risk factors and dementia in the HCAP and MexCog. The LDI related with demographic factors in expected ways and findings were robust to statistical approach used for measurement invariance testing.

COGNITIVE STATUS AND HEALTH CARE UTILIZATION IN AN EMERGENCY DEPARTMENT: EARLY RESULTS OF A LONGITUDINAL PILOT STUDY

Walter Dawson, Natasha Spoden, Sarah Gothard, Kirsten Wright, and Jeffrey Kaye, *Oregon Health & Science University, Portland, Oregon, United States*

Many people living with Alzheimer's disease and related dementias (ADRD) never receive a formal disease diagnosis. This compromises wellbeing and increases health services utilization and care costs. Wider screening and assessment for ADRD may increase access to supportive care, improve allocation of medical care, and foster interventions that prevent or delay disease progression. A sample of Medicare-enrolled individuals 65+ (n=60) consecutively presenting to the Oregon Health & Science University (OHSU) emergency department (ED) in Portland, Oregon consented to the study and were administered the TICS, a validated tool for telephone-based assessments of cognition, post-discharge from the ED. Study participants were asked about their physical health via the modified Cumulative Illness Rating Scale (M-CIRS), and their cognitive health via the PROMIS Cognitive Measure Questions on Mental Clarity. Care utilization patterns were measured via review of participants' electronic health records (EHR) for three years prior to study enrollment focusing on total hospitalizations, ED visits, and primary care (PC) visits. Medicare-enrolled adults 65+ recently discharged from the ED were a feasible population to perform a cognitive assessment. The study enrollment rate was 24.2% (n=60). Enrollment was limited to patients with their PC affiliated with the OHSU health system, which excluded the majority (792, 73.8%) of ED patients Medicare-enrolled, 65+ from our study (1,072). This study provides preliminary evidence to support focusing on older ED patients to administer cognitive assessments, linking outcomes to the EHR, and ultimately providing a platform for future research on impacts of under-diagnosed ADRD on population-level health outcomes and care utilization.

CO-DESIGNED PERSON-CENTERED NARRATIVES FOR PEOPLE WITH ALZHEIMER'S AND RELATED DEMENTIAS

Sarah Flessa,[1] James Harrison,[2] Tajalei Willard,[2] Michael Chandler,[1] and Stephanie Rogers[3], *1. MemoryWell, Washington, District of Columbia, United States, 2. UCSF School of Medicine, San Francisco, California, United States, 3. UCSF, San Francisco, California, United States*

MemoryWell's professional writers capture and share patient life stories with care teams and families in healthcare settings, with the goal of improving person-centered care. This mixed methods study employs participatory-design methods to assess the feasibility and acceptability of adapting this existing life story service to an acute care setting and implementing stories into the electronic health record (EHR) for older adults with Alzheimer's and Related Dementias (ADRD). Through in-depth interviews and surveys, we engage patients, family caregivers and care providers to co-design the life story process adaptation and development of EHR wireframes to iterate and pilot in the acute care setting. We will present the co-designed EHR wireframes and data analyzed using qualitative content analysis. Results describe life story utility and potential impacts on outcomes for people with ADRD. Findings from in-depth interviews with 11 providers indicated high feasibility and acceptability, e.g. describing a high likelihood of daily use. Providers shared barriers and facilitators, e.g. time and accessibility, and potential impacts on person-centered care and patient outcomes, e.g. trust, cultural competency, and delirium. Patient and caregiver data collection is underway; one patient and one caregiver have been interviewed out of ten for each respective group. Interviews with all groups have suggested that life stories would be useful for helping patients in unfamiliar and disorienting environments and learning information such as hobbies and interests would be helpful for providers to better understand and engage with patients.

CLAIMS-BASED FRAILTY INDEX (CFI) AS A MEASURE OF DEMENTIA SEVERITY IN MEDICARE BENEFICIARIES WITH ADRD

Chan Mi Park,[1] Stephanie Denise Sison,[2] Ellen McCarthy,[1] Natalia Gouskova,[1] and Dae Kim[1], *1. Hebrew SeniorLife, Roslindale, Massachusetts, United States, 2. Beth Israel Deaconess Medical Center, Brookline, Massachusetts, United States*

Lack of a dementia severity measure in administrative claims data is a major barrier in Alzheimer's Disease and Related Dementias (ADRD) research using such data sources. A claims-based frailty index (CFI; range 0 to 1, higher scores indicating greater frailty) is a validated measure of frailty that can be calculated from administrative claims data and is correlated with functional status. We conducted a cross-sectional study to examine whether CFI can be a claims-based measure to differentiate dementia severity in 814 participants with ADRD with linked to Medicare claims in the National Health and Aging Trends Study (NHATS). We estimated the Functional Assessment Staging Test (FAST) scale (3: mild cognitive impairment; 4: mild dementia; 5: moderate dementia; 6–7 moderate-to-severe dementia) using NHATS variables and calculated CFI from Medicare claims in the prior 12 months. The prevalence of FAST stage 5 or higher was 244 (weighted percentage, 25.9%). The C-statistic of CFI to identify FAST stage 5 or higher was 0.78 [95% CI:0.73–0.82], with a CFI cut-point of 0.3 achieving the maximum sensitivity 72.5% and specificity 67.5%. The equipercentile linking procedure showed that CFI scores of 0.30, 0.35, and 0.40 corresponded to FAST stages 4, 5, and 6, respectively. Our results support the utility of a CFI as a proxy of dementia severity in administrative claims data.

CAREGIVER USABILITY TESTING OF WEB-BASED AND VIRTUAL REALITY REMINISCENCE THERAPY FOR PERSONS WITH DEMENTIA

Winnie Sun, and Alvaro Quevedo, *Ontario Tech University, Oshawa, Ontario, Canada*

Reminiscence therapy (RT) is a multi-sensory treatment that uses a combination of sight, touch, taste, smell and sound to help persons with dementia (PWD) remember events, people and places from their past lives. Currently, digital technologies such as mobile applications and immersive solutions including virtual and augmented reality, are gaining momentum as supplementary tools for RT. This paper presents a usability study of a web-based and virtual reality application to understand the limitations and opportunities of digital platforms for facilitating engaging experiences for PWD towards recalling memories, while easing the therapy process for the caregivers. A total of ten healthcare caregivers were recruited from the Geriatric Dementia Unit and Geriatric Transitional Unit in Ontario Shores Center for Mental Health Sciences, Ontario Canada. Usability feedback from the caregivers were collected from the interviews after the completion of the System Usability Scale (SUS) questionnaire. Institutional caregivers found both web-based and virtual reality (VRRT) usable with SUS score above average (68/100), but required improvements related to the onboarding training of caregivers. The interview revealed four overarching themes related to the VRRT: (1) Ease of use; (2) Positive impact on caregiving; (3) Potential of reduction in responsive behaviors; (4) Feasibility for promoting social connection during COVID-19 pandemic. Next steps will focus on improving the user experience and expanding the application for immersive VR supporting head-mounted displays, hand tracking, and physiological measures, as well as conducting an usability study with PWD to expand our understanding of using RT digital tools with various levels of immersion.

ARTISTIC ENGAGEMENT AT A MEMORY CARE FACILITY, VIA A TELEPRESENCE ROBOT

Amy Knepple Carney, Vanessa Hillman, Chloe Lehman, Elizabeth Holland, and Lizzie Gowin, *University of Wisconsin- Oshkosh, Oshkosh, Wisconsin, United States*

There is a growing body of research that shows participation in arts interventions (e.g., poetry, storytelling, music, and dance) can be beneficial for those living with dementia. The current study examines social interactions when the artist is not physically present, but in the room via a telepresence robot. Through the telepresence robot, dementia care residents were connected to a network of arts presenters. Using a checklist examining social behaviors (verbal and non-verbal), we assessed residents' social engagement with the artist, other residents, and staff during these creative visits. Typical activities within the care facility were also observed. The observations were conducted on 10 individuals living within the memory care facility. Although the typical facility activities elicited social verbal behaviors, they tended to be more physical in nature and had a larger number of social nonverbal behaviors. When the behavior was verbal it tended to be more noises of excitement, such as "wooo" and "oh yeah." Although the artist engagement activities elicited social nonverbal behaviors, they tended to be more verbally engaging and there were a larger number of social verbal behaviors during these activities. With the artist engagement we observed residents spontaneously singing songs, and helping to create poetry. The facility was already using activities that allowed the residents to become physically engaged and with the addition of artist visits there was an increase in verbal engagement. By having greater options for residents to create engagement we may see people who don't typically engage become more involved.

ANXIETY, COGNITIVE FUNCTION, CHANGE, AND IMPAIRMENT AMONG DIVERSE OLDER HISPANICS/ LATINOS.

Roberto Gonzalez-Prado,[1] Alejandra Morlett Paredes,[2] Wassim Tarraf,[3] Ariana Stickel,[1] Fernando Testai,[4] Linda Gallo,[1] Frank Pendedo,[5] and Hector González[2], *1. San Diego State University, San Diego, California, United States, 2. University of California, San Diego, San Diego, California, United States, 3. Wayne State University, Detroit, Michigan, United States, 4. University of Illinois, Chicago, Chicago, Illinois, United States, 5. University of Miami, Coral Gables, Florida, United States,*

Introduction: Anxiety and depression often co-occur and may be risk factors for neurodegenerative diseases such as Alzheimer's disease and related dementias. We examined associations between symptoms of anxiety and cognitive change and impairment in middle-aged and older Hispanics/Latinos. Method: 6,162 participants aged ≥50 (mean age=63.4, SD=±8.2 years) were enrolled in the Study of Latinos-Investigations of Neurocognitive Aging study (SOL-INCA), an ancillary to the Hispanic Community Health Study/Study of Latinos (HCHS/SOL). Exposures included the Spielberger State-Trait Anxiety Inventory 10-item (STAI-10) and the Center for Epidemiology Scale for Depression 10-item (CESD-10) at HCHS/SOL Visit 1 (2008–2011). Outcomes include cognitive tests at Visit 1 and 2 about 7 years later in SOL-INCA and mild cognitive impairment diagnosis (MCI; NIA-AA diagnostic criteria). Separate models were created to examine associations between cognition and anxiety adjusting for demographic variables, antianxiety medication, and depressive symptoms. Results: After adjusting for demographic variables and medication use, STAI-10 scores were associated with Visit 2 cognitive function ($p < 0.05$) and MCI ($p < 0.01$), but not with changes in cognitive function over time. After adjusting for depressive symptoms, most effects of anxiety were attenuated, with exception of B-SEVLT-Recall ($p < 0.05$). Discussion: Anxiety symptoms were associated with lower memory function 7 years later among diverse older Hispanics/Latinos. Anxiety was associated with 7-year cognitive change and MCI, but those associations were explained by depressive symptoms and other covariables. Future research should examine cognition in relation to anxiety and depression since the two commonly co-occur.

ANTICIPATED SUICIDAL AND DEATH IDEATION IN RESPONSE TO AN IMAGINED DEMENTIA DIAGNOSIS

Molly Maxfield,[1] Allie Peckham,[1] Dara James,[2] Laura Lathrop,[3] and Amy Fiske[4], *1. Arizona State University, Phoenix, Arizona, United States, 2. University of South Alabama, Mobile, Alabama, United States, 3. University of Denver, Denver, Colorado, United States, 4. West Virginia University, Morgantown, West Virginia, United States*

Alzheimer's disease and related dementias are prevalent, incurable, and highly impactful diagnoses. Dementias are therefore feared diagnoses. Dementia-related anxiety (DRA) is anxiety about a current or future diagnosis of dementia and the associated complex symptoms. In a mixed methods study, semi-structured interviews were conducted to identify causes of DRA and revealed that numerous adults anticipated suicidal or death ideation if diagnosed with dementia. Fifty cognitively healthy, community-dwelling adults aged 58 to 89 (M = 70.92, SD = 6.08; 64% female) were recruited from a university participant registry and Memory Clinic. Among participants endorsing anticipated suicidal or death ideation, responses ranged from active plans, including interest in physician-assisted suicide, to more passive wishes to hasten death rather than continue to live with dementia. Within reports of both anticipated suicidal and death ideation, subthemes emerged, including the concern about becoming a burden to others in more advanced stages of dementia, the devaluation of life or the self with dementia, and the desire for (and anticipated thwarting of) control and independence. Statements of anticipated suicidal and death ideation were contingent on a future dementia diagnosis and may reflect errors in affective forecasting. Nevertheless, given the prevalence of dementias and older adults' elevated rates of suicide, the intersection of these two public health issues warrants greater attention and further investigation.

TRANSLATION AND CULTURAL ADAPTATION OF THE PREFERENCES FOR EVERYDAY LIVING INVENTORY INTO KOREAN

Jenny Kwon,[1] and So Young Shin[2], *1. Miami University, Oxford, Ohio, United States, 2. Inje University, Busan, Pusan-jikhalsi, Republic of Korea*

Valid and reliable measures are necessary to provide person-centered care tailored to the individual. However, there are no such measures in Korean nursing home settings. Therefore, the purpose of this study was to translate and culturally adapt the Preferences for Everyday Living Inventory (PELI); test face validity; and finalize a Korean version of PELI (PELI-K). The translation and cultural adaptation were done according to guidelines of the International Society for Pharmacoeconomics and Outcomes. After translating, cognitively capable Korean older adults (n=10) reviewed the PELI items and completed a questionnaire. Face validity was assessed by three questions regarding grammar and wording, understandability, and cultural relevance using a 4-point Likert scale: 1 (strongly disagree) to 4 (strongly agree). Higher scores indicate better validity. The mean (±SD) age of participants was 67 (±2.50) years. The mean score of appropriateness for grammar and wording was 2.70 (±.82); understandability was 3.70 (±.48); and cultural relevance was 3.70 (±.67). Participants found the Korean version of PELI easy to understand and interpret, and culturally relevant. However, some translations have room for improvement in rephrasing sentences and using alternative wording. Based on cognitive debriefing results and several suggestions from participants, necessary changes were made before creating a final version of PELI-K. These findings suggest that PELI was successfully translated and culturally adapted to Korean. Implementing PELI-K in Korean nursing home settings will help with eliciting individual preferences and incorporating them into care delivery. Next steps can evaluate care quality improvement and increased residents' satisfaction.

THE EFFECTS OF A HAND-BASED HOME-TRAINING PROGRAM ON FINE FORCE PERCEPTION IN OLDER ADULTS

Rachel Logue Cook, Kathy Kern, and Susan Brown,
University of Michigan, Ann Arbor, Michigan, United States

The ability to use and manipulate the hands is essential for completing daily activities such as dressing, food preparation, and medication adherence, but declines with age. Assessments of hand function typically include measures of maximum strength despite our recent findings that fine force control may be more indicative of function than strength. The purpose of this study was to determine the effectiveness of a hand-based intervention on improving various aspects of hand function in older adults. Eleven older adults (mean age: 77±6.8y, 7 females) completed a 6-week home-based training program consisting of a series of sensorimotor tasks. Hand assessments included tactile sensation, dexterity, maximum grip and pinch strength, and fine force control using a pinch force matching paradigm. In the fine force task, participants were given a reference force (25% MVC) and were instructed to match the force without visual feedback using either the same (ipsilateral) or opposite (contralateral) hand as the reference force. After the training program, older adults displayed a 35% reduction ($p < 0.01$) in matching error during the contralateral fine force control task. Additionally, both tactile sensation and dexterity showed improvements in the dominant hand ($p < 0.05$). No differences were observed in maximum pinch or grip strength. We observed improvements in fine force control, tactile sensibility, and dexterity, all of which contribute to hand function needed for daily activities, as a result of the home-based intervention. These results underscore the importance of measuring different aspects of hand function and the need for additional hand-based interventions in the aging population.

BRINGING THE HAND TO THE HEAD: AGE-RELATED CHANGES IN MOVEMENT STRATEGY

Andrew Droste,[1] Stephen Cain,[2] Tanner Trenary,[3]
Rachel Logue Cook,[3] Alanson Sample,[3] David Burke,[4]
Paula Anne Newman-Casey,[1] and Susan Brown[3], *1. University of Michigan Medicine - Kellogg Eye Center, Ann Arbor, Michigan, United States, 2. West Virginia University, Morgantown, West Virginia, United States, 3. University of Michigan, Ann Arbor, Michigan, United States, 4. University of Michigan Medical School, Ann Arbor, Michigan, United States*

Functional independence in older adults relies heavily on the ability to perform daily activities requiring motion of the upper extremity that brings the hand to the head. Such tasks include hygiene activities, eating and drinking, adjusting hearing aids, or putting in eye drops – all of which can be challenging for the older individual. Despite the importance of these activities of daily living, little is known regarding age-related changes in control strategies that may contribute to performance impairments. Twelve older (mean age: 75±5.5y) and 12 young (mean age: 23±1.6y) participants performed arm movements that stopped in front of the ipsilateral eye. Movements were made under proprioceptive guidance by occluding visual feedback via blindfold. Participants first made a reference movement to determine final hand position and then reproduced the memory-based movement. The task was performed by each arm from a seated position. Inertial sensors attached to each wrist captured movement data, which were used to calculate movement characteristics (velocities, timing, smoothness). As expected, proprioceptively guided movements made by the young group were highly irregular, particularly during the deceleration phase, indicating intermittent proprioceptive monitoring of arm position in the absence of vision. In contrast, a clear difference in movement strategy was seen in older adults where movements were faster and smoother ($p < 0.05$), suggestive of impaired utilization of movement-related position feedback. Future studies will determine to what extent such age-related differences in control strategy contribute to functional difficulties with tasks requiring accurate placement of the hand to the head.

VARIATION IN STATE ENFORCEMENT REGULATIONS REGARDING FINANCIAL PENALTIES AGAINST ASSISTED LIVING FACILITIES

Jacy Weems,[1] and Kali Thomas[2], *1. Brown University School of Public Health, Providence, Rhode Island, United States, 2. Brown University, Providence, Rhode Island, United States*

Provider behavior is known to be driven by market forces, including costs. Financial penalties are the primary enforcement remedy available to state agencies in deterring substandard practices in assisted living (AL) communities. States develop licensing and enforcement requirements for AL communities, and regulations vary by license. Using state regulations and statutes sourced for AL license types from Nexis Uni, we used key phrases to extract information from all 50 states and D.C. to characterize how state agencies calculate and assess financial penalties for licensed AL community violations. Fines are assessed for each day of substandard behavior or as a one-time amount; within the nursing home sector, per-day fines tend to be higher than per-instance fines as they accumulate. We found that of the states analyzed so far (n=25), ten states (40%) may impose either per-day or per-instance fines, nine (36%) can impose per-instance fines only, three (12%) may impose per-day fines only, and three (12%) incorporated facility size in assessing fine amounts. One state had no policies concerning AL fine enforcement. The median per-instance maximum fine amount is $2,000 [IQR $500-$5,000], while the median maximum per-day fine is $500 per day [IQR $150-$2,000]. Eleven states (44%) utilize tiered amount categories based on violation scope and severity. Agencies also consider characteristics such as community size and past performance when assessing fine amounts. Inconsistent penalties across states illuminate the need to assess the impact of current regulations, identify best enforcement practices to improve overall compliance, and share best practices between enforcement agencies.

LONELINESS AND PSYCHOLOGICAL DISTRESS AMONG AFRICAN AMERICAN ASSISTED LIVING RESIDENTS APPROACHING END OF LIFE

Christopher Arthur,[1] Alexis Bender,[2] and Molly Perkins[3], *1. University of Washington, Seattle, Washington, United States, 2. Emory University, Atlanta, Georgia, United States,* *3. Emory University School of Medicine, Atlanta, Georgia, United States*

Social isolation and loneliness are common at end of life and important contributors to psychological distress, particularly among older adults. Despite evidence that isolation and loneliness are generally prevalent in assisted living (AL), little research has examined these states within the context of end of life (EOL). This study uses secondary data from an EOL study in assisted living to qualitatively characterize the experience of isolation and loneliness in African American AL residents with varying levels of psychological distress. We performed a thematic analysis using ethnographic and interview data collected from 25 residents (64% female) in a large (90+ bed) all-African American AL community in metropolitan Atlanta. We assessed psychological distress using the PHQ-4 and used this measure in qualitative analysis to explore varying patterns of social isolation and loneliness across residents. Findings showed high variability in psychological distress based on PHQ-4 scores (range 0–12, mean = 3.5, SD = 3.75). Across themes of social isolation and loneliness, we compared experiences of residents with low and high psychological distress. The maintenance of agency in the face of isolation and loneliness was the predominant pattern among the low-distress group, while passive withdrawal was consistently identified among the high-distress group. We classified these themes in terms of individual interpersonal relationships characterized by self-isolation and negotiation of family connections, as well as AL community-level relationships characterized by the liminality of the lived AL experience. Results have important implications for multilevel interventions designed to reduce social isolation, loneliness, and psychological distress among this population.

ASSISTED LIVING ADMINISTRATORS' JOB SATISFACTION, WORK STRESSORS, AND INTENT TO LEAVE DURING THE COVID-19 PANDEMIC

Mary McSweeney-Feld,[1] Teta Barry,[2] Bo Yang,[1] and H. Wayne Nelson[1], *1. Towson University, Towson, Maryland, United States, 2. Arcadia University, Glenside, Pennsylvania, United States*

This study examines how job satisfaction in six sub-scales and selected stressors and demographic covariates influenced assisted living administrators' (ALF) intentions to quit during the COVID-19 pandemic. Quantitative and qualitative data were collected from 103 ALF administrators as part of a national study of long-term care administrators' intent to quit during the COVID-19 pandemic funded by the Foundation of the National Association of Long-Term Care Administrator Boards in Washington, DC. Descriptive statistics were collected for the sample, and correlations between variables were examined, as well as responses from 3 open-ended questions that were coded for analysis. Although generally satisfied, roughly 41 percent of ALF administrators reported that they were intending to quit. Qualitative data suggested that job satisfaction was influenced by a more nuanced interpretation of job characteristics and work environment intrinsic factors such as adequacy of staffing and resources, changing regulations during the COVID-19 pandemic, and external supports such as family and friends. Given the limited research on the impact of the COVID-19 pandemic on assisted living communities and their administrators, the results of this study can help to inform policies and strategies for providing support for this segment of long-term services and its workforce during widespread disasters.

FRAMEWORKS OF THE RELATIONSHIP BETWEEN HIV AND AGING AMONG HIV CLINIC PROVIDERS: A QUALITATIVE STUDY

Madeline Villalba,[1] Rachel Schenkel,[2] Michael Yin,[3] Peter Gordon,[3] and Abigail Baim-Lance[1], *1. Icahn School of Medicine at Mount Sinai, New York, New York, United States, 2. Emory University School of Medicine, Atlanta, Georgia, United States, 3. Columbia University Medical Center, New York, New York, United States*

As a result of advancements in antiretroviral therapy (ART), people living with HIV (PLWH) are living longer: it is estimated that 70% of PLWH in the US will be over the age of 50 by 2030, raising questions of what it means to age with HIV and how to care for these individuals most effectively. To qualitatively explore how providers who care for older PLWH and other comorbidities conceptualize the relationship between HIV and aging, we conducted 11 semi-structured interviews with physicians, RN case managers, and administrators at two health systems' HIV clinics in New York City and the Hudson Valley between November 2019 and July 2020. We coded the interviews, developing a codebook through an iterative process, and thematically analyzed the data. Analysis revealed a range of interrelationships between HIV, aging, and comorbidities across pathophysiological and psychosocial dimensions. Providers commonly espoused that, for older PLWH, comorbidities are comparatively more difficult to manage than HIV and constitute the primary driver of pathophysiology and/or mortality. In contrast, providers viewed patients as regarding HIV as more deadly and engaging with HIV care more diligently, which providers related to patients' long-term experiences of living through the HIV/AIDS epidemic. Providers' comorbidity-centric framings of the clinical relationship between HIV, aging, and comorbidities mark a departure from HIV-dominant forms of thinking. Our findings have important implications for interdisciplinary care management and suggest how to support the development of asset-based approaches to encourage patient engagement with comorbidity care based on fidelity to HIV regimens.

EXAMINING THE IMPACT OF HEART DISEASE AND DIABETES ON THE MENTAL HEALTH OF OLDER MINORITY ADULTS

Sree Saroj Sainath Panchagnula, *Jackson State University, Jackson, Mississippi, United States*

As the world's population ages and healthcare costs associated with the care of the elderly rise, it is pertinent to address these concerns. This study examines how older adults' mental health is affected by chronic medical illnesses. It is hypothesized that minority older adults, on average, have worse mental and physical health outcomes than their majority counterparts. A secondary data analysis of the National Health and Aging Trends Study, revealed that older minority adults experience higher rates of depression than non-minority older adults, as measured by the Patient Health Questionnaire – 2 (PHQ-2). European-Americans significantly differ from African Americans (AA) and

Hispanics regarding their level of anxiety, as measured by the Generalized Anxiety Disorder – 2 (GAD-2) measure. AA and Hispanics are significantly more likely to exhibit anxiety than their European-American counterparts. Minority older adults with a higher rate of surgeries are not substantially more likely to be depressed, according to the PHQ-2. Minority older adults who reported having a difficult time falling asleep are considerably more depressed than older minority adults who did not endorse depressive symptomatology on the PHQ-2. Minority older adults who had two or more social supports in their lives have lower levels of anxiety compared to older minority adults who have less than two social supports in their lives. The findings from this study serves as groundwork to promote equity between majority and minority older adults, which will improve their abilities to perform independent activities of daily living successfully.

COMPARTMENTAL FEMUR CORTICAL THICKNESS IN OLDER ADULTS DIFFERS BY DEMOGRAPHICS AND PHYSICAL FUNCTION

Justin Lam,[1] Delanie Lynch,[2] Diana Madrid Fuentes,[2] Karan Devane,[3] Marjorie Howard,[2] Kristen Beavers,[3] and Ashley Weaver[2], *1. Carnegie Mellon University, Pittsburgh, Pennsylvania, United States, 2. Wake Forest School of Medicine, Winston Salem, North Carolina, United States, 3. Wake Forest University Health Sciences, Winston-Salem, North Carolina, United States, 6. Wake Forest University, Winston-Salem, North Carolina, United States*

Previous studies have examined the relationship between cortical bone properties and fracture risk in older populations, but they have yet to examine how these properties change within the femur. Most hip fractures are classified by their location: femoral neck, intertrochanteric, or subtrochanteric fractures. Since cortical thickness can vary throughout the femur, a quantitative method of examining thickness by region was developed using a cortical mapping approach applied to computed tomography (CT) scans. Subject-specific finite element (FE) models of proximal femurs were created from baseline CT scans of 107 older adults (ages 60 – 85; 70% White; 72% Female) with obesity as classified by BMI (33.8 ± 4 kg/m2). An existing FE model was morphed to the segmented geometry of each subject's proximal femur. A nearest neighbor search assigned cortical thickness values to the nearest finite element model node. Cortical thickness was grouped into four femoral compartments: femoral head, femoral neck, intertrochanteric and subtrochanteric regions. Pairwise paired t-tests indicated that cortical thickness differed between femoral compartments ($p < 0.05$). Multivariate regression models showed greater cortical thicknesses in femoral head, neck, and intertrochanteric regions in African Americans compared to Whites ($p < 0.05$). Additionally, these models suggest an association between cortical thickness and physical function assessments, such as the timed up-and-go test and leg muscle strength test. Since cortical thickness is not constant throughout the femur, future studies can use the framework developed here to assess each compartment individually and investigate the relationships between cortical thickness, demographics, and functional assessments.

ACCELERATED BRAIN AGING IS ASSOCIATED WITH MORTALITY ACROSS RACE

Ramon Casanova,[1] Andrea Anderson,[1] Ryan Barnard,[1] Keenan Walker,[2] Timothy Hughes,[1] Stephen Kritchevsky,[1] and Lynne Wagenknecht[1], *1. Wake Forest School of Medicine, Winston-Salem, North Carolina, United States, 2. National Institute of Health, Baltimore, Maryland, United States*

There is an increasing interest in using machine learning and artificial intelligence to estimate chronological age using neuroimaging data. The gap between chronological age and estimated brain age (brain age gap, BAG) is used as a measure of accelerated/resilient brain aging. Accelerated brain aging has been associated with increased mortality risk. However, these reports are based on cohorts mostly composed by white individuals. Here we capitalized on the racially diverse nature of the Atherosclerosis Risk in Communities Study (ARIC) cohort to investigate associations of brain across race. We used brain MRI scans from 1172 cognitively normal ARIC participants that were collected at ARIC Visit 5. Of those 772 were White and 366 were African Americans. We used Cox regression models to investigate BAG values associations with mortality. There were 163 deaths (dw = 124 and daa = 39) over 8 years of follow-up. Participants were stratified by tertiles according to BAG values. We found that, compared to those individuals with BAG scores in the highest tertile (>=1.15), those who scored in the lowest tertile (<= -1.3 years) to be associated with significantly lower mortality among the White (HR=0.41, 95% CI, [0.26–0.66], $p < 0.001$) and Black (HR=0.43, 95% CI, [0.20–0.92], $p = 0.03$) participants after adjusting for age, race-center, sex, education, diabetes, smoking and hypertension. Our analyses show that our approach to estimate chronological age using high-dimensional elastic net regression, produces BAG values which are associated with mortality not only in White individuals but also in African Americans.

WHITE MATTER CHANGE NEAR CEREBRAL MICROBLEEDS AFTER MTBI INVOLVES AGE AND SEX DEPENDENT COGNITIVE DECLINE

ANDREI IRIMIA,[1] Van Ngo,[1] Nikhil Chaudhari,[1] Fan Zhang,[2] Shantanu Joshi,[3] Lauren O'Donnell,[2] Nasim Sheikh-Bahaei,[1] and Helena Chui[1], *1. University of Southern California, Los Angeles, California, United States, 2. Harvard Medical School, Boston, Massachusetts, United States, 3. University of California, Los Angeles, Los Angeles, California, United States*

We tested the null hypothesis that, after mild traumatic brain injury (mTBI), white matter changes near cerebral microbleeds (CMBs) are associated with cognitive decline. Magnetic resonance images were acquired from 62 adults with mTBI and from 203 matched healthy controls. A week post-injury, mTBI participants had 2.7±2.6 traumatic CMBs in WM, located 6.1±4.4 mm from the cortical mantle. About 6 months later, 97% of CMBs were associated with significant reductions (34%±11%, $q < 0.05$) in the fractional anisotropy (FA) of WM streamlines within ~1 cm of CMBs. Male sex and older age were significant risk factors for larger reductions ($q < 0.05$). CMBs in the corpus callosum, cingulum bundle, inferior and middle longitudinal fasciculi were associated with FA changes that were significantly and positively associated with changes in cognitive functions mediated by these structures (q < 0.05). These findings distinguish non-traumatic from traumatic CMBs according to CMB-related changes in surrounding WM. Our findings also challenge the assumption that traumatic CMBs are cognitively silent and identify older age and male sex as risk factors for mTBI-related cognitive decline in the presence of CMBs. In conclusion, mTBI with CMB findings on MRI can be described as a clinical endophenotype that warrants longitudinal mapping and quantification of cognitive function.

RACIAL AND ETHNIC DIFFERENCES IN LUNG CANCER SCREENING ELIGIBILITY AND HEALTH CARE UTILIZATION AMONG OLDER SMOKERS

Jaqueline Avila,[1] Ugoji Nwanaji-Enwerem,[2]
Randi Williams,[3] Hilary Robbins,[4] and Jasjit Ahluwalia[1],
1. Brown University School of Public Health, Providence, Rhode Island, United States, 2. Warren Alpert School of Medicine, Brown University, Providence, Rhode Island, United States, 3. Lombardi Comprehensive Cancer Center, Georgetown University Medical Center, Washington, District of Columbia, United States, 4. International Agency for Research on Cancer, Lyon, Rhone-Alpes, France

The United States Preventive Task Force (USPSTF) expanded the lung cancer screening guidelines with low-dose CT scan (LDCT) to narrow racial and ethnic screening disparities. However, there is a need to examine if eligible individuals can access and use health care. The objective was to examine racial and ethnic differences in LDCT eligibility and health services access and utilization among LDCT-eligible individuals. Data comes from adults 50 to 80 years old in the 2018 Health and Retirement Study (HRS), with at least a 20 pack-year smoking history who currently smoke, or have quit < 15 years ago (n=7,624). The outcomes were LDCT eligibility, access to health care (health insurance and usual place of care), and health care use (visits to the doctor). White individuals were more likely to be LDCT eligible than Black and Hispanic individuals. Among those LDCT eligible, Hispanic individuals were less likely to have insurance (OR:0.43, [95%CI: 0.21; 0.86]) and to visit the doctor than White individuals (OR: 0.38 [0.19; 0.76]). Compared to White individuals, Black individuals were more likely to say their usual place of care was the ER or "other" place (OR: 2.65 [1.63; 3.32] and Hispanic individuals were more likely to say they do not have a usual place of care (OR: 1.94 [1.10; 3.41]). Expanding the criteria for lung cancer screening may not be enough to reduce racial and ethnic disparities. More efforts should address racial and ethnic disparities in the implementation of lung cancer screening, including access and use of health care.

PANCREATIC CANCER PROLIFERATION IS INDUCED BY GLI2-COL1 SIGNALING IN FIBROBLASTS IN THE TUMOR MICROENVIRONMENT

Madeline Ross,[1] Renzo Vera,[2] Maite Fernandez-Barrena,[2]
Murat Toruner,[2] Ezequiel Tolosa,[2] Luciana Almada,[2]
Rolf Brekken,[3] and Martin Fernandez-Zapico[2], *1. St. Catherine University, St. Paul, Minnesota, United States, 2. Mayo Clinic Schulze Center for Novel Therapeutics, Rochester, Minnesota, United States, 3. UT Southwestern, Dallas, Texas, United States*

Pancreatic ductal adenocarcinoma (PDAC) affects many older adults in the United States. This aggressive type of pancreatic cancer is resistant to many chemotherapies, resulting in a poor prognosis and a five-year survival rate of less than ten percent. To study PDAC progression and develop novel therapies, it is important to better understand the tumor microenvironment (TME) and the contributing cell populations and molecular mechanisms. Despite the well-described role of soluble Type I collagen in the regulation of pancreatic cancer TME, the molecular events modulating its expression/activity remain elusive. Here, we describe a novel mechanism controlling the levels of soluble collagen in cancer associated fibroblasts (CAFs), a major producer of Type I collagen in pancreatic cancer TME. Specifically, we provide evidence that the transcription factor GLI2 is required for the expression of COL1A1, a key component of the Type I collagen fiber, stimulated by the transforming growth factor β (TGFβ). Our methodology included expression studies from patient samples, ChIP-qPCR, qPCR, RNA-seq analysis, gene set enrichment analysis, biological assays, and gene ontology analysis. Our results confirm that the TGFβ-GLI2 axis in CAFs is able to activate EGR1-proliferative signaling downstream of collagen signaling in pancreatic cancer cells contributing to our understanding of the molecular underpinnings of pancreatic cancer TME. Further studies that define the complete role of EGR1 in PDAC may lead to the development of novel therapies targeting EGR1 or CAFs to promote enhanced quality of life following a PDAC diagnosis.

OLDER CANCER SURVIVORS' POST-TRAUMATIC GROWTH DURING THE COVID-19 PANDEMIC

Kaleigh Ligus, Emily Fritzson, Caroline Salafia,
Crystal Park, and Keith Bellizzi, *University of Connecticut, Storrs, Connecticut, United States*

Older adults and immune-compromised individuals (e.g., cancer survivors) were quickly identified as high-risk groups during the COVID-19 pandemic. Research has examined adverse psychological consequences due to the pandemic in older adults with chronic conditions. However, no research has examined the potential for positive consequences of COVID-19 in older adults with cancer. The current study examined the association between COVID-19 risk, stress, exposure, and perceived post-traumatic growth (PPTG) in adults with cancer. Cancer survivors (n = 231) enrolled in an ongoing longitudinal study completed a one-time COVID-19 experience assessment, including PPTG as a result of the COVID pandemic. Participants (mean age = 68 years) had completed primary treatment for breast, prostate, or colorectal cancer within the past two years. On average, survivors reported modest PPTG related to COVID-19 (mean = 6.03, range = 0–20). Using linear regression, we found that gender, cancer type, and marital status were related to PPTG. Higher COVID-19 risk, more COVID-19 stressors, and higher illness exposure (e.g., having had COVID-19) were significantly positively associated with PPTG scores (ps < .05). In spite of the potential adverse psychological consequences of the COVID-19 pandemic, these results suggest adults with cancer, in our sample, report modest PPTG. Higher COVID-19-related perceived risk, stress, and exposure predicted higher PPTG scores. These findings are interesting in light of studies that suggest PPTG occurs only after time passes from the stressor. Future research could examine how coping with cancer may influence coping with a co-existing or subsequent stressor and its relationship to PPTG.

CORRELATES OF CANNABIS USE AMONG MIDDLE-AGED AND OLDER ADULTS: FINDINGS FROM NESARC-III

Kevin Yang,[1] Jaclyn Bergstrom,[1] and Alison Moore[2], *1. UC San Diego School of Medicine, San Diego, California, United States, 2. University of California, San Diego, La Jolla, California, United States*

Cannabis use is increasing faster among both middle-aged and older adults compared to younger adults, but its demographic and physical health correlates comparing middle-aged and older adults need further exploration. We examined data from a US representative sample of middle-aged (50–64 years, Nf8,932) and older (65+ years, Nf5,806) adults from the 2012–2013 National Epidemiologic Survey on Alcohol and Related Conditions (NESARC-IIII). We conducted logistic regression analyses to test associations of cannabis use with demographic and past-year physical health correlates and examined differences between the two age groups. An estimated 5.6% of middle-aged and 1.3% of older adults used cannabis in the past year. Compared to middle-aged adults, older adults had higher rates of cannabis use for medical purposes (15.8% vs. 12.3%, p=0.033). Both age groups had increased odds for being male (Odds Ratio (OR)=2.32 and 2.63, for middle-aged and older adults, respectively) and residing in the West (OR=1.82 and 3.04, respectively). Middle-aged cannabis users were at decreased odds for having at least some college education (OR=0.63), income >$70,000 (OR=0.37), being married (OR=0.32), and reporting excellent/very good general health (OR=0.65). Middle-aged cannabis users were at increased odds for reporting digestive disease (OR=1.96), musculoskeletal pain (OR=1.34), and nerve pain (OR=1.77), while older cannabis users were only at increased odds for reporting digestive disease (OR=2.91). Findings indicate differences in cannabis use correlates between middle-aged and older adults. With increasing legalization of cannabis nationally, improved understanding of these correlates among more recent cohorts will assist in monitoring cannabis use among the older adult population.

CANNABIS USE PERCEPTIONS, PATTERNS AND SYMPTOM MANAGEMENT IN OLDER VS. MIDDLE AGE AFTER A CANCER DIAGNOSIS

Margaret Fahey, and Erin McClure, *Medical University of South Carolina, Charleston, South Carolina, United States*

Prevalence of cannabis among U.S. older adults (> 65 years) is increasing and is also common among cancer patients of all ages. Less is known how cannabis beliefs and use differ in older vs. middle-age after cancer diagnosis. This NCI-funded P30 administrative supplement included a cross-sectional survey in a state with illegal access to cannabis. Participants (Nf1,038) had past cancer diagnosis (< 2 years). Comparisons were run between older (> 65 years; n=509) and middle-aged adults (45–64; n=378) relating to cannabis perceptions, patterns of use, and symptom management (among those endorsing use) with chi-square and t-test analyses. There were no age-group differences in prevalence of ever or current use, nor likelihood of discussing cannabis with provider. Use after diagnosis was less likely in older vs. middle-age (21% vs. 33%). Of those using after diagnosis, there were no age-group differences in reasons for use, but older adults reported less neuropathy relief and less digestive improvement from cannabis. When asked about potential benefits of cannabis, older adults were less likely to expect relief from neuropathy and nausea, increased appetite, decreased medication use, cancer cure, and treatment of another condition and more likely to expect improved sleep. When endorsing potential risks, older adults were more likely to report addiction and increased use of other substances and less likely to report legal reasons, job loss, and negative reactions. Findings indicate unique expectations and symptom management in older age, highlighting importance of oncology providers to discuss cannabis with this age group as rates rise.

MEASURING SPECIALTY CARE UTILIZATION AMONG MEDICALLY FRAGILE, LOW-INCOME OLDER OR DISABLED ADULTS

Kelly Goo, Mina Silberberg, Howard Eisenson, Fred Johnson, and Sandra Stinnett, *Duke University Medical Center, Durham, North Carolina, United States*

The purpose of this research was to quantify the rates of specialty care referral completion and identify variables associated with successful completion among a population of low-income, elderly and/or disabled homebound patients with barriers to accessing office-based care. This was a cross-sectional study using descriptive and multivariate predictive analysis of specialty care referral completion, operationalized as attending an appointment of the same specialty care type within 6 months of being referred. Independent variables include patient age, sex, race, marital status, health insurance, blood pressure, and body mass index. Patient characteristics, referral information, and appointment information from July 1, 2014 to July 1, 2019 were extracted from electronic health record data of patients enrolled in the Just for Us primary care home visiting program in Durham, NC. Specialty care referrals were restricted to those for office-based consultations for chronic disease co-management originating from an outpatient primary care provider. Of 443 total referrals identified from 162 patients, 36% were successfully completed. Being married and female gender were found to be associated with successful referral completion. Of the 217 total patients in the study sample, 25% were identified as not having any referrals. No included patient characteristics were found to be significantly associated with being referred to specialty care. This study demonstrates that the specialty care needs of a medically and socially vulnerable population of homebound patients are not being adequately met.

LESSONS FROM THE IMPLEMENTATION OF THE TRANSITIONAL CARE MODEL DURING THE COVID-19 PANDEMIC

Molly McHugh,[1] Karen Hirschman,[1] Brianna Morgan,[1] Monica Ahrens,[2] Alexandra Hanlon,[2] Onome Osokpo,[1] and Mary Naylor[1], *1. University of Pennsylvania, Philadelphia,* *Pennsylvania, United States, 2. Virginia Polytechnic Institute and State University, Roanoke, Virginia, United States*

Multiple randomized controlled trials (RCTs) evaluating the Transitional Care Model (TCM)- an advanced practice registered nurse-led (APRN), team-based, care management strategy- have shown improved outcomes for older adults transitioning from hospital to home. In the current RCT, enrollment of older adults hospitalized with heart failure, chronic obstructive pulmonary disease, or pneumonia began in February 2020, just as the COVID-19 pandemic developed across the U.S. The COVID-19 pandemic dramatically impacted healthcare delivery across diverse local contexts. This parallel convergent mixed methods study aimed to explore the implementation of the TCM intervention as intended during Year 2 of the RCT (February 2021 to January 2022). This mixed-methods analysis presents the challenges and strategies to a key TCM component, "hospital-to-home," which focuses on delivering in-person visits to patients, as identified through a qualitative descriptive analysis of 63 clinical team and leadership meetings combined with implementation fidelity data collected simultaneously on 188 TCM participants. In Year 2 of the trial, COVID-19-specific challenges continued, including COVID-19 exposure, policy changes, patients declining services, and limited safety equipment. Some challenges to the hospital-to-home TCM component occurred regardless of COVID-19, including patient (e.g., lack of engagement), nurse provider (e.g., TCM learning curve), and system (e.g., reduced primary care access) barriers. Collectively, these challenges resulted in lower fidelity to APRNs visit patterns during TCM delivery. Strategies to address these challenges were identified. The findings provide critical insight into how to target quality improvement strategies to improve the delivery of services, such as the TCM, from hospital to home settings.

THE EFFECTS OF TBI SEVERITY AND PTSD ON SUBJECTIVE COGNITIVE DECLINE IN OLDER VETERANS

Alin Alshaheri,[1] Monica Ly,[2] Kelsey Thomas,[2] and
Lisa Delano-Wood[2], *1. San Diego State University, San Diego, California, United States, 2. VA San Diego Healthcare System, San Diego, California, United States*

Both post-traumatic stress disorder (PTSD) and traumatic brain injury (TBI) have been linked to subjective cognitive complaints; however, less is known about the unique relationships of PTSD symptoms and TBI severity with domain-specific subjective cognitive declines in older Veterans. The current study included 215 Vietnam-Era Veterans from the Department of Defense-Alzheimer's Disease Neuroimaging Initiative (age M=69.62 years, SD=4.30). General linear models, adjusting for age, education, apolipoprotein E ε4 status, self-reported health, MMSE score, and depressive symptoms, examined the unique effects of PTSD symptoms (measured using the Clinician-Administered PTSD Scale) and TBI severity (none, mild, moderate/severe) on subjective cognitive decline measured using the Everyday Cognition (ECog) measure. Greater current PTSD symptoms were associated with greater subjective cognitive declines on the ECog total score (t=.198, p=.009) as well as memory (t=.197, p=.008), language (t=.228, p=.004), and visuospatial (t=.216, p=.007) subscales. Compared with participants with no TBI, mild TBI was associated with greater subjective cognitive decline on the ECog total score (t=.329, p=.026) as well as the language (t=.334, p=.030) and divided attention (t=.411, p=.007) subscales, while moderate-to-severe TBI was associated with greater subjective declines in planning (t=.291, p=.049) and divided attention (t=.320, p=.032). There was no interaction between PTSD and TBI severity on ECog scores. Results suggest that PTSD symptoms and mild versus moderate/severe TBI differentially impact specific domains of subjective cognitive decline. Future work should investigate how repetitive TBI may modify these relationships, and whether PTSD and TBI severity are associated with objective cognition and quality of life in older Veterans.

SOCIAL DETERMINANTS OF ORAL HEALTH AMONG OLDER ADULTS: RURALITY MATTERS

Aimee Ballard,[1] Maya Wetherbee,[1] Laura Bernstein,[2] and
Julie Hicks Patrick[2], *1. WVU, Morgantown, West Virginia, United States, 2. West Virginia University, Morgantown, West Virginia, United States*

Oral health is often viewed as a predictor of emotional well-being. Older age and any tobacco use are among the strongest predictors of poor oral health. We sought to examine the roles of age, tobacco use, and dental health in relation to emotional well-being. Moreover, we identified unique predictors of oral health. Data were provided by 197,786 adults completing the 2020 BRFSS (mean age = 54.3 yrs; 46% men; 80% white; 15% rural; 41% had ever regularly used tobacco). Although 53.6% reported no loss of natural teeth, 29.5% reported losing between 1 and 5 teeth and 17% reported having lost 6 or more natural teeth. Hierarchical linear regression analyses revealed that younger adults, smokers, urban-dwellers, and those with more tooth loss experienced more poor mental health days, F (4, 359016) = 4307.6, p < .001, R^2= .05. Tooth loss uniquely contributed to the variance explained, above and beyond the other predictors (Step 2: F (1, 359016) = 3722.01, p, .001). We also conducted a multinomial logistic regression to test whether age, tobacco use, and rurality could differentiate among levels of tooth loss. These equations were significant, with odds ratios showing that rurality was the strongest predictor of tooth loss. Our results suggest that rurality is a strong predictor of oral health, even beyond the influence of age and tobacco use. Future interventions used to improve the oral health of people, including older adults, must consider the greater needs present to rural-dwelling Americans

WOMEN'S HEALTH: PARADOXICAL HEALTH DISPARITIES AMONG ASIAN AMERICAN WOMEN

Janella Camp, Laura Bernstein, and Julie Hicks Patrick,
West Virginia University, Morgantown, West Virginia, United States

Asian Americans are among the fastest growing ethnic minority groups in the U.S (Budiman & Ruiz, 2017), but women's healthcare is understudied. This may allow potential health disparities to go unnoticed. Our study aims to determine whether Asian American women are utilizing preventative health care services and to examine relations with self-reported health. We used data from a national sample AQ1 of American women (Nf 58,934; mean age = 47.3 years; range 18 to 80+) from the 2020 Behavioral Risk Factor

Surveillance System (BRFSS) data of the Centers for Disease Control and Prevention (CDC). We examined the recency of receiving a PAP smear, a mammogram, and the HPV test, along with subjective assessments of health. Asian American women reported less recent PAP smears, mammograms, and HPV tests, relative to their counterparts. However, Asian American women reported better general and physical health than non-Asian American women. To examine whether Asian American status contributed to health reports above and beyond that accounted for by the preventative tests and age, we conducted a 3-step hierarchical regression. Even after controls, Asian American status accounted for unique variance in health outcomes [F (1, 58,928) = 36.51, p < .001]. Post hoc exploratory analyses further examine the role of race in women's preventative health care. Our findings indicate that Asian American women report less use of medical services, but better general and physical health. These results suggest that further studies are needed to explore other health behaviors that may account for better health reports among Asian American women.

HEALTH DISPARITIES RELATED TO COST OF MEDICAL COVERAGE

Nathaniel Palmer, Laura Bernstein, and Julie Hicks Patrick, *West Virginia University, Morgantown, West Virginia, United States*

Older age is often associated with challenges to functional ability. There are many government and private programs in place to help support the functioning of adults, including Medicaid, Medicare, and Tricare. These programs are not always effective, especially for middle aged and older adults. We examined whether cost was a barrier to receiving care and whether health insurance status acted as moderators of the relationship between age and functional ability. We used data from 379,606 adults who completed the 2020 Behavior Risk Factor Surveillance System (median age = 54.4 years; 54.2% women; 75.3% white non hispanic). The moderated regression equation was significant, F (7, 379598) 3275.74, p < .001, R^2 = .057. Although direct effects of age emerged as significant, the relation on functional ability was qualified by two 2-way interactions: age by insurance (b = .003) and age by prohibitive cost (b = .008). No other effects emerged as significant. Examination of the means revealed that lack of insurance was especially challenging to the functional ability of middle aged adults, whereas cost prohibitiveness was especially challenging for the functioning of older adults. Our results highlight the critical need to research the efficacy of health insurance policies amongst the middle aged and older populations in the United States

LIVING IN HISTORICALLY REDLINED NEIGHBORHOODS AND ACCELERATED BIOLOGICAL AGING AMONG OLDER ADULTS

Jennifer Ailshire,[1] Calley Fisk,[2] and Chelsey Jones[3], *1. University of Southern California, Los Angeles, California, United States, 2. University of Southern California, Columbia, California, United States, 3. Howard University, Washington, District of Columbia, United States*

Various neighborhood factors, including greenspace availability and neighborhood socioeconomic disadvantage, are associated with accelerated biological age (aging faster than expected based on chronological age) among older adults. Neighborhoods, however, evolve overtime and historical neighborhood conditions may be influential in the aging process of older residents. In the United States, many neighborhoods were impacted by historical redlining (a federally sponsored, discriminatory program targeting communities of color throughout the 1930s), wherein neighborhoods received grades based on demographics and quality of infrastructure. Overwhelmingly, neighborhoods with more residents of color were considered less desirable or "redlined" and prior research links living in historically redlined neighborhoods to poor health across the life course and worse neighborhood conditions. We link data on redlining of U.S. census tracts from the National Community Reinvestment Coalition (NCRC) to the 2016 Health and Retirement Study Venous Blood Study (HRS-VBS) to assess whether living in historically redlined neighborhoods is associated with advanced biological aging among adults aged 55 and older. Our indicator of expanded biological age is a summary measure of 22 biomarkers associated with cardiovascular, immune, and metabolic functioning. Using multivariate linear regression models controlling for an individual's age, sex, and race/ethnicity, we found that individuals living in neighborhoods historically designated as "declining" or "hazardous" were about 2 years older biologically than individuals living in neighborhoods designated as "best/desirable". These findings suggest that residing in neighborhoods differentially shaped by historical forces impacts rates of accelerated aging. Identifying these historical neighborhood conditions may help target interventions addressing disparities in aging.

INVESTIGATING THE ROLE OF STRESS PATHWAY ACTIVATION IN MEIOTIC DIFFERENTIATION AND REJUVENATION IN BUDDING YEAST

Akosua Biritwum,[1] and Alena Bishop[2], *1. Howard University, Bellevue, Washington, United States, 2. University of California, Berkeley, Berkeley, California, United States*

Sexually reproducing organisms undergo meiosis to produce gametes for the next generation. In budding yeast, meiosis resets replicative lifespan as gametes produced by aged progenitors are born young and devoid of any senescence-associated factors. In addition, certain transcription factors that are involved in stress response are expressed when yeast cells undergo meiosis. The overarching goal of this project is to determine the role of stress transcription factors in meiotic rejuvenation. As part of this goal, I set out to develop an assay to measure the fitness of yeast gametes that were depleted of a given stress response transcription factor. I focused on Yap1 and Skn7, two transcription factors involved in oxidative stress, and characterized gamete fitness by measuring survival in response to environmental stressors, including acid and alkaline. I found that gametes depleted for Yap1 have mild sensitivity to acid and dramatic sensitivity to alkaline. These findings implicate a role of Yap1 in gamete fitness in a physiologically relevant context since acidic and alkaline environments exist in the digestive tract of fruit flies, which are natural predators of yeast. Further investigation of how stress response transcription factors affect meiotic rejuvenation can help us develop strategies to counteract cellular aging in different contexts.

INVESTIGATING THE NEURAL AFFECTS OF 17 ALPHA-ESTRADIOL (17A-E2) ON APOE4 PHENOTYPES

Tavia Roache,[1] Christian Pike,[2] and Cassandra McGill[3], *1. Howard University, Washington, District of Columbia, United States, 2. USC, Los Angeles, California, United States, 3. University of Southern California, Los Angeles, California, United States*

Aging and APOE4 genotype are the primary risk factors for late onset Alzheimer's disease (AD). Previous drugs trials for AD have focused on amyloid beta which has yielded minimal effects; hence a drug targeting aging could prove more efficacious. 17 alpha-estradiol (17α-E2) is an enantiomer of 17 beta-estradiol that has been shown to extend lifespan in male mice. We hypothesize that 17α-E2 will improve aging related phenotypes caused by the APOE4 genotype. We enrolled 10-month-old APOE3 or APOE4 targeted replacement mice and randomized them to either control or 17α-E2 diet for 20 weeks. At weeks 15 to 17, mice underwent various behavior assays and tissues were collected at the end of the 20 weeks. We observed behavioral improvement in APOE4 mice treated with 17α-E2 and asked whether this effect is associated with: (1) change in activity or anxiety, (2) change in neural stem cells, or (3) change in microglial activation. Activity levels but not neurogenesis of microglial burden were affected by APOE genotype and 17α-E2 treatment, suggesting a potential contribution to observed memory improvement in APOE4 mice treated with 17α-E2. Continued research on the neural effects of 17α-E2 pose potential benefits to mitigate the effects of aging.

SESSION 9010 (POSTER)

LATE BREAKING POSTER SESSION II

USING VIRTUAL REALITY IN AGED CARE SETTINGS: A SCOPING REVIEW

Lillian Hung,[1] Flora To-Miles,[1] Winnie Kan,[1] Alisha Temirova,[1] Jim Mann,[2] and Christine Wallsworth[3], *1. University of British Columbia, Vancouver, British Columbia, Canada, 2. Community Engagement Advisory Network, Vancouver, British Columbia, Canada, 3 Vancouver, British Columbia, Canada*

Recent advancement of virtual reality (VR) technology has led to growing interest in using VR in aged-care settings. VR can help ameliorate experiences of loneliness and social isolation, which is especially important during the COVID-19 pandemic. As a result, increasingly more studies are being published on this topic, and a comprehensive review of studies examining the facilitators and barriers of adopting VR in these settings is needed. This scoping review reports the facilitators and barriers to implementing VR in care settings among older adults, as well as the impact on social engagement and/or loneliness. We followed the Joanna Briggs Institute scoping review methodology, and searched the following databases: CINHAL, Embase, Medline, PsycInfo, Scopus, and Web of Science. Inclusion criteria includes articles published in the last five years that focus on older adults using VR in aged-care settings. 199 articles were retrieved and 21 articles were included in our review. Most of the articles (38%) originated from Australia. Key facilitators for using VR in aged care settings are the technology being user-friendly, comfortable, and easy to clean. Barriers included: technology issues (e.g., internet connectivity), staff attitude/worries, and impact on residents, and structural considerations (e.g., lack of staff and time to assist with the VR program). VR technology can decrease loneliness and feelings of isolation, and provide opportunities to engage with others. Our review of the current evidence offers insights and recommendations for health care professionals to use VR technology in aged care settings, maximizing benefits and minimizing risks among users.

USING MDS TO MEASURE TRANSFER TRAUMA IN NURSING HOME RESIDENTS

Ana Montoya, Pil Park, Chiang-Hua Chang, and Julie Bynum, *University of Michigan, Ann Arbor, Michigan, United States*

Transferring long-term nursing home residents between facilities has been shown to compromise their quality of life. The negative consequences associated with transfers have been termed transfer trauma and its spectrum spans from functional, cognitive, and emotional decline to hospitalizations, and even death. The objective of this study was to develop a composite measure of transfer trauma after a nursing home-to-nursing home transfer using clinically relevant events and sub-measures covering functional, cognitive, behavioral, and emotional domains based on validated scales available in the Minimum Data Set (MDS) assessments. MDS Data were used to identify long-stay nursing home residents and obtain information on transfers, clinical assessments, and facilities. This study is a cross-sectional cohort analysis of long-stay nursing home residents in the state of Michigan who had a nursing home-to-nursing home transfer during our study period (March 1, 2018-October 31, 2018). We developed a measure of transfer trauma as a composite from 5 previously validated measures: 1) Activity of Daily Living (ADL) Self-Performance Scale; 2) Cognitive Function Scale (CFS); 3) Patient Health Questionnaire-9 (PHQ-9/PHQ-9-OV); 4) Agitated Reactive Behavior Scale (ARBS); 5) falls. The distribution and frequency of each sub-measure were analyzed to assess scaling of the composite measure. Of a total of 817 residents who transferred in our study period, 549 had complete composite measures, and from those 242 (44%) met criteria for transfer trauma. These findings demonstrate the need for further research to identify underlying transfer trauma and develop interventions to ameliorate the negative effects of transfers on this vulnerable population.

TRANSITION OF HEALTH PROFILES IN COGNITIVELY INTACT NURSING HOME RESIDENTS WITH SUICIDAL IDEATION

Yiyang Yuan,[1] Adrita Barooah,[2] Deborah Mack,[1] Kate Lapane,[1] Anthony Rothschild,[3] and Christine Ulbricht[4], *1. University of Massachusetts Chan Medical School, Worcester, Massachusetts, United States, 2. University of Massachusetts Boston, Boston, Massachusetts, United States, 3. UMass Chan Medical School, Worcester, Massachusetts, United States, 4. Takeda, Cambridge, Massachusetts, United States*

For older adults entering nursing homes with self-reported suicidal ideation (SI), little is known about how their health profiles change during the first 90 days post admission. Using the 9th Patient Health Questionnaire-9 item on Minimum Data Set 3.0, we identified 5,397 cognitively intact, older adults with SI at admission, 29% of whom continued to report SI at 90 days. Latent transition analysis identified five health profiles at admission: (1) frail, severe pain, all depressive symptoms (prevalence: 25%); (2) frail, moderate pain, depressed mood, insomnia/hypersomnia, fatigue (27%); (3) frail, no pain, depressed mood, fatigue, and worthlessness (18%); (4) pre-frail, no pain, depressed mood (15%); (5) robust, no pain, depressed mood, insomnia/hypersomnia, fatigue (15%). At 90 days, while the profiles remained mostly the same, improvement in depressive symptoms and pain were observed: (1) frail, severe pain, most depressive symptoms (17%); (2) frail, no pain, depressed mood, and fatigue (28%); (3) frail, no pain, depressed mood, fatigue, and worthlessness (15%); (4) pre-frail, no pain, no depressive symptoms (25%); (5) robust, no pain, depressed mood, and fatigue (16%). Most residents remained in the same profile over time. Of those who were in Profile (1) at admission, 20% transitioned into Profile (2), 12% to Profile (4), and 7% to Profile (5). This work highlights the need to now investigate the potential drivers for specific profile transitions among nursing home residents presenting with SI on admission, thereby informing interventions for improved identification and treatment of SI in the nursing home setting.

TRANSFER TRAUMA AND MAJOR EVENTS AMONG NURSING HOME RESIDENTS BEFORE AND DURING THE COVID-19 PANDEMIC

Ana Montoya, Pil Park, Chiang-Hua Chang, and
Julie Bynum, *University of Michigan, Ann Arbor, Michigan, United States*

The negative consequences of transfers are known as transfer trauma. Nursing home (NH)-to-NH transfers place long-term NH residents at risk for developing transfer trauma and this risk may have increased during the COVID-19 pandemic in the setting of a state policy that increased the number of residents who transferred between NHs. The objective of this cross-sectional cohort analysis was to assess the incidence of transfer trauma and major events (hospitalization/death/discharges) among long-term NH residents who transferred from one NH to another before and during the COVID-19 pandemic using a composite measure of transfer trauma based on validated scales from Minimum Data Set (MDS) assessments. A total of 750 residents transferred in the pre-COVID cohort and 795 in the COVID cohort were eligible for assessment of transfer trauma and major events. After adjusting for demographic characteristics, residents in the COVID cohort were almost twice more likely to die and almost three times more likely to discharge within 90 days compared to those in the pre-COVID cohort (AOR=1.94, 95%CI [1.15, 3.26] and AOR= 2.86, 95%CI [2.30, 3.56], respectively). Residents in the COVID cohort were less likely to experience transfer trauma compared to those in the pre-COVID cohort. In the during-COVID cohort, 26% of residents had a COVID-19 diagnosis and they were less likely to experience transfer trauma compared to residents without a COVID-19 diagnosis (AOR=0.34, 95%CI [0.23, 0.50]). It is important to note that some residents may have not stayed in the nursing home long enough to assess them for transfer trauma.

STAFFING DIFFERENCES IN NURSING HOME SPECIAL FOCUS FACILITIES AND SPECIAL FOCUS FACILITY CANDIDATES

Annie Rhodes,[1] Faika Zanjani,[1] Thomas Caprio,[2]
Tracey Gendron,[3] and Leland Waters[1], *1. Virginia Commonwealth University, Richmond, Virginia, United States, 2. University of Rochester, Rochester, New York, United States, 3. VCU, Richmond, Virginia, United States*

Introduction: Centers for Medicare and Medicaid Services designates “Special Focus Facilities” (SFF), which are nursing homes receiving special oversight for persistent quality problems. “Special Focus Facility Candidates” (SFFc) are nursing homes with quality problems that are designated as candidates to be future SFFs. Recent academic literature has not examined if SFF and SFFc have significant differences in staffing hours per resident day (HPRD). Methods: Nursing homes that were SFF or SFFc in 2020 were matched to 5-star nursing homes. Monthly staffing averages were aggregated, and two-way ANOVAs with Tukey Post Hoc were conducted to detect level differences in HPRD across the three facility groups. Gross and Case-Mix staffing HPRD were analyzed, along with daily resident census. Results: The final sample was n=197 SFFc, and n= 50 SFF, which were matched with n=247 5-star nursing homes for a total sample of Nf494. Over 2020, daily census for 5-star nursing homes was lower (M=72.36, SD=52.5) than SFFc (M=93.77, SD=68.34) or SFFs (M=97.88, SD=44.06). There was a significant difference between SFF and SFFc HPRD in Case-Mix Aide F(2, 5748)=187.6, p= < .005, and Registered Nurse (RN), F(2,5748)=323,p=.003 care. There were no significant differences between SFF and SFFc in HPRD Aide F(2,5748)=380,p=.63, Practical Nurse F(2,5748)=1.1, p=.211, Case-Mix Practical Nurse F(2,5748)=19.57,p=.39, Case-Mix RN F(2,5748)=9.51,p=.91 or Total HPRD F(2,5748)=472.6,p=.16, care. Discussion: There is only a significant difference in staffing levels observed between SFF and SFFc for Aide staffing and RN staffing. This information supports researchers and policymakers in delineating the differences and similarities between SFF and SFFcs.

RETHINKING NURSING HOME ARCHITECTURE AND DESIGN IN THE LIGHT OF THE COVID-19 PANDEMIC

Desmond O’Neill, Tom Grey, Dimitra Xidous,
Jennifer O’Donoghue, and Mehak Puntambekar, *Trinity College Dublin, Dublin, Dublin, Ireland*

Introduction: The huge death rate in nursing homes during the COVID-19 pandemic raised serious questions as to whether the built environment of nursing homes was a factor in this very high mortality, as well as a factor in quality of life. Method: We embarked on a wide-ranging study involving a review of Irish policy, stakeholder engagement, Irish case studies, literature review, and international case studies to understand the key issues that influence the planning, design, and operation of nursing home settings settings, and to identify how these shape care models and the physical environment. Results: The project generated the following key themes: a) including the voices of residents, family and staff in co-creation of design and research; b) integrating nursing homes with the overall housing spectrum; c) linking nursing homes with ageing in place policy; d) further research on optimal design; e) understanding resident diversity; f) greater inclusion of Universal Design principles; g) designing for resilience; and h) Convergence between infection control and quality of life Discussion: Our Research Findings have been developed to identify major current issues related to the built environment and its role in creating a balance between quality of life and COVID-19 infection control in Irish and international nursing home settings. These findings are relevant for a wide range of stakeholders and will be disseminated across a number of channels to continue this conversation and help to continue the evolution of nursing home design.

POSITIVE AFFECT AND SOCIAL SUPPORT SATISFACTION AMONG NEWLY ADMITTED LONG-TERM CARE RESIDENTS

Darby Simon, Benjamin Mast, Emilee Ertle, and Suzanne Meeks, *University of Louisville, Louisville, Kentucky, United States*

Social support serves as a protective factor against depression and other negative outcomes among older adults. Satisfaction with social support among long-term care residents has not received as much attention, and the experience of support among newly admitted long-term care residents has not been investigated. The current study examines what variables influence a long-term care resident's satisfaction with their social support. This sample consists of 48 individuals newly admitted into long-term nursing home care. This study used the Social Support Questionnaire (SSQ6) to gather information on social support network size and overall satisfaction of perceived social support. Correlations were estimated between social support satisfaction, social support network size, and psychosocial factors including depression (PHQ-9), anxiety (RAID), religious involvement, cognitive status (BIMS), positive and negative affect (PANAS). Satisfaction with support was significantly correlated with social network size ($r = .328$, $n = 48$, $p < .05$) and positive affect ($r = .437$, $n = 24$, $p < .05$). In a regression model with support satisfaction as the dependent variable, both social network size and positive affect contributed significantly to model R2 $F(2,21) = 2.441$, $p = .049$ $R2 = .250$. Satisfaction with support depends upon the number of supporters available, but also on levels of positive affect.

MEASURING WORKPLACE LEARNING CONDITIONS FOR NURSING STAFF IN LONG-TERM GERIATRIC CARE

Merel (E.A.) Van Lierop,[1] Judith Meijers,[1] Erik van Rossum,[2] and Sandra Zwakhalen[1], *1. Maastricht University, Maastricht, Limburg, Netherlands, 2. Zuyd University of Applied Sciences, School of Nursing, Heerlen, Limburg, Netherlands*

To deal with challenges in practice such as workload and complexity in long-term care delivery, learning in practice (workplace learning) is becoming increasingly important. Nursing staff needs to take the lead and learn continuously in practice using a bottom up approach to promote workplace learning. Therefore, insight in workplace learning conditions (like work culture and learning climate) in long-term care is necessary. Based on these insights, nurses can define challenges and goals on how to stimulate workplace learning. Currently, no instruments are available that measure these conditions in the long-term nursing care setting in a snap shot. Therefore, the goal of this study was to develop a quick-scan to measure workplace learning conditions for nursing staff in long-term geriatric care. This quick-scan was developed in 3 steps: (1) investigating how to measure conditions for workplace learning, (2) selecting appropriate measurement tools to measure conditions for workplace learning, and (3) testing the feasibility of the quick-scan in practice. As a result, the final feasible quick-scan measured 11 conditions regarding workplace learning: (1) Trust: values and culture, (2) Team: support and management, (3) Colleagues: support and respect, (4) Constraints in undertaking the job, (5) Urgency, (6) Learner agency, (7) Collaboration, (8) Hybrid learning, (9) Coaching, (10) Flexibility – formal and informal learning, and (11) Assessment-as-learning. Additionally, questions were added regarding availability of sources for learning, knowledge and skills, and communication. Validated questionnaires that were included were the Culture of Care Barometer and HILL model questionnaire.

MEASURING BARRIERS TO LONG-TERM CARE RESIDENT PREFERENCES: DEVELOPMENT AND CONTENT VALIDITY TESTING

Laura Block,[1] Ella Greenhalgh,[1] and Tonya Roberts[2], *1. UW-Madison School of Nursing, Madison, Wisconsin, United States, 2. University of Wisconsin-Madison, Madison, Wisconsin, United States*

Person-centered care (PCC), or delivery of care consistent with preferences, can improve outcomes for residents in long-term care (LTC). However, PCC has not been universally adopted. Few studies focus on measuring specific barriers to meeting resident preferences, hindering identification of actionable targets to improve PCC delivery. The purpose of this study was to develop and test the content validity of a survey that measures staff barriers to fulfilling resident preferences for daily care and activities. Item sets comprised of barriers and preferences were informed by a review of literature and a descriptive, qualitative study with 19 LTC staff. An expert panel (n=8) was convened to test content validity, and content validity indices (CVI) were calculated. The initial survey consisted of 12 item sets assessing whether knowledge gaps, resident characteristics (e.g. health needs), family, facility rules/policies, availability of options, or staffing/workload functioned as barriers to meeting resident preferences for daily care and activities (CVI = 0.76 barriers; CVI = 0.89 preferences). Revisions informed by expert feedback resulted in a total of 17 items sets. Second round testing with experts (n=10) revealed overall improved item sets (CVI = 0.77 barriers; CVI = 0.96 preferences). These findings indicate that the survey items have initial content validity in measuring staff barriers to meeting resident daily care and activity preferences. Further psychometric testing with LTC staff is needed prior to implementing the survey, which will represent the first tool of its kind for supporting measurement of staff-derived targets for PCC interventions and policy change.

INFORMATION TO BE COLLECTED IN THE ASSESSMENT FOR PARENTS AND CHILDREN WITH “8050 PROBLEMS” IN JAPAN

Takako Ayabe,[1] Yoshito Takemoto,[2] Shinichi Okada,[3] and Sadaaki Fukui[4], *1. BAIKA Women’s University, Ibaraki, Osaka, Japan, 2. Okayama Prefectural University, Soja, Okayama, Japan, 3. Osaka Metropolitan University, Osaka, Osaka, Japan, 4. Indiana University, Indianapolis, Indiana, United States*

In Japan, the “8050 problems” have become a social issue, where parents and children are parents in their 80s and children in their 50s and live together. In the case of parents and children with “8050 problems,” the parents are older, but the children are often dependent, withdrawn, and have financial problems. Recently, the number of such cases has increased in care management. The previous studies indicated that it was important to know what information was gathered in the assessment in such cases. The research was conducted from February to March of 2022 by self-administered questionnaires. The survey was mailed to all 1,410 care management centers in Osaka City. The response rate was 11.8%. The statistical analysis was an exploratory factor analysis. Six factors in the significant information in the assessment were extracted by the factor analysis: Physical, mental and living conditions of children; Parents’ physical and mental conditions; Parents’ perspectives on their lives; Parents and children’s financial situations; Living environment; and Relationships between the informal and formal supports and the parents and children. The Cronbach’s alpha for internal consistency was greater than 0.8 for each factor. In addition, the four factors were strongly associated among the six factors. In conclusions, the present study found that information about the physical and mental status, living conditions, community relations, and financial situations of the parents and children with “8050 problems” was important in the assessment of the parents and children, and that the information is closely related to each other.

CALL FOR ACTION: STRENGTHENING LONG-TERM CARE IN NEPAL

Usha Dhakal, and Sara McLaughlin, *Miami University, Oxford, Ohio, United States*

This paper aims to introduce the existing long-term care (LTC) system in Nepal, identify key emerging issues, and provide possible policy recommendations for addressing weaknesses in the current system. Although the majority of older Nepali adults rely on their adult children for care, this traditional care arrangement is weakening for a variety of reasons. As a result, older Nepali adults increasingly seek care elsewhere such as “old age homes” (OAH), which generally meet only their basic needs. More recently, adult day centers have been established that enable older Nepali to receive help with personal care and instrumental tasks and/or health care needs in the absence of their families; however, they are primarily located in big cities and largely limited to those who can afford to pay. With a growing older population and societal changes that make familial care increasingly challenging for adult children, the Government of Nepal must foster the development of a sustainable system of LTC. This will necessarily involve building and sustaining a skilled geriatric workforce, capitalizing on the natural “villages” that have existed in Nepal for hundreds of years, and standardizing and monitoring the operation of LTC facilities. Additionally, public service campaigns to help destigmatize the use of OAH and day centers and integration of home and community-based services to make care arrangements locally could help make these newer LTC approaches more acceptable. Finally, nationally representative studies aimed at understanding the health and care needs of Nepal’s rapidly increasing older population is of utmost priority.

BARRIERS AND FACILITATORS FOR FOREIGN EDUCATED NURSES TO PROVIDE QUALITY LONG-TERM CARE

Roy Thompson,[1] Kirsten Corazzini,[2] Thomas Konrad,[3] Michael Cary,[4] Susan Silva,[4] and Eleanor McConnell[4], *1. University of Missouri, Colombia, Missouri, United States, 2. University of New Hampshire, Durham, New Hampshire, United States, 3. University of North Carolina at Chapel Hill, Chapel Hill, North Carolina, United States, 4. Duke University, Durham, North Carolina, United States*

Unprecedented registered nursing shortages in long-term care (LTC) threaten the provision of person-centered care for older adults in the United States (US). LTC facilities recruit Foreign Educated Nurses (FENs) to address shortages, which raises concerns about care quality due to cultural, linguistic and communication differences among nurses; yet studies have not thoroughly explored FENs’ perspectives on these issues. The purpose of this study was to advance our understanding of FENs’ professional experiences as they began employment in LTC by exploring factors that inhibit or facilitate their provision of quality care. This qualitative descriptive study used purposive sampling to recruit FENs through professional organizations. Eligible FENs were ≥ 18 years old, worked ≥1 year in LTC, and represented racial and ethnic minority groups from Low and Middle Income Countries. In-depth narrative interviews, ranging from 45–60 minutes, were conducted. Applying content analysis, a priori and inductive coding generated themes. Participants (n=12) interviewed were all married females. Most were 50–59 years old (41.7%), Asian (75.0%), BSN-prepared (58.3%), and reported 31–50 years of nursing experience (50%). Positive facility characteristics, acculturation, effective workplace integration and positive support from colleagues, residents, and their families facilitated the provision of quality care. Conversely, negative facility characteristics, cultural barriers, discrimination and ineffective workplace integration were barriers to providing quality care. FENs highlighted culturally-sensitive strategies such as providing structured mentorship and preceptorship programs that supported them in providing person-centered care. FENs confirmed the need to address racial and anti-immigrant discrimination for achieving more equitable and inclusive workplaces.

VALIDITY EVIDENCE FOR THE MALE DEPRESSION RISK SCALE-22 (MDRS-22) IN YOUNGER AND OLDER ADULT MALES

Montgomery Owsiany, and Amy Fiske, *West Virginia University, Morgantown, West Virginia, United States*

Men are two times less likely to be diagnosed with major depressive disorder (MDD) than women. However, suicide rates are nearly four times higher in men than women, increasing to six times or more when comparing older men to older women. Masculine depression is characterized by symptoms that are not usually assessed by diagnostic criteria for MDD, including drug and alcohol abuse, anger and aggression, and risk-taking. Previous studies have largely neglected to consider the possibility of age-related differences in the presentation of masculine depression. Given research on age-related differences in MDD, there may be age-related differences in the presentation of masculine depression as well. The present study assessed age invariance of the MDRS-22 through a multi-group confirmatory factor analysis (CFA), evaluated validity evidence of the MDRS-22, and tested the MDRS-22's ability to assess suicidal ideation and behaviors. There was a significant difference between the configural and first-order metric models of the CFA showing that the MDRS-22 was not age invariant (ΔX2 = 451.47, Δdf = 16, p < .001). The MDRS-22 showed convergent validity evidence with assessments of MDD, alignment with masculine norms, suicidal behaviors, problematic alcohol use, and aggression. The MDRS-22 showed concurrent validity evidence with another assessment of masculine depression. Finally, MDRS-22 scores significantly predicted suicide risk above PHQ-9 scores (F(2,440) = 138.774, p < .001, R2 = .385). Overall, the study highlights the importance of screening males for masculine depression. Further research is needed to determine if masculine depression presents differently in younger and older males.

THE EFFECT OF SUPPLEMENTAL NUTRITION ASSISTANCE PROGRAM GENEROSITY ON DEPRESSIVE SYMPTOMS AMONG OLDER AMERICANS

Peiyi Lu, Katrina Kezios, and Adina Zeki Al Hazzouri, *Columbia University, New York, New York, United States*

Food insecurity has been indicated to associate with more depressive symptoms. Supplemental Nutrition Assistance Program (SNAP) is an established anti-poverty government program that targets food insecurity. The goal of this study was to assess whether SNAP generosity, defined at the state level, impacts the relationship of food insecurity and depressive symptoms among older Americans. We linked state-level SNAP policy data to the individual-level data of older adults (aged 60+) from the longitudinal Health and Retirement Study (Nf12,801). Our study baseline was survey year 2000. A state is considered SNAP generous when it eliminates income/assets limit from its SNAP eligibility criteria. All HRS participants reported their food insecurity status and depressive symptoms biennially. Participants were followed until 2018. We conducted state fixed-effect models adjusted for demographic and health measures. Results indicate household food insecurity was associated with higher risk of elevated depressive symptoms (OR=1.83, 95%CI=1.61, 2.07) from a fixed effect logistic model, and this effect was stronger when living in non-generous states compared with generous states though confidence intervals were too wide to be conclusive (OR_interaction =1.09, 95% CI= 0.83, 1.42). The relative excess risk due to interaction (RERI) was 0.17 (95%CI= -0.30, 0.63). Our study finding suggested that there is no to weak evidence that state-level SNAP generosity may alleviate or offset the risk of depressive symptoms associated with food-insecurity.

SOCIAL ENGAGEMENT IN LATER LIFE: INTERDEPENDENCE OF MARRIED COUPLE'S MENTAL HEALTH WELL-BEING.

Yulri Kim, *Iowa State University, Ames, Iowa, United States*

Social engagement in later life often provides a sense of belongings and social identity. Given its salient meanings for older adults in Korea where social ties play important roles on the mental health and well-being, different conceptualizations of social engagement have been examined, such as formal and informal social activities. As numerous studies have suggested, informal activities are associated with better well-being, however, it is unclear whether formal social engagement of husbands and wives influence the other partner's mental health outcomes. Based on the Interdependence Theory (Rusbult & Van Range, 2008), we expect that formal and informal social engagement of husbands and wives are associated with their own depressive symptoms and further those of their spouses. Using a sample of 1,195 couples (Nf 2,390) of married older adults aged 65 and above from the 8th wave of Korean Longitudinal Study of Aging (KLoSA), we tested the relationship between social engagement and depressive symptoms using actor partner interdependence model (APIM). The findings indicated that for both husbands and wives, there was a negatively significant association between one's informal social activity on their own depressive symptoms (actor effect) and their spouse's depressive symptoms (partner effect). No significant findings were observed for formal social activities. Overall, this study suggests the importance of informal social activity compared to formal social activity to lower depressive symptoms for themselves and their spouses in later life. Moving forward, incorporating a partner's informal social activity can provide useful information in predicting one's own mental health well-being.

RESILIENCY AS A PROCESS: A QUALITATIVE INVESTIGATION INTO U.S. VETERANS' EXPERIENCES AGING WITH HIV

Kiera Chan,[1] Alexis Bender,[1] Vincent Marconi,[2] Amy Justice,[3] Theodore Johnson,[1] Keith McInnes,[4] and Molly Perkins[5], *1. Emory University, Atlanta, Georgia, United States, 2. Emory University, Decatur, Georgia, United States, 3. Yale University, New Haven, Connecticut, United States, 4. Boston University, Boston, Massachusetts, United States, 5. Emory University School of Medicine, Atlanta, Georgia, United States*

U.S. military Veterans aging with HIV represent a unique special population. The aim of this qualitative study was to investigate risk and protective factors associated with Veterans' ability to age well with HIV. Participants included 25 Veterans (≥ age 50) participating in the Veterans Aging Cohort Study who were recruited from the Atlanta Veterans Affairs (VA) Medical Center. This study conducted semi-structured interviews, social network mapping, and sociodemographic and health surveys. Participants ranged in age from 50 to 72, with a mean age of 59. Most (80%) were male, and more than half (60%) were African American. Findings showed that many participants experienced adversity in childhood or early adulthood, including military sexual violence, childhood abuse, and non-military domestic violence, as well as harassment based on sexual identity. Many also had histories of substance abuse. Although military life provided stability for some, most experienced some form of instability after leaving the service, including financial difficulties and loss of valued military ties. Timing of diagnosis, whether in the military or after the military, impacted resiliency. Receiving an HIV diagnosis was an important turning point in participants' lives characterized by either maladaptive (e.g., suicide ideation) or therapeutic (e.g., health promoting behaviors) coping strategies. Positive social support, including close relationships many developed with providers at the VA HIV clinic, was an important protective factor. The sample experienced cumulative life events that shaped their ability to age with HIV. Findings have important implications for interventions to promote Veterans' ability to age well with HIV.

OLDER VETERANS' PREFERENCES FOR FORMAT AND DESIGN OF EDUCATIONAL MENTAL HEALTH BROCHURES

Ruifeng Cui,[1] Armando Rotondi,[2] Alaa Shalaby,[3] and Judith Callan[2], *1. VA Pittsburgh Healthcare System, Morgantown, West Virginia, United States, 2. VA Pittsburgh Health Care, Pittsburgh, Pennsylvania, United States, 3. VA Pittsburgh Healthcare System, Pittsburgh, Pennsylvania, United States*

Older Veterans may have lower mental health literacy and education than younger Veterans. The Veterans Affairs Healthcare System (VA) has created many educational brochures on mental health to facilitate service utilization by Veterans, however few studies have solicited Veteran stakeholder feedback pertaining to their design and effectiveness. The present qualitative pilot study aimed to develop a brief general mental health educational brochure for older Veterans seen in VA medical settings. The brochure aims to provide information on mental health symptoms and VA mental health resources. Participants (Nf5, mean age=67.2) were older adult White male Veterans. An iterative design process was used to develop and refine the educational brochure which consisted of qualitative interviews with Veteran stakeholders on their mental health needs and their feedback on the brochure. The brochure was then modified based on prior Veteran feedback before being tested with subsequent Veteran participants. The brochure received high ratings on clarity (8.8/10), conciseness (8.6/10), and importance (8.6/10). Qualitative interviews revealed that Veterans appreciated the simplistic presentation of the content ("It's very informative for being so simple, it caught my attention"), the generality of the content ("it is encouraging because it is a broad approach to a spectrum of mental health concerns"), and contact number content ("Direct lines, that's really nice"). These findings support the use of user-centered design methods to develop educational materials. The findings indicated that a brief educational mental health print brochure was an acceptable method to promote mental health literacy and use of VA mental health services.

DIFFERENCES AND SIMILARITIES OF ELDERLY PERSONS IN SWEDEN WITH A DIAGNOSIS OF PSYCHOSIS OR NON-PSYCHOSIS (SMI)

Per Bülow,[1] Pia H. Bülow,[2] and Deborah Finkel[3], *1. Jönköping University, School of Health and Welfare, Jönköping, Jonkopings Lan, Sweden, 2. School of Health and Welfare, Jönköping, Jonkopings Lan, Sweden, 3. Indiana University Southeast, New Albany, Indiana, United States*

Psychiatric care in Sweden is jointly organized by psychiatric practice and municipal social services. To determine who is entitled to support from the municipalities, the concept of "psychiatric disability" was created in connection with psychiatric reform in 1995. Psychiatric disability is a poorly identified concept and in Sweden, a person has severe mental illness (SMI) if they have difficulties in carrying out activities in crucial areas of life, these difficulties are caused by a mental disorder, and they are prolonged. Internationally, SMI is often synonymous with psychosis, but in Sweden other severe psychiatric conditions are included, but not dementia. Both practically and ethically, the unclear definition of SMI is a problem because it determines whether a person is granted interventions and what forms the interventions take. We investigated similarities and differences in people defined as SMI, divided into two groups, psychosis (Nf222) and non-psychosis (Nf253). Adults with SMI aged 65 or over (in 2016) have been assessed using data from four surveys carried out between 1996 and 2011, as well data available from national registers. People with psychosis had worse functional levels on the Global Assessment of Functioning and more unmet needs, according to Camberwell Assessment of Needs. However, differences between psychosis and non-psychosis groups varied across measures (e.g., education, income, living situation) and results differed depending on age at onset, year of first admission to a mental hospital, and length of institutionalization. These variables had a greater impact on the similarities and differences between measures than the diagnosis itself.

AFFORDABILITY, PERCEIVED RACISM, AND HEALTHCARE SYSTEM DISTRUST AMONG AFRICAN AMERICAN WOMEN AGED 45 AND OVER

Jacqueline Wiltshire,[1] Carla Sampson,[2] Keith Elder,[3] and Paul Musey[1], *1. Indiana University, Indianapolis, Indiana, United States, 2. New York University, New York, New York, United States, 3. Mississippi, Clinton, Mississippi, United States*

Unaffordable healthcare costs—a major concern for Americans--disproportionately affect African Americans (AA), who are more likely to distrust the healthcare system due to past mistreatment and discrimination. However, the relationships between affordability, mistreatment, discrimination, and healthcare system distrust are unclear. Using cross-sectional survey data from a community-based sample of 313 African American women aged 45 and over, we assessed the relationships between the ability to get needed care due to costs, negative healthcare experiences, perceived racism, and healthcare system distrust. Linear regression and mediation analyses were conducted to assess relationships. Approximately 23% of women reported the inability to get needed care because of costs, and 44% had a negative experience with a healthcare provider. Healthcare system distrust was higher among women unable to get healthcare because of costs (β = 2.66; p = 0.005) or had a negative experience with a healthcare provider (β = 3.02; p < 0.001). However, perceived racism in the healthcare system, a significant predictor of distrust (β = 0.81; p < 0.001), attenuated the relationships between inability to get health care because of costs (β = 1.74; p = 0.051) and negative experience with a healthcare provider (β = 1.79; p = 0.013). Perceived racism explains 34% and 46%, respectively, of the relationships between affordability, negative experience with healthcare provider, and healthcare system distrust. These findings are important given the relevance of building trust and understanding needs to address health inequities. Future research should explore whether these findings hold for AA men and other minoritized groups.

A COLLABORATIVE AUTOETHNOGRAPHY OF FOREIGN-BORN FACULTY IN THE FIELD OF AGING

Chih-ling Liou,[1] and Karel Kalaw[2], *1. Kent State University, North Canton, Ohio, United States, 2. University of Central Oklahoma, Edmond, Oklahoma, United States*

We draw from our personal insights as foreign-born females in the U.S. to explore how our minority status has affected our experiences/identities as faculty in the field of aging. We practiced intersectionality by considering how our understandings of "foreignness" in academia and the aging field are intertwined with other markers of difference, including race, national origin, language, and academic programs. We also draw from tenets of collaborative autoethnography to engage two autoethnographies from two countries in Asia to pool their lived experiences and collaboratively analyze and interpret them for commonalities and differences. We begin by sharing stories about graduate study pursuits and becoming faculty in the U.S. We note how our foreignness shapes our lives as aging scholars in the U.S. academy and our personal views on aging. After exchanging our first set of writings, we identified key experiences to focus on in the subsequent writing periods. Our minority backgrounds, teaching aging subjects, and using qualitative methodology are shared identification. However, our personal stories within the U.S. society and within the academy also diverge our identities and aging experiences from each other. Moreover, the themes that deal directly with identity development and the perception of aging provide a deep understanding of aging among the non-native-born population. This study highlights the value of collaborative autoethnography as a method of inquiry and reflection. Findings demonstrate that non-native-born female faculty in the field of aging faced multi-faceted challenges in both professional and personal realms. Implications for supporting foreign-born female aging scholars are discussed.

RACIAL-ETHNIC VARIATION IN MULTIMORBIDITY PATTERNS AND HEALTHCARE SERVICES AMONG OLDEST-OLD PATIENTS

Jinmyoung Cho,[1] Gelareh Rahimighazikalayeh,[2] and Heather Allore[3], *1. Baylor Scott & White Research Institute, Temple, Texas, United States, 2. Baylor Scott & White Research Institute, Dallas, Texas, United States, 3. Yale University, New Haven, Connecticut, United States*

Adults aged 85 years and older ("oldest-old") are perceived as survivors resilient to age-related risk factors. Although considerable heterogeneity has been often observed in this population, less is known about the unmet needs in health and healthcare service utilization for diverse patients in healthcare systems. We examined racial-ethnic variation in patterns of multimorbidity associated with emergency department (ED) and clinic visits among oldest-old patients with multiple chronic conditions (MCCs). Administrative and clinical data from an integrated healthcare system for five years included 25,801 oldest-old patients with MCCs. Hierarchical cluster analysis identified patterns of MCCs by four racial-ethnic groups (White, Black, Hispanic, & Other). Clusters associated with ED and clinic visits were analyzed using generalized estimation equations. The average of 5.79 (±2.79) MCCs ranging from 5.36 (±2.61) for Other to 5.82 (±2.79) for Hispanic patients at baseline decreased over time. Hypothyroidism, Alzheimer's Disease and related dementia, bone-and-joint, metabolism syndrome, and pulmonary-vascular clusters were commonly observed across the groups. Unique cluster patterns were identified among Black patients (e.g., renal diseases were grouped with metabolic syndrome cluster). While almost all clusters were significantly associated with ED and clinic visits among White patients, distinctive clusters were significantly related to ED and clinic visits among Hispanic patients (e.g., bone–and-joint cluster grouped with renal diseases was significantly associated with ED [RR=1.36, p < .0001] and clinic [RR=1.39, p < .0001] visits, respectively). Patterns of multimorbidity and its significant association with healthcare service utilization varied by race-ethnicity. Findings suggest a need for culturally tailored care management within integrated healthcare systems.

NEITHER HERE NOR THERE, YOU BECOME A STRANGER FOR BOTH SIDES: SUCCESSFUL AGING IN CHINESE AMERICAN OLDER ADULTS

Mushira Khan,[1] Chien-Ching Li,[2] and Ezer Kang[3], *1. Mather Institute, Evanston, Illinois, United States, 2. Rush University, Chicago, Illinois, United States, 3. Howard University, Washington, District of Columbia, United States*

Previous studies have critiqued the inordinate emphasis on high physical and cognitive functioning and a relative absence of cultural factors in our understanding of the aging process. The multi-year Perceptions of Aging Well in Diverse Populations study explores (1) the meanings attached to aging well across cultures and (2) similarities and differences in these perceptions within diverse racial and/or ethnic groups. This presentation highlights findings from in-depth, semi-structured qualitative interviews with Chinese Americans 50 years and older (n=25; 10 male, 15 female; mean age 58.3 years). Thematic analysis of the data showed that generation status, age at arrival, density of social networks, and level of acculturation were key determinants of successful aging. Specifically, those who were born in the United States or had immigrated at an early age appeared to value their independence and were actively making retirement plans. Late-life immigrants were often lonely and more dependent on their adult children. Financial security and healthcare access were important considerations for mid-life immigrants. Several participants felt like an 'outsider' in the US but also felt like they were regarded as 'foreigners' in their country of origin, resulting in feelings of ambivalence and alienation. Many participants, particularly women, reported feeling less safe in their neighborhoods given the increasing prevalence of violence against Asian Americans in recent years and some were even contemplating moving to another country post-retirement. These findings provide insights into how aging is experienced among Chinese Americans and may help inform initiatives to support successful aging in this population sub-group.

EXPLORING DEPRESSION AND ITS CORRELATES AMONG RESETTLED BHUTANESE OLDER ADULTS IN OHIO

Saruna Ghimire,[1] Bunsi Chapadia,[1] Isha Karmacharya,[1] Aman Shrestha,[1] Janardan Subedi,[2] and Robert Applebaum[1], *1. Miami University, Oxford, Ohio, United States, 2 Miami University, Oxford, Ohio, United States*

Following the “ethnic cleansing” by the Bhutanese government in the 1990s, Nepali-lingual Bhutanese fled from southern Bhutan and spent about two decades in refugee camps in Nepal before resettlement in the US and other countries. During post-resettlement, this population had a high rate of suicide and mental health problems. However, studies specifically among resettled older Bhutanese are lacking. This study aims to estimate the prevalence of depression and explore its correlates among resettled Bhutanese Older Adults in Ohio. A cross-sectional survey was conducted in Ohio (Columbus, Akron, Cleveland, and Cincinnati). The exploratory study surveyed 275 participants between January-June 2022, using snowball sampling, given the absence of a sampling frame. Study participants include adults 55 years and above, identified with the help of local community-based organizations. Depression was measured using the Geriatric Depression Scale, and life satisfaction, social support and resiliency were measured using validated standard tools. The prevalence of depression was 31.8%. In the adjusted model, factors associated with lower odds of depression were better self-reported health, satisfaction with life (OR=0.08, 95%CI: 0.01–0.46) and high social support (OR=0.23, 95%CI: 0.07–0.78). Resiliency was inversely associated with the odds of depression (low resiliency: OR=4.98, 95%CI: 2.02–12.28; high resiliency: OR=0.21, 95%CI: 0.07–0.64). Given the lack of a basic health profile of this population, this exploratory study is a necessary stepping stone and the first of its kind. This study will help to inform the relevant stakeholders and community leaders and provide baseline evidence for further research and programmatic actions.

ESTABLISHING A SPANISH FOCUSED ADVANCED CARE PLANNING EDUCATIONAL SESSION FOR LATINA BREAST CANCER SURVIVORS

Moroni Fernandez Cajavilca,[1] Kara Dassel,[2] Gabriela Portugal,[3] Rebecca Utz,[2] and Katherine Supiano[2], *1. University of Utah, Bronx, New York, United States, 2. University of Utah, Salt Lake City, Utah, United States, 3. Alliance Community, Murray, Utah, United States*

In this exploratory, qualitative study, a focus group was conducted with Latina breast cancer survivors and patients to explore their feedback on how a culturally, sensitive educational session looks like, and whether a Spanish-speaking advanced care planning (ACP) educational session might be able to identify barriers for promoting awareness and discussion of ACP. First, the educational session informed participants on ACP, specifically an advanced directive (AD) and barriers that contribute to decreased rates in ACP among Latino populations. Second, a group interview was facilitated by the project lead using a semi structured interview guide. Eight Latina cancer survivors or patients participated in the educational session. Thematic analysis revealed four themes: 1) Familial Involvement 2) Need for Advanced Care Planning Education 3) Addressing Language and Cultural Barriers and 4) Culturally Sensitive and Informative Resources. A Spanish focused educational session may reduce current barriers that hinder ACP conversations, and may lead to increased rates of participants engaging in AD documentation.

THE EFFECTS OF TYPE 2 DIABETES MELLITUS ON POSTURAL ADAPTATION DURING A VISUAL SEARCH TASK IN OLDER ADULTS

Alexander Wolfe,[1] Tongjian You,[2] Suzanne Leveille,[2] Brad Manor,[3] and Azizah Jor’dan[4], *1. University of Massachusetts Boston, Dorchester, Massachusetts, United States, 2. University of Massachusetts Boston, Boston, Massachusetts, United States, 3. Hebrew SeniorLife/ Harvard Medical School, Roslindale, Massachusetts, United States, 4. University of Massachusetts, Boston, Massachusetts, United States*

Type II diabetes mellitus (T2DM) is associated with a reduction in sensory integration capacity that often results in cognition and postural control deficits. The effects of T2DM on the ability to adapt one’s postural sway while standing and performing a visual search task (VST) are unknown. Twenty-three healthy older adults (HOA) (70–90 years) and 20 older adults with T2DM (67–93 years) performed multiple trials of quiet standing with and without a VST (i.e., counting 1 target letter in a grid of random letters). Postural sway acceleration measures were jerk, velocity, range, and pathlength in the anterior-posterior (AP) and medial-lateral (ML) direction, as well as elliptical area. Postural adaptation to the VST was defined as the absolute change between conditions. VST accuracy (%) was defined as the percentage of participant-reported target letters compared to total target letters. In general, for both groups, performing the VST resulted in an average reduction in sway jerk, velocity, pathlength, and range when performing the VST, compared to control (T2DM & HOA, $p < 0.04$). VST accuracy and the magnitude of postural adaptation to the VST were similar between groups ($p>0.15$). Within the T2DM group, those who performed worse on the VST exhibited less adaptation (i.e., smaller decrease) in ML velocity ($r=0.47$, $p=0.04$). No other differences or associations were observed. Compared to healthy older adults, those with T2DM demonstrated a similar capacity to adapt their postural control in response to a VST. However, this group exhibited different characteristic changes in sway which were linked to task performance.

EXAMINING THE IMPACT OF FAR-INFRARED TECHNOLOGY ON QUALITY OF LIFE IN OLDER ADULTS

Arianna Balingit,[1] and Joshua Guggenheimer[2], *1. St. Catherine University, St.Paul, Minnesota, United States, 2. St. Catherine University, St. Paul, Minnesota, United States*

The purpose of this study was to examine the effects of far-infrared heat (FIR) on pain management and quality of life (QOL) in older adults (OA). FIR utilizes a long-wave light that simulates dry sauna-like conditions. Examining the relationship between FIR and pain is important due to the increased prevalence of chronic pain associated with aging and the impact it has on QOL and physical performance. 9 OA completed the study, 8 of whom were women. Our intervention consisted of assigning participants to either a convective (CON) or a convective and far-infrared heat (FIR) group, with convective heat set to 60oC. Participants received 6, 30-minute heat sessions over 3 weeks. Pre- and post-test assessments included physical measures such as range of motion, gait speed, timed up-and-go, and hand grip strength. Additionally, we conducted standardized questionnaires to determine pain severity and interference on daily life, and the impact such has on overall QOL. T-tests were used to compare the groups' pre- and post-assessment responses. Results indicated that pain severity was significantly reduced (from 3.31 to 2.5, $P < 0.05$) in the FIR group from pre-to-post, and that pain inference was significantly reduced (from 1.26 to 0.43, $P < 0.05$) in the CON group from pre-to-post. There were no significant differences from pre-to-post testing for any other measures. These findings suggest that heat therapy was successful in reducing pain over time for OA, but that FIR heat specifically, was not superior to that of convective heat alone.

DIGITAL DIVIDE AND DIFFICULTIES IN ACQUIRING HEALTH RESOURCES IN DISABLED OLDER ADULTS DURING THE PANDEMIC

Eunjin Yang,[1] Min Jung Kim,[2] and Kyung Hee Lee[3], *1. Yonsei University College of Nursing, Seoul, Seoul-t'ukpyolsi, Republic of Korea, 2. College of Nursing, Yonsei University, Seoul, Seoul-t'ukpyolsi, Republic of Korea, 3. Yonsei University, Seoul, Seoul-t'ukpyolsi, Republic of Korea*

The digital divide refers to the gap between those who are connected and those who are not connected to the internet and technologies. Although COVID-19 worsens the digital divide and health inequality, few studies have focused on the relationship between digital divide and difficulties in acquiring of health resources during the pandemic. This study aimed to identify the relationship between internet use and difficulties in acquiring health resources among older adults with disabilities during the COVID-19 pandemic. This secondary analysis study included 4,871 older adults aged 55 and older among 7,025 total responders of the 2020 survey of people with disabilities in South Korea. As the results, only 23.7% of older adults with disabilities used the internet. Non-internet users are more likely to have difficulties in acquiring COVID-19-related information (aOR 1.59) and buying and using personal protective equipment (aOR 1.36). However, difficulties in using medical services (aOR 1.21) was not statistically significant. Considering that older adults with disabilities have triple burdens from old age, disabilities, and the digital divide amid COVID-19, healthcare providers need to pay more attention to mitigate gaps between internet users and non-non users among this population. By narrowing the digital divide, decreasing health gaps and increasing well-being among older adults with disabilities will be guaranteed.

EMERGENCY DEPARTMENT USE FOR DENTAL PROBLEMS AMONG MEDICARE FEE-FOR-SERVICE OLDER ADULTS IN THE U.S. (2016 TO 2020)

Roshani Dahal,[1] Stephanie Jarosek,[2] and Beth Virnig[3], *1. University of Minnesota, Twin Cities, Minneapolis, Minnesota, United States, 2. University of Minnesota, Minneapolis, Minnesota, United States, 3. University of Florida, Gainesville, Florida, United States*

Medicare Fee-for-Service (FFS) does not include dental coverage for older adults (65 years of age and older) but does cover emergency visits for dental problems. This study leverages Medicare Limited Data Sets to examine the use of emergency department (ED) for preventable, non-traumatic dental conditions (NTDCs) among Medicare FFS older adults from 2016 to 2020. Nationally, ~43.6 million beneficiaries sought care at the ED (average: ~8.7 million annually). Among these, ~550,000 ED visits (1.27%; ~110K annually) were for NTDCs as one of the diagnosis codes and ~200,000 ED visits (0.45%; ~40K annually) were for NTDCs as a primary diagnosis. Approximately, 5–6% of older adults with ED-NTDCs have multiple visits (94% with 1 ED-NTDC visit annually). Rates were similar in most years; however, ED use was lower in 2020 (COVID-19 pandemic). The most common diagnosis reasons include periapical abscess (tooth infection), sialadenitis, dental caries, jaw pain, and lesions of oral mucosa. Younger (65 to 74 years) and Black older adults were more likely to have primary ED-NTDC visits. Medicare paid ~$190 million for ED-NTDC visits (average: $38 million annually). Costs vary by inpatient (9%) and outpatient visits (91%). For ED-NTDCs as a primary diagnosis, the average Medicare payments for outpatient and inpatient visits were approximately $330 and $8,100, respectively. ED use for NTDCs indicates inappropriate use of valuable resources, because care provided in the EDs is incomplete (e.g., antibiotics, pain medication). Lack of follow-up with a dentist likely results in return ED visits, thus increasing costs to beneficiaries and public programs.

ACTIVITY GOAL SETTING ON CHRONIC LOWER BACK PAIN FOR OLDER VETERANS RECEIVING CHIROPRACTIC CARE

Casey Rogers,[1] Madeleine Hackney,[2] Lisa Zubkoff,[3] and Katharina Echt[4], *1. Birmingham/Atlanta VA GRECC, Birmingham, Alabama, United States, 2. Emory School of Medicine, Atlanta, Georgia, United States, 3. GRECC, Birmingham, Alabama, United States, 4. Birmingham/Atlanta GRECC, Birmingham, Alabama, United States*

There is currently no literature addressing the impact that chiropractic services have on older adults achieving individualized specific goals throughout a course of care for chronic low back pain. This study aims to explore the impact of setting a self-determined, "what matters most" activity/goal of rehabilitation care with relevant activities as part of standard chiropractic care on the self-rated pain and disability of older Veterans. Participants were randomized into two groups. The first, an experimental group where participants identified a goal and received standard chiropractic care. The second, a control group that received standard chiropractic care only. Participants underwent six sessions of care. Outcome assessment tools were utilized at pre- and post-treatment for both groups as primary measures and an individualized goal setting measurement tool was utilized for those randomized to the experimental group. After treatment, all participants had self-reported improvement in their condition and all participants assigned to a "goal setting group" achieved their desired goal. Despite some outcome measures remaining unchanged, this self-reported improvement may be important in the future of chiropractic services for the older Veteran population suffering with chronic low back pain in achieving self-determined goals of importance.

THE RELATION BETWEEN PROVIDER RESPONSES AND PATIENT AND CARE PARTNER SELF-EFFICACY IN PALLIATIVE CARE APPOINTMENTS

Hannah Silverstein,[1] Meghan McDarby,[2] and Brian Carpenter[3], *1. Washington University in St. Louis, St. Louis, Missouri, United States, 2. Memorial Sloan Kettering Cancer Center, New York, New York, United States, 3. Washington University in St. Louis, Saint Louis, Missouri, United States*

Person-centered palliative care (PC) fosters patient and care partner participation during medical appointments. The current study used Bandura's Social Cognitive Theory to examine whether the manner in which healthcare providers respond to patient and care partner questions during initial PC appointments is associated with their self-efficacy in question asking. We analyzed provider responses to direct and embedded questions during initial outpatient PC appointments at a large academic medical center. Provider responses were coded in terms of timeliness (number of dialogue exchanges between a question and a response) and completeness (how fully providers answered questions). Provider responses to direct questions were more timely (M = 1.91, SD = 3.55) compared to responses to embedded questions (M = 4.05, SD = 6.13), t(127) = -3.55, p < 0.001, whereas completeness was similar for both direct (M = 1.43, SD = 0.71) and embedded questions (M = 1.59, SD = 0.96), t(127) = -1.59, p = 0.114. On average, receiving more timely responses was not significantly correlated with self-efficacy, r(49) = -0.038, p = 0.791, nor was receiving more complete responses ρ(49) = -0.178, p = 0.211. These findings suggest that timeliness and completeness of responses may not be factors that affect self-efficacy, thus future research should continue to explore other factors, such as empathy present in provider responses. These findings also suggest that future research should investigate the role and effectiveness of embedded questions as an information-seeking behavior in patients and care partners given that providers took longer to respond to them.

CHILDHOOD ADVERSITY IMPACTS PERSONALITY DEVELOPMENT ACROSS ADULTHOOD

Sarah Miller, Meredith Willard, Jacob Alderson, and Nicholas Turiano, *West Virginia University, Morgantown, West Virginia, United States*

Throughout adulthood, people's personalities typically change favorably such that agreeableness and conscientiousness increase, and neuroticism decreases. However, the impact of early life adversity on these changes in personality has yet to be examined. We utilized data from 6,382 community dwelling adults (ages 25–75) that completed 3-waves of the Midlife Development in the U.S. Study (MIDUS) in 1995–96, 2005–06, and 2013–14. Early life adversity was computed using 16 retrospective items assessing emotional and physical abuse, socioeconomic disadvantage, familial instability, and early-life poor health. Personality was assessed with the Big 5 MIDI measure. Latent growth curves confirmed there was significant variability in change over the ~20 year follow-up (all RMSEAS < .06; and CFI/TLI > .96). More specifically, higher levels of early adversity predicted higher initial levels of neuroticism, and lower levels of conscientiousness and extraversion. Additionally, higher adversity predicted a steeper decrease in neuroticism across 20-years (all p's < .05). Examination of specific adversity types revealed that emotional abuse and having poor health at a young age were especially detrimental to personality development. This research provides evidence that high levels of adverse experiences in childhood predict unfavorable personality development throughout adulthood. Moreover, this research demonstrates that early life adversity, especially certain types, can have lifelong detrimental effects on development. Interventions for those who have experienced adversity should be implemented as early in life as possible to prevent suboptimal psychological development trajectories. Such interventions could improve life outcomes if personality development is more normalized.

'THEY ASKED ME TO JOIN; I JOINED:' LESSONS FOR SENIOR CENTERS ON SUPPORTING PHYSICAL ACTIVITY

Sarah Chard,[1] and John Schumacher[2], *1. UMBC, Baltimore, Maryland, United States, 2. University of Maryland, Baltimore County, Baltimore, Maryland, United States*

Among older adults, physical activity (PA) remains a foundation for maintaining and improving health. However, over 25% of adults aged ≥ 50 engage in no physical activity outside of work hours (CDC 2016). PA does correlate with senior center participation but little is known about the social factors that contribute to sustaining senior center PA routines. We report on findings from qualitative interviews conducted with Black older adults (Nf22) on the "story" of their senior center involvement, particularly their PA participation. Interviews were recorded and transcribed verbatim; co-authors independently conducted a line-by-line analysis to identify themes. They then reconciled and sorted themes. Four themes provided insights on participants' PA engagement: 1) Retirement as opportunity; 2) Invitation and welcome; 3) Physician messaging; and 4) Sense of community. Participants strongly connected retirement with the opportunity to engage in regular PA; work and family obligations previously prevented PA in daily life. Participants also linked trying new PA programs to the senior center's culture of extending one-to-one invitations. Physician messaging specifically "to exercise" provided additional validation for prioritizing senior center PA within daily schedules. Finally, a sense of community, of being missed if not attending, provided further incentive to sustain PA routines. These findings provide guidance and simple lessons that senior centers can employ to encourage participation in their PA programming. The themes may also inform the design of survey research examining patterns of PA among older adults.

THE DYNAMIC RELATIONSHIP BETWEEN MULTIDIMENTIONAL ENVIRONMENT AND PHYSICAL ACTIVITY PARTICIPATION

Yalu Zhang, Donghui Mei, Heming Pei, and Gong Chen, *Peking University, Beijing, Beijing, China (People's Republic)*

Objectives: Physical activity participation is a preventive factor in improving physical and cognitive functions. Both physical and social environments are essential in evaluating older adults' opportunities to participate in physical activities. This study aims at assessing the multidimensional environment in physical activity participation and examining how the change in the multidimensional environments could affect their participation in physical activities. Methods: This paper combined the nationally representative data, the China Longitudinal Aging Social Survey data 2014–2018, and the county-level administrative data extracted from various statistical yearbooks. It used the latent variable cross-lagged panel model to capture the dynamic relationship between environment and physical activities. Additionally, the dynamic analytical model considers a multidimensional environment, including indoor-, outdoor-, human-, social-environment, etc., by adding the latent variables. Results: The descriptive statistics show that older adults who are in a better environment (.147 in the indoor environment, $p < 0.001$; .389 in the outdoor environment, $p < 0.01$; .571 in family support, $p < 0.05$; .346 in childhood activity experience, $p < 0.001$) are more likely to frequently participate in physical activities (three times or more per week). The results of the latent cross-lagged panel models indicate that every one percent increase in the multidimensional environmental index is expected to cause a 4.1% increase in the likelihood of participating in physical activities among Chinese older adults. Discussion: In addition to the continuous efforts to improve the physical environment, policymakers and researchers should pay more attention to the social environment to encourage more older adults to participate in physical activities.

PHYSICAL ACTIVITY, BALANCE, AND BICYCLING IN OLDER ADULTS

Maya Baughn, Victor Arellano,
Brieanna Hawthorne-Crosby, Amanda Grimes,
Joey Lightner, and Gregory King, *University of Missouri-Kansas City, Kansas City, Missouri, United States*

Falls are a critical public health issue among older adults. One notable factor contributing to falls in older adults is a deterioration of the structures supporting balance and overall balance control. Preliminary evidence suggests older adults who ride a bicycle have better balance than those who do not. Cycling may be an effective intervention to prevent falls among older adults. This study aims to objectively measure the relationship between bicycling, physical activity, and balance for older adults. Older adult cyclists ($n=19$) and non-cyclists ($n=27$) were recruited to (1) complete a survey that assessed demographics; (2) wear an accelerometer for 3 weeks to objectively assess physical activity; and (3) complete balance-related tasks on force platforms. Mann-Whitney U-tests were performed to understand differences in balance and physical activity between cyclists and non-cyclists. Cyclists are significantly more physically than non-cyclists ($U = 102.00$, $p = .015$; $U = 81.00$, $p=.002$). Cyclists had less sway velocity in eyes open conditions than non-cyclists ($U = 360.00$, $p=.009$), indicating a more tightly regulated postural control strategy that may relate to higher stability in cyclists. Task duration among cyclists in single-leg stand was longer than non-cyclists (left leg: $p < .001$ and right leg: $p < .005$) indicating increased postural stability. This study demonstrates the possible implications for cycling on balance and reducing fall risk.

PHYSICAL ACTIVITY IN DEMENTIA PATIENTS AND CAREGIVERS

Prabhash Kakarla,[1] Madieska Ramirez,[2] Jessica Alvarez,[2]
Marzena Gieniusz,[2] ann swartz,[3] sergey tarima,[4]
Chris Nouryan,[5] and Edith Burns[6], *1. Hofstra University, New Hyde Park, New York, United States, 2. Hofstra-Northwell, New Hyde Park, New York, United States, 3. University of Wisconsin-Milwaukee, Milwaukee, Wisconsin, United States, 4. PhD., Milwaukee, Wisconsin, United States, 5. Zucker School of Medicine at Hofstra Northwell, Uniondale, New York, United States, 6. Zucker School of Medicine at Hofstra Northwell, Manhasset, New York, United States*

Many studies have explored the benefits of physical activity (PA) in mitigating risk for and symptoms of dementia. However, there are challenges to implementing PA with dementia patients. We conducted an acceptability/feasibility study of PA in patients with Dementia and their caregivers. A semi-structured telephone interview was conducted. Questions piloted with 2 independent faculty for content validity. A random sample of 10 participants was recruited from patient-caregiver dyads enrolled in an Alzheimer's Dementia Care program (ADCP) at an academic geriatrics practice. Responses manually recorded and personal health information omitted. Descriptive statistics generated using SPSS and response themes categorized by the authors. Major themes included lack of time for caregivers; time requirement would increase caregiver burden (50%). Caregivers of patients with home health aides were less likely to consider time a barrier. Other themes included functional status as a challenge (40%), difficulty motivating patient (40%), unsteady gait (20%), difficulty using devices for video-based exercise (20%). Caregivers expressed preference for asynchronous, in-home PA that could be adapted to their schedules and patient capabilities. Although PA is beneficial for patients with dementia, multiple challenges to PA implementation exist. Main barriers are time requirements and greater caregiver burden. Time would be required to motivate patients, assist with managing technology, and functional impairment that poses potential risk of injury (e.g., gait instability). Engaging Home Health Aides in PA programs could address some of these barriers. Alternative PA (i.e.: chair exercises) could be a solution. Responses will be utilized to modify a future PA intervention.

OLDER ADULT ONLINE EXERCISE CLASSES DURING THE COVID-19 PANDEMIC: A SURVEY OF SERVICE PROVIDER PERSPECTIVESS

Dallas Murphy,[1] Michelle Porter,[2] Ruth Barclay,[2]
Stephen Cornish,[2] Jacquie Ripat,[2] Kathryn Sibley,[2]
Sandra Webber,[2] and Nicole Dunn[2], *1. University of Manitoba, WINNIPEG, Manitoba, Canada, 2. University of Manitoba, Winnipeg, Manitoba, Canada*

COVID-19 rendered the availability of exercise facilities sporadic and online exercise programs subsequently became more common. This research explored online exercise classes delivered to older adults during the pandemic from the perspective of service providers. Sixty-seven service providers completed the survey (88% female). The majority (54%) of respondents had worked in the fitness industry for greater than 10 years, and 66% were fitness class instructors, while fewer were managers (9%) and personal trainers (8%). Three participants had experience providing online exercise classes prior to the pandemic, while 43 more had experience providing online exercise classes since the pandemic began. Of these 46 service providers, 87% offered classes live through Zoom. The majority (64%) offered classes through an organization, and 61% charged a fee for participants to take part. The most common type of class was a general fitness class (63%), followed by yoga and flexibility classes (39%), and strength training (17%). Regarding equipment used, weights were most frequently required (69%), followed by resistance bands (49%) and mats (44%). Most classes lasted 40–60 minutes (59%) and were low intensity (74%). Of the 21 respondents who did not provide online exercise classes, 43% indicated this was because of a lack of interest, and 19% cited not knowing how to use technology to deliver classes online, though most (71%) indicated they would consider offering online classes in the future. This research reveals the adaptability of service providers and may serve to inform the continued development of online exercise programs for older adults.

OBESE AFRICAN AMERICAN OLDER WOMEN'S EFFECT OF EXERCISE TRAINING ON HEALTH CAPABILITIES AND LIFE SATISFACTION

Dongwook Cho,[1] and Sung Kyeom Kim[2], *1. Alcorn State University, Lorman, Mississippi, United States, 2. Dongseo University, Busan, Pusan-jikhalsi, Republic of Korea*

The purpose of this study is to determine whether a 12-week exercise course influences obese African American older women's health capabilities and life satisfaction levels. Participants, who passed an initial screening and pre-assessment, were asked to measure current health capabilities and life satisfaction levels both prior to, and following, the 12-week exercise training. Researchers found that improvement in health capabilities, although there were no significant differences following exercise training participation, while obese African American older women had significantly higher life satisfaction levels. The findings suggest that a 12-week exercise training can be beneficial to enhance obese African American older women's health capabilities and life satisfaction levels. Professionals in the field of gerontology and exercise should provide the appropriate exercise trainings so that obese African American older women would be able to optimize their life satisfaction levels.

MUSCLE GROUP SPECIFIC SKELETAL MUSCLE AGING: A FIVE YEAR LONGITUDINAL STUDY IN SEPTUAGENARIANS

Masatoshi Naruse, William Fountain, Alex Claiborne, Holmes Finch, Scott Trappe, and Todd Trappe, *Ball State University, Muncie, Indiana, United States*

Most of the scientific literature on human skeletal muscle aging has focused on the quadriceps femoris, with the remaining few hundred skeletal muscles receiving limited specific investigation. This longitudinal investigation compared changes in skeletal muscle size via computed tomography of the quadriceps (rectus femoris, vastus lateralis, vastus medialis, vastus intermedius), hamstrings (biceps femoris short and long heads, semitendinosus, semimembranosus), psoas, rectus abdominis, lateral abdominals (obliques and transversus abdominus), and paraspinal muscles (erector spinae and multifidi) of older individuals from the Health ABC study at baseline and 5.0±0.1 years later (n=469, 73±3y & 78±3y, 49% women, 33% black). Skeletal muscle size decreased ($p < 0.05$) in quadriceps (-3.3%), hamstrings (-5.9%), psoas (-0.4%), and rectus abdominus (-7.0%). The hamstrings and rectus abdominus atrophied approximately twice as much as the quadriceps ($p < 0.05$), while the quadriceps atrophied substantially more than the psoas ($p < 0.05$). The paraspinals (+4.3%) and lateral abdominals (+5.9%) hypertrophied ($p < 0.05$) to a similar degree ($p>0.05$) over the 5 years. These data suggest that skeletal muscle mass in older individuals changes in a muscle group specific fashion in the eighth decade, a critical time period in the aging process. A broader understanding of muscle group specific skeletal muscle aging is needed to better guide exercise programs and other interventions that mitigate decrements in physical function with aging.

INFLUENCE OF ASPIRIN ON AGING SKELETAL MUSCLE SIZE

William Fountain, Masatoshi Naruse, Alex Claiborne, Holmes Finch, Scott Trappe, and Todd Trappe, *Ball State University, Muncie, Indiana, United States*

Aspirin is one of the most commonly consumed cyclooxygenase (COX)-inhibitors and anti-inflammatory drugs and may provide insight into the control of age-related skeletal muscle atrophy. This investigation compared skeletal muscle size (via computed tomography) of older individuals from the Health ABC study that did not consume aspirin or any other COX-inhibiting drug (non-consumers; n=1,155, 74±3y, 48% women, 45% black) to those that consumed aspirin daily (and not any other COX-inhibiting drug) and for at least one year (aspirin consumers; n=515, 74±3y, 39% women, 30% black, average aspirin consumption: 6y). In white and black men, the long-term aspirin consumers had significantly larger quadriceps muscle size compared to non-consumers ($p < 0.05$). In white men only, these differences were influenced by age ($p < 0.05$). In white and black women, quadriceps muscle size was not different between the aspirin consumers and non-consumers ($p>0.05$). In men and women of either race, there was no hamstrings muscle size difference between the aspirin consumers and non-consumers ($p>0.05$). These data suggest that long-term regulation of the COX pathway with the common over-the-counter drug aspirin may impact aging muscle mass in a sex and muscle group specific fashion, which is supported by previous mechanistic human and animal studies.

FEASIBILITY AND ACCEPTABILITY OF A HYBRID AEROBIC EXERCISE PROGRAM FOR OLDER ADULTS DURING THE COVID-19 PANDEMIC

Emily Erlenbach,[1] Revati Malani,[2] Edward McAuley,[1] and Neha Gothe[3], *1. University of Illinois, Urbana Champaign,* *Urbana Champaign, Illinois, United States, 2. University of Illinois--Urbana-Champaign, Urbana Champaign, Illinois, United States, 3. University of Illinois at Urbana Champaign, Urbana, Illinois, United States*

The COVID-19 pandemic and ensuing lockdowns, physical distancing and mask mandates exacerbated the challenges older adults (OAs) face towards exercise engagement. We present data on the feasibility, safety, and acceptability of a hybrid (in-person and virtual) aerobic exercise program for OAs. Nf39 (30 females, Mage=64.10) low-active OAs completed an aerobics-based exercise program as part of a larger ongoing RCT. Participants exercised 3x/week by attending one in-person and two Zoom-based exercise classes. Attendance, attrition, format preferences, and adverse events were documented. Participants also completed an anonymous survey to detail their experiences with the hybrid delivery model. Thirty participants completed the program. Total average attendance of 83.64%; 58.93% and 24.71% of the attended sessions were on Zoom and in-person, respectively. On post-program surveys, 36.67% reported preferring Zoom sessions, followed by 33.33% preferring both formats equally. No adverse events were reported. From the anonymous program feedback surveys, common reasons for preferring the Zoom sessions included convenience; not having to wear a mask; not worrying about COVID exposure; and not feeling self-conscious about exercising with others. Commonly reported reasons for preferring the in-person sessions were increased motivation from group energy; social support; more space to move around; and better engagement with instructors. Collectively, these findings show a hybrid aerobic exercise program is feasible and safe for OAs to engage in and is overall well-accepted. Findings are encouraging for the design of future exercise programs for OAs, who continue to remain a vulnerable population during the pandemic but need a structure to remain sufficiently active.

EFFECTS OF FLAVANOL (+)-EPICATECHIN ON SKELETAL MUSCLE OF AGED RATS

Israel Ramirez-Sanchez,[1] Viridiana Navarrete,[2] Leonor Galera,[2] and Francisco Villarreal[3], *1. University of California San Diego, Mexico City, Distrito Federal, Mexico, 2. IPN, Mexico City, Distrito Federal, Mexico, 3. UCSD, San Diego, California, United States*

Sarcopenia is a progressive and generalized age-related skeletal muscle (SkM) disorder characterized by the accelerated loss of muscle mass (atrophy) and function. SkM atrophy is associated with increased incidence of falls, functional decline, frailty and mortality. In its early stage, SkM atrophy is associated with oxidative stress, increased pro-inflammatory cytokine levels and proteasome-mediated protein degradation. These processes also link to the activation of atrophy associated factors and signaling pathways which lack any approved, targeted pharmacotherapy. We have characterized the capacity of flavanols specifically, epicatechin to favorably modulate SkM mass and function in animal models of SkM disease and in proof of concept studies in humans including muscular dystrophies. In this study we wished to evaluate the capacity of this flavanol to ameliorate aging associated sarcopenia. Using 24-month-old male rats a 4 week oral administration of the flavanol (+)-epicatechin (1mg/kg/day) was implemented while control rats only received vehicle (water). SkM strength (grip) and endurance (treadmill walk), muscle size, (muscle mass, cross sectional area of fibers), ubiquitin-proteasome atrophic pathway (including myostatin, Murf1 and Atrogin1 by Western blots) and markers of oxidative stress and inflammation in gastrocnemius were quantified. We also analyzed a relevant protein synthesis pathway (IGF/AKT/mTOR). The use of (+)-epicatechin in aged rats led to significant changes as follows: 1) improved SkM mass and function, 2) downregulation of atrophic pathway, 3) reduced levels of oxidative stress and proinflammatory cytokines and, 4) upregulation of protein synthesis pathway. Given its safety and tolerance profile this agent warrant its rigorous investigation in clinical trials.

EFFECTS OF A SIX-MONTH EXERCISE PROGRAM ON PHYSICAL ACTIVITY AMONG OLDER ADULTS WITH CHRONIC CONDITIONS

Revati Malani,[1] Emily Erlenbach,[2] Edward McAuley,[2] and Neha Gothe[3], *1. University of Illinois--Urbana-Champaign, Urbana Champaign, Illinois, United States, 2. University of Illinois, Urbana Champaign, Urbana Champaign, Illinois, United States, 3. University of Illinois at Urbana Champaign, Urbana, Illinois, United States*

Health benefits of structured physical activity (PA) for older adults have been well documented. Older adults are highly impacted with major chronic conditions, leading to limitations in daily activities. This study examined the effects of an exercise program on moderate-vigorous physical activity (MVPA) and sedentary time after six months of exercise. Participants from a larger-ongoing trial were randomized into either yoga, aerobic or stretch-tone groups. A subsample of 58 participants was classified as chronic individuals (CI) based on presence of at least one chronic condition, and 31 as healthy individuals (HI), who completed accelerometer measures before and after the exercise program. A repeated measures analysis was performed to identify changes in PA over time for HI and CI. At both time-points, MVPA was significantly higher for HI. There was a significant increase in MVPA at month six for all participants, irrespective of health status. Mean MVPA in minutes for baseline HI: 153, CI: 98 and for month 6 HI: 188 CI: 116. There were no significant differences in sedentary time after the six-months of exercise. Although there was an increase in MVPA for HI and CI after structured exercise, no change was noted for sedentary time. Increased sedentary time has been proven to be a risk factor for poor health and although meeting criteria for MVPA is important, it is essential to address sedentary time in CI by implementing educational and interventional components that focus specifically on sedentary time. Funding: This data is from NCT04323163 funded by NIH-NIA – grant-AG066630.

DOES TAI CHI PROMOTE COGNITIVE FUNCTION WITHOUT THE EFFECTS OF PHYSICAL FUNCTION?: META-REGRESSION APPROACH

Rhayun Song,[1] Moonkyoung Park,[1] Jacqueline Shin,[2] Xianqi Gao,[1] and Yuelin Li[1], *1. Chungnam National University, Daejeon, Taejon-jikhalsi, Republic of Korea, 2. Indiana State University, Terre Haute, Indiana, United States*

This systematic review aimed to examine the effects of TCQ on cognitive and physical functions in older adults using a meta-regression approach. The systematic search in 13 electronic databases identified 19 randomized studies (n=2365, mean age=70.3 years) published in English (k=17), Korean (k=1) and Chinese (k=1). A review of bias was assessed by two raters according to Cochrane RoB 2.0, resulting in low risk (k=6), some concern (k=12), and one high-risk study. Tai Chi (k=16) and Qigong (k=3) were applied for an average duration of 20.2 weeks. The control groups received either alternative exercise (k=14) or no treatment (k=5). The results of the meta-analysis on 19 RCTs using a random-effects model showed the significant effect of TCQ on cognitive function (Hedges's g =0.32, 95% CI= 0.18, 0.46) and physical function (Hedges's g= 0.35, 95% CI= 0.21, 0.49). In addition, meta-regression was used to explore the effect size of TCQ in association with the level of physical function. The effects of TCQ on cognitive function remained significant (Q=38.86, p=.003) when controlling for the effect of physical function in this model (unexplained variance = 0.0199). The coefficient of the physical function was significant (b=0.47, p=.008), showing that 58% of heterogeneity was explained by physical function as a moderator variable. It confirmed that changes in physical function were associated with changes in cognitive function. The findings imply the potential health benefits of TCQ in promoting cognitive function among older adults directly and indirectly through improving physical function.

CONSTRUCT VALIDITY OF EXERCISE ADHERENCE RATING SCALE IN COMMUNITY DWELLING OLDER WOMEN: PROOF OF CONCEPT

Helen Graham, Judith Scott, and Melissa Benton, *University of Colorado Colorado Springs, Colorado Springs, Colorado, United States*

Exercise is an effective health promotion strategy that has a positive effects on frailty and sarcopenia, particularly in older women, yet they do not adhere to exercise guidelines. Accurate assessment is critical for clinical management and research with this population. Interviews and exercise logs are most commonly used to assess adherence to exercise. However, they are burdensome and not highly reliable. A brief validated measure of exercise adherence for assessment is greatly needed. The six-item Exercise Adherence Rating Scale (EARS) was originally validated among a clinical orthopedic population but not been used in community-dwelling adults. Our aim was to determine the feasibility of using the EARS to assess exercise adherence among community-dwelling older women. Twelve women (age=72±7 years) completed one-time assessment for this proof-of-concept study. For the EARS, overall Cronbach's alpha was 0.78 with inter-item correlations of 0.72–0.89 for all but item three that pertains to healthcare professionals (correlation of 0.27). When item three was removed, overall Cronbach's alpha increased to 0.80. Correlation analysis with the reduced five-item scale demonstrated good construct validity. There were significant relationships with global quality of life (r=0.76, p < .01) and physical function (r=0.61, p < .05). There were also moderate to strong relationships with variables expected to be linked to exercise adherence including mobility (r=0.57), BMI (r=0.51), vigorous (r=0.40) and moderate (r=0.36) exercise, upper body strength (r=0.41) and lower body strength (r=0.30). Based on these findings use of a five-item version of the EARS is feasible and appears to be a valid measure of exercise adherence.

THE IMPACT OF THE OLD AGE PENSION EXPANSION ON BLOOD PRESSURE AMONG OLDER MEN IN RURAL SOUTH AFRICA

Haeyoon Chang,[1] Janet Jock,[2] Molly Rosenberg,[3] and Lindsay Kobayashi[4], *1. University of Michigan-Ann Arbor/School of Public Health, Ann Arbor, Michigan, United States, 2. O'Neill School of Public and Environmental Affairs, Bloomington, Indiana, United States, 3. Indiana University/School of Public Health, Bloomington, Indiana, United States, 4. University of Michigan, Ann Arbor, Michigan, United States*

The impact of improved socioeconomic welfare after retirement on cardiovascular health among older men in low-income settings is unknown. Using natural experiment, we investigated the impact of eligibility for additional Old Age Pension (OAP) income on systolic blood pressure (SBP) among older men in rural South Africa using data from 1,208 men aged ≥60 in the population-representative "Health and Aging in Africa: A Longitudinal Study of an INDEPTH Community in Rural South Africa" (HAALSI) cohort. The South African Old Age Pension (OAP) incrementally expanded age eligibility for men from age 65 prior to 2008 to age 60 in 2010. This expansion provided exogenous variation in pension income among men, based on their year of birth. We estimated predicted SBP among the birth cohorts of men who were eligible for one through five extra years of OAP income, using a multivariable linear regression model estimated in those without access to extra pension income (over age 65 when the expansion rolled out) based on covariates. We then estimated mean SBP difference scores among men in each of these five birth cohorts, based on their observed SBP minus predicted SBP. Men in OAP expansion birth cohorts had lower SBP than those who were not exposed to extra pension, although the differences were not statistically significant (5-years estimate = -2.735 (p=0.353) vs. 1-year estimate = 1.633 (p=0.531)). This trend suggests a possible long-term benefit of blood pressure control with greater cumulative pension income among men living in rural, low-income settings.

ENTERING MEDICARE ADVANTAGE FROM EMPLOYER-SPONSORED PLANS: CHANGE IN OUT-OF-POCKET COSTS AND UTILIZATION AT AGE 65

Alexandra Glynn Hames, and Eric Roberts, *University of Pittsburgh, Pittsburgh, Pennsylvania, United States*

An increasing proportion (nearly 40%) of older adults entering Medicare at age 65 are electing to enroll in private Medicare Advantage (MA) plans, which reflects more generous coverage relative to traditional Medicare and similarity to many features of employer sponsored plans. However, few studies have examined the impact of transitioning to MA from an employer-sponsored plan on out-of-pocket costs and health services utilization. We used longitudinal administrative data from Optum Insights between 2010 and 2021 to follow individuals from ages 62 through 67, spanning continuous enrollment in employer-sponsored insurance and MA. We employed an event-study design to estimate within-person changes in our outcomes after individuals entered to MA at age 65 (n=5,548), controlling for linear age trends. Relative to ages 62–64, MA enrollees at ages 66 and 67 had lower out-of-pocket spending on outpatient services (-$503/year, 95% CI: -$602, $404), emergency department visits (-$27/year, 95% CI: -$35, -$19), and prescription drugs (-$77/year, 95% CI: -$101, -$53). In contrast, utilization of outpatient services increased (1.4 visits/year, 95% CI: 0.8, 2.0), including physician evaluation and management visits (0.46 visits/year, 95% CI: 0.25, 0.68). After entering MA, individuals were more likely to have physician office visits with no out-of-pocket costs than at ages 62–64 (0.99 additional zero-cost visits/year, 95% CI: 0.81, 1.2). These results suggest MA may offer older adults more affordable care for routine and chronic conditions, compared to employer-sponsored insurance. These findings are timely as policymakers continue to deliberate proposals, such as expanding Medicare eligibility, to improve access to affordable insurance.

ASSESSING THE NEW INFLATION REDUCTION ACT'S IMPACT ON EXPANDING MEDICARE PART D LOW-INCOME SUBSIDIES

Feng-Hua Loh,[1] and Bruce Stuart[2], *1. Touro College of Pharmacy, New York, New York, United States, 2. University of Maryland School of Pharmacy, Baltimore, Maryland, United States*

The recently enacted Inflation Reduction Act (IRA) of 2022 extends full low-income subsidies (LIS) to Medicare Part D recipients with limited assets and incomes up to 150% of the Federal Poverty level (FPL) beginning in 2024. Under current law, full Part D subsidies (no annual premiums and nominal cost sharing) are available only to those with incomes up to 135% of the FPL. Partial subsidies are available to those with incomes between 135% and 150% of FPL. Increasing the level of benefits to those currently only eligible for partial subsidies has the potential of significantly lowering out-of-pocket medication costs that pose a barrier to adherence for many low-income Medicare beneficiaries, but the outcome of the new policy will depend on how many enroll. Historically, enrollment among those eligible for partial subsidies has hovered around 30%, but the latest data on LIS participation rates are for 2014. We undertook this study to update LIS eligibility and enrollment numbers to 2019, with a particular emphasis on identifying characteristics of beneficiaries who may benefit from the new policy. Using data from the Medicare Current Beneficiary Survey, we determined that 73% of beneficiaries eligible for full subsidies under current law were enrolled, but only 25% eligible for partial subsidies were enrolled. We conclude that while the IRA will raise the overall level of Part D subsidies, it will be important to engage stakeholders and promote outreach to maximize participation in the leadup to implementation.

AGE DIFFERENCES IN DISTINCT TYPES OF SOCIAL INTERACTIONS AND EMOTIONAL WELL-BEING

Yuxuan Chen,[1] Kevin Chi,[2] and Laura Carstensen[2], *1. Stanford University, Stanford, California, United States, 2. Stanford University, Palo Alto, California, United States*

Social interaction is central to emotional well-being. However, less is known about how the surroundings of social interactions are associated with emotional well-being and whether they differ by age. The present study examined age differences in the predication of emotional well-being as a function of two aspects of social interactions: (1) the extent to which individuals would rather be interacting with someone else and (2) the degree of closeness to the interactant(s). A sample of 190 people, aged 18 to 94 years, participated in an experience sampling study where they reported emotional experience and aspects of the social interaction at five randomly selected times each day across a one-week period for a total of 35 randomly selected occasions. Across age groups, the greater the extent to which people would rather be interacting with someone else was associated with higher levels of negative emotion and lower levels of positive emotion. However, these associations were more pronounced for younger adults, who compared to older adults, experienced greater increases in negative emotions and greater decreases in positive emotion in these contexts. Furthermore, younger but not older adults experienced lower levels of negative emotion when interacting with someone they knew well. Results highlight the important role that age plays in the link between daily social interactions and emotional well-being. Age differences in social interactions, emotional resilience, and situation selection will be discussed.

VARIATIONS IN BENEFITS OF INTERGENERATIONAL TUTORING IN THE "NEW NORMAL"

Peter Sun,[1] Nancy Morrow-Howell,[2] Mary Click,[3] and Kendra Minch[3], *1. Washington University in St. Louis, Clayton, Missouri, United States, 2. Washington University in St. Louis, St. Louis, Missouri, United States, 3. The Oasis Institute, St. Louis, Missouri, United States*

This study explored variations in self-perceived benefits of intergenerational tutoring. The study's sample consisted of 329 older adults who tutored children in-person in the 2021–2022 school year. Due to the COVID-19 pandemic, some of the respondents had experienced a period in which volunteering was remote, virtual, or not possible. Demographic information was collected in a fall pre-test survey, identifying first-time volunteers (first time volunteering in ten years), caregivers (100 or more hours in the last two years helping someone who needed assistance), and male volunteers. Self-perceived benefits of tutoring (physical, emotional, and cognitive health, increased social activities, use time more productively, contribute to the well-being of children, and feel better about myself) were collected in a spring post-test survey. Being a first-time volunteer was significantly associated with improved health (X2 = 4.17, p = 0.041, Cramer's V = 0.11), even after controlling for baseline self-reported health (p = 0.020). A larger proportion of first-time volunteers (34.2%) reported improvements in at least two areas of health (physical, emotional, and cognitive) due to their involvement in the intergenerational tutoring program, compared to non-first-time volunteers (18.5%). There were no significant differences in perceived benefits for caregivers or males. These findings suggest that targeting non-volunteers for involvement in tutoring programs may maximize health benefits of engagement. Specifically targeting males and caregivers may not be necessary, given that they benefit similarly to other populations.

TRAIT SELF-CONTROL AND ATTACHMENT ANXIETY IN RETIREES' DEPRESSIVE SYMPTOMS AND EMOTIONAL WELL-BEING.

Jensine Paoletti,[1] E. Lim Lydia Wu-Chung,[1] Ryan Brown,[2] Michelle Chen,[3] Angie LeRoy,[4] and Christopher Fagundes[1], *1. Rice University, Houston, Texas, United States, 2. Rice University, Houston, Texas, United States, 3. Northwestern University, Evanston, Illinois, United States, 4. Baylor University, Waco, Texas, United States*

Trait self-control (TSC) is a well-known predictor of well-being. TSC may reduce distraction from hedonistic pursuits and enable more effective goal-directed behavior. Attachment anxiety (AA) is a trait that predicts lower relationship quality and lower well-being; people high on AA are characterized by hyper-sensitivity, proximity-seeking and excessive rumination. In retirement, these traits may interact to predict wellbeing. Methods: 120 retired participants took part in data collection (M = 62.37 years old; SD = 10.07 years; 68% women, 70% white). Data collection included self-reported AA (Experience in Close Relationships), TSC (Brief Self-Control Scale), depressive symptoms (Center for Epidemiological Studies Depression Scale) and emotional well-being (RAND 36-Item Health Survey). We conducted hierarchical linear regressions and accounted for demographic and health-related covariates. Results: TSC was negatively related to depressive symptoms and positively related to emotional well-being. AA was positively related to depressive symptoms and negatively related to emotional well-being. We found an interaction predicting depressive symptoms such that participants with low TSC and high AA had the highest depressive symptoms ($p = .036$). This interaction was not significant for emotional well-being. Discussion: After retiring, maintaining a healthy social life may be more effortful, as there are fewer 'built-in' social interactions (i.e., with coworkers). Retirees with higher TSC may be able to maintain their social life more effectively than those with lower TSC. Similarly, people with lower AA may be able to obtain more enjoyment from their social lives. Together, lower AA and higher TSC may be protective mechanisms for depressive symptoms.

PARKINSON'S DISEASE AND STIGMA: A MULTIPLE CASE STUDY

Beth Mastel-Smith, and Melinda Hermanns, *The University of Texas at Tyler, Tyler, Texas, United States*

Parkinson's disease (PD) is a neurodegenerative disorder caused by dopamine deficiency. PD affects emotional and physical health and causes people with PD and caregivers to experience stigma. Four types of stigma have been described: public, associated, self-, and structural. The aims of this study were to explore (a) how stigma is experienced by people with PD and caregivers, (b) whether stigma towards people with PD and caregivers is represented in the literature and social media and (c) examine whether findings support Stigma Theory and theoretical propositions. This was a multi-case qualitative study. Cases included a literature review, interviews with people with PD and caregivers, and examination of social media posts. A purposive sample included seven people with PD and five caregivers who were interviewed online using an interview guide. The study was approved by the University IRB and participants signed consent. Thematic analysis identified codes which aligned with conceptual definitions of Stigma Theory. Findings revealed that public stigma was presented in all four cases. Self- and structural stigma were represented in the literature and interviews with people with PD and caregivers. Associated stigma appeared in the literature and from caregivers' descriptions. Three of six theoretical propositions were supported. Four types of stigma toward people with PD were prevalent and interrelationships between types of stigma noted. A multi-pronged approach to reducing stigma is needed at the individual, organizational and community levels. Research regarding stigma experienced by diverse populations and the health effects of stigma for people with PD is recommended.

CONTEMPLATING TEMPORAL LANDMARKS, SENSING TIME, AND PURSUING A MEANINGFUL LIFE IN ADULTHOOD

DaEun Kim, and Hsiao-Wen Liao, *Georgia Institute of Technology, Atlanta, Georgia, United States*

Research has shown that experiencing and anticipating temporal landmarks affect one's goal priorities and motivation. Particularly, milestone birthdays (MBD) remind people of where they stand in life timeline, prompting time experience that has consequences for pursuit of meaning. The current study examines this thesis in the context of adult development and aging. We tested whether (1) thinking about past and future MBDs (vs. a regular birthday) affects young, middle-aged, and older adults' possession of and search for meaning in life and (2) sense of time, and (3) the association between contemplating MBDs and meaning in life is, at least in part, explained by sense of time. Participants (N = 239) were randomly assigned to one of the three conditions to verbally visualize a past MBD, a future MBD, or an upcoming regular birthday. They then completed a meaning in life questionnaire, which assessed presence of and search for meaning (Steger et al., 2016). Future time perspective (Lang & Carstensen, 1996) and time savoring (Carstensen et al. in prep) were also measured. We found that thinking about past and future MBDs (vs. regular birthdays) prompted people to search for meaning. Thinking about past MBDs (vs. regular birthdays) also elicited a sense that time left in life is limited. Mediation analysis indicated that perceived future time constraints helped explain the relation of recalling past MBDs to search for meaning. Results held when age effects were considered. We draw on motivation theories of temporal landmarks and socioemotional selectivity to discuss the findings.

BASELINE PURPOSE IN LIFE PREDICTS FUNCTIONAL HEALTH ACROSS 16 WEEKS IN OLDER ADULTS WITH PROGRESSIVE VISION LOSS

Wingyun Mak,[1] and Silvia Sörensen[2], *1. The New Jewish Home Research Institute on Aging, New York, New York, United States, 2. University of Rochester, Rochester, New York, United States*

Greater purpose in life is associated with various positive outcomes in later life, such as, lower mortality risk, protection against cognitive decline, and lower spending on medical care and emergency room visits. Recent research

from the Health and Retirement Study has shown that older adults with greater purpose in life have fewer physical limitations after four years. There has been no research to investigate purpose in life in older adults with progressive vision loss. The aim of this study is to examine whether purpose in life predicts functional health (i.e., activities of daily living) across a 16-week period of time in a sample of older adults (aged 60–96) with vision loss due to macular degeneration who were enrolled in a resilience building program (Nf 122). A repeated measures GLM showed that functional health did not change across 16 weeks (ns). Age ($F(1, 112)=8.91$, $p=.003$, $\eta p2=.07$) and purpose in life ($F(1,112)=13.21$, $p < .001$, $\eta p2= .11$) were significant overall predictors of functional health across time. Gender, education, cognition, marital status, depression, and loneliness at baseline were not associated with overall functional health. People who were younger were more likely to have better functional health over 16 weeks; purpose in life added 11% of explained variance. Because purpose in life is malleable and also significantly associated with better functional health in older adults with progressive vision loss, future interventions that enhance purpose in life should be studied with this population.

TESTING A NEW MODEL OF REABLEMENT-FOCUSED INTEGRATED CARE IN ADULT DAY SERVICE USERS IN TAIWAN: A PRELIMINARY STUDY

Yu-Ting Chang,[1] Hsiao-Wei Yu,[2] and Pay-Shin Lin[1], *1. Chang Gung University, Taoyuan, Taoyuan, Taiwan (Republic of China), 2. Chang Gung University of Science and Technology, Taoyuan City, Taoyuan, Taiwan (Republic of China)*

There is a growing consensus that implementing personal-centered therapeutic activities at adult day services (ADS) leads to functional improvement in care recipients and reduces the burden on caregivers. Taiwan has introduced reablement-focused integrated care (RFIC) model for ADS users, the effects of this new model merit investigation. This study aimed to examine whether the RFIC model promotes physical and mental function in care recipients and improves caregiver satisfaction. We recruited ADS-care recipients and their family caregivers ($N = 14$ dyads) through purposive sampling for a quasiexperimental study. Six dyads were assigned to the RFIC intervention group and eight dyads to the control group. The RFIC intervention consisted of ten one-hour sessions over two months. The functional abilities of care recipients and the care satisfaction of caregivers were assessed at baseline and after the intervention. The RFIC group, compared to the control group, showed an improvement in care satisfaction score, and the group difference was significant (RFIC group: mean (SD) change score = 1.17 (2.64); control group: mean (SD) change score = −3.38 (2.20); $p < 0.01$). There were no differences in physical and mental function between the RFIC and control groups. These preliminary results suggest that when reablement is used as a means of personal-centered therapeutic training for ADS users, it can help caregivers cope with care problems and improve how they appraise their mastery and satisfaction as regards care. However, the effects of RFIC on the physical and mental function of care recipients require further investigation.

PHOTO-ELICITATION- A VIEW OF DEEP OLD AGE AND SOCIAL INCLUSION

Elaine Eliopoulos, *University College London, London, England, United Kingdom*

Photo-elicitation- A View of Deep Old Age and Social Inclusion While visual methodologies have gained prominence in aging research, focus on deep old age has been uncommon. The variety of visual representations portraying a range of 'ageless aging' to frail older people may not fully capture daily lived experience. The inclusion of those in deep old age to depict their aging bodies is a crucial missing element enhancing our understanding of the nuances of deep old age. This study fills that gap. Photo-elicitation, followed by semi-structured interviews, was used to examine the role of the body for participants 80 years+ in three US island contexts to understand what impact, if any, their bodies had on their ability to be socially included in ways they chose. Digital cameras were provided to participants to photograph their lived bodily experience. Those who had visual challenges were assisted in taking photographs. Recent analysis of the photographs revealed important findings that will contribute to theoretical development of deep old age: participants who took photos without assistance did not take a single photograph of their bodies. They took photos primarily of their environment and places of community connections while minimising physical challenges. Their photos contextualised their experience of the physical challenges that played a role in their sense of inclusion within their communities. This finding questions current dominant models of the third and fourth age as dichotomous formulations related to embodied agency. In doing so it opens new possibilities for theoretical reflection on deep old age.

PERCEPTIONS OF ADRD CARE PARTNERS IN A VIRTUAL CO-DESIGN PROCESS

Nicole Werner,[1] Anna Jolliff,[1] Reid Parks,[2] Anna LINDEN,[3] Christian Elliott,[4] and Matthew Zuraw[5], *1. Indiana University School of Public Health-Bloomington, Bloomington, Indiana, United States, 2. University of Wisconsin - Madison, Madison, Wisconsin, United States, 3. University of Wisconsin-Madison, Madison, Wisconsin, United States, 4. CareVirtue, Palm Springs, California, United States, 5. DialedIn Solutions, San Diego, California, United States*

Participatory design, or co-design, is an effective method for creating useful digital products with older adults. However, little is known about older adults' perceptions of virtual co-design. The purpose of this study was to explore ADRD care partner perceptions of their participation in virtual co-design, including the degree to which participants felt their participation influenced the design. After participating in a 5-session virtual co-design process, care partners completed individual semi-structured interviews and surveys focused on exploring their perceptions of the co-design process. Surveys used three sliding scale items and open text responses. Interview transcripts and survey data were analyzed using thematic analysis and descriptive statistics, respectively. Co-designers were Nf7 older adults (71% female) with a mean age of 65. On a scale of 1–100, co-designers rated the extent to which their own participation influenced the design process at a mean of 88, their fellow co-designers at 90, and the research team at 82. Thematic analysis identified five design process perceptions: 1) the process built community among co-designers; 2) sessions were well-facilitated and organized; 3) the prototype would be helpful to other care partners like them; 4) co-designers felt ownership over the prototype; and 5) co-designers had long-term goals for the product. Results suggest that care partners perceived themselves as having considerable influence on the final prototype. Those designing interventions for ADRD care partners should be encouraged that involving them in the design process may provide unanticipated benefits to care partners and build an intervention responsive to care partner needs.

IMPROVING MEDICATION MANAGEMENT FOR HOME-DWELLING OLDER ADULTS WITH COGNITIVE IMPAIRMENT: END-USER INPUT

Rana Zadeh,[1] Cary Reid,[2] Elaine Wethington,[3] Sara Czaja,[2] Elizabeth Capezuti,[4] Wendy Shields,[5] and Deb Traunstein[6], *1. Cornell University, Ithaca, New York, United States, 2. Weill Cornell Medicine, Ithaca, New York, United States, 3. Cornell, Ithaca, New York, United States, 4. Hunter College of the CUNY (City University of New York), New York, New York, United States, 5. Johns Hopkins University, Baltimore, Maryland, United States, 6. Visiting Nurse Service of Ithaca and Tompkins County, Ithaca, New York, United States*

HOPES™ Program is a joint community-university partnership, intended to build capacity for improving medication adherence and reducing medication mistakes, misuse, and abuse for community-dwelling older adults with reduced cognitive functioning (CWCs) in New York State (NYS). The goal of this program is to contribute to the health and safety of older adults, empower them and their caregivers to reduce medication non-adherence consequences and risks, and enable older adults to continue living at home while managing their health conditions. This program applied a collective user-centered approach to connect resources, identify and address barriers, and reach the most vulnerable groups. One aspect of our user-centered approach included a medication management and safety training module video that was adapted from the Medication Use Safety Training for Seniors™ (MUST for Seniors™) and underwent alpha and beta testing. A qualitative analysis was also conducted on input from home-care providers, CWCs, and their designated caregivers about the current practices, challenges, and solutions related to medication management. Our preliminary findings demonstrated a need for research on reducing the steep estimated national costs of medication non-adherence. Thus, a sub-team has developed a methodology to build an economic perspective on the scope and magnitude of interventions to enhance medication management practices for CWCs. A NYS-specific survey was also developed in close collaboration with providers, university partners, and state-level advocacy organizations according to our preliminary findings to document the state and magnitude of medication non-adherence, discern risk factors and determinants of non-adherence, and explore solutions and barriers.

CARING FOR CHILDREN WITH DISABILITIES, WORKING, AND SAVING FOR RETIREMENT OVER THE LIFE COURSE

Shirley Porterfield,[1] and Eunsun Kwon[2], *1. University of Missouri-St. Louis, Saint Louis, Missouri, United States, 2. Fairleigh Dickinson University, Florham Park, New Jersey, United States*

In the US, financial security in retirement depends on having savings and other assets accumulated during the pre-retirement years. Pension savings accrue over the working life, in defined-benefit or defined-contribution retirement plans. Mothers with children with disabilities experience different life-course work trajectories than mothers without children with disabilities, though data used in previous studies primarily examine a single point in time or a short span of years. This paper draws longitudinal data from the nationally-representative 1979 National Longitudinal Survey of Youth for the years 1987 through 2018, using a life-course perspective and sequence analysis to identify long-term work patterns among women with children who do and do not have disabilities with an explicit focus on variations in occupational class and employment status. We found a distinctive pattern of long-term work history with five types: Full-time semi-professional to not working, Constantly not working, Semi-professional full time, Professional full time, and Not working to full time work. Results from regression analyses revealed variation in mothers' household financial preparation for retirement at late mid-adulthood. Compared with mothers who held professional full-time jobs throughout their adulthood, mothers who started full time jobs in middle age and have children with disabilities were less likely to have pension plans. Mothers of children with disabilities who left the labor force in early middle age tended to have lower retirement savings. Policy interventions to address these mothers' caregiving ability to stay engaged in the workforce and prepare for their retirement need to be explored.

ANTI-AGING COMPOUNDS METFORMIN AND THIOFLAVIN T CAN ACT ON GENETICALLY DIVERSE, PROTEOSTASIS-COMPROMISED STRAINS

Monica Driscoll,[1] Brian Onken,[2] Yunpeng Xu,[2] Yuhua Song,[2] Madhuri Achanta,[2] Christine Sedore,[3] Patrick Phillips,[3] and Gordon Lithgow[4], *1. Rutgers, The State University of New Jersey, New Brunswick, New Jersey, United States, 2. Rutgers University, Piscataway, New Jersey, United States, 3. University of Oregon, Eugene, Oregon, United States, 4. Buck Institute, Novato, California, United States*

The Caenorhabditis Intervention Testing Program (CITP) seeks to identify robust and reproducible pro-longevity interventions affecting a genetically diverse panel of representative Caenorhabditis strains from each of 3 species – C. elegans, C. briggsae, and C. tropicalis. The CITP test strains represent genetic diversity on the order of mouse to human. Anchoring principles of the CITP are that efficacious interventions that target fundamental and conserved biology will hold strong potential for translation to higher organism benefit and that such interventions can be rapidly identified using Caenorhabditis models. The CITP is creating multi-species "at risk" test sets, in which components of aging hallmarks (such as proteostasis, stress response circuits) are genetically compromised in diverse genetic backgrounds. Such genetic test sets might expand understanding of intervention action and help rank compounds for translational testing. Toward this end, we used CRISPR to generate deletion mutants of arsenite-inducible protein (C. elegans aip-1, human AIRAP/ARAPL) in which proteostasis and oxidative stress responses are compromised across phyla. All aip-1 mutants are short lived compared to their control wild type strains, highlighting the essential role of proteostasis in maintaining healthy aging. Our previous studies identified metabolic modulator Metformin and anti-amyloid Thioflavin T as effective pro-longevity, pro-healthspan interventions in multiple CITP test strains. We find that Metformin and Thioflavin T impact the aip-1 deletion strains similarly to WT variants. Together, our results demonstrate that Metformin and Thioflavin-T can positively impact lifespan in diverse genetic backgrounds in which proteostasis is compromised, suggesting wide-ranging health benefits of these potent pro-longevity compounds.

WOMEN AT RISK: SOCIOECONOMIC STATUS, LIFESTYLE FACTORS, AND BRAIN VULNERABILITY AMONG JAPANESE AND SWEDISH FEMALE

Yingxu Liu,[1] Yasuko Tatewaki,[1] Benjamin thyreau,[1] Yinghao Liu,[2] Ye Zhang,[3] Nina Karalija,[4] Carl-johan Boraxbekk,[4] and Yasuyuki Taki[1], *1. Institute of Development, Aging and Cancer, Tohoku University, Sendai, Miyagi, Japan, 2. Tohoku University, Sendai, Miyagi, Japan, 3. Tohoku University, Sendai, Miyagi, Japan, 4. Umeå University, Umeå, Vasterbottens Lan, Sweden*

Background: While multiple modifiable lifestyle factors and disease management have been highlighted for preventing dementia and ameliorating neurodegeneration, women and the disadvantaged socioeconomic status (SES) population still bear disproportionate burdens. Objective: Investigate and compare the potential pathways of SES, lifestyle factors, imaging biomarkers, and cognition in two community dwelling cohorts in Japan and Sweden. Subjects: The Kumamoto Cohort included 576 cognitively healthy females (73.66 ± 5.96 years); the Betula Cohort included 195 cognitively healthy females (63.91 ± 13.41 years). Methods: We constructed structural equational modeling by lifestyle factors including exercise, social activity, sleep, drinking, and smoking status; disease conditions included obesity, diabetes, hypertension, and depressive disorder; brain imaging biomarkers included regional gay matter volume (GMV) and cortical thickness obtained from T1 weighted magnetic resonance imaging scans and global cognition score. We also examined SES-related gray matter volume and cortical thickness map locations at the whole brain level. Results: SES was positively associated with GMV of limbic lobe (not cortical thickness), Kumamoto Cohort: standardized direct β =0.21 (0.13;0.28); Betula Cohort: standardized direct β =0.27 (0.13; 0.41). This SES-GMV association was mediated by disease conditions and lifestyle in Kumamoto Cohort: indirect β =-0.013 (0.001; 0.054). We also found several regions, including the medial frontal gyrus, superior frontal gyrus, hippocampus, and thalamus, were commonly sensitive to SES status in two cohorts. Conclusions: Although the observational nature of the study precludes proof of causality, our findings suggest that promoting disease management is crucial to tackling the neurodegeneration burden in the female facing SES disparities.

THE EFFECTS OF VISUAL SEARCH ON POSTURAL SWAY COMPLEXITY IN OLDER ADULTS WITH AND WITHOUT TYPE 2 DIABETES

Kellyn Jason,[1] Junhong Zhou,[2] Wanting Yu,[3] Brad Manor,[4] and Azizah Jor'dan[5], *1. University of Massachusetts Boston, Boston, Massachusetts, United States, 2. Harvard Medical School/Hebrew SeniorLife, Roslindale, Massachusetts, United States, 3. Hebrew SeniorLife, Roslindale, Massachusetts, United States, 4. Hebrew SeniorLife/ Harvard Medical School, Roslindale, Massachusetts, United States, 5. University of Massachusetts, Boston, Massachusetts, United States*

Type II diabetes mellitus (T2DM) is linked to impairments in the interconnecting and interacting components (e.g., cognitive-motor demand) essential for standing postural control. The temporal dynamics of postural sway are complex, thus higher complexity reflects the system's capacity to adapt to cognitive-motor demands. We aimed to characterize the effects of T2DM on postural sway complexity during visual search tasks (VST). Twenty-four older adults without T2DM (OA) (age=67–93 years) and 20 older adults with T2DM (age=70–90 years) performed multiple trials of quiet standing with and without a VST. The VST consisted of low difficulty (LD) (i.e., counting the frequency of one designated letter in a random grid of letters) and high difficulty (HD) (i.e., counting two different letters). The complexity of the postural sway acceleration signals in the anterior-posterior (AP) and medial-lateral (ML) directions were quantified using multiscale entropy. Across participants, matched-pairs analyses revealed that both AP and ML sway complexity increased during the LD condition, compared to control ($p < 0.007$). During HD, only the AP sway complexity increased, compared to control ($p=0.0001$). Within the OA, both AP and ML sway complexity increased during the LD condition ($p < 0.009$), while performance of the HD task showed an increase in AP sway complexity compared to control ($p=0.0002$). Within the T2DM, AP sway complexity increased only during LD, compared to control ($p=0.03$). The multi-scale dynamics of postural control when standing while performing VSTs differ among older adults with and without T2DM, reflected by diminished capacity to increase complexity during the visual search conditions.

NEUROFILAMENT LIGHT CHAIN (NFL) AND GENERAL COGNITIVE ABILITY IN ADULTS APPROACHING MIDLIFE

Chandra Reynolds,[1] Andrew Smolen,[2] Christopher Link,[2] Donald Evans,[2] Ryan Bruellman,[1] Luke Evans,[2] and Sally Wadsworth[2], *1. University of California, Riverside, Riverside, California, United States, 2. University of Colorado Boulder, Boulder, Colorado, United States*

Neurofilament light chain (NfL) is a biomarker indexing axonal integrity where small NfL variations may be associated with cognitive performance in early adulthood and high values associated with neurodegenerative disorders such as Alzheimer's disease. In the Colorado Adoption/ Twin Study of Lifespan behavioral development and cognitive aging (CATSLife1) individuals were tested at 28–49 years (M=33.1, SD=4.9). Quanterix Simoa assays of plasma NfL (pNfL) were measured in duplicate, and we included values for 1159 individuals where 1098 had available general cognitive ability scores and sociodemographic covariates. Unadjusted NfL values were consistent with other studies of early-mid adulthood (M = 5.9, SD = 3.1, range = 1.14 – 40.1 pg/mL) and 6% showed values outside expected normal reference limits (>10 pg/mL). After adjusting for technical covariates and skew, higher natural log-transformed pNfL was associated with age (r = 0.27) and female sex (r = 0.07). Moreover, adjusting for sociodemographic covariates, higher pNfL was associated with lower general cognitive ability (GCA) (r = -.06), where associations were more pronounced above the mean pNfL value (r = -.08). Multi-level regression analyses suggested that GCA-NfL associations were modified by age, whereby the worse performance was observed at higher ages and pNfL values (p <= 0.03), accounting for sibling relatedness and sociodemographic covariates. We observed small negative associations of higher plasma NfL and lower cognitive performance, where associations may become magnified with increasing age in early- to mid-adulthood.

EXERCISE SLOWS NEURAL STEM CELL AGING AND AD RISK WITH CLONAL SELECTION

Wang Xiang, Lei Peng, Maxwell Bay, Michelle Liu, Jonathan Levi, Tianli Ding, Fifi Pan, and Michael Bonaguidi, *University of Southern California, Los Angeles, California, United States*

Exercise acts as a countermeasure against aging and Alzheimer's disease (AD). Several lines of evidence indicate that the beneficial effects of exercise target neurogenesis and synaptic plasticity. However, how exercise shapes neural stem cell (NSC) function to maintain lifelong hippocampal plasticity remains unknown. Here, we utilize single-cell technologies to uncover exercise slows NSC aging and reduces AD risk. In vivo single-cell lineage tracing revealed that exercise promotes clonal selection by activating quiescent NSCs for self-renewal and depleting neurogenic NSCs. Interestingly, NSC symmetric self-renewal compensated for those lost to differentiation allowing for enhanced neurogenesis without prematurely depleting the overall NSC pool. Prolonged clonal tracing further showed that the selected self-renewed NSCs are more resistant to aging-related NSC depletion. Single-cell RNA-sequencing and multiple bioinformatic analyses determined that exercise slows NSC molecular aging. In particular, exercise mitigates an age-associated increase of AD risk gene expression within NSCs. Our results demonstrate a new regenerative function of exercise to promote healthier brain aging.

EFFECTS OF REMOVING VISUAL INPUTS ON POSTURAL SWAY COMPLEXITY IN YOUNG ADULTS AND OLDER ADULTS WITH AND WITHOUT T2D

Kellyn Jason,[1] Junhong Zhou,[2] Wanting Yu,[3] Brad Manor,[4] and Azizah Jor'dan[5], *1. University of Massachusetts Boston, Boston, Massachusetts, United States, 2. Harvard Medical School/Hebrew SeniorLife, Roslindale, Massachusetts, United States, 3. Hebrew SeniorLife, Roslindale, Massachusetts, United States, 4. Hebrew SeniorLife/Harvard Medical School, Roslindale, Massachusetts, United States, 5. University of Massachusetts, Boston, Massachusetts, United States*

Standing postural control is complex and involves sensory inputs from the visual, vestibular, and somatosensory systems. Postural sway complexity, as often assessed by multiscale entropy, has been linked to the ability of the postural control system to adapt to "stressors," including the removal of visual inputs. We aimed to determine the effects of removing visual inputs (i.e., eyes closed, EC) on postural sway complexity in young adults (YA), and older adults (OA) with and without type 2 diabetes mellitus (T2DM). Twenty-five YA (age=21–30 years), 25 OA (age=70–90 years), and 19 T2DM (age=67–93 years) stood for 30 seconds under two conditions – eyes open (EO), and EC for three trials. Postural sway acceleration was measured in the medial-lateral (ML) and anterior-posterior (AP) direction during EO and EC conditions. Sway complexity was quantified using multi-scale entropy. The YA group had a significant reduction in ML and AP sway complexity during EC when compared to EO (p=0.04 and p < 0.001, respectively). Though not significant, the OA group exhibited a trend towards increased ML sway complexity during EC compared to EO standing (p=0.07). No significant changes in AP sway complexity were observed in OA or T2DM, or in ML sway complexity in T2DM. The dynamics of postural control differ between YA, OA, and T2DM groups. There was a significant difference in postural sway complexity between the EO and EC among YA, with no differences in OA and T2DM between conditions. The lack of change suggests maladaptation to stressors, such as vision loss.

SEX DIFFERENCES IN SKELETAL MUSCLE ENERGETICS AMONG OLDER ADULTS

Philip Kramer,[1] Giovanna Distefano,[2] Sofhia Ramos,[3] Bret Goodpaster,[2] Paul Coen,[3] David Marcinek,[4] Peggy Cawthon,[5] and Anthony Molina[6], *1. Wake Forest University School of Medicine, Winston-Salem, North Carolina, United States, 2. Translational Research Institute for Metabolism and Diabetes, AdventHealth, Orlando, Florida, United States, 3. AdventHealth, Orlando, Florida, United States, 4. University of Washington, Seattle, Washington, United States, 5. University of California, San Francisco, San Francisco, California, United States, 6. UC San Diego School of Medicine - Division of Geriatrics, Gerontology, and Palliative Care, La Jolla, California, United States*

Mobility impairment is the most common disability among older adults, with an earlier presentation, higher prevalence, and greater severity in women compared to men. A decline in skeletal muscle metabolism contributes to the loss of mobility with age. However, it is unknown if sex-specific differences in muscle energetics can explain the disparity in mobility impairment among men and women. In the Study of Muscle, Mobility, and Aging (SOMMA), muscle energetics was characterized using in vivo Phosphorus Magnetic Resonance Spectroscopy and High-Resolution Respirometry of permeabilized fiber bundles from muscle biopsies. In this analysis of 773 participants aged 70–94 years, 519 were women, of which 16% were deemed lower extremity mobility impaired based on a Short Physical Performance Battery (SPPB) score

MUSCLE MITOCHONDRIAL ENERGETICS ARE ASSOCIATED WITH GREATER MULTIMORBIDITY IN MEN

Theresa Mau,[1] Terri Blackwell,[2] Anne Newman,[3] Peggy Cawthon,[4] Steve Cummings,[1] Philip Kramer,[5] Russell T. Hepple,[6] and Stephen Kritchevsky[7], *1. San Francisco Coordinating Center, San Francisco, California, United States, 2. California Pacific Medical Center, San Francisco, California, United States, 3. University of Pittsburgh, Pittsburgh, Pennsylvania, United States, 4. University of California, San Francisco, San Francisco, California, United States, 5. Wake Forest University School of Medicine, Winston-Salem, North Carolina, United States, 6. University of Florida, Gainesville, Florida, United States, 7. Wake Forest School of Medicine, Winston Salem, North Carolina, United States*

Older adults who have poorer muscle mitochondrial energetics tend to have lower cardiorespiratory fitness—which is associated with the risk of cardiovascular disease, cancer, and dementia. In the Study of Muscle, Mobility, and Aging (SOMMA), we tested the associations of muscle mitochondrial energetics (MME) with a multimorbidity index in this cohort of women (Nf507) and men (Nf349) 70+ years of age. The index included 13 age-related chronic conditions (arthritis, cancer, cardiac arrhythmia, chronic kidney disease, chronic obstructive pulmonary disease, coronary artery disease, congestive heart failure, dementia, depression, diabetes, osteoporosis, stroke, and aortic stenosis). Participants were grouped by 0, 1, 2, or 3+ conditions and were on average 76.3 years old, 59.2% women, 12.5% Black, 85.5% White, with 2.0% reporting other identities. MME were measured in permeabilized muscle fibers by high-resolution respirometry in vitro (Leak and MaxOXPHOS) and in vivo by 31P-magnetic resonance spectroscopy (ATPmax). The gender interaction p-value with MME was 0.04 (Leak), 0.34(MaxOXPHOS), and 0.09(ATPmax). In men, we found that for every 1 SD decrease of mitochondrial respiration, there was a significant increase of proportional odds ratio (POR) for higher multimorbidity count: POR (95%CI) for Leak was 1.47(1.18, 1.86), $p < 0.001$ and for Max OXPHOSCI+CII was 1.35(1.08,1.68), $p < 0.01$. For ATPmax, was 1.22(0.98,1.52), p=0.08. These were adjusted for age, race, site, education, smoking status, weight, height, weight*height, and self-reported physical activity. These trends were absent in women (Leak=0.97(0.79, 1.20), p=0.79, MaxOXPHOS=1.05(0.86, 1.28), p=0.66, ATPmax=0.98 (0.82, 1.17), p=0.81), and future analyses will deconstruct the multimorbidity index to determine gender-specific associations with each condition.

IMPACT OF INTERGENERATIONAL SERVICE LEARNING ON PSYCHOLOGICAL DISTRESS FOR HOMEBOUND OLDER ADULTS DURING COVID

Keith Chan,[1] Christina Marsack-Topolewski,[2] Maggie Ratnayake,[3] Jillian Graves,[2] Sarah LaFave,[3] and Diane Fenske[2], *1. Hunter College, City University of New York, New York City, New York, United States, 2. Eastern Michigan University, Ypsilanti, Michigan, United States, 3. Lori's Hands, Newark, Delaware, United States*

More than 2 million of older adults are homebound and 5 million need help leaving their homes. They often experience social isolation, food insecurity, and lack of connection to community resources, which for many has intensified since the pandemic. To date, home-based services for those aging in place are lacking. Using newly available data, this study examined the benefits of an intergenerational home-based service learning program in reducing psychological distress for a community-based sample of 190 homebound older adults during the COVID-19 pandemic. Multivariate regression analyses were conducted to examine the association of living in one's own home, disability status, presence of child and spousal caregivers, and length of services from the program with psychological distress. Findings indicated that length of service with the intergenerational in-home support program was associated with lower psychological distress ($\beta = -0.16$, $p < 0.05$). Having a child as a caregiver was associated with lower psychological distress ($\beta = -0.15$, $p < 0.05$). Poor health status was associated with higher levels of psychological distress ($\beta = 0.16$, $p < 0.05$). Living in one's own home, having a spouse as a caregiver, disability status, and having a long-term medical condition were not associated with psychological distress in the analysis. Results from this study suggest that intergenerational in-home support services can help reduce psychological distress for homebound older adults. Policies and practice can support a pipeline of geriatric health professionals through innovative service learning models to benefit older adults, caregivers, and students.

SLEEP AND CAREGIVER BURDEN FOR CAREGIVERS OF PERSONS WITH DEMENTIA: A SCOPING REVIEW

Meghan Mattos,[1] Veronica Bernacchi,[2] Kelly Shaffer,[3] Virginia Gallagher,[3] Shinae Seo,[1] and Carol Manning[4], *1. University of Virginia, School of Nursing, Charlottesville, Virginia, United States, 2. Penn State College of Medicine, State College, Pennsylvania, United States, 3. University of Virginia, Charlottesville, Virginia, United States, 4. UVA, Charlottesville, Virginia, United States*

Caregivers of persons with dementia report worse sleep when compared to the general population. This scoping review synthesizes evidence regarding the link between caregiver burden and dementia caregivers' sleep. A systematic search was completed in PubMed, CINAHL, PsycINFO, and Web of Science for pertinent literature published through March 2022. Included original research articles studied informal adult caregivers of persons living with mild cognitive impairment or dementia, documented the relationship between subjective caregiver burden and caregiver sleep, and were written in English. Extracted data were organized in tables, compared, and synthesized. The search yielded 540 non-duplicate articles screened by title and abstract; 118 full-text articles were reviewed; of these, 26 were included. Most studies were cross-sectional, with variable sample sizes (range n=40–669). Sleep was operationalized across the 25 quantitative studies in terms of subjective quality (n=19) and objective sleep parameters using actigraphy (n=4), and polysomnography (n=2). Of studies reporting subjective sleep quality, 16 reported a significant positive association between caregiver burden (84%) with the remaining found null results. Half of the studies that used objective measures of sleep (actigraphy and polysomnography) found a positive association between sleep and caregiver burden, while the other half did not (n=3). Results suggest that, while subjective sleep quality is commonly impacted by dementia caregiving burden, there is a lack of corresponding evidence on the relationship between burden and objective sleep metrics. Caregiver burden was also not measured consistently across studies, and future studies should focus on consistent measurement of caregiver burden and determination of directionality.

RURAL/URBAN DIFFERENCES IN LIFETIME OCCUPATION AND ALL-CAUSE MORTALITY AMONG MEXICAN ADULTS

Mariela Gutierrez,[1] Rebeca Wong,[2] and Yong-Fang Kuo[3], *1. University of Texas Medical Branch, School for Public and Population Health, Galveston, Texas, United States, 2. University of Texas Medical Branch, Galveston, Texas, United States, 3. University of Texas Medical Branch at Galveston, Galveston, Texas, United States*

Mortality is affected by occupation dimensions, such as physical and mental demands, environmental exposures, and access to resources. Few studies have examined the relationship between occupation and mortality in countries with shifting occupation profiles, such as Mexico. We used 2001–2018 data from the Mexican Health and Aging Study to investigate the association between lifetime occupation type and all-cause mortality among participants aged 50 and older. We grouped participants' longest-held occupations into five categories: (1) no main job; (2) agriculture; (3) domestic, service; (4) administrative, professionals, sales; and (5) production, industrial, transportation. We used Cox Proportional Hazard regression to study death risk associated with occupation, adjusting models for baseline demographic, health, and job characteristics. We stratified analysis by rural and urban to account for differences in occupation composition. Our sample included 10,482 participants, with 4,147 deaths occurring during follow-up. The percentage of participants in administrative, professional or sales was higher in urban areas than rural areas (60.7% vs. 20.5%). The percentage of participants in agriculture was higher in rural areas than urban areas (81.8% vs. 18.2%). Compared to professionals, participants in agriculture, industry, or transportation had a slightly higher risk of death (HR=1.65, 95% CI 1.59 to 1.77). Agriculture workers in rural areas had a higher risk of death than non-agriculture workers in rural areas. Considering rural/urban differences in occupations and their effect on mortality can inform policy aimed at improving the working environment for Mexican adults. Understanding rural/urban differences in mortality associated with occupation can elucidate socioeconomic inequalities in mortality.

REEXAMINING RACE AND ETHNICITY FROM A STRUCTURAL RACISM AND SOCIAL DETERMINANTS OF HEALTH LENS IN COHORT STUDIES

Shawna Follis, *Stanford University, San Francisco, California, United States*

To advance research on the role of race, ethnicity, and structural racism in health disparities, recent calls-to-action have described methods to correct race and ethnicity categorization and to measure structural and social determinants of health (SSDOH). Following the rapid advance in the understanding of race and SSDOH, long running cohort studies typically lack access to this novel data, which has limited SSDOH evidence to cross-sectional and ecological associations. We implemented methods to rectify this data gap in prospective cohort studies, using The Women's Health Initiative (WHI) cohort of women age 50–79 years at baseline as a case study. We evaluated the quality, precision, and representativeness of race, ethnicity, and SSDOH data compared with the target US population and operationalized methods to quantify structural determinants in cohort studies. The use of a revised race and ethnicity categorization aligned with theory-based recommendations and improved measurement precision, including decreasing missing data and participants reporting "other" race. The revised categorization was harmonized to the US Census permitting description of the generalizability of WHI race and ethnicity groups in relation to the target population of US women. We found that WHI women reflected broader trends to the target population in relation to structural racism between race and ethnicity groups, while mean rates of SSDOH were systematically more advantageous in WHI. These results underscore the need to implement theoretically justified race and ethnicity measurement to accurately investigate the intersectional role of SSDOH underlying racial and ethnic health disparities among older age women.

DO ADVERSE ADULT LIFE EVENTS MODERATE THE IMPACT OF CHILDHOOD ADVERSITY ON COGNITION AFTER AGE 50?

Kimson Johnson, *University of Michigan, Ann Arbor, Michigan, United States*

Population-based studies of childhood adversity and adulthood trauma have shown varying prevalence and incidence rates due to differences in conceptualization and assessment of these events. Adverse childhood and adult events are prevalent in the general population and have deleterious effects on adult health over the life course. Exposure to adverse childhood events (ACEs) (i.e., household dysfunction) and adverse adult events (AAEs) (i.e., history of military combat or incarceration) can shape health behaviors, overall health, and disease trajectories. Despite the well-known lasting health effects of ACEs and AAEs, little is known about these events' singular and cumulative effects on cognitive health in mid to late life. The objective of this study is to examine if AAEs moderate the relationship between ACEs and cognitive functioning. Data was utilized from the 2010–2018 waves of the Health and Retirement Study (HRS) (N =3,320). Latent Growth Curve Modeling indicated that one or more ACEs were associated with a significant decrease in cognitive functioning (β=-0.19, $p < .05$). However, one or more AAEs were not significantly associated with a decrease in cognitive functioning (β=-0.19,$p>.05$). Finally, moderation analysis shows that AAEs do not significantly moderate the relationship between ACEs and cognitive functioning (β=-.32, $p>.05$). A better understanding of the timing and distribution of exposures to ACEs and AAEs can support targeting interventions and prevention screening measures. Inclusion of ACEs and AAEs in cognitive assessments could provide information about modifiable risk factors to reduce the potential negative impact of these stressors on cognitive aging trajectories in mid to late life.

DISPARITIES IN LATE-STAGE BREAST/COLORECTAL CANCER DIAGNOSIS AMONG HISPANIC, WHITE, & BLACK TX MEDICARE PATIENTS

Mathilda Nicot-Cartsonis,[1] Mukaila Raji,[2] Yong-Fang Kuo,[2] and Biai Digbeu[2], *1. John Sealy School of Medicine, Galveston, Texas, United States, 2. University of Texas Medical Branch at Galveston, Galveston, Texas, United States*

Disparities in late-stage breast or colorectal cancer diagnosis in younger populations are associated with Social Determinants of Health-SDOH (education, poverty, housing, employment). We hypothesized that—in older Medicare beneficiaries—disparities in late-stage cancer diagnosis between Hispanics, non-Hispanic Blacks (NHB) and non-Hispanic white (NHW) would be associated with SDOH, comorbidities and primary care-PCP access. We thus used 2005–2017 Texas Cancer Registry data linked with Medicare data for patients aged ≥66 (Nf86,501). Variables included were age at diagnosis, sex, comorbidities, poverty level, education, primary care provider, and breast/colorectal cancer screening within 1 year. For breast cancer in women (Hispanic n=6380, NHW n=39, 225, non-Hispanic Black n=4055), fully adjusted model showed significantly higher odds of late-stage cancer diagnosis only in NH Black patients (OR= 1.11 95% CI= 1.01–1.22) compared with NHW; adjustment for comorbidities and SDOH partially decreased the odds of late-stage diagnosis relative to NWH. Interaction terms between race-ethnicity and poverty were not significant. For colorectal cancer, fully adjusted multivariate model showed significantly higher odds of late-stage diagnosis among Hispanics (n=6053, OR=1.07;95% CI= 1.00–1.15) and NH-Black patients (n=3318, OR=1.29 95% CI= 1.19–1.40) relative to NHW (n=27,470); adjustment for SDOH was associated with a partial decrease in the high odds of late-stage diagnosis in Hispanic and NH Black patients. Interaction terms between race-ethnicity and poverty were not significant. Racial disparities in late-stage breast and colorectal cancer diagnoses remained after adjusting for SDOH and other clinically-relevant factors, underscoring needs for studies on optimizing access to screening and timely cancer treatments in racial/ethnic minorities.

ASSOCIATION BETWEEN LIMITED ENGLISH PROFICIENCY AND MEDICARE ENROLLMENT CHOICE

Lilly Estenson, and Mireille Jacobson, *University of Southern California, Los Angeles, California, United States*

Choosing between traditional Medicare and Medicare Advantage (MA) is an important health and financial decision that can be especially complicated for Medicare beneficiaries who have limited proficiency speaking or reading English (LEP). In this study, we used data from the 2016–2018 Medicare Current Beneficiary Survey and ordinary least squares regression to examine the association between LEP and MA enrollment. Among the 19,621 respondents (32,912 person-year observations) who answered LEP questions, 9.2% self-reported having LEP and 38% were enrolled in MA. Limited proficiency reading English was significantly associated with enrollment choice; respondents who reported reading English "not well" or "not at all" were 6.7 percentage points less likely to enroll in MA than respondents who reported reading English "well" or "very well" (SE=0.025; $p < 0.01$). However, when we stratified respondents by language spoken at home, we discovered considerable variation in this association among language subgroups (English: -6.5 percentage points, SE=0.029, $p < 0.05$; Spanish: -1.5 percentage points, SE=0.051, p=NS; other: -11.2 percentage points, SE=0.065, $p < 0.10$). Additionally, respondents with limited proficiency reading English were 8.0 percentage points less likely to positively rate their Medicare knowledge (SE=0.022, $p < 0.01$) and 6.4 percentage points less likely to review their Medicare options annually (SE=0.023, $p < 0.01$) than respondents with English reading proficiency. Limited proficiency speaking English was not significantly associated with MA enrollment, Medicare knowledge, or annual options review. These findings suggest that English literacy rather than speaking proficiency may be a crucial determinant of enrollment choices. Language access around health insurance information is critical for equitable Medicare enrollment.

THE RISE OF LONELINESS: TRENDS AMONG A LARGE MEDICARE ADVANTAGE COHORT OVER THE COVID-19 PANDEMIC

Kelsey McNamara, and Ellen Rudy, *Papa Inc., Miami, Florida, United States*

Loneliness is an established risk factor for premature mortality, especially among older adults. National trends are indicating an increase in loneliness after the COVID-19 pandemic. We sought to explore annual trends in loneliness and quality of life among a large dataset of Medicare Advantage (MA) members. Papa Inc. is a national service that pairs older adults with "Papa Pals" who provide companionship and assistance with everyday tasks. Participants have free access if their health plan offers it. Analysis included members from MA plans that were active with Papa January 2020 through March 2022. Members (n=11,037) were assessed at enrollment screening (UCLA Three-Item Loneliness Scale, CDC's Healthy Days Measure). Analysis used Chi-square tests, significance set at $p < 0.05$. Among the sample, 81% were aged 65+, 14% were from a majority non-white community. Analysis revealed the following trends in annual prevalence rates (2020; 2021; 2022): lonely (43.2%; 39.3%; 40.9%), severely lonely (9.2%; 12.1%; 15.1%), 14+ physically unhealthy days (24.3%; 19.9%; 39.3%). In regression analysis, loneliness score increased by 0.05 (95CI: 0.02 - 0.07) per quarter over the 27 months. Our data mimics other sources highlighting a slow and steady increase in loneliness suggesting older adults' hesitancy to engage in "normal activities." Changes in unhealthy days follow COVID-19 trends with a significant increase during the height of the Omicron variant. The prolonged effects of isolation and loneliness are profound, thus greater emphasis should be placed on population level interventions, especially those connected to the healthcare system, to help address loneliness.

PATHWAYS OF IMPROVING SOCIAL CAPABILITY OF OLDER ADULTS WITH FUNCTIONAL LIMITATIONS: FINDINGS FROM MIXED METHODS

Yalu Zhang, Yiyi Xiong, and Gong Chen, *Peking University, Beijing, Beijing, China (People's Republic)*

Objectives: Social capabilities are the opportunities to realize people's potential. Despite an established positive link between health status and social capabilities among older adults, the relationship mechanisms are understudied. Methods: Using the China Longitudinal Aging Social Survey data 2014–2018, this paper examined the possible mediating role of community participation through which older adults (aged 60 and above) in China with functional limitations improved or maintained their social capabilities. By conducting the 12 in-depth interviews, this study explores how community participation altered the negative associations between functional limitations and social capabilities among Chinese older adults. Results: Findings from the quantitative study show that both physical (-.136, $p < 0.001$) and cognitive (-.149, $p < 0.001$) functional limitations showed consistent and negative effects on the social capabilities of older adults, and the effects varied between males and females. The mediation analysis results show that community participation accounted for a substantial proportion of the impact of functional limitations (36.33%) on social capabilities. However, functional limitations still had strong, negative direct effects of their own. Findings from the qualitative narrative synthesis show that peer companionship, regular physical activities, and reduced digital obstacles to accessing online social media during social participation are the self-perceived driving force in enhancing their sense of security, freedom of expression, and sense of social cohesion. Discussion: Findings from this study highlight the need for more social policies and services to encourage community participation among older adults.

LONELINESS AND SELF-RATED DAILY SLEEP QUALITY: RESULTS FROM THE EINSTEIN AGING STUDY

Jee eun Kang,[1] Orfeu Buxton,[1] Jinshil Hyun,[2] and Martin Sliwinski[1], *1. The Pennsylvania State University, University Park, Pennsylvania, United States, 2. Albert Einstein College of Medicine, Bronx, New York, United States*

Poor sleep quality is a common problem and has profound physical and mental effects on older adults. Loneliness, another common and harmful condition for older adults, is associated with heightened levels of vigilance and feeling unsafe, which may contribute to poor sleep. Although some studies show that trait loneliness is related to compromised sleep, there are few studies examining whether and how day-to-day variations in loneliness relate to sleep quality. The current study aimed to examine within- and between-person associations of loneliness and daily self-rated sleep quality using ecological momentary assessment (EMA) approach. Community-dwelling participants (n=317, Mage=77 (range=70–90), 56% white) reported loneliness and self-rated sleep quality during a 14-day EMA study via mobile phones. Trait loneliness was measured once prior to EMA. Unexpectedly, multilevel modeling showed that the amount of loneliness experienced on a given day did not predict sleep quality, however lower levels of prior night sleep quality predicted elevated levels of loneliness ($p < .01$). Regarding the between-person association, individual differences in trait loneliness were not related to sleep quality, but differences in average levels of EMA loneliness were related to sleep quality, such that people who felt higher levels of loneliness on average during the 14 days reported worse quality of sleep during that time period than others ($p < .0001$). These results suggest that worse sleep quality may be a factor that increases loneliness, and may not be a consequence of loneliness. Potential benefits of using EMA loneliness in research of daily sleep quality in older adults will be discussed.

LONELINESS AMONG OLDER IMMIGRANTS LIVING IN SUBSIDIZED SENIOR HOUSING: DOES PERCEIVED SOCIAL COHESION MATTER?

Jihye Baek,[1] BoRin Kim,[2] Sojung Park,[3] and Byeongju Ryu[1], *1. Washington University in St. Louis, St. Louis, Missouri, United States, 2. University of New Hampshire, Durham, New Hampshire, United States, 3. Washington University in Saint Louis, Saint Louis, Missouri, United States*

The study compared the level of loneliness among older immigrants living in subsidized senior housing to non-immigrant residents. Also, the role of perceived social cohesion on loneliness was investigated, focusing on the differential influence among older immigrants and non-immigrants. Residents of subsidized senior housing in St. Louis and the Chicago area were recruited, and 182 responses were used in the analysis (126 immigrants and 56 non-immigrants). Descriptive analysis examined the difference in loneliness between immigrants and non-immigrants. Also, multiple regression models estimated the association between 1) immigrant status and loneliness, 2) perceived social cohesion and loneliness, and 3) the moderating role of immigrant status. Linear regression model showed that there was no significant difference between loneliness levels between immigrants and non-immigrants. However, perceived social cohesion was negatively associated with loneliness (β=-.338, SE= .025, $p < .001$). Additionally, immigration status moderated the relationship between perceived social cohesion and loneliness (β=-1.143, SE= .052, $p < .01$), which implies that immigrants may benefit more from higher perceived social cohesion in terms of loneliness compared to their non-immigrant counterparts. High perceived social cohesion might be an important community-level protective factor against loneliness in old age, especially for low-income older adults living in subsidized senior housing. Creating socially cohesive environments, particularly for this subgroup, would be crucial for mitigating loneliness and facilitating aging-in-place.

COMPANION CARE ASSOCIATED WITH REDUCTION IN ADMISSIONS AND EMERGENCY DEPARTMENT USE AMONG OLDER ADULTS

Kelsey McNamara,[1] Ellen Rudy,[1] Anne Armao,[2] Kerri Towsley,[2] Samantha Lang,[3] and Carla Perissinotto[4], *1. Papa Inc., Miami, Florida, United States, 2. SummaCare, Akron, Ohio, United States, 3. Weill Cornell Medicine, New York, New York, United States, 4. UCSF, San Francisco, California, United States*

Older adults with unmet social needs, including social isolation and loneliness, have higher rates of hospital readmission and emergency department (ED) use. Our objective was to determine if Papa Inc., a nationwide service that pairs older adults with "Papa Pals" for companionship and assistance, was associated with reductions in readmissions and ED visits. SummaCare, a Medicare Advantage Organization in Ohio, partnered with Papa to offer free companion care to their members. We explored changes in inpatient admission rates and ED high-utilizers (defined as members with 4+ ED visits in a calendar year) from 2018 through 2021 using a claims-based analysis. Analysis included members who used 30+ minutes of Papa services in 2021 and had historical claims data from 2019 (n=1,420), matched 1:1 to a non-Papa comparison group (n=1,420) using a validated risk scoring model. Overall, average age was 78, 62% were female, 2% were ED high-utilizers in 2021. Increased enrollment in Papa occurred post hospitalization. The case-mix adjusted 30-day readmission rate in 2021 was 12.6% for Papa users (compared to 14.1% for non-Papa; and 14.5% for Papa users before enrollment), revealing a 1.5% to 2% decline in readmission rate after enrollment in Papa. Using case-mix adjusted relativities, Papa members had 0.89 readmissions for every 1.00 readmission for non-Papa users. Compared to the matched cohort, the Papa cohort had 34% fewer ED high-utilizers during the intervention year. Results provide preliminary evidence that a social companionship service may reduce readmissions and frequent ED use, and can inform future trials on companion-based interventions.

SEX DIFFERENCES IN MITOCHONDRIAL RESILIENCE: EVIDENCE FROM BABOON HEPATOCYTES

Daniel Adekunbi,[1] Cun Li,[1] Peter Nathanielsz,[1] and Adam Salmon[2], *1. University of Wyoming, Laramie, Wyoming, United States, 2. The University of Texas Health Science Center at San Antonio, San Antonio, Texas, United States*

Events that occur in utero set the trajectory for later-life diseases and longevity. Compelling data exist for interactions between developmental programming and aging, but the underlying mechanisms are not clearly defined. Fetal exposure to glucocorticoids (GC) is associated with alteration in hepatic enzymes and metabolic function in later life. We previously reported increased hepatic lipid accumulation and obese phenotype in middle-age male baboons exposed to GC as fetuses. The mitochondria play significant roles in cellular processes including stress responses and possibly a nexus between developmental programming and aging. The present study investigated the long-term effects of in utero GC exposure on mitochondrial bioenergetics using hepatocytes derived from aging baboons (16–18 years, average lifespan 21 years). Mitochondrial bioenergetics of both left and right lobe liver hepatocytes were examined as well as potential sex differences in mitochondrial function. Cell viability following isolation was similar among sexes and liver lobes but hepatocytes from males were highly energetic compared to females. Significant bioenergetic differences were observed in hepatocytes isolated from female baboons' left and right liver lobes, with higher basal, maximal, and ATP-linked respiration in left lobe hepatocytes compared to the right lobe. These lobe-specific bioenergetic differences were absent in males. Interestingly, H2O2-induced oxidative stress significantly modified male baboon hepatocyte bioenergetics but females were unaffected, suggesting mitochondrial resilience in females compared to males. These data demonstrate that early life exposure to GC elicits a sex-specific effect on mitochondrial function. These mitochondrial differences might drive differences in cell senescence between males and females.

SASP PROTEIN ASSOCIATIONS WITH HUMAN AGING HIGHLIGHTS THE ROLE OF GDF15, CST3, AND IGFBP2

Daniel Evans,[1] Danielle Young,[1] Toshiko Tanaka,[2] Nathan Basisty,[3] Luigi Ferrucci,[4] Judith Campisi,[5] and Birgit Schilling[5], *1. California Pacific Medical Center, San Francisco, California, United States, 2. NIA IRP, Baltimore, Maryland, United States, 3. National Institute of Aging, Baltimore, Maryland, United States, 4. National Institute on Aging, Baltimore, Maryland, United States, 5. Buck Institute for Research on Aging, Novato, California, United States*

Cellular senescence is a hallmark of aging and can result in a Senescence-Associated Secretory Phenotype (SASP). SASP is characterized by an increased production of proinflammatory cytokines and damage to surrounding tissues. There is substantial evidence from non-human models demonstrating that SASP contributes to tissue dysfunction and pathogenic effects of aging. However, there are relatively fewer studies on the relationship between SASP and aging in humans. In this report, we determined the relationship between SASP circulating proteins and a wide range of aging-related clinical traits in two human cohort studies (BLSA and InChianti) using aptamer-based proteomics. Clinical traits examined were waist circumference, glucose levels, systolic and diastolic blood pressure, C-reactive protein, Interleukin-6, alkaline phosphatase, blood urea nitrogen, gait speed, grip strength, albumin, and red blood cell distribution width. In the meta-analysis of regression model results from both studies, 38 of the 77 SASP proteins examined were significantly associated with age. Of the 38 age-associated SASP, 26 were associated with one or more age-associated clinical traits. A cluster of three SASP proteins (GDF15, CST3, and IGFBP2) showed significant associations with inflammatory markers, renal function and hematological traits. A second cluster was significantly associated with grip strength and gait speed, two measures of physical function that are both strongly associated with mortality. Taken together, these results support the relevance of SASP proteins to human aging and point to specific protein components of the SASP that should be further examined for the potential to be biomarkers of human aging.

SALIVA BASED BIOMARKERS TO IDENTIFY COGNITIVE IMPAIRMENT IN OLDER ADULTS

Vinod Yata,[1] Shalini Jain,[2] Michal Masternak,[3] Peter Holland,[4] Marc Agronin,[5] Hariom Yadav,[2] and MiaGB Consortium Team[2], *1. Center for Excellence of Aging and Brain Repair, USF Health, Tampa, Florida, United States, 2. University of South Florida, Tampa, Florida, United States, 3. University of Central Florida, Orlando, Florida, United States, 4. Florida Atlantic University, Boca Raton, Florida, United States, 5. Miami Jewish Health, Miami, Florida, United States*

The prevalence of cognitive decline and dementia is increasing in older adults, their prognosis is poor. Multiple emerging evidence shows that early intervention can delay and /or prevent their progression, however, early-detection markers are invasive, expensive, and not easy to routinely measure. Saliva can be an attractive source of early cognitive decline markers because oral health is linked with cognitive function and oral fluids are connected with brain fluids, and abnormal brain protein markers can leak out to saliva and vice-versa. Using global unbiased LC-MS/MS-based proteomics of 22 saliva samples of cognitively impaired and 39 cognitively healthy older adults (>60 years old) from large, multi-site study called Microbiome in aging Gut and Brain (MiaGB) consortium, revealed that 22 proteins were uniquely for cognitively impaired group while 44 were unique for cognitively healthy controls. In addition, among 78 differentially abundant proteins between cognitively impaired and control groups, half (39) were upregulated, and half (39) were downregulated. Notably, unique proteins in saliva of participants with cognitive impairment were from neurological pathways like NGF signaling, mTOR signaling and LPS-stimulated MAPK signaling. In addition, differentially abundant proteins in participants with cognitive impairment enriched with glucocorticoid receptor signaling, LXR/RXR activation, and L-DOPA degradation-pathways, while they were deficient of pathways like complement C3 and lysozyme pathways. We discovered that the novel saliva proteins and their pathways could blindly differentiate cognitive impaired from healthy older adults. These data suggest that we discovered novel saliva-based proteins that can be used as biomarker to predict/diagnose cognitive-impairment in older adults.

ROBUST LONGEVITY EFFECTS OF NOVEL COMPOUNDS TESTED BY THE CAENORHABDITIS INTERVENTION TESTING PROGRAM

Monica Driscoll,[1] Brian Onken,[2] Christine Sedore,[3] Anna Coleman-Hulbert,[3] David Hall,[4] Gordon Lithgow,[4] Patrick Phillips,[3] and Viviana Perez Montes[5], *1. Rutgers, The State University of New Jersey, New Brunswick, New Jersey, United States, 2. Rutgers University, Piscataway, New Jersey, United States, 3. University of Oregon, Eugene, Oregon, United States, 4. Buck Institute, Novato, California, United States, 5. National Institute on Aging, Bethesda, Maryland, United States*

Many efficacious interventions that promote mouse longevity (sirtuins, TOR, insulin signaling) have identification roots in invertebrate genetics. The Caenorhabditis Intervention Testing Program (CITP) was charged by the NIA to evaluate pharmacological interventions that promote healthy aging in a robust and reproducible manner across diverse genetic backgrounds of natural variant Caenorhabditis strains. The central premise of the CITP effort is that compounds that have strong effects across diverse genetic backgrounds have enhanced probability of translatability into pre-clinical research. Indeed, some CITP-verified compounds have been shown to promote healthspan and longevity in mouse models, in support of this fundamental premise. One example that supports the Geroscience hypothesis (anti-aging compounds will promote systemic health) is our finding that when HBX, the counterpart of one of the strongest C. elegans longevity interventions (ThioT), was tested in a comprehensive multi-laboratory collaboration (Buck Institute), a remarkable increase in bone health in aging mice emerged (PMID 33778327). Our current effort includes pursuing compound submissions from the larger scientific aging community, as well as identification of candidates via high-throughput screening of chemical libraries and data mining of peer-reviewed publications. We now evaluate whole-organism RNA sequence data to estimate the mode of action for successful interventions, and conduct mortality analysis from a generalized family of distributions on high-resolution automated lifespan data to determine whether a given intervention changes the rate or onset of aging. Our recent lifespan-altering discoveries include a small molecule, a proprietary compound, an isothiocyanate and a vitamin derivative. We will present on the breaking compound successes.

FACTORS AFFECTING ANHYDROBIOSIS SURVIVAL IN EUTARDIGRADE PARAMACROBIOTUS EXPERIMENTALIS (MACROBIOTIDAE)

Amit Kumar Nagwani, *Adam Mickiewicz University, Poznan, Wielkopolskie, Poland*

Amit Kumar Nagwani, Iwona Melosik, Łukasz Kaczmarek, Hanna Kmita Faculty of Biology, Adam Mickiewicz University Poznań, Poland

Background: Tardigrades, considered among animals the most resistant to complete loss of body water (desiccation) occurring during anhydrobiosis, are also interesting because of their place between the two primary invertebrate model organisms (Caenorhabditis elegans and Drosophila melanogaster). The effect of anhydrobiosis intensification on tardigrades' age-specific survival has rarely been studied. The eutardigrade Paramacrobiotus experimenatlis is an excellent model of the study because their remarkable capacity for anhydrobiosis. This gives also possibility to apply the species in research on anhydrobiosis as an anti-aging strategy. Aim: Main goal of present study was to determine the effect of anhydrobiosis intensification, due to application of different duration and numbers of desiccation episodes, on the age-specific survival of Pam. experimenatlis. Methods: Tardigrades were cultured under laboratory conditions, divided according to their age and sex, and subjected to several short and long desiccation episodes (3 and 30 days, respectively). The revival from desiccation was evaluated after 2-48h following rehydration. Results: Individuals` age and anhydrobiosis intensity affected tardigrades` survival. Young adult animals survived the best, and the oldest ones the worst. The number of desiccation episodes affected animal survival stronger than desiccation duration. Conclusion: The results are important for anhydrobiosis study as an-anti aging strategy. The work was supported by the research grants of the National Science Centre, Poland, NCN: 2016/21/B/NZ4/00131 and 2021/41/N/NZ3/01165.

GLYNAC SUPPLEMENTATION IN OLDER ADULTS PROTECTS FROM MEAL DRIVEN OXIDATIVE STRESS AND INFLAMMATION: RESULTS OF A RCT

Rajagopal Sekhar, George Taffet, and Premranjan Kumar, *Baylor College of Medicine, Houston, Texas, United States*

Elevated oxidative stress (OxS) and inflammation are linked to many age-associated abnormalities, but underlying contributing factors are not well understood. In a randomized clinical trial (RCT) in older adults (OA), we investigated the contribution of a single carbohydrate-meal on OxS and inflammation, and tested the protective effect of supplementing GlyNAC (combination of glycine+N-acetylcysteine) from the meal-driven rise in OxS and inflammation. We studied 20 OA and 10 YA (young-adults) to (1) compare the impact of a 75g oral glucose-meal on plasma markers of OxS (as TBARS) and inflammation (as IL-6); (2) re-assess these outcomes after supplementing OA with either GlyNAC or isonitrogenous placebo (alanine) for 16-weeks, and YA with GlyNAC for 2-weeks. We found that (1) 2-hours after a glucose-meal, compared to YA the OA had higher increases (expressed as percent-change over baseline) of OxS (TBARS –0.1 +/- 0.6 vs. 5.6 +/- 0.6, p < 0.0000) and inflammation (IL-6 3.5 +/- 1.2 vs. 11.2 +/- 0.7, p < 0.0000); (2) GlyNAC supplementation in OA protected against the glucose meal-driven increase in OxS (TBARS pre vs post: 4.8 +/- 0.9 vs. -0.4 +/- 0.8, p=0.002) and inflammation (IL-6 pre vs. post: 10.8 +/- 3.2 vs. 4.2 +/- 2.3, p=0.0001). No improvements occurred in OA receiving placebo or YA receiving GlyNAC. These findings suggest that: (1) In OA, a single carbohydrate-meal significantly increases OxS and inflammation; (2) GlyNAC supplementation protects from carbohydrate meal-driven increases in OxS and inflammation. Additional research to investigate the implications of supplementing GlyNAC on improving meal-related health in aging are warranted.

BIOPHYTIS BIO101 IN SARCOPENIA: UPDATE ON THE SARA PROGRAM: FROM SARA-INT TOWARDS THE PHASE 3 STUDY

Cendrine Tourette,[1] Waly Dioh,[2] Carole Margalef,[2] Jean Mariani,[2] Sam Agus,[3] Rob Van Maanen,[2] and Stanislas Veillet[2], *1. Biophytis SA, Paris, Ile-de-France, France, 2. Biophytis, Paris, Ile-de-France, France, 3. Biophytis Inc., Cambridge, Massachusetts, United States*

Sarcopenia is a progressive muscle disorder increasing with age that may lead to mobility disability. SARA program strives to develop a viable option to treat community dwelling older adults suffering from sarcopenia. SARA-INT is a randomized three-arm interventional study (BIO101 175 mg bid / BIO101 350 mg bid / placebo) with treatment duration of 6 months. Eligibility criteria for sarcopenia were meeting FNIH criteria and Short Physical Performance Battery (SPPB) score ≤ 8/12 in men and women aged ≥ 65 years; primary endpoint was the 400-meter walking test (400MWT). 233 participants aged 65 years and older were randomized, 232 and 156 participants were included in the Full Analysis Set (FAS) and Per-Protocol (PP) populations, respectively. Due to COVID-19 pandemic, most end-of-treatment efficacy assessments are missing for 55% of the participants, reducing the studies' power. BIO101 350 mg bid treatment led to an improvement in the primary endpoint, the gait speed from the 400MWT of 0.07 m/s in the FAS population (not statistically significant) and of 0.09 m/s in the PP population (nominally statistically significant, p=0.008) after 6 months; this is close to MCID in sarcopenia (0.1 m/s). BIO101 350mg bid treatment effect on the 400MWT is confirmed in PP sub-populations at high risk of mobility disability. Trends were observed with other endpoints. BIO101 showed a very good safety profile at both doses. Biophytis will initiate the phase 3 program by end 2022, targeting a severe sarcopenic population. Outcomes of the interactions with regulatory agencies on study design will be presented.

PATTERNS OF MULTIMORBIDITY IN AGING, RADIATION-EXPOSED NON-HUMAN PRIMATES

Ellen Quillen,[1] Maggie Stainback,[1] Jamie Justice,[2] John Olson,[1] George Schaaf,[1] and J. Mark Cline[1], *1. Wake Forest School of Medicine, Winston Salem, North Carolina, United States, 2. Wake Forest School of Medicine, Winston-Salem, North Carolina, United States*

Resilience to stressors is a major component of biological aging and may mediate the onset of multimorbidity in older adults. The Wake Forest Non-Human Primate Radiation Survivor Cohort (RSC) provides a novel opportunity to study aging and resilience in 250 rhesus macaques (Macaca mulatta) with single-dose radiation exposures 0–15 years prior and 50 controls with semi-annual clinical, imaging, and biomarker measurements taken over their lifespan. Multimorbidity is extremely common among irradiated animals. Only 38% of animals have none of 20 common chronic diseases, falling to 16% of animals over age 8 and 11% over age 10 (middle-aged animals). 70% of animals have 5 or more diagnoses in this oldest cohort. The presence of any one disease increases the likelihood of having a second, co-morbid condition. Nevertheless, some animals continue disease-free until late in life, highlighting substantial variability in resilience. To identify patterns of multimorbidity, survival curves for each diagnosis were generated for age and time since radiation and k-median clustered resulting in four groupings of aging-associated morbidities. Bone, brain, and gastrointestinal disorders arise 3.5 years after radiation on average, followed by skin, heart, and cataracts. At 4.65 years, animals are at increased risk of being underweight and overweight and developing diabetes, hypertension, and hepatic dysfunction. Tumor, lung, and kidney disorders arise approximately 6 years after exposure. In all cases, these age-related disorders occur significantly earlier in irradiated animals than controls. These findings highlight the clustering of multimorbidities in aging, radiation-challenged primates and the potential of the RSC in studying resilience.

EVALUATING INSTRUMENTS FOR ASSESSING HEALTHSPAN: A MULTI-CENTER CROSS-SECTIONAL STUDY IN THE COMPANION DOG

Frances Chen,[1] Tarini Ullal,[2] Jessica Graves,[3] Ellen Ratcliff,[3] Alexander Naka,[3] Brennen McKenzie,[3] Tennery Carttar,[3] and Michael LaCroix-Fralish[4], *1. Loyal, part of Cellular Longevity Inc, San Francisco, California, United States, 2. University of CA, Davis, Davis, California, United States, 3. Cellular Longevity Inc, San Francisco, California, United States, 4. Marist College, Poughkeepsie, New York, United States*

The companion dog is an emerging model in translational geroscience and offers novel opportunities to investigate aging biology and potential gerotherapeutics. However, there is a scarcity of validated tools and clinical outcome measures to characterize and understand the impact of aging in this translational species. Here we report on a multi-center, cross sectional veterinary clinical study, where we evaluated a clinical questionnaire (Canine Frailty Index; CFI; Banzato et al., 2019) to assess frailty and an owner assessment tool (VetMetrica HRQL) to evaluate HRQL in 451 adult companion dogs. Results support evidence of validity for the tools by confirming expectations that frailty and HRQL deteriorate with age. CFI scores were significantly higher (higher frailty) and HRQL scores significantly lower (worse HRQL) in old dogs (≥ 7 years of age) compared to young dogs (≥ 2 and < 6 years of age). Body size (small < 25lbs or large > 50lbs) was not associated with CFI or total HRQL score. However, older, larger dogs showed faster age-related decline in HRQL scores specific to owner-reported activity and comfort. Findings suggest that the clinician-assessed CFI and owner-reported VetMetrica HRQL may be useful tools to evaluate two determinants of healthspan in dogs: the accumulation of frailty and the progressive decline in quality of life. Establishing validated tools that operationalize the assessment of canine healthspan is critical for the linking pathophysiological mechanisms to aging phenotypes in the companion dog and for accelerating the development of gerotherapeutics that benefit both human and veterinary medicine.

SEX DIFFERENCES IN LIFESPAN RESPONDING TO EARLY AND LATE ONSET DIETARY RESTRICTION

Nisi Jiang, Vivian Diaz, Randy Strong, and James Nelson, *UT Health San Antonio, San Antonio, Texas, United States*

Dietary restriction (DR) extends lifespan in many animal models. In mice, a range of factors affects the magnitude of the pro-longevity effect of DR, including the strain, restriction level, sex, and age of treatment onset. Early onset DR dramatically prolongs lifespan, whereas DR started later in life has diminished or no significant effect. The lifespan responses of males and females to DR also differ. Whether there is a sex difference in the lifespan response to the age of onset of DR has not been examined. Probing the basis for the variable response to DR can help elucidate the underlying mechanisms that mediate lifespan extension. We diet restricted UM-HET3 mice of both sexes from either 5 months (early-onset) or 20 months (late-onset) of age and monitored their survival. Early onset DR significantly prolonged lifespan in both males and females, which increased median lifespans by 54% and 18.5%, respectively. By contrast, although late onset DR prolonged lifespans in both sexes, the magnitude of increase in males (1.4%) was significantly lower than in females (15.8%, p=0.0474). Moreover, the decrease in the magnitude of the response to late-onset DR compared to that of early-onset DR is more dramatic in males than females. Further analysis found a significant interaction (p=0.0001) between early and late-onset DR in males but not in females (p=0.3818). Together, these results indicate that the lifespan response to delayed onset of DR diminishes more in males than in females, providing another model to probe the underlying mechanisms of DR.

FOOD AND SUPPLEMENT COMBINATIONS TO PREVENT OR POSTPONE AGING, MCI, AND ALZHEIMER'S DISEASE.

Alec Pruchnicki,[1] Barrie Kavasch,[2] Barrie Sachs,[3] Roseanne Schnoll,[4] and Rolf Martin[3], *1. Vista on 5th, New York, New York, United States, 2. Blueberry Study MMT Corporation, Sherman, Connecticut, United States, 3. MMT Corporation, Sherman, Connecticut, United States, 4. Brooklyn College, CUNY, Sherman, Connecticut, United States*

Evidence of many interacting causes of aging has renewed interest in food and nutrient combinations that may blunt the main causes[PMC9184560, PMC8889622] and postpone aging, mild cognitive impairment and Alzheimer's ("A-MCI-Alz") in contrast to prior failures[PMC9232186]. We present an updated list of anti-aging/pro-longevity strategies to address limitations of previous food/nutrient combinations. Our list has two unusual features: (i) all interventions should be administered concurrently so no fundamental causes of A-MCI-Alz are without remediation and can inflame and leave smoldering important causal factors, (ii) all interventions should be provided daily or weekly to help avoid re-ignition of key factors driving A-MCI-Alz. These two features can help explain past longevity-trial failures[PMC9310407]: no previous study to our knowledge has included most or all of the following interventions, so untreated causes of A-MCI-Alz likely remained active[PMC9114803]. Our recommended interventions include intermittent-or-continuous calorie restriction or fasting[PMID: 33138875, PMC9351392, PMC7956384], protein- and/or methionine-restriction[PMC9197402, PMC4023024, PMC9197406], consumption of moderately-strong metal chelators (e.g. polyphenols in blueberries[PMC1413581], other berries[PMC8271923], grapes[PMC7096489, PMC6386230], cherries[PMC8745076], fruits with hesperidin/hesperitin [PMC9310407] like oranges, soybeans with genistein [PMC4286753], ginger [PMC5852742], ginseng [PMC9358063, PMC3830124, PMC6874434], green/rooibos/oolong teas[PMC6567241, PMIDs: 33285593, 19996359], coffee[PMC4926853, PMC9145055], chocolate[PMC9287426]), antioxidant-rich foods[PMC7530501], B vitamins including vitamin B5 (pantothenic acid[PMC9232186, PMC8725342, https://doi.org/10.3181%2F00379727-99-24442]) to help metabolize partly-toxic aldehydes[PMC6802361] and improve/lower lactate/pyruvate and NAD+/NADH ratios[PMC7346061], ingesting adequate-to-high amounts of longevity-correlated tyrosine[PMC6681387], cysteine[PMID: 20191258], glutathione[PMC8912885, PMC5005830], niacin, nicotine acid and/or NADH[PMC7346061, PMC6982340], spermidine[PMC8436989], anti-inflammatory NSAIDS[PMC4270464], autophagy inducers[PMC6191153] fiber[PMC8705837] and fluids[PMID: 21585170] to help remove excess metals, toxic metabolites and damaged organelles, while limiting methionine-rich, other pro-aging foods[PMC4023024].

INVESTIGATING MALE INFERTILITY: EDITING GENES IMPORTANT FOR SPERMATOGENESIS IN A CELL CULTURE SYSTEM

Cassandra Norbeck, and Kellie Agrimson, *Saint Catherine University, Saint Paul, Minnesota, United States*

The four levels of aging include the specific disease, the systemic complications that lead to the disease, the loss of cellular integrity that affects the system, and macromolecule malfunction that alters cellular integrity. Similarly, this project investigates infertility and testicular cancer, misregulation of the endocrine system, problems with germ and Sertoli cell maintenance, and ultimately gene expression changes that alter cellular proliferation and death. Infertility affects 4.5–6% of North American males and up to 15% of couples worldwide. Infertility may be caused by unknown genetic factors, as up to 2,300 genes are pertinent to male fertility. This research project aims to create the molecular toolbox needed to evaluate gene function in cultured male germ cells. We will use mouse primary spermatogonial stem cells and a human testicular cancer cell line to knock out the functions of genes Phosphoprotein 1 (Spp1) and Inhibitor of DNA Binding 4 (Id4) in the testis to determine the effect of the knockouts on male germ cell proliferation and cell death. We designed single guide RNAs (gRNAs) using online bioinformatic tools and amplified the genes from human and mouse genomic DNA to demonstrate the effectiveness of our gRNAs in vitro. These gRNAs and Cas9 compose the beginnings of the molecular toolbox used to electroporate cultured cells. This research will contribute to the greater scientific community by providing insight into the function of Spp1 and Id4 relating to male fertility and providing a methodology for future research in aging-related fertility diseases and testicular cancer.

P16-EXPRESSING SENESCENT CELLS ARE A DOUBLE-EDGED SWORD IN SHAPING IMMUNE RESPONSES WITH AGE

Blake Torrance, Hunter Panier, Andreia Cadar, Dominique Martin, Erica Lorenzo, Jenna Bartley, and Laura Haynes, *UConn Health, Farmington, Connecticut, United States*

Aging results in the accumulation of senescent cells which can cause dysfunction in many contexts but the effects on immune responses remain unclear. Here, we aimed to probe the effects of clearing senescent cells in aged mice on the immune response to influenza infection. We utilized a powerful p16 trimodality reporter mouse model (p16-3MR): under the control of the p16 promoter, these mice express cassettes encoding luciferase, RFP, and herpesvirus thymidine kinase (HSV-TK). p16 is commonly upregulated in senescent cells so this model allows us to selectively delete those cells by treating with ganciclovir (GCV), which will induce apoptosis in cells expressing HSV-TK. We hypothesized that while p16-expressing senescent cells may exacerbate dysfunctional responses to a primary infection, they may play a protective role in resolving inflammation and fostering memory cell generation. We found that deletion of p16-expressing cells enhanced viral clearance and decreased infiltration of pro-inflammatory flu-specific CD8 T cells during the primary response to infection. Conversely, at 30 days post infection, there were fewer flu-specific CD8 memory T cells and lower amounts of anti-viral antibodies in the lungs of GCV treated mice. We also observed perturbations in memory T cell trafficking in GCV treated mice. Furthermore, GCV treated mice were unable to mount an effective memory response and were unable to control viral load following a heterosubtypic challenge. This suggests that targeting senescent cells may potentiate primary responses while limiting the ability to form durable and protective immune memory with age.

ARE WE GOING TO FEEL COMFORTABLE THERE?: EMERGENT FINDINGS FROM THE DIVERSITY IN LIFE PLAN COMMUNITIES STUDY

Mushira Khan,[1] Pankaja Desai,[2] and Catherine O'Brien[3], *1. Mather Institute, Evanston, Illinois, United States, 2. Rush University Medical Center, Chicago, Illinois, United States, 3. Mather, Evanston, Illinois, United States*

Life Plan Communities (LPCs), formerly known as Continuing Care Retirement Communities, offer an array of amenities as well as a continuum of care where residents may live independently or access assisted living or skilled care if needed. Racial/ethnic minority older adults are under-represented among LPC residents. One likely contributor to this lack of diversity is that racial/ethnic minorities make up a relatively small proportion of higher income groups. However, there may be additional reasons for their relative absence in most LPCs. The purpose of the 'Diversity in Life Plan Communities' study is to (1) identify barriers that impact the decision to move into an LPC for racial/ethnic minorities, and (2) identify strategies to increase resident diversity in LPCs. In this presentation we share preliminary findings from in-depth, semi-structured, qualitative interviews with community-dwelling Black, Latinx, and South Asian adults (n=10) living in Chicagoland and case study interviews with current LPC 'resident champions' (n=3) who are actively involved in efforts to increase resident diversity at their respective LPCs. Thematic analysis of the data showed that lack of awareness about LPCs, concerns about racism, desire to age-in-place among loved ones, and perceived non-availability of culturally-congruent activities were key barriers to moving into an LPC. These findings suggest that in order to increase resident diversity within their communities, LPC operators, staff, and current residents may consider targeted outreach efforts in racial/ethnic communities, take steps to create a welcoming environment and engage in more culturally congruent activities, and involve adult children/grandchildren in the decision-making process.

SESSION 9020 (POSTER)

LATE BREAKING POSTER SESSION III

ADVANCE CARE PLANNING MOTIVATED BY THE COVID-19 PANDEMIC

Karuna Thomas,[1] Fursan Sahawneh,[1] and Brian Carpenter[2], *1. Washington University in St. Louis, St. Louis, Missouri, United States, 2. Washington University in St. Louis, Saint Louis, Missouri, United States*

The COVID-19 pandemic has exposed older adults to complex healthcare situations, via personal experience or media stories about serious illness. Hearing about lengthy intubation, sedation, rapid decline, and distress at the end of life has the potential to prompt people to reevaluate their perspective on their own end-of-life care. This study explored advance care planning (ACP) among older adults and whether COVID-19 experiences altered their healthcare preferences and planning. One hundred and fifty-one respondents (M age = 71.2 yrs, range = 55–93) completed an online survey about ACP completion, ACP conversations, and life-prolonging interventions. Respondents were mainly female (78%), White (71%), and well educated (77% with at least a bachelor's degree). A substantial proportion had not completed an advance directive (31%) or chosen a medical power of attorney (33%), and 78% of them intended to complete them in the next year or had initiated ACP. Among those who had completed ACP, a quarter intended to make changes, with 13% less open to life-prolonging medical treatments and 13% more open to them. Despite these intentions, a small proportion of people had ACP conversations since the start of the pandemic with their spouse/partner (37%), children (25%), siblings, (19%), friends (27%), primary care physician (16%), or other healthcare provider (12%). Results of this study suggest that now may be a critical moment to encourage older adults to have ACP conversations, in light of how their experience during the pandemic has motivated a reconsideration of treatment preferences.

VIEWS OF OLDER ADULTS ON SUPPORT OPTIONS TO RELIEVE THEIR WORKING INFORMAL CAREGIVERS: A STORY COMPLETION STUDY

Eline Vos,[1] Simone de Bruin,[2] Suzanne Pees,[1] Allard van der Beek,[3] and Karin Proper[1], *1. National Institute for Public Health and the Environment, Bilthoven, Utrecht, Netherlands, 2. Windesheim University of Applied Sciences, Zwolle, Overijssel, Netherlands, 3. Amsterdam Public Health research institute, Amsterdam UMC, Amsterdam, Noord-Holland, Netherlands*

Older care recipients living at home increasingly rely on support from informal caregivers, who often combine their caregiving tasks with a paid job. Because of this combination of tasks, working caregivers may become overloaded. Different caregiver support options are available, that also affect older care recipients' lives, such as respite care, technology, or home care. The aim of this qualitative study was to obtain insight into the perceptions, concerns and preferences of older informal care recipients about the use of support to relieve their working informal caregivers. We performed a story completion writing task among 23 informal care recipients aged 65 years or older, using hypothetical situations to let participants reflect on different caregiver relief support options. The task was followed-up by a story-mediated interview. We used thematic analysis to inductively analyze story completions and interviews. We found that older adults were often willing to use support to relieve their caregivers, to ensure their wellbeing. However, they were also concerned about how the use of such support may conflict with their interests, preferences and values (e.g. respect for their autonomy, privacy, having a trusting relationship with caretakers, paying attention to human aspects in care). Older adults were most hesitant to use adult day care facilities and technological support options. While these areas of tension cannot always be completely resolved, it is important to jointly identify and discuss these, and work towards solutions to balance the respective interests, values and needs of older adults and caregivers.

USING SOCIAL MEDIA TO UNDERSTAND FAMILY CAREGIVER PERSPECTIVES ON ASSISTIVE TECHNOLOGY FOR PERSONS WITH ALS

Yong K Choi and Salhah Alomairi, *University of California Davis School of Medicine, Sacramento, California, United States*

ALS Forum (alsforums.com) is an online support group for those who have motor neuron disease or amyotrophic lateral sclerosis (ALS). It provides information, advice, connection, care, and assistance to persons living with ALS and their family caregivers. This study aimed to analyze the online discussion posts by caregivers of persons with ALS and assess their perceptions, experiences, and challenges of using assistive technologies (AT). Posts were extracted from the ALS caregiver discussion forum via web scraping using Python in March 2022. The extracted posts are dated between June 2005 and January 2022. The total number of posts and replies generated during this period was 52,292 by 2,397 unique users. Additional searches were conducted using assistive technology-related keywords to create the text dataset. A total of 263 posts by 137 unique users were identified. After the initial review, 186 posts were included in the final analysis. Thematic analysis revealed six major themes: (1) Uses of AT (automation/control, communication, mobility); 2) Barriers and Facilitators (cost, effort to learn new technology, rejection, interoperability, customer service); 3) Usability (hardware and software-related); 4) Sharing Experience on AT; 5) Giving Advice; 6) Seeking Information on AT. The findings are consistent with previous literature that online health discussion forums provide access to rich data that contains lived experiences of patients and caregivers. The findings may inform the design of future assistive technology that incorporates the patients' and caregivers' perspectives to increase the adoption and long-term sustainability of the technology for people living with ALS and their caregivers.

OLDER ADULTS INFLUENCING THE CIVIC ENGAGEMENT OF VOLUNTEER CAREGIVERS DURING THE COVID-19 PANDEMIC

Kathleen Gale, *Eras Senior Network Inc., Waukesha, Wisconsin, United States*

Older adults who do not qualify for government entitlement programs but lack sufficient financial or other personal resources help them to age in place rely on community organizations to assist them with social determinants of health. However, these organizations struggle with high rates of volunteer caregiver turnover, a looming crisis spotlighted during the COVID-19 pandemic. At least one group of volunteer caregivers continued to serve during this period. This phenomenological study investigated the experiences of eight volunteer caregivers who served older adults through a Faith in Action model volunteer driver program during the first year of the pandemic. Findings indicate that a volunteer's commitment to older adults, awareness of the needs of older adults, and established relationships with older adults were more important than concerns about COVID-19. Study participants were alert to the needs of older adults during and between service activities, making personal sacrifices of time, money, and physical exertion to accommodate needs. Participants approached service caring for the older adult and expected reciprocal care in the form of appreciation and respect. They considered discontinuing service if efforts weren't appreciated or if deeply held values were violated. The volunteer service organization was key in mitigating conflict within the relationship of the volunteer and older adult, thereby increasing the likelihood that the volunteer would continue serving. Implications include training older adult clients to meet expectations of care and appreciation for volunteers, managing volunteers whose personal sacrifices exceed the scope of volunteer service, and supporting volunteers whose values have been violated.

ASSOCIATION OF RELIGIOUS ATTENDANCE WITH NEUROPSYCHIATRIC SYMPTOMS, COGNITION, AND SLEEP IN COGNITIVE IMPAIRMENT

Katherine Britt,[1] Kathy Richards,[2] Shelli Kesler,[2]
Gayle Acton,[2] Jill Hamilton,[3] and Kavita Radhakrishnan[2],
1. University of Pennsylvania, Austin, Texas, United States, 2. University of Texas at Austin, The, Austin, Texas, United States, 3. Emory University, Atlanta, Georgia, United States

Neuropsychiatric symptoms (NPS), cognitive decline, and sleep disturbances are common among older adults with cognitive impairment. Religious practices may protect mental and physical health, yet few studies have been reported in older adults with cognitive impairment. Utilizing the Health and Retirement Study in 2006 and 2008 and sub study, Aging, Demographics, and Memory study in 2006–2007 and 2008–2009, we examined the association of religious attendance with NPS, cognition, and sleep disturbances controlling for social interaction in older adults with cognitive impairment (N = 63). Bootstrapped Spearman's partial Rho correlation was conducted separately for time points one (T1) and two (T2); Wilcoxon signed-rank tests were used to examine significant change over time. Mean age was 81.89(5.26) years, 65.9% were non-Hispanic White, 50.1% were female, and mean cognition (Clinical Dementia Rating) was .94(.228). Significant changes over 1.5 years were found for sleep disturbances but not for NPS and cognition. Significant associations were found for religious attendance and NPS (T1: rs (97)= - .103, 95% CI [-.108, -.098], p < .0005 and T2: -.243, 95% CI [-.246,-.239], p < .0005), cognition, (T1: rs (97) = - .119, 95% CI [-.122, -.115], p < .0005, and T2: rs (97) = -.104, 95% CI [-.107,-.102], p < .0005), and sleep disturbances, (T1: rs (97) = .028, 95% CI [.023, .033], p < .001, and T2: rs (97) = -.051, 95% CI [-.056,-.047], p < .001). Increased religious attendance was associated with lower NPS and cognition at both time points and greater sleep disturbances at T1 but lower at T2. Longitudinal studies are needed to examine associations further.

THE EFFECTS OF ENVIRONMENT-INDUCED RELAXATION ON COGNITIVE FORAGING UNDER STRESS IN MIDLIFE AND BEYOND

Jessie Chin, Shannon Mejía, Smit Desai,
Faith-Christina Washington, Durga Ramesh,
Falguni Deshpande, and Sanjana Dash, *University of Illinois at Urbana-Champaign, Champaign, Illinois, United States*

We defined enrichment seeking as the capacity for adults to engage in the novel and intellectually challenging activities for exploring diverse experience. Although enrichment seeking is associated with cognitive resilience in older adulthood, the tendency for older adults to adopt explorative behavior decreases with age in concert with decline in executive control. The goal of our study was to examine to what extent older adults can adjust their cognitive foraging performance under stress by inducing relaxation through the task environment. We used cognitive foraging games (including word search puzzle games) to understand how older adults optimize their search performance by the tradeoff between exploration (seeking new information) and exploitation (staying at old information). A modified Trier paradigm, where game performance was observed by a neurologist via video conferencing, induced stress; relaxation was manipulated by turning on an electric fireplace in the study room. The study followed a 2 (relaxation) X 2 (stress) within-subjects experimental design. Sixty-one adults (34 middle-age; 27 older adults; 54% women) played games on a tablet under stress / no stress conditions with and without the fireplace in a simulated smart home environment. The interaction effect of relaxation and stress on cognitive foraging performance was significant, indicating that with the relaxation elements in the environment (i.e., a fireplace), older adults are likely to have better cognitive foraging performance under stress. The association can be in part explained by individual differences in cognitive abilities and strategies. Implications on facilitating enrichment seeking through environmental factors are discussed.

THE EFFECT OF DEPRESSION AND SUBJECTIVE HEALTH CONDITION ON INTRA-INDIVIDUAL COGNITIVE VARIABILITY

Shayne Lin, and Rebecca Allen, *University of Alabama, Tuscaloosa, Alabama, United States*

Intra-individual cognitive variability (IICV) is defined as variability in performance across cognitive domains during neuropsychological assessment. High cognitive variability (i.e., IICV) is associated with Alzheimer's disease diagnosis and mortality among older adults (Anderson et al., 2016; Watermeyer et al., 2021; Vaughan et al., 2013). To date, no research has explored, to the author's knowledge, the effect of depression and physical health on IICV among older adults. The current investigation used the nationally represented Health and Retirement Study (HRS) data set and explored the effect of depression, measured by Center for Epidemiological Studies Depression (CESD), and subjective health, rated on a 5-point Likert scale, on IICV. Data from 39,800 participants and 11 time points were analyzed. IICV was calculated by the individual t score standard deviation divided by the individual mean t score. Dependent variables were centered before being entered into a multilevel model that took time of data collection into consideration. With multilevel modelling, after controlling for demographics (i.e., gender, race, ethnicity, and age), both depression, b = 0.003, SE = 0.0001, p < .001, and subjective health condition, b = 0.006, SE = 0.0002, p < .001, were associated with IICV. This study has implications about the use of IICV in neuropsychological assessment with older adults. In addition to one's cognitive functioning, both depression and physical health have direct effect on IICV, which may be more than merely a cognitive marker for Alzheimer's disease as researchers have previously found.

SOCIAL ENGAGEMENT AND SUBJECTIVE COGNITIVE FUNCTION AMONG OLDER ADULTS: RURAL-URBAN DIFFERENCES

Alisha Thompson, Scott Wilks, and Michelle Livermore, *Louisiana State University, Baton Rouge, Louisiana, United States*

Increasing age significantly relates with a decline in subjective cognitive function, while age and cognitive function decline strongly links with a diagnosis under the umbrella of Alzheimer's disease and related dementias (ADRD). Recent literature points to social engagement as a potential mitigator to cognitive function decline. Social engagement often differs by geography of residence, with typically higher engagement among those in urban areas compared to rural counterparts. The purpose of this study was twofold: (a) to explore the relationship between social engagement and subjective cognitive function among community-dwelling older adults; and (b) to examine any disparity in social engagement apropos to rural vs. urban residency within this population. The theoretical framework, combining activity theory and cognitive reserve theory, guided the understanding of the relationship between social engagement and subjective cognitive function. A functionalist lens was included to explain rural-urban differences. Secondary data of community-dwelling older adults from AARP's 2016 Social Engagement and Brain Health Survey (Nf746) were utilized. Results from descriptive analyses, correlations, and several regression models were reported. Bivariate regression models examined primary predictor variables – social engagement and geography of residence. Multivariate models examined sample characteristics, engagement, and geography of residence. Neither social engagement nor rural vs. urban residence achieved statistical significance in the models. Physical health, emotional wellbeing, marital status (identifying as married), and ethnicity (identifying as Black or African American) were positively, significantly associated with subjective cognitive function. Implications for community-dwelling older adults are discussed.

RELIABILITY AND VALIDITY OF A REDUCED SET OF NAVIGATION ITEMS IN COMMUNITY-DWELLING OLDER ADULTS

Michael Prevratil, Dorota Kossowska-Kuhn, Nicholas Gray, and Neil Charness, *Florida State University, Tallahassee, Florida, United States*

Navigation is a complex skill that is used in everyday living, whether it be to travel across a country or to travel to a local store. How one successfully navigates through their environment involves many different processes, including spatial navigation, route generation, and orientation. An issue with investigating those separate constructs within navigation is the number of questions required to assess them reliably. As a part of a larger project, a large sample of community-dwelling older adults (ages 60–90) completed an online survey answering questions related to navigation. Among those were three subscales: a general wayfinding subscale, a subscale asking how often they felt lost when moving around near and far spaces, and a subscale asking how often they needed help navigating around near and far spaces. Each of these subscales contained fewer than eight items. The goal of the analysis was to determine the reliability and validity of these subscales, and this was accomplished through calculating Cronbach's α and an exploratory factor analysis (EFA). Cronbach's α for each of the individual subscales were above 0.8, indicating high reliability. EFA results output five unique factors. Noticeably, the wayfinding subscale was broken into two factors, one for route generation ability and one for mental mapping ability. while the "Feeling Lost" and "Needing Help" subscales produced a dichotomy between nearer distances (ex. Your immediate neighborhood) and farther distances (ex. Your state). This contrast, along with its implications, are discussed further.

RACE AND DETERMINANTS OF HEALTH MODERATE ASSOCIATIONS BETWEEN COGNITIVE DECLINE AND DRIVING MOBILITY OVER 10 YEARS

Katie Wheeler,[1] Caitlin Pope,[2] Tyler Bell,[3] Brooke Carroll,[1] Lesley Ross,[4] and Karlene Ball[1], *1. University of Alabama at Birmingham, Birmingham, Alabama, United States, 2. University of Kentucky, Lexington, Kentucky, United States, 3. University of California, San Diego, La Jolla, California, United States, 4. Clemson University, Clemson, South Carolina, United States*

The ability to drive a vehicle is an everyday function that helps older adults maintain independence. Few observational studies have examined the relationship between cognitive decline and driving mobility and in context of racial differences and social determinants of health (SDOH). To address this empirical gap, this study aimed to characterize how cognitive functioning is longitudinally associated with driving mobility (driving space, driving exposure, and driving difficulty) in older age, and how it may vary by race and SDOH. Using the control arm of the Advanced Cognitive Training in Vital Elderly study (n=581, 24.5% Black), multilevel models examined longitudinal associations between processing speed, visual attention, memory, and reasoning with driving mobility outcomes. Race and SDOH moderations were explored. Only declines in reasoning and processing speed related to driving mobility, moderated by race and SDOH. Reasoning decline related to increased driving space in White (β=-.21,p=.006) but not Black older adults (p=.286). Processing speed decline related to greater driving exposure in Black older adults (β=-.15,$p < .001$) but less driving exposure in White older adults (β=.13,p=.006). Processing speed decline related to reduced driving exposure (β=-.06,p=.001) and increased driving difficulty (β=-.35,$p < .001$), but only in people living in poorer neighborhood and built environment and poorer social community contexts, respectively. Overall, findings emphasize that relationships between cognitive decline and driving mobility are dependent on race and SDOH. Consideration of such factors may help target those in greatest need to sustain safe driving mobility and functional independence.

PHENOME-WIDE SEARCH OF COGNITIVE RESERVE PROXIES ACROSS AGE COHORTS

Anqing Zheng,[1] Sally Wadsworth,[2] Naomi Friedman,[3] and Chandra Reynolds[4], *1. University of California, Riverside, riverside, California, United States, 2. University of Colorado Boulder, Boulder, Colorado, United States, 3. University of Colorado, Boulder, Boulder, Colorado, United*

States, 4. University of California, Riverside, Riverside, California, United States

Cognitive reserve (CR) refers to adaptability allowing for better cognitive outcomes given the degree of brain changes or other risk factors for cognitive decline. Despite significant research efforts, our knowledge of cognitive reserve proxies remains limited. Studies predominantly use a single sociodemographic variable (e.g., education attainment) as a proxy measure when CR can manifest in multiple domains. Studies also tend to rely on older samples, whereas adversity factors of cognitive performance may have differing onset ages, suggesting different risk or protective mechanisms at different ages. We examine two cohort datasets spanning from early adolescence (Adolescent Brain Cognitive Development study, N = 5559) up to the cusp of mid-adulthood (Colorado Adoption/Twin Study of Lifespan behavioral development and cognitive aging; CATSLife, N = 1327) to evaluate the role of CR proxies across over 100 variables. Defined as a moderator between a cognitive outcome and structural brain measure, these variables cover behavioral, environmental, physical and mental health, and psychological trait domains. Using cross-validated regularized regression, we identified dozens of factors acting as CR proxies (e.g., leisure reading as protective and screen usage as a risk factor during adolescence). We then use a within-family design to examine the moderation effect over and above genetic and environmental covariates. For example, adolescents who read more tend to show better cognitive performance given their gray matter volume (b = .093, 95%CI = [0.035, 0.152]). This study aims to identify factors that could be targeted with scalable prevention and intervention efforts earlier in life to maximize cognitive functioning.

NEW EVIDENCE OF HEALTHIER AGING. POSITIVE COHORT EFFECT ON COGNITIVE DECLINE.

Fernando Massa,[1] Alejandra Marroig,[2] Graciela Muniz Terrera,[3] and Scott Hofer[4], *1. Universidad de la República, Montevideo, Montevideo, Uruguay, 2. Universidad de la Republica Uruguay, Montevideo, Montevideo, Uruguay, 3. Ohio University, Athens, Ohio, United States, 4. University of Victoria, Victoria, British Columbia, Canada*

Cross sectional studies have shown cohort effects in cognition, limited research exists about cohort effects on cognitive trajectories. Indeed, most longitudinal research conducted to study aging-related cognitive change focus on the association between risk factors and mean change in cognition, considering individual differences too, but longitudinal norms of cognitive function are less studied. In this study, we aim to test whether cohort effects exist across the distribution of verbal fluency trajectories, that is, whether cohort effects vary across different trajectory quantiles. With this purpose, we estimated norms using data from 9 waves of the English Longitudinal Study of Aging (ELSA). We considered the individuals born in the 1920s, 1930s, and 1940s to assess cohort effects. The methodological framework consisted of quantile mixed models where the effect of age was adjusted using splines. To test for possible cohort effects across the 5th, 50th and 90th quartiles, the coefficients associated with the splines varied among cohorts. Our results suggest that cognitive decline is less pronounced for individuals born in more recent decades ($p < 0.001$), supporting our hypothesis of cohort effects. Moreover, these results are consistent across quantiles (p-value < 0.001). Additionally, we found that quantiles of verbal fluency at a certain age is higher in participants from more recent cohorts compared to those in older cohorts. Our findings contribute to a better understanding of cognitive decline in older adults, demonstrating population changes over time at different levels of changes in verbal fluency.

EDUCATION AND COGNITIVE ABILITY: EXPLORING DIRECT AND INDIRECT EFFECTS IN THE UNITED STATES AND MEXICO

Joseph Saenz, and Amina Khan, *University of Southern California, Los Angeles, California, United States*

Education positively relates with cognition, which may be explained by enhanced cognitive reserve. However, education may also impact cognition indirectly by improving health, health behaviors, and life-course socioeconomic status (SES). This analysis explores the associations between education and cognition in the US and Mexico and quantifies the extent to which associations are direct versus indirect through health and SES. We use data from two studies: the MexCog in Mexico (n=2,042) and US Harmonized Cognitive Assessment Protocol (HCAP, n=3,267). Cognitive domains included Memory, Executive Function, Language, Visuospatial, and Orientation. Karlson-Holm-Breen (KHB) methods were used in linear regression models to quantify how much of the associations between years of education and cognitive domains were direct versus indirect through chronic conditions, income, wealth, smoking, and exercise. In regression models, years of education related positively with all cognitive domains in both studies, even when controlling for health and SES. KHB mediation analyses suggested that most of the education-cognition association was direct. In MexCog, estimates of the percent of the education-cognition association that was indirect through health and SES ranged from 4.17% (Memory) to 5.15% (Executive Function). In HCAP, indirect effects ranged from 8.95% (Orientation) to 12.15% (Language). Education was associated with better cognitive abilities in the US and Mexico regardless of cognitive domain or adjustment for late-life health and SES. Results suggested that education primarily related with cognition directly and that effects of education on cognitive abilities are not eliminated by reducing educational disparities in the late-life health and SES factors we analyzed.

COGNITIVE INTERFERENCE ACROSS THE LIFESPAN

Rachel Cole, Arturo Espinoza, Brooke Yeager, and Nandakumar Narayanan, *University of Iowa, Iowa City, Iowa, United States*

Mental processes that facilitate goal-directed behavior can be negatively affected by age-related biological and physiological changes. Such cognitive changes impact daily activities like driving and using the computer, which can in turn influence social relationships and capacity to work. Previous research has shown that older adults are more affected by interference than young adults. It is critical to understand how cognition changes across the adult lifespan, as cognition during middle age may be predictive of cognitive decline in older age. We evaluated performance on the MultiSource Interference Task (MSIT). The MSIT draws on Stroop, Flanker, and Simon-type tasks; it taxes interference resolution and typically results in interference-related slowing. We studied 60 individuals (32 adults 18–39 years old, 17 adults 40–59 years old, and 11 adults 60–99 years old). As expected, age had a significant effect on accuracy interference (difference in errors between interference and control trials). Surprisingly, however, young adults demonstrated the highest (worst) accuracy interference cost, while middle-aged and older adults had similar interference cost. Replicating previous findings, age group did not have an effect on reaction time interference cost (slowing of response between interference and control trials). It is notable that, in this study, older adults did not fare worse than middle-aged adults. These surprising findings challenge long-held theories that age negatively impacts interference resolution. Understanding differences (and similarities) between cognition in middle-age and older age will be critical for promoting healthy cognition throughout the lifespan, which benefits daily activities and quality of life.

CHARACTERIZING PERFORMANCE VARIABILITY ACROSS COGNITIVE TASKS IN OLDER ADULTS WITH AND WITHOUT ADHD

Laura M. Klepacz,[1] Eric Cerino,[1] and Almar A. L. Kok[2], *1. Northern Arizona University, Flagstaff, Arizona, United States, 2. Amsterdam University Medical Center, Amsterdam, Noord-Holland, Netherlands*

Most research on cognitive performance among individuals with Attention Deficit/Hyperactivity Disorder (ADHD) focuses on younger persons and on cognitive variability within speeded response-time tasks. Dispersion, i.e., variability across a range of cognitive domains, is emerging as a promising indicator of age-related and pathological cognitive impairment. However, there has yet to be an evaluation of differences in dispersion among older adults with and without ADHD. We address this gap by assessing associations of age and ADHD status with dispersion. We hypothesize older adults will exhibit greater dispersion than comparatively younger adults and explore whether individuals with ADHD exhibit greater dispersion than individuals without ADHD. In a sample of 231 adults from the Longitudinal Aging Study Amsterdam (Average age=71.64 years, SD=7.7, 59% female), 23 individuals met DSM-IV criteria for ADHD and 208 were classified as neurotypically functioning. Participants completed 13 tasks spanning domains of attention, fluency, memory, processing speed, and reasoning. Dispersion across the tasks was calculated as an intraindividual standard deviation. We regressed dispersion on age and ADHD status and adjusted for sex. Older age was significantly associated with greater dispersion (Est =0.06, SE=0.03, p=0.01). However, dispersion profiles did not vary as a function of ADHD status (Est.=-0.25, SE=0.67, p>05). Preliminary results suggest that dispersion across cognitive tasks may not be a sensitive marker of ADHD in older adults, although statistical power to detect differences was relatively low in the current study. As expected, age was a significant predictor of increased dispersion, consistent with accounts of age-related changes in neurological integrity.

ASSOCIATION OF COGNITIVE STATUS AND CONSUMPTION OF UNPROCESSED AND ULTRA-PROCESSED FOODS IN BRAZILIAN OLDER ADULTS

Graziele Silva,[1] Carol Freiria,[2] Tábatta Brito,[3] Flávia Arbex Silva Borim,[2] and Ligiana P. Corona[4], *1. UNICAMP, Limeira, Sao Paulo, Brazil, 2. Universidade Estadual de Campinas, Campinas, Sao Paulo, Brazil, 3. Universidade Federal de Alfenas, Alfenas, Sao Paulo, Brazil, 4. Universidade Estadual de Campinas/ Faculdade de Ciências Aplicadas, Limeira, Sao Paulo, Brazil*

The decrease in consumption of fresh or minimally processed foods and the increase in ultra-processed foods are being observed in the diet of older adults and these changes may lead to worsening health status and cognition. We aimed to evaluate the association between cognitive status and food consumption according to the level of processing in Brazilian older adults. Cross-sectional study, with a sample of 585 older adults (≥60 years). Cognition was evaluated using the Cognitive Skills Screening Instrument (CASI-S), considering cognitive deficit when scores < 23 in participants aged 60–69 and < 20 in those aged ≥70 years. Foods reported in 24-hour food recall were classified according to their processing level into four groups of NOVA proposal: 1) unprocessed/minimally processed foods, 2) culinary ingredients, 3) processed foods (products made only from groups 1 and 2); and 4) ultra-processed foods. We estimated the means of total CASI-S score and its four domains according to the quartiles of intake of each food group, and evaluated the association between cognitive decline and each food group intake using logistic models adjusted for gender, age, schooling. Individuals in the highest quartile of unprocessed/minimally processed foods intake had higher scores in temporal orientation (p=0.034), verbal fluency (p=0.002), and total CASI-S score (p=0.004). The scores did differ according to the intake of the other food groups. The ultra-processed was the only group associated with cognitive deficit (OR:1.02; p=0.002). Results suggest nutritional counselling for older adults should focus in reducing ultra-processed and increasing unprocessed foods to help preventing cognitive deficit.

ASSOCIATION OF COGNITION AND SMARTPHONE SURVEY ATTRIBUTES IN THE ELECTRONIC FRAMINGHAM HEART STUDY

Chathurangi Pathiravasan,[1] Alexa Beiser,[1] Sudha Seshadri,[2] Claudia Satizabal,[3] Yuankai Zhang,[1] Xuzhi Wang,[4] Chunyu Liu,[1] and Joanne Murabito[5], *1. Boston University School of Public Health, Boston, Massachusetts, United States, 2. University of Texas Health Sciences Center, San Antonio, Texas, United States, 3. Glenn Biggs Institute for Alzheimer's & Neurodegenerative Diseases, University of Texas Health Sciences Center, San Antonio, Texas, United States, 4. Department of Biostatistics, Boston University School of Public Health, Boston, Massachusetts, United States, 5. Boston University, Boston, Massachusetts, United States*

Mobile technology offers a remote method to monitor health in older adults and it may provide a platform for early detection of cognitive decline. We aimed to examine attributes of smartphone survey use in the electronic Framingham Heart Study (eFHS) cohort in relation to cognitive testing performed at the time of enrollment. eFHS participants who returned smartphone surveys and underwent cognitive testing were considered in the study (n=1810). The CERAD recall score, Victoria Stroop test interference score, and dichotomous AD8 and MOCA (MOCA score ≤ 19, AD8 score ≥2) were considered as primary exposures. App-based survey adherence was defined as a dichotomous outcome based on whether at least one survey was completed at each 3-month period from baseline to 12 months. Several time attributes were considered including survey return time, touch time, step time, and question completion time. Linear mixed models (LMM for time attributes outcomes and generalized LMM for adherence outcome) were fitted for each cognitive score as the predictor adjusting for age, sex, race/ethnicity, and education level. Results suggest that higher CERAD recall scores were associated with higher odds of completing surveys. There was a significant association between all cognitive exposures and survey time attributes. Participants with poorer cognitive function (lower CERAD, higher stroop interference, MOCA score ≤ 19, AD8 score ≥2) had delayed survey return times, higher touch time, higher step time and higher question completion time. This study contributes to the growing body of evidence that smartphones may be an important tool to identify cognitive decline.

REIMAGINING AGING: EXAMINING THE IMPACT OF LIFETIME DISCRIMINATION EXPERIENCES ON EVERYDAY METAMEMORY

Timothy Ly, Jeanne Cundiff, Jason DeCaro, and
Rebecca Allen, *The University of Alabama, Tuscaloosa, Alabama, United States*

Lifetime and recent experiences of discrimination (based on race, gender, religion, sexual orientation, etc.) contribute to impaired performance on cognitive assessments. However, the underlying mechanism by which discrimination negatively impacts cognition is unclear. Recent research investigating stress-induced impairment of metamemory may address the relationship between discrimination experiences and cognitive impairment. The aim of this study was to determine the relationship between lifetime experiences of discrimination, especially recent experiences, and everyday metamemory from a lifespan perspective (ages 20–75), using data collected from the Midlife in the United States (MIDUS Refresher 1) Daily Diary Project (N = 782). Results from a 2-level multilevel model showed that the relationship between recent experiences of discrimination explained unique variance in impaired metamemory accuracy (25%; $\beta = .377$, $\sigma = .052$, 95% CI [.275, .479]), suggesting that individuals with recent discrimination experiences reported more cognitive complaints. Furthermore, the relationship between age, recent experiences of discrimination, and impaired metamemory showed that younger individuals reported more complaints after experiencing discrimination than older individuals ($\beta = .192$, $\sigma = .092$, 95% CI [.011, .373]. Individual differences accounted for 45% of the variance in the number of cognitive complaints. These findings demonstrate the need for more research into understanding metamemory accuracy as an underlying mechanism by which the psychosocial stressor of discrimination impacts cognition across the lifespan. Moreover, understanding the experiences of diverse aging populations, including experiences of discrimination, and their impact on cognition will inform research on interventions to promote positive cognitive health outcomes across the lifespan.

PROLONGED NIGHTLY FASTING AMONG OLDER ADULTS: A PILOT STUDY EXPLORING CHANGES IN COGNITIVE FUNCTION

Dara James,[1] Dorothy Sears,[2] Linda Larkey,[2]
Molly Maxfield,[2] Edward Ofori,[2] Seung Yong Han,[2]
Kate Alperin,[2] and Peyton Osha[2], *1. University of South Alabama, Mobile, Alabama, United States, 2. Arizona State University, Phoenix, Arizona, United States*

Aging is significantly associated with cognitive decline. A growing number of US adults ages ≥ 65 years have neurocognitive impairment resulting in compromised immediate and/or long-term health outcomes. Interventions to mitigate cognitive decline and promote healthy aging are needed. Research in intermittent fasting (IF) suggests positive health outcomes related to improvements in circadian rhythm and metabolism, which influence cognition. IF regimens may therefore result in improved neurocognitive health. We conducted an IF single-group, pre/post pilot study to explore changes in neurocognitive. Older adults (≥65 years of age; Nf18) with self-reported memory decline engaged in an 8-week, remotely-delivered, prolonged nightly fasting (PNF) intervention (14-hour nightly fasting, 10-hour daytime eating window). Our primary exploratory outcome was 8-week change in neurocognitive function assessed via composite score of the Memory and Attention Phone Screener (MAPS). Trends in outcome change were assessed with paired t-tests. Participants were mean age 69.7 years, non-Hispanic White, predominantly female (94%), married (50%), and employed (65%). Completion defined as percentage of participants that completed the intervention from those that started the intervention; completion rate was 90%. Paired t-test indicated a significant increase in scores on a neurocognitive screen (MAPS) pre/post-intervention (p=0.02) with a medium effect size (Cohen's d=0.58). Findings suggest that PNF, a type of IF regimen targeted to align food intake with circadian rhythms, may significantly improve neurocognitive function among older adults with self-reported memory decline. These promising pilot results suggest a need for fully-powered, randomized controlled trials to test the efficacy of this non-pharmacological, low cost-to-burden ratio intervention.

PHYSICAL ACTIVITY TOGETHER FOR COUPLES WITH MILD COGNITIVE IMPAIRMENT: A FEASIBILITY STUDY

Sangwoo Ahn,[1] Sandy Cobb,[1] Scott Crouter,[1]
Chung Eun Lee,[2] and Joel Anderson[1], *1. University of Tennessee at Knoxville, Knoxville, Tennessee, United States, 2. Baruch College, New York, New York, United States*

Spouses often assume the role of informal caregivers for older adults living with mild cognitive impairment (MCI). These couples represent a population with low levels of physical activity, however, there is limited research regarding promotion of physical activity among these dyads. The purpose of this study was to evaluate the feasibility of a dyadic intervention, hypothesized to enhance physical activity via mutual support. We recruited three dyads (mean age: 66 [MCI] and 67 [spouse] years) from a local memory clinic. The dyads were asked to engage in physical activity together for 16 weeks. The weekly intervention consisted of 150 minutes of moderate-to-vigorous physical activity (MVPA) on their own and two lower body strength training sessions per week, one videoconferencing-supervised and one on their own. The adherence rate to the weekly MVPA and strength training was 88% and 83%, respectively. However, the percentage meeting the goal of 150 minutes/week of MVPA as measured using a Fitbit was 31% and 73% among those with MCI and spouses, respectively. There were no issues with the retention rate (100%) or safety; satisfaction scores were high (MCI = 93%, spouses = 98%). Exit interviews revealed three key themes: (1) value of the program (accountability, togetherness), (2) difficulties (differences in physical capacity between spouses), and (3) suggestions to improve the program (incorporating various types of strength training). Our dyadic intervention was feasible to support regular physical activity for older adults living with MCI and their spouses. Future work will incorporate participants' feedback to optimize the intervention.

EVERYDAY FUNCTION PROFILES IN PRODROMAL STAGES OF MOTORIC COGNITIVE RISK SYNDROME: A PROSPECTIVE COHORT STUDY

Nigel Kravatz, Dristi Adhikari, Emmeline Ayers, and Joe Verghese, *Albert Einstein College of Medicine, Bronx, New York, United States*

Assessment of everyday function is crucial to diagnosing pre-dementia and dementia syndromes in older individuals. Prodromal stages of mild cognitive impairment (MCI) are associated with mild limitations in complex activities of daily living. It is unknown whether such limitations exist in the prodromal period before criteria is met for motoric cognitive risk syndrome (MCR), a pre-dementia syndrome defined by subjective cognitive complaints and slow gait speed. We compared complex everyday functional profiles at baseline in 46 community-dwelling older individuals (aged 65+) with normal cognitive performance at baseline who went on to develop incident MCR ('pre-MCR') with 265 older individuals who remained cognitively normal over follow-up. Patients diagnosed with MCI and global cognitive function scores more than 1.5 standard deviations below the mean at baseline were excluded. The mean number of limitations on complex everyday function at baseline was 3.52±3.1 in the pre-MCR cases and 1.78±2.2 in the 265 normal controls (OR 1.28; 95% CI 1.14–1.43). After adjusting for demographic factors, comorbidities, and follow-up time, the overall number of limitations remained significantly higher in the pre-MCR participants compared to the normal participants (OR 1.18; 95% CI 1.02–1.37). Of the limitations, difficulty completing hobbies and handling finances were associated with pre-MCR after adjustments. Limitations on complex everyday functions in individuals occur before they meet criteria for incident MCR on longitudinal follow-up. Such limitations over time will help clinicians identify individuals at-risk for dementia early in clinical practice.

DEPRESSIVE SYMPTOMS AND SUBJECTIVE MEMORY AMONG MIDDLE-AGED AND OLDER MIDWESTERN COUPLES

Lisa Thrane,[1] Dan Russell,[1] Rachael Turner,[2]
Peter Rendell,[3] Jyoti Savla,[4] Celinda Reese-Melancon,[2] and Jennifer Margrett[1], *1. Iowa State University, Ames, Iowa, United States, 2. Oklahoma State University, Stillwater, Oklahoma, United States, 3. Australian Catholic University, Fitzroy, Victoria, Australia, 4. Virginia Tech, Blacksburg, Virginia, United States*

Older adults face unique challenges with the COVID-19 pandemic and its effects on mental health and cognition (Lebrasseur et al., 2021). Across the age spectrum, depression is associated with self-reported forgetfulness (Loprinzi, 2018; Ronnlund et al., 2011), and this trend is consistent among older adults with mild cognitive impairment (Ryu et al., 2016). There is some suggestion of gender differences in prospective and retrospective memory ratings among couples (Smith et al., 2000). However, little is known about how depression relates to perceptions of everyday memory performance among couples. In the current study, 47 married or cohabiting couples completed a baseline survey. The mean age of both women and men was 62 years. An Actor-Partner Interdependence Model with latent variables was employed to examine depressive symptoms with an adapted version of the Center for Epidemiological Studies-Depression scale (CES-D; Radloff, 1977) and responses to the Prospective and Retrospective Memory Questionnaire (PRMQ; Smith et al., 2000). Both constructs were parceled separately by gender and summed prior to the analysis. For women, preliminary findings revealed that higher levels of depressive symptoms were related to a negative perception of their own memory ($\beta = .28$). Conversely, men's memory abilities were not associated with their depressive symptoms. Lastly, higher levels of depressive symptoms in men were associated with an increase in women's self-reported forgetfulness ($\beta = .24$). These findings are suggestive of a "couple-oriented" effect (Kenny et. al., 2006), whereas there was not a statistically significant relationship between women's depressive symptomology and men's cognitive functioning.

COGNITIVE-FOCUSED INTERVENTIONS FOR ADULTS WITH DIABETES: AN INTEGRATIVE REVIEW

Bohyun Kim, and Jie Hu, *The Ohio State University, Columbus, Ohio, United States*

Adults with diabetes and impaired memory and executive functions are more likely to experience difficulties in diabetes self-management resulting in poor glycemic control. Cognitive-focused interventions are widely accepted as an effective way to improve cognitive function in individuals at high risk of mild to severe cognitive dysfunction. This review synthesizes the effects of cognitive-focused interventions on cognitive ability, diabetes self-management, and glycemic control in adults with diabetes. A systematic review of randomized controlled/clinical trials studies published in English between 2012–2022 was conducted using the Preferred Reporting Items for Systematic Reviews and Meta-Analysis guideline. PubMed, CINAHL, Embase, and Web of science were searched. Cochrane Collaboration's Risk of Bias tool was used to evaluate the bias and quality of the studies. Nine studies met the inclusion criteria. Cognitive ability and diabetes self-management were assessed using different measurements and glycemic control was measured with A1C. Seven studies applied cognitive training, one provided working memory training, and one used occupational therapy. Seven studies combined cognitive training with a co-intervention including self-efficacy, lifestyle management, physical training, chronic disease self-management program, square-stepping exercise, psychoeducational intervention, and empowerment. Two studies provided a cognitive-focused intervention only. All nine studies showed statistically significant improvements in at least one outcome variable. Cognitive-focused interventions have a positive effect on improving memory and executive function. However, the evidence of cognitive-focused interventions on self-management and glycemic control has not been established. Future studies to improve cognitive using effective strategies to improve cognitive function enhancing diabetes self-management behaviors and glycemic control are warranted.

COGNITIVE FUNCTION AND LONELINESS AMONG OLDER ADULTS: DYNAMICS OF SOCIAL NETWORK AND PERCEIVED SOCIAL SUPPORT

Soobin Park,[1] Sojung Park,[2] BoRin Kim,[3] Jihye Baek,[4] and Takashi Amano[5], *1. Washington University in St. Louis, Saint Louis, Missouri, United States, 2. Washington University in Saint Louis, Saint Louis, Missouri, United States, 3. University of New Hampshire, Durham, New Hampshire, United States, 4. Washington University in St. Louis, St. Louis, Missouri, United States, 5. Rutgers University-Newark, Newark, New Jersey, United States*

As cognitive reserves diminish with age, older adults become aware of age-related losses and allocate their resources accordingly. Drawing on the selective optimization with compensation and socioemotional selectivity theory, older adults may select emotionally close social relationships to manage emotional distress caused by deterioration in cognitive functions. This study investigates whether different levels of cognitive functions [no impairment (NI), cognitive impairment no dementia (CIND), and dementia] influence the degree of loneliness among older adults, and how heterogeneous patterns of social relations affect this association. We used data from the 2018 Health and Retirement study, which included 4,500 respondents over 51 years of age who completed a modified Telephone Interview for Cognitive Status. Using comprehensive social-relational indicators for the structure and quality of four relational sources (spouse or partner, children, family, and friends), we applied latent class analysis and identified five subgroups of social relations: restricted–limited support (Nf190, 4.22%), family and friends focused–ambivalent (Nf1,252, 27.82%), diverse–positive (Nf2,203, 48.96%), negative (Nf500, 11.11%), and spouse focused–ambivalent (Nf355, 7.89%). Hierarchical regression showed that those in the CIND ($p < .032$) and dementia group ($p < .037$) were more likely to experience loneliness than those in the NI group, and those with dementia who were in the category of spouse focused–ambivalent support ($p < .001$) had relatively lower levels of loneliness. Reliance on spousal support may be due to people selecting and adapting increasingly on closer relations to counter their vulnerability and feel less lonely. Interventions to sustain this core relationship should be encouraged, including spousal-caregiving relief programs.

COMFORT COMMUNICATION IN HOME HEALTH: FEASIBILITY, ACCEPTABILITY, AND PRELIMINARY EFFECTIVENESS

Sharon Bigger,[1] Noah Zanville,[2] Elaine Wittenberg,[3] Gail Towsley,[4] and Lee Glenn[1], *1. East Tennessee State University, Johnson City, Tennessee, United States, 2. HCA Healthcare, North Carolina Division, Asheville, North Carolina, United States, 3. California State University Los Angeles, Los Angeles, California, United States, 4. University of Utah, Salt Lake City, Utah, United States*

Home health is the fastest-growing long-term care setting in the U. S.. However, evidence on effective clinician-patient-family communication in home health is lacking. This prospective, two-arm, pre-post randomized controlled trial aimed to assess feasibility, acceptability, and preliminary effectiveness of the COMFORT (Connect, Options, Meaning-making, Family Caregiver, Openings, Relating, and Team) communication model in home health interprofessional staff (IHHS). IHHS ($n = 18$) were randomized into two groups: Group 1 (control) ($n=10$) received seven asynchronous modules, and Group 2 (intervention) ($n = 8$) received the same modules plus a 2-hour synchronous class with interactive slide presentation and exercises. Measures included completion rates, acceptability ratings, comfort with communication in palliative and end-of-life care (C-COPE), and moral distress in health professionals (MMD-HP). Regardless of group, COMFORT was highly acceptable (>4) to IHHS. COMFORT was positively correlated with improved C-COPE scores ($p = 0.037$). Moral distress scores did not differ before and after the intervention; however, baseline moral distress scores were found to be higher in IHHS when compared to an academic medical center sample from a previous study. Levels of acceptability of COMFORT were significantly related to clinician levels of considering leaving a job due to moral distress (chi square = 7.6, $p = 0.02$, Kruskal-Wallis rank sum test). Findings suggest that COMFORT training increases IHHS comfort with palliative and end-of-life communication, especially among clinicians with histories of considering leaving a job or having left a job due to moral distress.

ADDRESSING SOCIAL ISOLATION IN NURSING HOMES DURING COVID-19: A NATIONAL SURVEY

Natalia Nielsen,[1] J. Lee Hargraves,[2] Carol Cosenza,[3] Emily Lim,[3] Adrita Barooah,[3] Emily McPhillips,[4] Catherine Dube,[4] and Kate Lapane[5], *1. University of Massachusetts Medical School, Worcester, Massachusetts, United States, 2. University of Massachusetts - Boston, Boston, Massachusetts, United States, 3. University of Massachusetts Boston, Boston, Massachusetts, United States, 4. UMass Chan Medical School, Worcester, Massachusetts, United States, 5. University of Massachusetts Chan Medical School, Worcester, Massachusetts, United States*

COVID-19 related policies introduced extraordinary social disruption in nursing homes. In response to the unprecedented COVID-19 pandemic, congregated long term care living facilities attempted and/or implemented innovative intervention strategies to alleviate loneliness in residents. We surveyed Directors of Nursing/Administrators of 1,669 homes sampled in strata defined by size (number of beds 30–99, 100+) and quality ratings (1, 2–4, 5) between February-May 2022. The response rate was 30%. Almost 2/3rds of respondents completed it online and the rest via paper. Analyses included nonresponse survey weights to provide nationally representative results. Among a list of 17 situations that occurred, staff shortages was identified as extremely stressful by the majority. Staff were extremely stressed about doing more to meet resident needs and keeping up with rapidly changing regulations which often lacked clinical sense. One third of respondents were extremely concerned about their home's ability to meet residents' social needs before vaccines, dropping to 13% after vaccines. Nursing homes tried and perceived as most useful using technology (tablets, phones, emails), assigning staff as a family contact, and staff spending more time with residents. Nearly 60% were extremely concerned about staff burnout/mental health before vaccines and 40% remained extremely concerned after vaccines. Many nursing homes attempted to mitigate the harmful effects of social isolation during the pandemic, despite the stressful circumstances in which staff worked. The extent to which various approaches were implemented varied. While concerns about social isolation reduced after vaccines were available, administrators remain extremely concerned about staff burnout and mental health.

ADDRESSING SOCIAL ISOLATION IN NURSING HOMES DURING COVID-19 – QUALITATIVE DATA FROM A NATIONAL SURVEY

Emily McPhillips,[1] Catherine Dube,[1] Natalia Nielsen,[2] J. Lee Hargraves,[3] Carol Cosenza,[4] Emily Lim,[4] Adrita Barooah,[4] and Kate Lapane[5], *1. UMass Chan Medical School, Worcester, Massachusetts, United States, 2. University of Massachusetts Medical School, Worcester, Massachusetts, United States, 3. University of Massachusetts - Boston, Boston, Massachusetts, United States, 4. University of Massachusetts Boston, Boston, Massachusetts, United States, 5. University of Massachusetts Chan Medical School, Worcester, Massachusetts, United States*

The COVID-19 pandemic had dramatic, sometimes devastating impacts on nursing homes, residents, and staff. Rapid deployment of innovative approaches to resident care was required even while under sustained distress. We collected textual responses to open-ended questions about COVID-19 experiences through a national nursing home survey of Directors of Nursing/Administrators in February-May 2022. We employed a stratified (by size and quality ratings) sample of 1,669 nursing homes. Response rate was 30%, and 51% of responders answered > 1 open-ended question. We conducted an iterative thematic qualitative analysis yielding 10 themes. Respondents described addressing social isolation using new technology; enlisting staff from across the nursing home [beyond-the-call effort, gifting of voluntary time], and new ways for residents to safely connect with family. Respondents felt severely limited by COVID regulations that seemed to ignore residents' mental health needs. The majority of respondents felt significant professional and personal impact of the pandemic experience: "The pandemic was the most stressful situation I have encountered in 26 years of nursing" – "What a toll it took on all us emotionally, physically, and mentality" – "Every day was a challenge and I felt hopeless" – Some respondents plan to quit: "I am now seeking other employment. It has been too much for too long and has directly affected my mental health." Nursing homes reported extraordinary efforts put forth by administration and staff to meet the needs of residents. Efforts to retain nursing staff are needed given profound impacts of the pandemic on their personal and professional lives.

WHEN THE LIGHTS WENT OUT AT ADULT DAY CENTERS: CAREGIVER WELL-BEING DURING THE COVID-19 LOCKDOWNS

Rachael Turner,[1] Celinda Reese-Melancon,[1] Erin Harrington,[2] and Micaela Andreo[3], *1. Oklahoma State University, Stillwater, Oklahoma, United States, 2. Pennsylvania State University, University Park, Pennsylvania, United States, 3. University of Texas at Dallas, Dallas, Texas, United States*

Adult Day Centers (ADC) are community-based programs that provide services to adults with dementia or other disabilities. Unfortunately, many ADCs were closed during the early stages of the COVID-19 pandemic, leaving caregivers without an important resource. The current study sought to identify novel challenges that caregivers experienced with the closure of ADCs. From May to July 2020, caregivers were recruited from ADCs across the United States and completed an online survey regarding ADC use, feelings of caregiver burden, perceived stress, and perceived change in these variables and others (i.e., time spent caregiving, caregiver and care recipient memory) resulting from the pandemic. Qualitative reports of additional pandemic-related caregiving experiences were also captured. The current work included 70 caregivers, most of whom were caring for a family member with dementia. Correlational analyses indicated that more frequent ADC use prior to the pandemic was associated with reporting an increase in the amount of time spent on caregiving tasks, an increase in caregiver burden, and increased feelings of stress since the onset of the pandemic. Prior use was not related to change in perceptions of caregiver forgetfulness or changes in care recipient memory behaviors. Prominent themes from caregivers' qualitative reports included mental health concerns, apprehension regarding the virus itself, and the need for respite. These findings support theories of caregiver stress (Pearlin et al., 1990) and provide insight into how caregivers were impacted by the loss of a key resource to support their caregiving.

THE RISK OF COVID-19-RELATED MYOCARDITIS IN OLDER ADULTS WITH A HISTORY OF CORONARY ARTERY DISEASE

Andrew Crawford,[1] Ali Vaeli Zadeh,[2] Andres Redondo,[3] Karen Bravo-Ramirez,[4] Ana De Diego Diaz,[5] Ricardo Criado Carrero,[6] Elias Collado,[2] and Joshua Larned[7], *1. Holy Cross Health-University of Miami, Fort Lauderdale, Florida, United States, 2. Holy Cross Health-Jim Moran Cardiovascular Research Institute, Fort Lauderdale, Florida, United States, 3. University of Miami, Fort Lauderdale, Florida, United States, 4. University of Miami at Holy Cross, Miami, Florida, United States, 5. University of Miami/Holy Cross Hospital, Fort Luderdale, Florida, United States, 6. University of Miami/ Holy Cross Hospital, Fort Lauderdale, Florida, United States, 7. Holy Cross Health- University of Miami, Miami, Florida, United States*

Background: Data suggest an increased incidence of myocarditis (MC) associated with the COVID-19 virus. However, the risk factors for COVID-19-related MC remains poorly understood and debated. Therefore, we sought to evaluate the correlation of a history of coronary artery disease (CAD) with MC in older adults admitted for COVID-19. Methods: Data were obtained from the PearlDiver database (PearlDiver Technologies, Fort Wayne, IN). The study included patients aged 65–75, hospitalized with a primary diagnosis of COVID-19, and Elixhauser Comorbidity index(ECI) >4. History of CAD upon admission was used to split the cohort into two propensity score-matched groups considering age, gender, other cardiovascular diseases, and ECI. Records from both groups were reviewed to identify patients diagnosed with MC during and up to one month after admission. Pearson's chi-squared test was used to compare groups. The strength of association was reported using Risk Ratios (RR). A p-value < 0.05 was deemed significant. Results: 182,556 patients with and 218,729 without a history of CAD admitted for COVID-19 were identified. Patients with a history of CAD were more likely to be male(54.7% vs. 42% $p < 0.0001$), older(mean age 70.62 vs. 70.30, $p < 0.001$), and had more comorbidities(ECI=11 vs. 8, $p < 0.0001$). After propensity score matching, 0.13% of patients with CAD and 0.12% without CAD developed MC within one month of admission(RR= 1.05, CI95%=0.87–1.26, p=0.61). Conclusion: One month following admission for COVID-19, the risk of MC was not significantly higher in older persons with a history of CAD.

THE COVID-19 PANDEMICS' IMPACTS ON OLDER ADULTS' MENTAL HEALTH: THE BUFFERING EFFECTS OF NEIGHBORHOOD COHESION

Kedong Ding, *Case Western Reserve University, Cleveland, Ohio, United States*

Background: During the COVID-19 pandemic, many older adults reported less frequency of having in-person contact due to the worries of COVID -19, which raises concerns about their mental health. The past research suggests neighborhood cohesion can facilitate social participation and have positive effects on mental health. This study aims to examine the impact of the decreased social contacts due to COVID on older adults' depressive symptoms, and whether the relationship is moderated by neighborhood cohesion. Method: Data were from the 2020 waves of the Health and Retirement Study (HRS) (n=2,732). Participants included community-dwelling adults aged 65 years or older. The independent variable is the perceived changing amount of in-person contact due to the pandemic. Neighborhood cohesion was measured by four-item sales that assess the extent to which respondents feel about the neighborhoods and neighbors' trust. The depressive symptoms were measured by the 8-item CES-D scale. All models were controlled for sociodemographic characteristics and health status. Multivariate regression models were used to and an interaction term was created to examine the moderating effects of neighborhood cohesion. Results: The results from the multivariate regression model show that perceived neighborhood cohesion was associated with fewer depressive symptoms ($\beta=-.16$, $p < 0.001$). Not having enough in-person contact since the pandemic is associated with more depressive symptoms ($\beta=.24$, $p < 0.001$). High perceived neighborhood cohesion attenuates the relationship between not having enough in-person contact and depressive symptoms. Conclusion: This study demonstrates the buffering effects of neighborhood cohesion on Covid-19 impacts on older adults' in-person contact and mental health outcomes.

TELEMEDICINE TRENDS IN THREE NURSING HOMES DURING THE COVID-19 PANDEMIC

Lindsay Sandell,[1] Tena Baar,[2] Raza Haque,[2] and Angela Zell[2], *1. Michigan State University College of Human Medicine, Grand Rapids, Michigan, United States, 2. Michigan State University, East Lansing, Michigan, United States*

Physical distancing and visiting restrictions during the COVID-19 pandemic posed significant challenges in providing timely medical care in nursing homes. The rising number of new COVID-19 cases created hardship in providing scheduled and non-urgent care visits. Virtual visits were pivotal in providing patient care. However, the additional responsibility of facilitating virtual visits for both social and clinical purposes further constrained the ability of nursing home staff to provide care. The critical deficiency of the workforce, rising numbers of new cases, and required triage of patients have been significant barriers to regularly scheduled care. We hypothesize that regular non-COVID-19 services in the evaluated nursing home facilities were lower than COVID-19 visits during this period. Our goal is to show the types of services affected during the pandemic. In this study, we analyzed 563 virtual visits during the COVID-19 pandemic in three nursing home facilities in Michigan from December 2020 through February 2022. Upon analyzing the types of services and trends, our results revealed that the number of COVID-19 related visits (68) was significantly lower than non-COVID-19 related visits (485), refuting our hypothesis. This illustrates that routine care could still be delivered during the pandemic. Additionally, the overall number of virtual visits declined steadily over the study period. This trend could suggest an increase of in-person services or a decrease in COVID-19 cases. The decline could also be related to the barriers faced by the nursing home workforce considering the time and additional responsibility of monitoring a virtual visit.

RESILIENCE AMONG RESIDENTS, THEIR FAMILY, AND STAFF OF A CONTINUING CARE RETIREMENT COMMUNITY

Justine Sefcik, Yeji Hwang, Zachary Hathaway, Martha Coates, Shelby Hufnal, Isabella Stoll, Rose Ann DiMaria-Ghalili, and Kathleen Fisher, *Drexel University, Philadelphia, Pennsylvania, United States*

There is emerging literature about older adults' experience of loneliness during the COVID-19 pandemic in long term care (LTC) facilities due to isolation protocols. Additionally, staff challenges while providing care for older adults in LTC has also been highlighted. While the literature emphasizes negative pandemic experiences, a gap exists with understanding resilience during the pandemic in LTC settings. The aim of this qualitative descriptive study was to explore the experience of resilience in a Continuing Care Retirement Community (CCRC) among residents, their family members, and staff. We conducted 19 in-person interviews and 1 via

Zoom in fall 2021 with 5 residents (65 and older), 5 family members, and 10 staff (e.g., administrators, nurses, nursing assistants). A conventional content analysis was employed. While we did hear how the pandemic had a negative impact on everyone, the main themes of resilience identified were: 1) overcoming the pandemic together (sense of community); 2) experience and adaptation (over time being able to adapt to the disruption in their life); 3) staying safe (engaging in precautions and self-care strategies); and 4) positivity (mindset of getting through anything and relying on spirituality). Study findings can inform CCRC administrators on how to support residents, their family, and staff during future pandemics and other challenging times that may disrupt normal routines.

RACE AND AGE DIFFERENCES IN DEPRESSION AND ANXIETY DURING COVID-19: A LONGITUDINAL STUDY

Xiaochuan Wang, Mengyu Xu, Kim Gryglewicz, and Susanny Beltran, *University of Central Florida, Orlando, Florida, United States*

The COVID-19 pandemic has negatively affected the physical and mental health of many. It remains unclear whether such impacts differ across diverse races or age groups, or along the course of the pandemic. This study assessed trends in levels of depression and anxiety symptoms among U.S. adults during COVID-19 and whether differences emerged across race and age. Data were drawn from the Understanding America Study (UAS) COVID-19 survey, a longitudinal panel survey of a nationally representative sample of over 6,000 individuals. A mixed effect linear model was conducted to assess the influence of race and age on the level of depression and anxiety over time during the pandemic, controlling for covariates such as marital status, employment status, and household income. Results indicate that greater age was associated with lower levels of depression and anxiety. Additionally, trends in levels of depression and anxiety vary across races (e.g., minority populations generally reported lower or comparable levels of depression and anxiety comparing to the White). Findings further suggest significant interactions between age and race, especially among minoritized adults. Study findings underscore the importance of future research and tailored strategies to improve culturally sensitive and age-appropriate mental health services targeting diverse populations.

PANDEMIC RECOVERY IN NURSING HOMES: IMPACT OF A 5-WEEK CURRICULUM ON RESILIENCE AND GROWTH IN DIRECT CARE WORKERS

Susan Wehry[1] and Prakash Patel[2], *1. University of New England, Biddeford, Maine, United States, 2. University of New England College of Osteopathic Medicine, Biddeford, Maine, United States*

The COVID-19 pandemic significantly impacted people working and living in nursing homes. A virtual five-week curriculum was developed to support recovery and foster growth in direct care workers (DCWs). We hypothesized DCWs would be interested, acquire knowledge and self-care skills, and utilize a post traumatic growth (PTG) self-assessment tool for reflection. The 5 week voluntary program was offered twice. Sessions consisted of a didactic presentation, Q&A, skill practice and action commitment. Each 30 minute session was offered twice weekly, a.m. and p.m., to accommodate shift schedules. Polls were conducted within sessions. Participants who attended all sessions received a certificate of attendance and completed a 4 question, 5-point Likert scale survey and the PTG tool. 53 DCWs participated in at least one session; 30 completed the program and ranked weeks 2 (95%), 3 (65%), and 4 (60%) as most useful. Most used skills were breathing (95%), gratitude practice (91%), catch-check-change (61%), self-massage (61%), and reducing exposure to toxic news (61%). DCWs endorsed self-improvement (96%), curiosity (91%), and “having a hard time” (61%) as most common reasons for enrolling. 100% reported the course completely or almost completely met their goals. In-session polling indicated attendees “felt better or more confident” at the conclusion of each session. 100% successfully utilized the PTG tool. The curriculum was responsive to DCWs needs and interests. DCWs acquired and utilized resilience skills. Some components of the curriculum were more effective than others. Shorter staff training sessions are more attractive to staff and employers. Further study is warranted.

OPTIMIZING MEDICATION RECONCILIATION AMONG OLDER ADULTS DURING COVID-19 INFECTION TREATMENT WITH PAXLOVID

John Chen, and Tarah Browne, *Kaiser Permanente Med Group/Southern California, Harbor City, California, United States*

COVID-19 infection treatment (CIT) has reframed optimizing medication reconciliation in older adults. In December 2021, FDA authorized Emergency Use Authorization of Paxlovid (Nirmatrelvir/Ritonavir), protease inhibitor blocking SARS-CoV-2 replication, to reduce severe COVID-19 and mortality in high-risk patients1. Pharmacodynamic and pharmacokinetic changes in geriatric population warrant a stepwise, patient-centered approach for prescribing Paxlovid by reviewing - 1) drug-drug interactions with current medications2, 2) renal dosing, 3) risks-benefits-alternatives, 4) adverse drug events (ADE), i.e. polypharmacy and prescribing cascade. Case A – Community-dwelling 65-year-old Hispanic male history of paroxysmal ventricular tachycardia and end-stage renal disease (ESRD) requiring CIT- 1) Paxlovid contraindication with Amiodarone2 2) ESRD – not candidate 3) risks outweigh benefits, 4) safer alternatives with less ADE. Case B – Long term care 80-year-old Hispanic female history of stroke, type 2 diabetes mellitus and dementia requiring CIT -1) Paxlovid contraindication with Atorvastatin2 (Atorvastatin held during Paxlovid treatment then restarted at lower dose “deprescribing”), 2) estimated glomerular filtration rate 46 with renal dosing – Paxlovid 150mg/100mg, 3) benefits outweigh risks, 4) monitored ADE in controlled setting. Optimizing medication reconciliation during CIT in older patients can decrease preventable ADE. Further research is essential to align CIT efficacy with the fundamental geriatric principles, including shared decision-making, long-term prognosis, and life care planning. 1Najjar-Debbiny R, Gronich N, Weber G, Khoury J, Amar M, Stein N, Goldstein LH, Saliba W. Effectiveness of Paxlovid in Reducing Severe COVID-19 and Mortality in High Risk Patients. Clin Infect Dis. 2022 Jun 2:ciac443.

LACKING FAMILY TIES DURING A GLOBAL PANDEMIC: OLDER ADULTS CONCEPTUALIZATIONS OF SOCIAL SUPPORT

Bryce Van Vleet, Emily Kinkade, Heather Fuller, and Andrea Huseth-Zosel, *North Dakota State University, Fargo, North Dakota, United States*

Social support from family provided benefits for coping during the COVID-19 pandemic; however, not all older adults had access to family. The present study investigates how older adults without access to traditional family ties conceptualized their social relationships throughout the first two years of the pandemic. A subsample of eight older adults without direct access to traditional family ties were identified from a larger 5-wave interview study conducted between April 2020 and June 2022. Transcripts were holistically coded and three overarching themes emerged: constraints of place, redefining family, and feelings of isolation and closeness. The first theme addressed having family members living far away and uncertainty of when they would get to see them again. However, these distance barriers could be overcome through technology. The second theme illuminated that during the pandemic, those without access to traditional family ties redefined their social relationships by developing fictive kin from neighbors, colleagues, and friends. The third theme highlighted that some older adults felt they were lacking strong social networks and were concerned they had nobody to contact if they needed help, while others felt that despite limitations, their social relationships grew closer due to connection through alternative forms of communication (e.g. texting). Results from this study clarify how traditional family ties were challenged and strengthened during physical distancing for some older adults. These findings extend the literature on how fictive kin forms in older adulthood during temporary crises and suggests potential avenues for social connection for older adults lacking traditional family support.

INFLAMMATORY BIOMARKERS DIFFER AMONG HOSPITALIZED VETERANS INFECTED WITH COVID-19 VARIANTS

Catherine Park,[1] Benjamin Seligman,[2] Bret Hicken,[3] Shahriar Tavakoli-Tabasi,[4] Amir Sharafkhaneh,[4] Christopher Amos,[4] Andrew Chou,[4] and Javad Razjouyan[1], *1. Veterans Affairs, Houston, Texas, United States, 2. David Geffen School of Medicine at UCLA, Los Angeles, California, United States, 3. Veterans Affairs, Salt Lake City, Utah, United States, 4. Baylor College of Medicine, Houston, Texas, United States*

The SARS-CoV-2 infection pathogenesis reported a complex interplay between virus and host immune response. In this study, we hypothesized that Omicron variant causes less inflammation and cytokine release than Delta and Alpha variants as measured by the first laboratory biomarkers during hospitalization. This is a retrospective cohort study of veterans who tested positive for COVID-19 and were hospitalized at the Veterans Health Administration due to COVID-19 infection. We defined three groups of patients based on highly likely period representing variants: Alpha (12/01/2020-05/31/2021), Delta (09/01/2021-11/30/2021), and Omicron (02/01/2022-07/11/2022). The risk of abnormality levels in biomarkers (C-reactive protein [CRP], ferritin, albumin, alanine aminotransferase [ALT], aspartate transaminase [AST], and lactate), as well as in-hospital mortality, were calculated using logistic regression adjusted by age, sex, body-mass-index, race, Charlson comorbidity index, VA frailty index, and vaccine record status. Of 414,213 Veterans tested for COVID-19, 74,342 Veterans (age: 67.8±14.3 years, BMI: 29.4±7.1 kg/m2) met the criteria: Alpha, 18,159 (34.4%); Delta, 23,414 (44.4%); Omicron, 11,207 (21.2%). Compared with Omicron, we observed significantly higher odds of abnormality levels in CRP (Alpha, adjusted odds ratio (aOR)=1.38; Delta, aOR=1.74), ferritin (Alpha, aOR=2.02; Delta, aOR=2.33), albumin (Alpha, aOR=1.16; Delta, aOR=1.15), ALT (Alpha, aOR=1.13; Delta, aOR=1.12), AST (Alpha, aOR=1.31; Delta, aOR=1.57), and lactate (Alpha, aOR=1.62; Delta, aOR=2.27) as well as mortality (Alpha, aOR=2.19; Delta, aOR=2.95). Veterans infected with Omicron showed less severe biomarkers' responses compared to Alpha and Delta and lower mortality risk. Understanding the biomarkers' responses of each patient across the different variants could be used to enhance acute patients' management.

IN THEIR VOICES: A QUALITATIVE STUDY OF OLDER ADULTS' PERSPECTIVES OF COVID-19 PANDEMIC

Chih-ling Liou, *Kent State University, North Canton, Ohio, United States*

Older adults are a very heterogeneous group and are likely to experience the pandemic in a variety of ways. This study is to give older adults voices to share their experiences of this pandemic. Data were collected in spring 2022 using semi-structured interviews with 46 adults (74% females) aged 66 and 97 residing in the Midwestern United States. Participants were asked to share how the pandemic affects them, their vision for the future, and how they cope during the pandemic. Participants expressed both positive and negative effects of pandemics. Although they shared more information and examples of the negative effects, most of them did express an optimistic view of the future. The most reported negative effects were few contacts with family and friends, isolation/loneliness, and confinement/restrictions. The most reported positive effects were having more time, getting things done, driving less, and becoming more appreciative. Their perspectives toward the COVID-19 pandemic are varied: some believed that the effects of the pandemic are just temporary, and others compared it to the wars that were much worse. Findings reveal that oldest-old (85+) and old-old (75–84) participants are better at regulating their negative effects compared to the young-old (65–74). Older adults during the pandemic are not just passive help receivers but can be proactive helpers to give advice and coping strategies as well as provide emotional support to others. Older adults' adaptability during the COVID-19 pandemic should be better understood to reverse the image of their vulnerabilities and promote late-life coping during crises.

IMPACT OF COVID-19 PANDEMIC ON MENTAL HEALTH IN OLDER ADULTS: COMPARISON BETWEEN 2020 AND 2022

Dara Kiu Yi Leung,[1] Tianyin Liu,[1] Wen Zhang,[2] Wai-wai Kwok,[2] Lesley Sze,[2] Gloria H.Y. Wong,[2] and Terry Lum[2], *1. The University of Hong Kong, Hong Kong, Hong Kong, 2. The University of Hong Kong, Hong Kong, Hong Kong*

The COVID-19 pandemic had a major impact on older adults' mental health, but less is known about its longer-term effect. We examined changes in depressive and anxiety symptoms among older adults between the onset and two years into the pandemic. Data were drawn from two cross-sectional telephone surveys conducted with older adults aged ≥ 60 years in Hong Kong in 2020 and 2022. Respondents were screened for depression and anxiety using Patient Health Questionnaire-2 (PHQ-2) and General Anxiety Disorders-2 (GAD-2) and, if screened positive (i.e. scoring ≥ 3 in PHQ-2 or GAD-2), evaluated with PHQ-9 and GAD-7 for symptom severity. After case-control matching baseline age, gender, living districts, and pre-existing mental health conditions based on the respondent ratio between the two surveys (i.e. 2:1 ratio), 4095 and 2099 respondents from the 2020 and 2022 surveys were included in the analysis. Respondents' average baseline age was 75 years old, 77% were female, and 13% had a pre-existing mental health condition. There were significant increases in the proportion of older adults screened positive for depression (8.3% to 13.5%) and anxiety (6.9% to 11.4%) and a significant increase in depressive symptom severity (4.63 to 7.72) between 2020 and 2022 (p < .001). Logistic regression suggested that, over two years, older adults with pre-existing mental health conditions were 1.59 times more likely to screen positive for depression than those without such conditions. Linear regression suggested that males were associated with increased depressive (B=-2.42, p=.004) and anxiety (B=-2.49, p=.021) symptom severity than females over the years.

HOW DOES THE COVID-19 PANDEMIC AFFECT LATE WORKING LIFE? EUROPEAN EMPLOYMENT TRAJECTORIES FROM 2011 TO 2021

Wiebke Schmitz, *University of Vechta, Vechta, Niedersachsen, Germany*

Background: One of the immediate impacts of the pandemic was the increase in unemployment and the reduction of working hours - especially among women, those with lower job security and in countries with a weaker social welfare system. The aging society is at further risk, which is already challenged by a growing shortage of workers and the rising costs of pensions. To understand the long-term consequences of COVID-19 for the aging workforce, this paper advances existing research by exploring from a life-course perspective how employment after the COVID-19 outbreak is anchored in larger employment histories (2011–2021). Methods: Sequence-analyses are applied using retrospective life history data combined with both COVID-19 Surveys (2020–2021) from SHARE including respondents aged 50+. Using cluster-analyses, the resulting sequences are classified into six groups. By applying descriptive-analyses, I examine how these groups differ by gender, work quality, and country. Results: Older workers – especially men – with continuous full-time employment histories are less frequently affected by unemployment and fewer working hours during COVID-19. Whereas those – especially women – with disruptive employment and part-time work histories are more frequently affected by unemployment after the outbreak of COVID-19. Respondents in countries characterized by social democratic welfare compared to liberal welfare regimes are less likely affected by unemployment during the pandemic. Discussion: The pandemic particularly puts older workers with disruptive employment histories at additional risk of labor market exit. Therefore policymakers need to address inequalities in earlier life to prevent long-term consequences of social inequality caused by the pandemic.

HALF OF OLDER ADULTS HOSPITALIZED WITH COVID-19 EXPERIENCE SYMPTOMS ONE YEAR LATER

Aleda Leis,[1] Sydney Fine,[2] E.J. McSpadden,[1] Carrie Karvonen-Gutierriez,[1] Emily Nichols,[3] Lois Lamerato,[4] Anurag N. Malani,[5] and Emily Martin[2], *1. University of Michigan, Ann Arbor, Michigan, United States, 2. University of Michigan School of Public Health, Ann Arbor, Michigan, United States, 3. UM Michigan Center for Respiratory Research and Response, Ann Arbor, Michigan, United States, 4. Henry Ford Health, Detroit, Michigan, United States, 5. St. Joseph Mercy Hospital, Ypsilanti, Michigan, United States*

Older adults hospitalized with severe COVID-19 are at higher risk of experiencing serious in-hospital outcomes and long-term health consequences following discharge. Declines in health and functional ability post-hospitalization are important infection-related outcomes. This study's aim was to examine functional recovery one year following COVID-19 hospitalization. Twenty-one adults ≥60 years of age hospitalized with confirmed COVID-19 infection between 3/2020–5/2020 in Southeast Michigan completed a survey 9–15 months post-discharge including items from the Fried Frailty score, Short Form 36 Physical Assessment, PROMIS Dyspnea Scale, and the World Health Organization Disability Assessment Schedule. Mean age at hospital admission was 69 (standard deviation 7). Half of participants (52%) indicated they had too little energy to do the things they wanted to do, 52% (n=11) indicated moderate to severe shortness of breath when walking up two flights of stairs, and 43% (n=9) indicated they were limited a lot in walking several blocks. Additionally, 57% (n=12) indicated they were severely or extremely emotionally affected by their health due to their COVID-19 infection. Results were similar in only those ≥70 years (n=7). Our survey indicates that half of patients hospitalized with severe COVID-19 from the first infection wave in Southeast Michigan are significantly affected up to a year or more after their initial infection, and may benefit from long-term outpatient care. More research is needed to inform development of effective treatments for the long-term emotional and physical impacts of severe COVID-19.

FINANCIAL HARDSHIPS AND MEDICATION ADHERENCE DURING THE COVID-19 PANDEMIC

Megan Lytle,[1] Dawn Carr,[2] and Patricia Homan[2], *1. Florida State University, Tallahassee, Florida, United States, 2. Florida State University, Tallahassee, Florida, United States*

Medication nonadherence is associated with numerous negative health outcomes among older adults, including myocardial infarction, stroke, preventable hospitalizations, and increased risk of decline in self-reported health status. Maintaining continuous use and access to needed medications in later life has important implications for quality and length of life. A primary barrier shown to interfere with medication adherence in older adults is an inability to pay for medication. Relative to their younger counterparts, older adults have more financial protections that increase access to needed prescription medication through health insurance coverage. Despite these added protections, older adults are more likely to experience financial insecurity, with some evidence suggesting that COVID-19 accentuated existing vulnerabilities. Data are derived from the Health and Retirement Study (HRS), leveraging data drawn from the 2016, 2018, and 2020 study waves (n=3,185). Logistic models were used to evaluate the association between five COVID-19 related financial setbacks (i.e., inability to pay mortgage/rent, credit card bills, utility or insurance bills, medical bills, and inadequate money for food), and medication nonadherence among adults 60+. Results show that net of pre-COVID financial vulnerabilities and socioeconomic status, individuals who reported being unable to pay medical bills and those unable to pay rent/mortgage after the start of the pandemic reported higher odds (19% higher and 230% higher odds, respectively) of not taking/filling their prescription medication due to cost. Results suggest that greater financial protections for housing and medical bills among financially vulnerable older adults will increase medication adherence.

FINANCIAL HARDSHIPS AND DEPRESSIVE SYMPTOMS DURING COVID: THE MODERATING ROLE OF RESILIENCE

Brooke Helppie-McFall,[1] Dawn Carr,[2] Miles Taylor,[2] and Amanda Sonnega[1], *1. University of Michigan, Ann Arbor, Michigan, United States, 2. Florida State University, Tallahassee, Florida, United States*

Financial hardships during COVID (FHDC) are a particularly salient stressor that older people faced during the pandemic. Financial stress is associated with increased depressive symptoms and may be especially consequential to mental health among older people who have fewer resources (i.e., financially vulnerable). Recent evidence shows that psychological resilience has important protective effects for mental health among older adults who experience major stressors. This study, based on the recently released full 2020 core wave of the Health and Retirement Study, examines the association between having experienced one or more major financial setbacks following the start of the pandemic and depressive symptoms. We evaluate the consequences of FHDC for mental health, how FHDC are associated with previous financial vulnerability, and the role of psychological resilience in shaping the effects of FHDC. Results show that having experienced FHDC is associated with an increase in depressive symptoms. In addition, reporting financial vulnerabilities four years prior to the pandemic was also associated with increased depressive symptoms. Finally, psychological resilience was associated with a significant, protective effect on depressive symptoms, and moderated the consequences of FHDC. Specifically, we find that those who had FHDC and had average or below average resilience experienced significant increases in depressive symptoms, but those with above average resilience did not experience increases in depressive symptoms despite having FHDC, accounting for the consequences of previous financial vulnerabilities. These results suggest that psychological resilience has potential to be a protective resource for mental health consequences of financial stress among older adults.

DIFFERENTIAL ROLES OF COVID-19-RELATED STRESSORS IN MENTAL HEALTH PROBLEMS: A NETWORK APPROACH

Wen Zhang,[1] Tianyin Liu,[2] Dara Kiu Yi Leung,[2] Wai-wai Kwok,[1] Lesley Sze,[1] Gloria H.Y. Wong,[1] and Terry Lum[1], *1. The University of Hong Kong, Hong Kong, Hong Kong, 2. The University of Hong Kong, Hong Kong, Hong Kong*

COVID-19-related stress is heterogeneous and associated with increased mental health conditions in older adults. This study is to investigate relationships between different stressors and how different stressors may increase risks for mental health conditions through a network approach. A telephone survey was conducted among 4,921 older adults (age≥60) from April to June 2022 during the biggest community outbreak of COVID-19 in Hong Kong. The validated 8-item COVID-19-Related Stress Scale (CSS-old) (Cronbach's α: 0.91) was used to investigate the different stressor for older people in Hong Hong. Respondents were screened for depression using the Patient Health Questionnaire-2 (PHQ-2), anxiety using the Generalized Anxiety Disorder 2-item (GAD-2), and stressors with the CSS-old, 4708 responded to all questions. A regularized partial correlation network via graphical LASSO procedure was computed to analyze the relationship between 8 stressors; a directed acyclic graph (DAG) via a Bayesian hill-climbing algorithm was generated from CSS-old and comorbidity network with PHQ-2 and GAD-2 items. Network analyses identified CSS-old item 6 (families or friends infected), item 3 (daily life interrupted), item 5 (fear of infection affecting the family), and item 8 (worry for community's health) as the core stressors. DAG analysis found a key triggering role for item 1 (suspension of community services), and the activation of the mental health problems occurred through item 1, which bridged the COVID-19-related stress and mental health problems. These findings suggested that providing support for families with COVID-19 patients and alternative services during community service suspension may reduce mental health problems risks.

CULTURAL AND SOCIAL FACTORS IN CARE DELIVERY BY AFRICAN AMERICAN CAREGIVERS OF ADULTS WITH DEMENTIA AND COVID-19

Idorenyin Udoh, and Elias Mpofu, *University of North Texas, Denton, Texas, United States*

African American /Black caregivers make up 13% of the total number of adult caregivers in the United States and

41% more likely to provide help greater than three activities of daily living than other ethnicities. How they perceive socio-cultural factors to influence their care giver roles is less documented. This study aims to synthesize the evidence on the role of culture and social factors in African American caregiver perceptions delivering care to older adults with dementia and COVID-19. Searches of the Ageline, Medline, PsycInfo, Academic search complete Psychology and Behavioral science collection and Google scholar for empirical study publications on socio-cultural factors for dementia care and COVID-19 among African American caregivers yielded six studies. To be included, studies met the following criteria (a) focus on African American caregivers of older adults with dementia and focus on Covid-19 (b) socio-cultural factors (c) perceptions and practices. (d)published between 2019–2022. Studies indicate compassionate care practices by African American caregivers of persons with dementia and Covid-19. African American care givers of persons with dementia and COVID19 perceive caregiving as a responsibility they owe and not a job. They also perceived to be guided by their racial identity and faith beliefs, integrating family values and culture into caregiving. African American carers of persons living with dementia and COVID-19 have compassion and resilient care self-perceptions in caregiving to people with Dementia and COVID-19. Supporting compassionate care delivery by African American carers requires understanding social and cultural factors driving their commitment to quality care.

COVID-19 WIDOWHOOD OR PANDEMIC WIDOWHOOD: EXAMINING THE DIFFERENTIAL IMPLICATIONS FOR MENTAL HEALTH

Haowei Wang,[1] Emily Smith-Greenaway,[2] Shawn Bauldry,[3] Rachel Margolis,[4] and Ashton Verdery[5], *1. The Pennsylvania State University, Quincy, Massachusetts, United States, 2. University of Southern California, Los Angeles, California, United States, 3. Purdue University, West Lafayette, Indiana, United States, 4. Western University, London, Ontario, Canada, 5. The Pennsylvania State University, State College, Pennsylvania, United States*

Millions of COVID-19 widows worldwide face elevated mental health risks that foreshadow worsening physical health and elevated mortality. It remains unknown whether the excess mental health problems for COVID-19 widows are a result of the "bad death" experiences from COVID-19 (e.g., unexpected death and high levels of medical intervention) or pandemic-induced social changes (e.g., social isolation and limited funerals). This study examines whether older adults whose spouses died of COVID-19 disease have worse mental health (self-reported depression, loneliness, and trouble sleeping) than those whose spouses died from causes other than COVID-19 before and during the pandemic. We used Survey of Health, Ageing and Retirement in Europe data collected before (Wave 8, fielded October 2019 to March 2020) and during the pandemic (COVID-19 Supplement-2, fielded June to August 2021) to compare three groups whose spouses died (a) before the pandemic, (b) from COVID-19 during the pandemic, and (c) from non-COVID-19 causes during the pandemic. We find those spouses died from COVID-19 have higher risks of self-reported depression, loneliness, and trouble sleeping than those losing a spouse before the pandemic. However, losing a spouse due to non-COVID-19 causes during the pandemic is not significantly associated with worse mental health compared to pre-pandemic scenarios. During the pandemic, older adults whose spouses died from COVID-19 report higher risks of loneliness than those spouses died from non-COVID-19 causes. This study suggests losing a spouse due to COVID-19 presents unique mental health risks for older adults, clarifying prior theories about mental health impacts of pandemic bereavement.

COVID-19 VACCINATIONS AMONG COMMUNITY-DWELLING PERSONS LIVING WITH DEMENTIA AND THEIR CAREGIVERS

Brandy Renee McCann,[1] Jyoti Savla,[1] Karen Roberto,[2] and Rosemary Blieszner[1], *1. Virginia Tech, Blacksburg, Virginia, United States, 2. Virginia Polytechnic Institute & State University, Blacksburg, Virginia, United States*

There is a paucity of information regarding the uptake of the COVID-19 vaccine among community-dwelling persons living with dementia and their family caregivers. We examined factors influencing COVID-19 vaccine acceptance and hesitancy among community-dwelling persons living with dementia and their family caregivers during the early months of the vaccine rollout (February-March, 2021). Data came from three waves of telephone interviews (Mtime = 38.33 minutes) with 26 family caregivers living in rural Appalachian Virginia (96% White, 81% Female, Mage= 63±12 years, 42% Spouse Caregivers). We conducted a four-stage trajectory-based thematic content analysis and used the health belief model to interpret the data. Whereas all family caregivers and their relative living with dementia were eligible for the vaccine at Wave 3, only 10 dyads received it, while 10 dyads did not. In two families, the caregivers received the vaccine but not the person living with dementia; in four families, the caregiver had not received the vaccine, but their relative did. COVID vaccination acceptance was influenced by perceived direct and indirect health risks, cues from trusted allies, and ability to overcome vaccination barriers. Homebound people living with dementia faced unique barriers including transportation to vaccine sites and providers' inability to deliver the vaccine to the home. Caregivers who refused or delayed vaccinations for themselves or their relatives discussed confusion about eligibility, low perceived risk of COVID, vaccine fear, and personal choice beliefs. Findings inform direct care delivery for interdependent family members who live in remote locations facing a public health crisis.

COVID-19 RELATED MEDICAL CARE DELAYS IN UNDERSERVED AFRICAN AMERICAN OLDER ADULTS WITH COMORBIDITIES

Edward Adinkrah, Sharon Cobb, Lucy Kibe, Roberto Vargas, and Mohsen Bazargan, *Charles R. Drew University of Medicine and Science, Los Angeles, California, United States*

Health seeking behaviors have been negatively impacted during the COVID-19 pandemic particularly among minority older adults. There is a paucity of data concerning African American older adults who delayed, reduced, or stopped visits to primary and specialty providers. To outline the magnitude of this health disparity, this study examines the patterns and correlates of seeking preventive and specialized healthcare within this population. One-hundred and fifty (150) underserved African Americans older adults took part in this health advisor-led cross-sectional study. They completed a survey that inquired about seeking medical, dental, emergency room, and/or specialty care. We employed descriptive analyses to assess patterns of healthcare and multinomial logistic regression to document correlates of healthcare utilization. Almost one-third of participants (32%) delayed or did not get at least one type of care because of COVID-19. Dental care was the most frequent healthcare service that was missed (23%), followed by primary care (10%) and specialty care (7%). A higher level of depressive symptoms, lower level of educational attainment, and higher number of chronic conditions were associated with a higher number of delayed or cancelled medical care. Almost one-third of participants had never used any type of telehealth. Additionally, access and use of telehealth had no impact on healthcare utilization. One-year post pandemic, while vaccines are widely available, COVID-19 is disproportionately worsening healthcare disparities that exist even among African American older adults in underserved and under-resourced communities with access to healthcare. Interventional studies are urgently needed.

CLINICIANS' PERSPECTIVES ON THE EVOLUTION OF PALLIATIVE CARE DELIVERY DURING THE COVID-19 PANDEMIC

Laura Quintero Silva,[1] Andiara Schwingel,[2] Julie Bobitt,[3] and Minakshi Raj[4], *1. University of Illinois Urbana-Champaign, Champaign, Illinois, United States, 2. University of Illinois, Urbana Champaign, Urbana Champaign, Illinois, United States, 3. University of Illinois at Chicago, Chicago, Illinois, United States, 4. University of Illinois Urbana Champaign, Champaign, Illinois, United States*

Palliative care has been primarily delivered to patients in person since its inception. During the Covid-19 pandemic, providing palliative care was especially challenging for clinicians due to public health measures to contain the virus that required them to interact virtually with patients and families. While the rapid implementation of telehealth has been examined in other clinical contexts, limited research has studied the impact of the pandemic on palliative care delivery. This study examined the experiences clinicians faced when providing palliative care to older adult patients during the pandemic. Between April 2021 and March 2022, we interviewed 29 geriatricians and palliative care specialists from 11 institutions across the US. We asked clinicians about their experiences with palliative care during the pandemic, including challenges and opportunities related to the changing nature of palliative care delivery. We analyzed interviews using reflexive thematic analysis. The following three themes emerged from the analysis: (1) Clinicians' challenges adjusting to virtual care; (2) System-level barriers, restrictions, and uncertainties about Covid-19; and (3) Older adult patients' context and vulnerability (i.e., loss of social engagement, isolation, loneliness, delayed access to care) that increased the complexity of their health conditions. In conclusion, clinicians' experiences during the pandemic shed light on the evolution of palliative care delivery and the importance of preparing them for new care models that account for virtual delivery and that address the diverse needs of older adults that emerge during public health crises.

CHANGES IN OLDER ADULTS' LONELINESS OVER TWO YEARS OF COVID-19: A MIXED-METHODS ANALYSIS

Emily Kinkade, Heather Fuller, Bryce Van Vleet, and Andrea Huseth-Zosel, *North Dakota State University, Fargo, North Dakota, United States*

Throughout the COVID-19 pandemic, social distancing and stay-at-home behaviors have been recommended to protect older adults from severe illness. However, despite disease reduction benefits, self-isolation may place older adults at an increased risk for loneliness, another serious public health concern. This longitudinal, mixed-methods study investigates whether older adults' perceptions of loneliness changed across two years of the pandemic and how older adults described their experiences with loneliness at different points of the pandemic. Between April 2020 and June 2022, five waves of interviews were conducted with 76 Midwestern older adults between the ages of 70 and 97. At each interview, participants completed the UCLA Three-Item Loneliness Scale and answered several open-ended questions about their current daily life, social connections, and experiences and perceptions during the pandemic. A repeated-measures ANOVA indicated that participants' loneliness scores significantly decreased between the first and final interview, although there was a nonsignificant increase in loneliness at the third interview. Thematic coding of the interview transcripts identified four emergent themes related to loneliness across two years of the pandemic: 1) differentiation of isolation from loneliness, 2) acceptance of circumstances, 3) adaptation to prevent loneliness, and 4) barriers to adaptation. Findings suggest older adults had nuanced and shifting experiences of loneliness throughout the pandemic, in which they generally showed increasing acceptance and strong adaptation to feelings of loneliness. However, adaptation was also challenged as the pandemic endured. Our discussion will highlight protective and risk factors for older adults' loneliness and directions for future study and practice.

BEFORE & AFTER THE 2020 NATIONAL SHUTDOWNS: PANDEMIC EXPERIENCES OF OLDER AMERICAN ADULTS WITH & WITHOUT A DISABILITY

Fanni Farago, *AARP, Washington D.C., District of Columbia, United States*

Since the onset of the COVID-19 pandemic, there have been drastic changes to people's day-to-day lives. Following the 2020 U.S. national shutdown, day-to-day life included increased social isolation, COVID-19 anxieties, disruptions to employment, and limited access to staple goods for many. Compared with the general population, the impacts of these changes are much less understood for the aging population, and particularly for older adults with a disability or chronic disease, who are at greater risk of adverse effects from COVID-19 and related circumstances. Drawing on the breaking results of the AARP Vital Voices national survey (n=2071), conducted throughout the pandemic (2019 to 2021), this poster presentation sheds light on the pandemic experiences of older American adults with and without disability or chronic disease. Interesting findings are discussed across age groups and by gender. Overall, the results show notable differences in the social connection experiences of older adults with a disability or chronic disease (n=571) pre-and-post the national shutdown, along with differences in the accessibility of household items, staple foods, and medical care in the wake of the 2020 U.S. national shutdown. The implications of these findings are discussed in the context of related literature.

ASSOCIATIONS BETWEEN COVID-19 RELATED STRESS, COVID-19 EXPERIENCES, AND MENTAL HEALTH RISKS IN OLDER PEOPLE

Tianyin Liu,[1] Dara Kiu Yi Leung,[1] Wen Zhang,[2] Wai-wai Kwok,[2] Lesley Sze,[2] Edwin Wong,[2] Gloria H.Y. Wong,[2] and Terry Lum[2], *1. The University of Hong Kong, Hong Kong, Hong Kong, 2. The University of Hong Kong, Hong Kong, Hong Kong*

There is increasing recognition of the need to understand the mechanism of psychological impact brought by COVID-19. The present research used the Delphi technique to develop a COVID-19-Related Stress Scale for older people in Hong Kong (CSS-old) (study one) and examined its associations with COVID-19 experiences and mental health risks (study two). In study one, 17 helping professionals and 20 service users co-developed an 8-item CSS-old through four rounds of Delphi. In study two, a cross-sectional telephone survey was conducted between April and June 2022 among 4,921 older people (age≥60) recruited through community centres. Respondents were assessed using Patient Health Questionnaire-2 (PHQ-2), Generalized Anxiety Disorder 2-item (GAD-2), and CSS-old; their experiences with COVID-19 (infection, close friend/family infection) and demographical information were collected. A three-factor solution of CSS-old was identified after dropping one item (X2(df) = 83.53(11), CFI=0.996, TLI=0.993, RMSEA=0.037): (1) disruption to routines; (2) fear of infecting families/friends; and (3) concern for the community's health. Structural equation modelling analyses revealed that being female (B=0.45), having close friend/family infected (B=1.10) and having a pre-existing mental health condition (B=1.87) were positively associated with COVID-19-related stress. Infection of COVID-19 (BPHQ=0.22; BGAD=0.24) and a pre-existing mental health condition (BPHQ=0.71; BGAD=0.59) had direct associations with depressive and anxiety symptoms; COVID-19-related stress mediated the relationship between close friend/family infection with depressive (B=0.20) and anxiety symptoms (B=0.21, all $p < 0.05$). These results suggest that older people's COVID-19-related stress is beyond infection of the disease, and different experiences with COVID-19 may increase depression and anxiety risks through different pathways.

COMPARING INFORMANT BASED MEASURES OF COGNITIVE FUNCTIONING BETWEEN THE US AND MEXICO

Yuan Zhang,[1] Phillip Cantu,[2] and Joseph Saenz[3], *1. University of North Carolina at Chapel Hill, Chapel Hill, North Carolina, United States, 2. The University of Texas Medical Branch, Galveston, Texas, United States, 3. University of Southern California, Los Angeles, California, United States*

Informant reports are important for understanding cognitive impairment and dementia in older populations. Recently, several population-based aging studies have included harmonized direct and informant assessments to assess the prevalence of dementia globally as part of the international Harmonized Cognitive Assessment Protocol (HCAP). However, the social and cultural contexts of nations, sociodemographic characteristics of informants, and the subject-informant relationship may affect the meaning and accuracy of informant reports of cognitive decline and functioning. This study examines the extent to which informant characteristics and the informant-respondent relationships are associated with informant-reported cognitive function in the United States and Mexico. Data are from the 2016 US Health and Retirement Study (HRS) HCAP (Nf 2,918) and the Ancillary Study of Cognitive Aging in Mexico (Mex-Cog) (Nf 1,750). Informant-reported cognitive function was measured by the informant Community Screening Instrument for Dementia (CSI-D). Linear regression is used to assess the association of informant characteristics and the information-participant relationship with the total CSI-D score. We find older Americans have worse informant-reported cognitive functioning but higher directly-assessed cognitive functioning than Mexicans. Nearly 80% of informants lived with the subject in Mexico, compared to less than half in the US. In both countries, older informants, children and other family members (compared to spouse) report less cognitive impairment. In Mexico, female informants reported more impairment. In the US, coresident informants reported more impairment. This research shows how social environments influence informant reporting. Understanding heterogeneity in informants is vital when examining informant measures of cognitive function in cross-countries studies.

A CROSSWALK OF COMMONLY USED FRAILTY SCALES

Stephanie Denise Sison,[1] Sandra Shi,[2] Kyung Moo Kim,[3] Gahee Oh,[2] Nessa Steinberg,[2] Sohyun Jeong,[2] Ellen McCarthy,[2] and Dae Kim[4], *1. Beth Israel Deaconess Medical Center, Brookline, Massachusetts, United States, 2. Hebrew Senior Life, Roslindale, Massachusetts, United States, 3. John A. Burns School of Medicine University of Hawaii, Honolulu, Hawaii, United States, 4. Hebrew Senior Life, Boston, Massachusetts, United States*

Several validated scales have been developed to measure frailty, yet it remains unknown how these measures are related. We used data from 7,070 community-dwelling older adults who participated in National Health and Aging Trend Study round 5 to construct a crosswalk among frailty measures. We operationalized the 60-item Frailty Index (FI), Study of Osteoporotic Fracture (SOF) Index, FRAIL Scale, Frailty Phenotype, Clinical Frailty Scale (CFS), Vulnerable Elder Survey-13 (VES-13), Tilburg Frailty Indicator (TFI), Groningen Frailty Indicator (GFI), and Edmonton Frailty Scale (EFS). Missing data, needed for the calculation of frailty scores, were imputed using multiple imputation by chained equations method. We then linked the scores of each frailty measure to FI using the equipercentile method, a statistical procedure that links different scales by equating percentile distributions. Participants considered frail on FI (cutpoint of 0.25) corresponded to the following scores on each frailty measure: SOF 1.3, FRAIL 1.7, Phenotype 1.7, CFS 5.3, VES-13 5.5, TFI 4.4, GFI 4.4, and EFS 5.8. Conversely, individuals considered frail on each frailty measure corresponded to the following FI scores: 0.37 (SOF), 0.40 (FRAIL), 0.42 (Phenotype), 0.21 (CFS), 0.19 (VES-13), 0.28 (TFI), 0.22 (GFI), and 0.37 (EFS). The CFS, VES-13, TFI and GFI each discriminates between non-frail and frail people in the pre- to mildly frail spectrum on the FI, whereas the SOF, FRAIL Scale, Phenotype, and EFS detect those in the higher frailty spectrum on the FI. Our results provide clinicians and researchers with a useful tool to convert and interpret frailty across scales.

ULTRASOUND MUSCLE THICKNESS AS AN EASY METHOD TO ASSESS LEAN MASS AND GRIP STRENGTH IN OLDER ADULTS

Lara Vilar Fernandes,[1] Gabriela Benatti De Oliveira,[2] Ana Carolina Junqueira Vasques,[1] Flavia Andrade,[3] Xia Yu Summer Chen,[4] and Ligiana P. Corona[5], *1. University of Campinas - UNICAMP, Limeira, Sao Paulo, Brazil, 2. University of Campinas - UNICAMP, Campinas, Sao Paulo, Brazil, 3. University of Illinois--Urbana-Champaign, Urbana, Illinois, United States, 4. University of Illinois at Urbana Champaign, Urbana, Illinois, United States, 5. Universidade Estadual de Campinas/ Faculdade de Ciências Aplicadas, Limeira, Sao Paulo, Brazil*

Ultrasound is emerging as an effective method for measuring muscle mass in older adults, being more cost-effective than other image methods, such as Dual-energy X-ray absorptiometry (DXA) and computed tomography, and more accurate than bioelectrical impedance and anthropometry. We aimed to evaluate the correlation between measurements of muscle thickness (MT) measured by a portable A-mode ultrasound, the total lean mass (TLM) measured by DXA, and grip strength (GS) among community-dwelling Brazilian older adults. This is a cross-sectional pilot study with 30 participants (9 men and 21 women) aged 60–78. MT was assessed in five anatomic sites (triceps, biceps, anterior and posterior thigh, calf) using a portable A-mode ultrasound (BodyMetrix BX-2000 - IntelaMetrix, Inc.); TLM was assessed by DXA (GE Healthcare's Lunar iDXA), and GS was assessed using a Saehan dynamometer. Pearson´s test was used for correlation analysis between each site MT and TLM; linear regressions were estimated to verify the association between GS and each site MT, controlling for age. Lower limb measurements (anterior and posterior thigh, calf) were not associated with TLM and GP. Triceps MT was significantly correlated to TLM (r=0.565; p=0.001) and associated to GS (β=0.699; p=0.004); biceps MT was also correlated to TLM (r=0.425; p=0.019) and associated to GS (β=0.652; p=0.012). Our results suggest that upper limb ultrasound measurements using portable equipment can be a helpful cost-effective indicator of muscle mass and function in older adults. Further results and conclusions will be reported after completing the study with the total planned sample (n=150).

SEX DIFFERENCES AND LONGITUDINAL QUANTILES OF FRAILTY TRAJECTORIES WITH MISSING DATA DUE TO DEATH

Alejandra Marroig,[1] Fernando Massa,[2] Scott Hofer,[3] and Graciela Muniz Terrera[4], *1. Universidad de la Republica Uruguay, Montevideo, Montevideo, Uruguay, 2. Universidad de la República, Montevideo, Montevideo, Uruguay, 3. University of Victoria, Victoria, British Columbia, Canada, 4. Ohio University, Athens, Ohio, United States*

Scarce evidence exists about frailty trajectories, but the evidence suggests that women live longer with higher levels of frailty. When progression of frailty was studied, the focus has been on mean trajectories and research has ignored death. Here, we aim to assess the role of sex, age, and education in different quantiles of the distribution of frailty trajectories. We derived a frailty index (FI, range 0–1) based on the accumulation of deficits in individuals aged 65 at baseline (n=6929) using data from the Survey of Health, Ageing, and Retirement in Europe (SHARE). We applied weighted Generalized Estimating Equations (weighted GEE) to adjust the quantiles of the FI trajectory by sex, and education. The results show that the median FI trajectory increases with age (b_age0.5=0.008, $p < 0.001$) and this increase is higher for women than men (b_age*sex0.5=0.003, $p < 0.001$), but sex differences disappear for the most frail (0.9 percentile) once the missing data process is accounted for (b_age*sex0.9=0.002, p=0.085). For the most frail the increase with age is higher than for those at the median (b_age0.9=0.018, $p < 0.001$; test diff, $p < 0.001$) and education reduces the progression of the median FI (b_age*edu0.5=-0.0003, $p < 0.001$). Our approach advances the understanding of frailty trajectories of older adults, showing differences across quantiles. Thus, this may improve the practice and design of interventions aimed at older adults. In addition, we address the process of missing information and the results show new insights, particularly for those who are most frail.

SERUM PROGRANULIN AS A POTENTIAL BIOMARKER FOR FRAILTY IN CHINESE OLDER ADULTS

Pan Liu,[1] Yun Li,[1] Shijie Li,[1] Yaxin Zhang,[1] Yu Song,[1] Tong Ji,[2] Ying Li,[1] and Lina Ma[1], *1. Xuanwu Hospital Capital Medical University, Beijing, Beijing, China (People's Republic), 2. Capital Medical University Xuanwu Hospital, Beijing, Beijing, China (People's Republic)*

Background: Frailty increases the risk of adverse health outcomes in older adults. Progranulin is a secreted glycoprotein involved in regulating various biological processes. A few studies have investigated the relationship between progranulin and frailty in middle-aged and older populations; however, different perspectives exist. We aimed to evaluate the association of progranulin with frailty in older Chinese adults. Methods: We included 265 older in-patients who were divided into the frail (n=107) and non-frail (n=158) groups according to the FRAIL scale. Serum IL-6, CXCL-10, and progranulin levels were assayed. Spearman's correlation analysis and logistic regression models were used to analyze the association of serum biomarkers with frailty, and the ROC was used to evaluate the diagnostic progranulin value for frailty. Results: The frail group was older, had lower

BMI, higher prevalence of coronary heart disease, worse grip strength and walking speed, and higher serum levels of IL-6, CXCL-10, and progranulin, than the non-frail group. Progranulin levels were negatively correlated with grip strength and positively correlated with IL-6 and CXCL-10. The logistic regression analysis showed that IL-6, CXCL-10, and progranulin were associated with frailty, respectively. Furthermore, progranulin remained associated with frailty after adjusting for age, sex, BMI, smoking, and chronic diseases (OR=1.003, 95%CI=1.001–1.005, p=0.013). The AUC of serum progranulin levels for diagnostic frailty was 0.872 (95%CI=0.829–0.914, $p < 0.001$). Conclusion: High serum progranulin levels were observed in frail older in-patients and associated with worse physical function and chronic inflammation. This association indicates that progranulin may be a potential biomarker for frailty.

PSYCHOMETRICS IN THE DEVELOPING OF LONGITUDINAL MEASURES OF FRAILTY

Stacey Voll,[1] Graciela Muniz Terrera,[2] and Scott Hofer[1], *1. University of Victoria, Victoria, British Columbia, Canada, 2. Ohio University, Athens, Ohio, United States*

Frailty has become an increasingly important aspect in the field of health research in studies of vulnerability to adverse events and individuals functioning due to accumulated health deficits. Yet, there is no agreement on how to measure frailty or identify adults as frail, resulting in high heterogeneity between estimates of frailty and identification of frail individuals. The purpose of this poster is to provide a summary of the process in the development of a frailty index with robust psychometric properties to be used in research using longitudinal health study sets.

DEVELOPMENT OF PREDICTIVE MODELS FOR INCIDENT FRAILTY IN OLDER ADULTS: MACHINE LEARNING APPROACHES

Heeeun Jung,[1] Miji Kim,[2] Mina Park,[3] Jinhyung Ryu,[4] Kyung-Ryoul Mun,[4] and Chang Won Won[1], *1. Kyung Hee University, Dongdaemun-gu, Seoul-t'ukpyolsi, Republic of Korea, 2. Kyung Hee University, Seoul, Seoul-t'ukpyolsi, Republic of Korea, 3. Korea University, Seongbuk-gu, Seoul-t'ukpyolsi, Republic of Korea, 4. Korea Institute of Science and Technology, Seongbuk-gu, Seoul-t'ukpyolsi, Republic of Korea*

Frailty is not only a clinical symptom accompanying adverse health outcomes but also a syndrome that involves a dynamic transition between varying phases. This study aimed to develop machine learning (ML) models for predicting incident frailty over a 2-year follow-up period among Korean community-dwelling adults aged 70 years and older. We conducted prospective analyses (n=2,408) among participants who underwent measurement of frailty status at baseline and 2-year follow-up from the Korean Frailty and Aging Cohort Study. Frailty was defined as the presence of three or more of five components using the Fried frailty phenotype. A total of 2,250 participants classified as non-frail at baseline and 116 (5.2%) with incident frailty during the 2-year follow-up. 32 variables selected by stepwise analysis were used as inputs among 77 variables composed of sociodemographic and clinical characteristics. The different ML models such as Logistic Regression(LR), K-Nearest Neighbor(KNN), Gaussian Naïve Base(NB), Support Vector Machine(SVM), and Random Forest(RF) with the 10-fold cross validation were compared. A feature selection, grid search, and data resampling methods were applied to find the best inputs and models. The best performing inputs of 16 variables were found and Gaussian NB achieved the highest accuracy of 0.82 and F1-score of 0.79 in predicting frailty incidence after 2-years with selected 16 inputs, followed by RF (accuracy 0.82, F1-score 0.76) and LR (accuracy 0.80, F1-score 0.76). We developed ML models for predicting frailty and is expected to contribute to the early prediction of frail older adults and timely intervention in clinical and community settings.

"IBASHO" AND THE OBJECTIVE WELL-BEING OF OLDER ADULTS IN A MARGINALIZED COMMUNITY.

Yuichi Watanabe, *Musashino University, Nishitokyo, Tokyo, Japan*

"IBASHO" in Japan means a place where people can feel safe, have roles, and recognize their lives as meaningful. If IBASHO helps older adults to see their lives as meaningful, implementing "IBASHO" in the community would possibly contribute to community members' objective well-being. This research examines the relationship between the activities that make up "IBASHO" and the objective well-being of older adults. Data were gathered by surveying a marginalized community every two years from 2009 to 2019 (Nf882). Multiple regression analysis was conducted. A six-point scale derived from a survey question measured the objective well-being of older adults as the dependent variable. For measuring "IBASHO," five items asked about engagement in activities such as "hosting a tea meeting" or "holding a hobby workshop," with the extent of engagement measured using a five-point scale. The total of these five items' points (Cronbach's alpha=.860) was analyzed as an independent variable. Gender, age, economic status, health status, and living alone were also included in the analysis. Results show "IBASHO" activity is a significant predictor of the objective well-being of older adults ($p < .000$) in the full model. Age, economic status, and health status are also significantly associated with well-being. Findings suggest that implementing "IBASHO" within community settings is associated with higher levels of well-being among older adults in the community. "IBASHO" is crucial to realizing the "no one left behind" policy in Japan.

YOU'VE GOT A FRIEND: SOCIAL FACTORS AND DEPRESSIVE SYMPTOMS IN OLDER ADULTS

Erika Fenstermacher,[1] and Amy Fiske[2], *1. West Virginia University, Pursglove, West Virginia, United States, 2. West Virginia University, Morgantown, West Virginia, United States*

Depression in late life is associated with disability, lower quality of life, increased mortality, and risk of suicide. Research suggests that functional disability, which is often brought about by a medical condition, may precede depressive symptoms and may be a major factor for older adults developing depression. Social support can be beneficial for both emotional and physical health. Numerous studies demonstrate that social networks, perceived and subjective social support, and satisfaction with support received moderate the relation between health problems and depression. Findings are mixed regarding received and objective social support and only one study was found that examined the impact of giving support to others. The current study addressed gaps in the literature by focusing on three facets of social relationships: availability of support, participant giving help, and participant receiving help. Data from the 2011 wave of the Wisconsin Longitudinal Study were used ($N = 3906$; mean age of 71.27; $SD = .948$). We examined the relationships between medical conditions, functional impairment, depressive symptoms, and social support using regression analyses. Medical conditions and functional impairment each independently predicted depressive symptoms. Availability of support significantly predicted lower levels of depressive symptoms and amount of help received predicted higher levels of depressive symptoms, controlling for medical conditions and functional impairment. These findings suggest that simply having someone available, not necessarily interacting with them for help, could reduce depressive symptoms in older adults.

WHAT I KNOW NOW THAT I WISH I HAD KNOWN WHEN I WAS YOUNGER: OLDER WOMEN'S RELATIONSHIP ADVICE AS SKINNY POETRY

Wendy Watson, Sandra Faulkner, and Charlie Stelle,
Bowling Green State University, Bowling Green, Ohio, United States

Research has demonstrated that relationships are important in the lives of older women. Eighteen women between the ages of 64–84 participated in interviews about their lives and relationships across the life course. As a final question, the women were asked, "What do you know now about relationships that you wish you'd known when you were young?" Responses to that question were examined using a skinny poem. The Skinny poem is a short poetry form that portrays a vivid image in 11 "skinny" lines. It is a type of lyric poem that uses condensed images, expressions of personal feelings, and demonstrations of emotional context in musical lines. Skinnys were written by one author and analyzed by a second author. This poster will present the 18 skinny poems and the analysis of the poems. In these skinnys, one can see the relationship experiences the women had throughout their lives. There is a connection to wisdom, a recognition that they have grown and learned about relationships over time and have advice they wished their younger selves had known. Emotions range from anger and anxiety to trepidation and regret. Most of the women reflect on things they would have done differently, from how they treated others to how they felt about themselves. They recognize that relationships take work and that as older women, they still do not know everything about relationships. They also learned about themselves as individuals and wished they had not searched for their identity and self-worth in their connection to others.

THE INFLUENCE OF MARRIAGE AND COHABITATION ON PHYSICAL ACTIVITY AMONG MIDDLE-AGED AND OLDER PEOPLE

Shuhan Yuan,[1] Kit Elam,[1] Jeanne Johnston,[2] and Angela Chow[2], *1. Indiana University, Bloomington, Bloomington, Indiana, United States, 2. Indiana University Bloomington, Bloomington, Indiana, United States*

The Behavioral Risk Factor Surveillance System (2020) indicates that 30.6% of middle-aged and older adults were physically inactive. Whereas marital status is linked to physical activity (PA), it is increasingly common for couples to cohabitate, making it important to capture these relationships. The stress/social support theory(Burman & Margolin, 1992) highlights the importance of relationship quality in long-term relationships, but this hasn't been cohesively examined relative to PA. This study investigated whether partnered living status (married/cohabitating) and partnered living quality (support/strain from partner, partner disagreements) were associated with PA in middle-aged/older adults. Data were from a nationally representative longitudinal study, Midlife in the United States(waves 1–3; Nf1113; aged 49–93). Subjects were categorized into four groups based on partnered living status over the three waves: partnered living at all waves (57.9%), non-partnered living (separated, divorced, widowed, or never married) at all waves (17.6%), change from partnered living to non-partnered living (20.8%), and change from non-partnered living to partnered living (3.8%). Regressions were conducted to test the effect of partnered living status and relationship quality on the frequency of moderate and vigorous PA at wave 3. Subjects who changed from non-partnered to partnered living had the highest moderate and vigorous PA levels. Partner support was positively associated with moderate PA ($\beta=0.50$, $p < 0.01$), and partner disagreements was negatively associated with vigorous PA ($\beta=-0.27$, $p < 0.01$). Results suggest that relationship status and quality can influence PA among the aging population. Public health educators should provide additional social support to older adults to promote PA.

PREDICTORS OF INDIVIDUAL TRANSPORTATION ALTERNATIVES IN THE TRANSITION TO NON-DRIVING

Kellia Hansmann,[1] Carolyn McAndrews,[2] and Stephanie Robert[3], *1. William S Middleton Memorial Veterans Hospital, Madison, Wisconsin, United States, 2. University of Wisconsin Madison, Madison, Wisconsin, United States, 3. UW-Madison, Madison, Wisconsin, United States*

For older adults who transition to non-driving, successful coping includes maintaining mobility. Individual transportation alternatives, e.g. rides from friends and family, are important coping factors in the transition to non-driving. However, it is unclear to what extent social network composition predicts the accessibility of these individual transportation alternatives. We examined whether various aspects of social networks (including living with a spouse/partner; having a child; living with a child; having other household members; having anyone to talk to about important things) were associated with the actual receipt of rides from family and friends. Using the National Health and Aging Trends Study (NHATS), a nationally representative cohort of Medicare beneficiaries ages 65 and older, we conducted a cross-sectional analysis using a subsample of community-dwelling older adults whose driving status was known at the baseline interview in 2015 ($n = 5{,}889$). We used logistic regression to estimate the association between social network indicators with the odds of receiving a ride from a family member or friend. When adjusting for biopsychosocial characteristics and current driving status, we found that having a spouse or partner was associated with a significant odds of having received a ride (adjusted OR, 95% CI = 1.41, 1.05–1.90) as was being able to name at least five people the participant could talk to about important things (adjusted OR, 95% CI = 1.65, 1.14–2.38). Our findings support previous evidence that marital status and support from social network members outside one's household may be particularly important for accessible individual transportation alternatives.

ARE OLDER ADULTS' SOCIAL PARTICIPATION AND RELATIONSHIP QUALITY RELATED TO THEIR SPOUSE'S COGNITION?

Changmin Peng,[1] Yan Lin,[2] Shan Qu,[3] and Yiyang Yuan[4], *1. University of Massachusetts Boston, Brookline, Massachusetts, United States, 2. University of Massachusetts Boston, Bedford, New Hampshire, United States, 3. University of Massachusetts Boston, Boston, Massachusetts, United States, 4. University of Massachusetts Chan Medical School, Worcester, Massachusetts, United States*

Limited studies have quantified older adults' profiles of social participation and relationship quality. How such profiles were associated with their spouse/partner's cognitive function also remains unknown. Using the Health and Retirement Study (2014/2016), we identified 3,722 community-dwelling, cognitively intact, married/partnered respondents living with their spouse/partner. Spouse/partner's cognitive function was ascertained by the Langa-Weier Classification [Intact/Cognitively Impaired but not Demented (CIND)/Demented]. Social participation was measured by the frequency of volunteer, charity, education, sport/social clubs, and non-religious organization activities. Relationship quality was measured by the perceived positive and negative support from spouse, children, relatives, and friends. Latent profile analysis identified profiles of social participation and relationship quality. Multinomial logistic regression estimated the association between spouse/partner's cognitive function and the respective profiles. Three social participation profiles were identified: (1) Limited social participation (prevalence: 69%; reference); (2) Frequent volunteer participation (10%); (3) Frequent non-volunteer participation (21%). Three relationship quality profiles were identified: (1) Positive overall support (68%; reference); (2) Positive spousal support (18%); (3) Negative spousal support with positive non-spousal support (14%). Those with a spouse/partner that were CIND or demented were significantly less likely to frequently participate in volunteer or non-volunteer activities, while more likely to perceive negative spousal support and positive non-spousal support. Given these findings and the essential role of social participation and relationship quality in older adults' well-being, programs focusing on older adults living with a spouse/partner with impaired cognition are needed to help them maintain social connectedness.

INVOLUNTARY JOB LOSS AND GENDERED HEALTH OUTCOMES IN MIDDLE AGE AND LATER LIFE: A LIFE COURSE ANALYSIS

Qian Song,[1] and Caitlin Connelly[2], *1. Universiy of Massachusetts Boston, Boston, Massachusetts, United States, 2. UMASS Boston, Boston, Massachusetts, United States*

Job loss is associated with a range of negative health outcomes. However, the causality of job loss and poor health is unclear, due to issues of endogeneity and reverse causality (i.e., adverse health causing job loss). We also need a better understanding of the long-term effects of job loss, and how the life stage in which job loss occurred yields different health outcomes for women and men in later life. To address these gaps, we take advantage of a quasi-experimental setting — the policy-driven layoffs of the State-Owned-Enterprises (SOEs) during the 1990s – mid-2000s in urban China. Using the life history survey of the China Health and Retirement Longitudinal Study 2014 and the 2015 wave, we examine the long-term effects of job loss on self-rated health (scored 1 – 5) of individuals in middle age and later life (aged 45+). After controlling for individual childhood health, life-time work history, as well as demographics and socioeconomic status, results from linear regressions show that overall, job loss from SOEs reduces self-rated health by 0.12 ($p < .05$) for both women and men. However, job loss hurts females' self-rated health the most when job loss occurred in early-life, a life stage in which childbearing and child caregiving were most intensive (aged 35 or earlier; $\beta = -0.24$, $p < .05$), whereas males' self-rated health is hardest hit if job loss occurred in mid-life (aged 36 – 45; $\beta = -0.35$, $p < .01$). The results suggest that involuntary job loss produce gendered health outcomes due to gendered life courses.

SHORT-TERM DIESEL EXHAUST PARTICLE NEUROTOXICITY MEDIATED BY TLR4 ACROSS AGE AND SEX

Kristina Shkirkova,[1] Hongqiao Zhang,[2] Arnold Diaz,[3] Wendy Mack,[4] Constantinos Sioutas,[2] Caleb Finch,[2] Christian Pike,[2] and William Mack[2], *1. USC Keck School of Medicine, Los Angeles, California, United States, 2. USC, Los Angeles, California, United States, 3USC, Los Angeles, Armed Forces - AP, United States, 4. USC, Los Angeles, California, United States*

Experimental animal exposures show neurotoxic effects of diesel in young mice even after short-term exposures. We hypothesize that neuroinflammatory effects of diesel exhaust particles (DEP) are mediated by toll-like receptor 4 (TLR4) activation in brain microglia. We studied both sexes of young (2 months) and middle-aged (18 months) TLR4 flx/flx (CX3CR1CreER +/-) mice, in which macrophage-specific TLR4 deletion is induced by tamoxifen. DEP from National Institute of Science and Technology (NIST 2975) was suspended in pure water and re-aerosolized for 5 hr exposure at 100 µg/m3 concentration. Experimental groups were Filtered Air+Corn Oil, DEP+Corn Oil, Filtered Air+Tamoxifen, DEP+Tamoxifen. We studied markers of inflammation, oxidative stress, and microglia activation in the white matter of corpus callosum. At baseline, middle-aged mice showed higher levels of microglia activation (Iba-1), complement activation (C5, C5a), and oxidative stress (8-OHdG, 4HNE). DEP significantly increased microglial activation, inflammation, and oxidative stress. TLR4 knockdown showed a rescue effect in DEP group for Iba-1 and 8-OHdG in young but not in middle-aged mice. Both C5a and 4HNE were rescued by TLR4 knockdown in young and middle-aged mice, possibly with less robust effects in older mice. No significant sex effects were observed. Middle-aged mice have higher levels of baseline white matter inflammation and oxidative stress. DEP exposure caused robust neuroinflammatory and oxidative responses in white matter across ages. TLR4 knockdown attenuated DEP caused neuroinflammatory and oxidative responses, suggesting that microglia play an important role in DEP neurotoxicity.

PREDICTORS OF 400M WALKING TIME: THE STUDY OF MUSCLE MOBILITY AND AGING (SOMMA)

Steve Cummings,[1] Sheena Patel,[2] Peggy Cawthon,[3] Paul Coen,[4] Russell T. Hepple,[5] Theresa Mau,[1] and Anne Newman[6], *1. San Francisco Coordinating Center, San Francisco, California, United States, 2. CPMC Research Institute, San Francisco, California, United States, 3. University of California, San Francisco, San Francisco, California, United States, 4. AdventHealth, Orlando, Florida, United States, 5. University of Florida, Gainesville, Florida, United States, 6. University of Pittsburgh, Pittsburgh, Pennsylvania, United States*

Longer 400m walking time has been strongly associated with overall mortality and many other aging-related outcomes in prior studies. Inability to walk 400m defines ‘mobility disability’. We assessed characteristics that might contribute to 400m walking time in SOMMA, a cohort of 879 men and women over age 70. We excluded people with a gait speed < 0.6 m/s. The analysis included 49 factors representing several domains: muscle mass and strength, body composition, oxygen delivery, muscle mitochondrial ATP generation, fitness by cardiopulmonary exercise testing (VO2 peak), fatigability by questionnaire, usual physical activity, depressed mood, cognitive performance, lower extremity pain, lower extremity sensation, smoking, wealth and income, and general health. We used both elastic net and forward step-wise regression to generate multivariate models. Factors associated with longer (worse) walking time in both elastic net and forward step-wise regression models were: *weaker leg power, *fatigue during treadmill testing, *higher BMI, *greater self-reported fatigability, *worse performance on the timed DSST test, *fewer hours spent walking, *taking more medications, *older age, *poorer fitness (VO2peak), *more joint stiffness, *smoking, and *reduced peripheral sensation. These results indicate that 400m walk time is influenced by numerous factors. Some are also associated with overall mortality and aging outcomes and therefore they might underlie the prognostic value of the 400m walk. Additionally, some of the predictors could be improved, such as leg strength, cardiopulmonary fitness, more time walking, quitting smoking, and treatment of joint stiffness, perhaps reducing the risk of mobility disability.

RURAL AGE-FRIENDLY ECOSYSTEMS: A SCOPING REVIEW WITH RECOMMENDATIONS FOR AGE-FRIENDLY COMMUNITIES

Daniel Liebzeit,[1] Anna Krupp,[2] Jacinda Bunch,[2] and Harleah Buck[3], *1. University of Iowa, North Liberty, Iowa, United States, 2. University of Iowa, Iowa City, Iowa, United States, 3. Csomay Center for Gerontological Excellence, Iowa City, Iowa, United States*

The population of older adults in rural areas is rising, and they experience higher rates of poverty and chronic illness, have poorer health behaviors, and experience different challenges than those in metropolitan areas. Promoting age-friendly rural communities and healthcare is key to improving outcomes and addressing disparities. This international scoping review seeks to 1) map the state of the science of age-friendly systems in rural areas regarding structural characteristics, processes for delivering age-friendly practices, and outcomes of age-friendly systems, 2) analyze strengths, weakness, opportunities, and threats of age-friendly system implementation, and 3) make person, practice, and policy-level recommendations to support active aging. Articles were retrieved from PubMed, CINAHL, AgeLine, PsychINFO, EMBASE, Scopus, and Academic Search Elite on 10/26/21 and included if they used age-friendly framing, self-identified as rural, and reported empiric data. Data were charted across three analytic layers: socioecological model, Donabedian’s framework, and SWOT analysis. While age-friendly systems in this review were heterogeneous, many utilized the World Health Organization age-friendly cities framework. Results reveal limited data on outcomes relevant to organizations. While the SWOT analysis revealed many strengths of age-friendly systems, it also revealed several weaknesses, threats, and gaps. Weaknesses included over-reliance on trained volunteers and staff, communication, and teamwork. Threats included community and health system barriers and challenges in developing regions. Despite the benefits of age-friendly systems, we must acknowledge limitations of the evidence base, pursue opportunities to examine organizational metrics to support implementation and sustainability of age-friendly systems, and leverage improvements in age-friendliness at a community level.

AN EVIDENCE-BASED APPROACH TO TELEPHONE REASSURANCE CALLS: A RANDOMIZED CONTROLLED TRIAL PROTOCOL

Morgan Minyo,[1] David Bass,[2] Catherine McCarthy,[3] Katherine Judge,[1] Fatima Perkins,[4] and Douglas Beach[4], *1. Cleveland State University, Cleveland, Ohio, United States, 2. The Benjamin Rose Institute on Aging, Cleveland, Ohio, United States, 3. Benjamin Rose Institute on Aging, Cleveland, Ohio, United States, 4. Western Reserve Area Agency on Aging, Western Reserve Area Agency on Aging, Ohio, United States*

The COVID-19 Pandemic forced many health and community organizations to suspend some previously offered services and supports for older adults. This created heightened concerns about negative impacts of isolation and loneliness on already vulnerable older adults. In response, the Western Reserve Area Agency on Aging (WRAAA) began the TeleCare Program, providing weekly telephone reassurance calls to home and congregate meal clients to maintain contact and identify unmet service needs. Because of its success, the TeleCare Program has continued as a regularly offered service, but the WRAAA sought to improve the Program by integrating it with BRI Care ConsultationTM, an evidence-based program of the Benjamin Rose Institute on Aging (BRIA). This poster reports on initial results of a randomized controlled trial to test the efficacy and feasibility of a new protocol for delivering telephone reassurance calls. The new protocol is modeled after the Initial Assessment in BRI Care

Consultation, which is a semi-structured, telephone conversation covering a comprehensive range of potentials problems. The protocol also connects high-risk clients to existing available home- and community-based services. Results demonstrate that components of proven evidence-based interventions are feasible to integrate into existing programs and services. This includes adapting a model for problem-identification and assessment based on a consumer-driven conceptual framework, a record keeping system to enhance consistency and fidelity of program delivery, and establishing a formal referral protocol to more seamlessly link clients to other available services.

AGE AND SITE DIFFERENCES IN PLANNED AND PERFORMED ACTIONS IN RESPONSE TO IDENTIFIED RISKS IN OLDER ADULTS

Deborah Finkel,[1] Linda Johansson,[2] Björn Westerlind,[3] Ulrika Lindmark,[4] and Marie Ernsth-Bravell[2], *1. Indiana University Southeast, New Albany, Indiana, United States, 2. Jönköping University, Jönköping, Jonkopings Lan, Sweden, 3. Linköping University, Linköping, Ostergotlands Lan, Sweden, 4. Karlstad University, Karlstad, Varmlands Lan, Sweden*

The Swedish health care system focuses on allowing older adults to “age in place”; however, that approach assumes that home health services are adequate to support health and prevent unnecessary decline. Data from the Senior Alert national quality register in Sweden were examined to compare the quality of care across care locations. First registration in Senior Alert was available for 2914 adults aged 57–109 (median age = 81): 3.6% dementia unit, 7.8% home health care, 4.4% rehabilitation unit, 62.8% hospital, 21.4% care home. There were significant differences across units in the number of identified risks in 4 categories: falls, malnutrition, oral health, and pressure ulcer. Individuals in rehabilitation units averaged 2.4 risks, individuals in dementia and care homes averaged 2.0 risks, and individuals in home health care and hospitals averaged 1.4 risks. For individuals with identified risks, the differences between planned and performed actions for each risk independently were greatest for those in home health care. Moreover, the correlation between total planned and performed actions in home health care was .79 for adults aged 65–80 years and .39 for adults aged 81 and over. The correlation did not differ across age for the other care units. Results suggest that individuals most in need of actions to address health risks (older adults in home health care) are least likely to have the actions performed. Training and support of workers responsible for home health care need to be improved if the “age in place” policy is to continue.

TRAJECTORIES OF HEALTH RECOVERY AFTER HIP FRACTURE IN OLDER ADULTS: A SCOPING REVIEW

Tingzhong (Michelle) Xue,[1] Jiepin Cao,[2] Leila Ledbetter,[3] Margaret Graton,[3] Yan Zhan,[4] Dingyue (Demy) Wang,[3] Youran Lee,[3] and Eleanor McConnell[3], *1. Duke University School of Nursing, Durham, North Carolina, United States, 2. NYU Grossman School of Medicine, New York City, New York, United States, 3. Duke University, Durham, North Carolina, United States, 4. Yale University, Orange, Connecticut, United States*

Hip fracture recovery outcomes in older adults are characterized by high mortality, lowered functional status, and feelings of being disrupted from a normal life. Studying recovery trajectories through the lens of resilience can provide novel perspectives for developing interventions targeting to promote recovery. However, the lack of knowledge of recovery trajectories and their variations in hip fracture patients impedes such efforts. This review aims to synthesize current evidence on how multiple health domains change longitudinally after hip fracture in older adults. The Joanna Briggs Institute scoping review methodology was followed, and seven databases were searched including Medline (PubMed), EMBASE, Web of Science Core Collection, CINAHL, Proquest Dissertations and Theses, Cochrane Central Register of Controlled Trials, and Cochrane Database of Systematic Reviews. No date limits were applied, and the final search resulted in 7,515 articles. Articles in English with participants aged 60 years and above who experienced a low-energy, nonpharmacological hip fracture in any health setting were selected. Results regarding multiple domains of health outcomes will be synthesized, including physical health (e.g. functional status, pain, nutrition, and mobility/physical performance), cognition, psychosocial health (e.g. depression, anxiety, social isolation, loneliness, and behavioral and psychological symptoms of dementia when individuals with dementia were included), and multidimensional outcomes such as health-related quality of life. Methodological challenges and limitations will be discussed. This review has important implications for clinicians and researchers to improve individualized treatment plans and research methodologies by providing a comprehensive, critical review of knowledge regarding health trajectories in older adults after hip fracture.

PHYSICAL SYMPTOM TRAJECTORIES OF OLDER ADULTS DURING THE COVID-19 PANDEMIC

Dylan Lee,[1] Soyoung Choun,[2] Hye Soo Lee,[2] Maria Kurth,[2] and Carolyn Aldwin[3], *1. Touro University Nevada, Henderson, Nevada, United States, 2. Oregon State University, Corvallis, Oregon, United States, 3. Oregon State University, Corvallis, Oregon, United States*

Older adults experience increased risk for morbidity and mortality during the COVID-19 pandemic (CDC, 2021). Social distancing and lockdown to prevent contagion may affected physical and mental health. We examined the fifteen physical symptom trajectories of older adults during the early months of the COVID-19 pandemic. We also examined age, gender, and marital status differences in each physical symptom trajectory. The sample consisted of 247 older adults (Mage = 71.1, SD = 7.3, 88.7% White, 73% women, 73.4% married), who participated in eight weekly longitudinal online surveys from April 28 to June 23, 2020. Random-effects logistic regression analysis controlling for age, gender, marital status, and depressive symptoms showed that the nine physical symptoms (headache, constipation/diarrhea, muscle soreness, shortness of breath, tightness of chest, backache, heart pounding, congestion, and sore throat) significantly decreased in the first few weeks, but then six symptoms (constipation/diarrhea, shortness of breath, tightness of chest, heart pounding, congestion, and sore throat) increased in later weeks of the study period.

Middle-aged participants reported higher number of headache, tightness of chest, heart pounding, and nausea/upset stomach than older participants. Women experienced more constipation/diarrhea, trembling/shaking, and sore throat than men. Those who were not married responded with higher number of shortness of breath, backache and poor appetite compared to married participants. Higher depressive symptoms were significantly related to each physical symptom. The results suggest that healthcare providers should evaluate physical symptoms focusing on the patients who are at greater risk of poor health during the pandemic.

LIKELIHOOD OF ADOPTION OF CAREMOBI: ADDRESSING COMMUNICATION GAPS BETWEEN ADULT DAY HEALTH CENTERS AND PRIMARY CARE

Zuha Ali,[1] and Tina Sadarangani[2], *1. Indiana University School of Medicine, Indianapolis, Indiana, United States, 2. New York University, New York, New York, United States*

Adult Day Health Centers (ADHC) are non-residential congregate facilities that serve 250,000 cognitively and functionally impaired adults daily. These centers are effective platforms for chronic disease management and interdisciplinary care coordination, with serial observations on participants over multiple hours and days per week. However, previous research indicates that ADHCs experience challenges in communication with primary care providers (PCPs). This is because 92% of ADHCs lack interoperable EHRs (electronic health record systems) and do not have the financial and technical infrastructure to implement them. CareMOBI (Mhealth for Organizations to Bolster Interconnectedness) is a mobile application in development meant to streamline the information communication between ADHC, PCP, and family caregiver populations. The purpose of this study was to understand the likelihood of adoption of CareMOBI by primary care providers. Demographics of the study included 87.50% female and 12.5% male primary care providers with a median age of 38 years. Participants were recruited through parallel convergent design, and data was merged into a matrix defined by 4 major themes: perceived value in geriatric care, ease of use, fit within workflow, and likelihood of adoption. The results revealed that a majority percentage of providers were likely to adopt the app, saw the app as valuable, and easy to use. In response to fit within a provider's workflow, apprehensions surrounding interoperability arose. These apprehensions regarding interoperability are the most important to address through a user-centered approach and as the app is pilot tested into adult day health centers.

INVESTIGATING OLDER ADULTS' PERSPECTIVES ON TELEHEALTH ROBOTICS

Samuel Olatunji,[1] Husna Hussaini,[2] Kenneth Blocker,[1] Naveen Uppalapati,[3] Girish Krishnan,[3] and Wendy Rogers[4], *1. University of Illinois Urbana-Champaign, Champaign, Illinois, United States, 2. University of Illinois Urbana-Champaign, Urbana Champaign, Illinois, United States, 3. University of Illinois at Urbana Champaign, Urbana Champaign, Illinois, United States, 4. University of Illinois Urbana Champaign, Champaign, Illinois, United States*

The current social distancing directives have heightened the need for older adults to seek remote healthcare solutions. Telehealth robots could support home health by carrying out on-demand tasks for diagnosis and treatment at the user's home through remote teleoperation by the healthcare provider. Acceptability of such telehealth robots by older adults is critical to their successful deployment. The overall goal of this research was to investigate older adults' perceptions and attitudes towards a telehealth robot supporting health checkups at home. Specific objectives were to explore potential healthcare use cases for the robot; identify facilitators and barriers to its use; and elicit design requirements for use in healthcare contexts. We interviewed 5 men and 5 women (ages 66–73) after they viewed a series of videos demonstrating the potential uses of the telehealth robot. The older adults had positive first impressions towards the telehealth robot and were generally open to the idea of using it for telehealth tasks. They conveyed a high level of trust with the robot, especially if it were controlled by a healthcare provider, yet expressed concerns with privacy and security of health information that would need to be addressed in the design of security protocols. They described added value of the robot's healthcare support while suggesting potential improvements to the robot. This research provided insights into older adults' perceptions and attitudes towards a telehealth robot as well as identified potential healthcare use cases that would inform the design requirements for telehealth robots in different home healthcare contexts.

COMMUNITY-RECRUITED OLDER ADULTS DIFFER FROM PATIENT POPULATIONS

Catherine Striley, Piyush Chaudhari, Roger Fillingim, and Linda Cottler, *University of Florida, Gainesville, Florida, United States*

Researchers often conduct randomized controlled trials among patient populations that may not reflect the community in which findings will be translated. The University of Florida's community engagement program HealthStreet provides a diverse sample in which to consider differences between people 65 years of age and older who have seen a physician in the past 12 months and those who have not. This provides a conservative test of potential biases in patient-only samples. Based on a sample of 1,663 people, 65 years of age and older, who were recruited by Community Health Workers in the North Florida region from November 2011 through July 2022, 88% had seen a physician in the past 12 months. Those who had not (12%) were significantly more likely to be non-white than white, to be in good/excellent than fair/poor health, and significantly less likely to have a range of health conditions including high blood pressure, depression, heart conditions, diabetes, a digestive health condition, a dental health condition, or cancer. Yet residents who hadn't seen a doctor were just as likely to be willing to participate in a future health study (both 94%) that only asked about health, accessed medical records (both 87%) or didn't provide reimbursement (both 81%), and were not significantly different in attitudes toward participating in research in general. Recruiting of older adults should be conducted in the community, not just in patient populations, which are likely to be less diverse and sicker than those recruited through a community engagement program.

SELF-TAILORED SUCCESSFUL AGING: OLDER ADULTS' POINTS OF VIEW

Michal Tsadok Cohen,[1] Sara Rosenblum,[1] and Sonya Meyer[2], *1. Haifa University, Haifa, Hefa, Israel, 2. Ariel University, Ariel, HaMerkaz, Israel*

The study aimed to map out the main constructs involved in aging successfully, as perceived by older adults, and highlight the importance of self-management. This qualitative study was comprised of eighteen interviewees and sixty participants across nine focus groups, including: Independent older adults aged 65 to 84 years living at home, health professionals working with older adults, and family members of older adults. Participants shared experiences concerning their everyday occupations and routines. Focus groups were recorded, transcribed verbatim, and qualitatively analyzed, using the constructivist grounded theory principles.

Results: Three successful aging theoretical categories emerged: self-management abilities, daily lifestyle, and individual differences. An example for self-management abilities can be described by a 67-year-old man's son, who said: "He is a very busy man, he doesn't have any commitments, but he always creates things for himself to do". Results revealed diversity in how older adults perceive successful aging. For example, a 68-year-old woman said: "Retirement is like heaven, I enjoy every moment, there's a lot to do", whereas a 69-year-old man claimed: "Nobody needs you anymore… I retired a year ago and I still haven't succeeded in organizing a daily schedule". Additional results and quotes reflecting the categories will be represented. Conclusion: Older adults who succeed in managing their daily life, and experience control of their own life, delineate successful aging. The diversity accentuates that each older adult needs to tailor their own self fitted "suit" to wear as they stride successfully into their aging years.

FEASIBILITY OF INTEGRATED TECHNOLOGIES TO PROMOTE LEISURE ACTIVITY ENGAGEMENT AMONG ASSISTED LIVING RESIDENTS

Phyllis Gaspar,[1] Elena Do,[2] Junhyoung Kim,[3] Angela Chow,[4] Adam Sobol,[5] Raia Francisco,[2] and Lisa McFarland[6], *1. CareBand Inc., Sioux Falls, South Dakota, United States, 2. CareBand Inc., Chicago, Illinois, United States, 3. Indiana University, Bloomington, Indiana, United States, 4. Indiana University Bloomington, Bloomington, Indiana, United States, 5. Careband Inc., Chicago, Illinois, United States, 6. Axiatp, Zionsville, Indiana, United States*

Research suggests that advanced technologies, such as wearable technology and tablets, can serve an important role in the cost-effective, accessible delivery of health promotion that is individualized, immersive, and engaging for users. The present study was designed to test the feasibility and acceptability of two integrated technologies among assisted living facility residents: CareBand's wearable technology and Eperture's RememberStuff (R/S) tablet platform. The purpose of the qualitative component of the project was to provide preliminary information from the perspective of the assisted living facility participants on these two technologies. Another goal was to assess the challenges of their participation. Drawing on qualitative thematic analyses of data collected from semi-structured interviews with 16 participants (four staff members and 12 residents) prior to and following the 6-week integrated technology program, three themes emerged as positive outcomes of the technology experiences: (a) leisure activity engagement, (b) exploration of tablet features, and (c) cognitive stimulation. This finding suggests that these technologies may enhance leisure engagement and cognitive function. On the other hand, there were three challenges that participants experienced while participating in the program: (a) inability to grasp functionality, (b) need for continued education for the technology, and (c) negative stereotypes toward technology use. These challenges provide guidance for future protocol design in follow-up studies to further explore the integrated technology efficacy for older adult users. The practical implications of this study and suggestions for health professionals are discussed.

COMMUNITY CENTERED APPROACHES TO INCREASE PARTICIPATION OF AFRICAN AMERICANS IN BRAIN HEALTH AND ADRD RESEARCH

Priscilla Barnes,[1] Bianca Cureton,[2] Nenette Jessup,[2] Natalie Sutton,[3] Carl Hill,[4] Patrick Shih,[5] Hugh Hendrie,[6] and Yvonne Lu[7], *1. Indiana University at Bloomington, Bloomington, Indiana, United States, 2. IU School of Nursing, Indianapolis, Indiana, United States, 3. Alzheimer's Association, Greater Indiana Chapter, Indianapolis, Indiana, United States, 4. Alzheimer's Association, Chicago, Illinois, United States, 5. Indiana University School of Informatics, Computing, and Engineering, Indianapolis, Indiana, United States, 6. Indiana University School of Medicine, Indianapolis, Indiana, United States, 7. Indiana University School of Nursing, Indianapolis, Indiana, United States*

African Americans/Blacks continue to be underrepresented as participants in Alzheimer's Disease and related dementia (ADRD) and brain research. Numerous challenges such as lack of information about the Alzheimer's Disease and related dementia (ADRD), socioeconomic barriers, historical and systemic racism, and distrust of research goals and processes persist in research participation. Research approaches tend to be more recruitment oriented rather than partnership driven that do not address these challenges. As a result, community engagement approaches are increasingly being recognized as a means of building trust and creating new pathways for participation in ADRD studies. This poster focuses on the preliminary work of the Collaborative on Aging Research and Engagement (CARE) --- a community academic partnership comprising the CARE Advisory Team (a community action team of 10 African American leaders), Alzheimer's Association, the Alzheimer's Association Greater Indiana Chapter, IU Schools of Nursing, Public Health, and Informatics, Computer Science, and Engineering, and the Indiana Alzheimer's Disease Research Center. The goal of the partnership is to facilitate active engagement of African Americans aged 45 years and older in research opportunities taking place in in Central and Northwest Indiana. Experiences and perspectives shared at the CARE Advisory Team meetings as well as memos from the researcher staff generated five lessons learned in building relationship oriented, as opposed to recruitment driven, processes. These lessons will be used to develop a community engagement framework focused on the integration of culturally relevant outreach practices in promoting ADRD research opportunities in African American/Black communities.

THE SOCIAL COST OF MODIFIABLE RISK FACTORS IN SINGAPORE

Vanessa Tan,[1] Stefan Ma,[2] and Cynthia Chen[3], *1. National University of Singapore, Singapore, Singapore, 2. Ministry of Health Singapore, Singapore, Singapore, 3. National University of Singapore, Singapore, Singapore*

Close to half of total disease burdens are attributable to modifiable risk factors, indicating that many illnesses are preventable by modifying behaviours such as increasing physical activity levels or maintaining a healthy diet. This study measures the social costs attributable to modifiable risks in Singapore, one of the most rapidly ageing populations in the world. Measuring the social cost of modifiable risk factors can help public health policymakers prioritise public health programmes and allocate resources. Our study builds on the comparative risk assessment framework from the Global Burden of Disease study. We used a prevalence-based cost-of-illness approach to estimate the social cost attributable to modifiable risk factors. We included healthcare costs from inpatient hospitalisation and productivity losses from absenteeism and premature mortality. Our results found that metabolic risks had the highest social cost of S$2.20 billion in 2019, followed by lifestyle risks of S$1.98 billion and substance risks of S$1.56 billion. Across the risk factors, the social costs were largely driven by productivity losses, heavily skewed towards the older working-age group. For metabolic risks, approximately 80% of the total cost (S$1.82 billion) was from those aged above 45 years old. This study provides evidence of the high social cost of modifiable risks and highlights the importance of developing holistic public health promotion programmes. Our findings suggest that implementing effective population-based programmes targeting multiple modifiable risks would have a strong potential to manage rising disease burdens and healthcare costs, especially with an ageing population.

THE EFFECTS OF LOSING A SECURE JOB ON HEALTH BEHAVIORS ACROSS THE LIFE COURSE

Qian Song,[1] Emily Lim,[2] and Jackie Zhang[3], *1. Universiy of Massachusetts Boston, Boston, Massachusetts, United States, 2. University of Massachusetts Boston, Boston, Massachusetts, United States, 3. Grand Valley State University, Allendale Charter Township, Michigan, United States*

Involuntary, no-fault job loss from a relatively secure position has become more common among workers. However, it is not clear how displaced workers cope with the stress induced by the job loss and change their health behaviors due to work precarity, especially in the long-term. To address these gaps, we take advantage of the case of policy-driven layoffs from the State-Owned Enterprises in transitional China (1990s – mid-2000s), which resembles a quasi-experimental design, and examine effects of losing a secure job on dietary diversity, drinking, and smoking behaviors. We use the China Health and Nutrition Survey (1989–2015) and fixed effects models for controlling individual confounders. The results show that job loss decreases displaced workers' dietary diversity (β=-.18, $p < .05$); however, the decline bounced back after three years after job loss. The career stage in which job loss occurred made a difference. The reduction of dietary diversity only applies to early-career job loss (aged 35 or younger, β=-.24, $p < .1$), and mid-career job loss (aged 36 – 45, β=-.37, $p < .01$). Job loss increases probability of drinking (OR=1.36, $p < .1$), but the effect is only statistically significant for late-career job loss (aged 45+, OR=1.60, $p < .1$). Risks of heavy drinking are only increased for early-career job losers (OR=2.09, $p < .05$). Risks of smoking are not impacted by job loss. The findings highlight how health behaviors serve as coping strategies for job loss, how the effects vary by the timing of job loss, and how health promotions could be helpful to address the potential risks of work displacement.

TRUST IN GOD AND THE CHURCH, NOT NEIGHBORS: EXPLORING SOCIAL COHESION AMONG AGING HIV+ INDIVIDUALS

Thi Vu,[1] Katherine Dunham,[2] Anna Lin-Schweitzer,[2] Meron Girma,[3] Megan Lee,[4] and Yusuf Ransome[2], *1. Yale University, New Haven, Connecticut, United States, 2. Yale School of Public Health, New Haven, Connecticut, United States, 3. Yale University School of Public Health, New Haven, Connecticut, United States, 4. Yale School of Medicine, New Haven, Connecticut, United States*

Rates of new HIV diagnoses among people 55+ years old remained unchanged between 2015–2019, suggesting potential HIV prevention challenges in the aging population due to co-morbidities, social isolation, and age-related stigma. Socio-cultural factors play a strong role in influencing HIV outcomes. Social cohesion — including appraisals of trust in neighbors and levels of belongingness to a community — has been shown to be an important channel for HIV prevention in the general population. However, there is scant evidence about how social cohesion relates to HIV prevention and care engagement among older adults. We employed a convergent, parallel mixed-methods study to investigate this topic among a sample (n =17) of adults aged 50+ living with HIV in New Haven, CT. We conducted semi-structured interviews which were analyzed using thematic analysis in NVivo.v12. We also collected quantitative data in RedCap and calculated descriptive statistics in STATA.v16. Participants were on average 57 years of age (SD=4); 53% female, and 69% Black/African American. Participants' trust in their neighborhoods was low [mean=2.61 (range 1 - 5, where 5 indicates high trust)]. In interviews, trust did not significantly influence one's HIV status disclosure or care management. Instead, participants often identified their faith in God or relationship with local churches as significant sources of social and informational support they often rely on for their HIV-related needs. Our results show that investigating the impact of religious belonging on outcomes may be a fruitful path of research to improve HIV outcomes among the aging population.

IFIT3 GENE EXPRESSION AND FUNCTION CONTRIBUTE TO HAND PATHOLOGY EVEN WITH ANTIRETROVIRAL THERAPIES (CARTS).

Ranjit Kumar Das,[1] Deepa Roy,[2] Nirakar Sahoo,[1] and Upal Roy[2], *1. The University of Texas Rio Grande Valley, Edinburg, Texas, United States, 2. The University of Texas Rio Grande Valley, Brownsville, Texas, United States*

The advent of cART has revolutionized the management of HIV-1 infection and saved the lives of millions of people worldwide. Yet, HIV-Associated Neurocognitive Disorder (HAND) continues to be clinically relevant with aging people with HIV-1 (PWH). The underlying mechanism of HAND remains poorly understood. In this regard Signal transducer and activator of transcription 1(STAT1) and interferon-induced protein with tetratricopeptide repeats 3 (IFIT3) genes have been shown to induce neuroinflammation and neuronal cell death. However, the role of IFIT3 in HAND pathology has not been well established. Therefore, the present work investigated the significant role of IFIT3 gene in the development of HAND. In the current study, we used an in-vitro model to expose the neuroblastoma cell-line SH-SY5Y with clinically relevant cARTs drug and HIV Tat protein to observe the STAT1 and IFIT3 genes dysregulation. Furthermore, study also investigates the STAT1 and IFIT3 protein dysregulation through immunocytochemistry and western blot assay. Overall observation indicated that HIV-Tat protein upregulated gene expression whereas with the cART exposure there was a downregulation of STAT1 and IFIT3 genes. We next aim to investigate the role of STAT1 and IFIT3 genes in HIV-induced neuroinflammation. The current study has established IFIT3 as a biomarker marker for the detection of HAND.

ASSESSING THE NIH TOOLBOX EMOTION BATTERY AMONG PEOPLE AGING WITH HIV AND WHO USE METHAMPHETAMINES.

Alexis Bender,[1] Hannah LF Cooper,[1] David Moore,[2] Molly Perkins,[3] and Regine Haardoerfer[1], *1. Emory University, Atlanta, Georgia, United States, 2. University of California at San Diego, San Diego, California, United States, 3. Emory University School of Medicine, Atlanta, Georgia, United States*

Measurement of social relationships is challenging because constructs have dimensions that can be assessed at multiple levels. Consequently, researchers often operationalize social relationships differently, making it difficult to compare results with the same outcome across studies. The National Institutes of Health (NIH) commissioned the Toolbox Assessment of Neurological and Behavioral Function to create a set of harmonized measures to use across studies. The NIH Toolbox-Emotions Battery (NIHTB-EB) was normed in English and Spanish-speaking populations, which found support for a three-factor structure (negative affect, social satisfaction, and psychological well-being). Here we investigated the factor structure of the NIHTB-EB among a sample of 862 people aged 17 to 82 with and without HIV and methamphetamine use in comparison to the factor structure found in the NIH Toolbox norming project. Initial confirmatory factor analysis did not support the three-factor structure identified previously for the full sample or subsamples. Subsequent exploratory factor analyses showed a good model fit for a four-factor solution for the full sample, with slight variations in factor loading across subgroups. In addition to the three factors described in the norming project, our solution contains an additional factor, "rejection and hostility," which includes scores from social satisfaction and negative affect in the normative population. The four-factor solution will be utilized for subsequent analyses using the NIHTB-EB in these study samples. Our analyses highlight the importance of assessing measures in distinct sub-populations to understand possible challenges to measurement invariance and ultimately allow the use of NIHTB-EB across groups.

PAY RATES AND EMOTIONAL LABOR: CONTENT ANALYSIS OF JOB ADVERTISEMENTS FOR HOME HEALTH AIDES

Brittney Pond, *University of California, San Francisco, San Francisco, California, United States*

In the United States, over 3.5 million home health aides provide care and assistance to older adults and people with disabilities living in the community (Almeida, Cohen, Stone, & Weller, 2021). These providers are often tasked with emotionally and physically demanding work and are poorly compensated for their labor. In this poster I discuss the connection between the emotional demands of home health care jobs and their compensation through a quantitative content analysis of online job advertisements for home health aide positions (n=312). This research addresses two primary research questions: 1) what are the prevailing pay rates for home health aides and how do they compare to living wages? 2) what is the relationship between emotion work requirements and pay rates in home health aide job advertisements? In about 57% of the job advertisements hourly wages were not sufficient to meet the living wage level according to the MIT Living Wage Calculator. Using linear probability models, I found that there is no statistically significant difference between pay rates listed by home health agencies requiring emotional labor and home health agencies not requiring emotional labor while holding education, experience, and licensure requirements constant. Stratifying the data by home health agency/company size (1,000 employees or less and 5,000 employees or more) yielded no statistically significant results. These findings support and expand upon existing literature that home health aides are undercompensated for their work regardless of agency size, and provide evidence for the need for fair compensation and support.

IMPACT OF RECEIVING HOME-BASED PRIMARY CARE FOR PERSONS LIVING WITH DEMENTIA: PATIENT AND CAREGIVER PERSPECTIVES

Meghan Mattos,[1] Veronica Bernacchi,[2] Karen Duffy,[3] Laura Jepson,[4] Stephanie Gonzalez,[1] and Justin Mutter[4], *1. University of Virginia, School of Nursing, Charlottesville, Virginia, United States, 2. Penn State College of Medicine, State College, Pennsylvania, United States, 3. UVA Health, Charlottesville, Virginia, United States, 4. University of Virginia, Charlottesville, Virginia, United States*

Homebound persons living with dementia (PWD) require healthcare services that proliferate with physical and cognitive changes over time. PWD often experience fragmented care that results in poor health outcomes and delayed healthcare access. The objective of the Virginia at Home Program (VaH), a recently initiated home-based primary care (HBPC) program, is to promote long-term sustainability and proliferation of HBPC. The study purpose was to examine the impact of VaH on the overall care and outcomes of homebound PWD and their families. We used quantitative and qualitative methods to describe the impact of VaH on patient care and outcomes over six months. We compared clinical outcomes (e.g., activities of daily living, frailty, behavioral symptoms) at baseline and six months using paired t-tests. We also conducted semi-structured phone interviews at baseline and six months with PWD-caregiver dyads. Thirty PWD-caregiver dyads enrolled. Of the 17 dyads that completed both visits, PWD's physical function and caregiver's burden decreased significantly over time (ps < .05). There was a significant improvement in PWD's behavioral symptoms over the six-month period (p=.03). Three preliminary themes emerged from qualitative data: 1) participants established trusting relationships with the VaH team, 2) VaH supported caregivers in their caregiving responsibilities, and 3) participants met their pre-program goals through increased healthcare access. Findings suggest that the HBPC intervention improved care satisfaction and healthcare access and alleviated caregiver burden. Future studies should consider introducing HBPC programs in this hard-to-reach population to decrease acute care utilization and health care costs while improving care satisfaction and quality.

PET OWNERSHIP AND MAINTENANCE OF EXECUTIVE FUNCTION IN OLDER ADULTS–EVIDENCE FROM THE BLSA

Erika Friedmann,[1] Nancy Gee,[2] Eleanor Simonsick,[3] Melissa Kitner-Triolo,[4] Erik Barr,[5] Barbara Resnick,[6] Ikmat Adesanya,[6] and Merve Gurlu[1], *1. University of Maryland Baltimore, Baltimore, Maryland, United States, 2. Virginia Commonwealth University, Richmond, Virginia, United States, 3. National Institute on Aging, Baltimore, Maryland, United States, 4. Brain Aging & Behavior Section, Baltimore, Maryland, United States, 5. University of Maryland School of Nursing, Baltimore, Maryland, United States, 6. University of Maryland, Baltimore, Maryland, United States*

Pet ownership (PO) or human-animal interaction (HAI) has been associated with better physical and mental health in individuals with existing disease or disability. In experimental studies, HAI improves some aspects of cognitive function. No research addresses HAI and longitudinal changes in cognitive function in older adults. We examined the relationship of PO to maintaining executive function (EF) within generally healthy community-dwelling older adults in the Baltimore Longitudinal Study of Aging (BLSA). We hypothesized less EF deterioration among pet owners than non-owners; and less deterioration among dog-walkers than owners who don't walk their dogs. 637 women (55.9%) and men aged 50–100 years (M=68.3, SD=9.6) completed a PO questionnaire which ascertained ownership history and comprehensive examination every 1–4 years over 1–13 years (M=7.5, SD=3.6). Linear mixed models with time varying PO examined changes in EF according to PO. Pet owners (n=185) were younger (p < 0.001) and healthier (p=0.030) than non-owners; thus, age and comorbidities were included as covariates in the longitudinal analyses. EF, assessed using the Trail-Making Test (TMT), deteriorated with age (p's < 0.001). Deterioration was less severe among pet owners than non-owners (TMT A: p < 0.001; B: p < 0.001; difference: p=0.042) and dog owners than non-owners (TMT A: p=0.025; B: p=0.009; difference: p=0.076), but not among cat owners than non-owners. Among dog owners (n=73), dog walkers experienced less deterioration than non-walkers (TMT A: p=0.156; B: p=0.001; difference: p < 0.001). This study provides the first longitudinal evidence that PO may contribute to maintaining EF among community-dwelling generally healthy older adults as they age.

EXAMINING HUMAN-ANIMAL INTERACTIONS AND THEIR EFFECT ON FRAILTY IN LATER LIFE: A SCOPING REVIEW

Ashley Taeckens-Seabaugh, Mary Corcoran, and Kevin Morris, *University of Denver, Denver, Colorado, United States*

Research suggests that human-animal interactions (HAIs) can improve the health and well-being of humans throughout their lifespan. While HAIs may facilitate healthy aging broadly, scant research has focused on HAIs as an intervention for adults aged 50 and older as it pertains to a comprehensive perspective of frailty. Moreover, scholarly literature lacks a consistent frailty definition, resulting in a lack of cohesion when evaluating the effectiveness of frailty interventions. This scoping review research proposes a comprehensive frailty definition and explores what is known about HAI interventions available to older adults as they relate to frailty statuses. Despite broad inclusion criteria, only four articles were relevant to this literature review, confirming the scarcity of relevant completed research thus far. Thematic analysis of reported results includes dog ownership as a protective factor regarding frailty statuses, the interconnected health effects of pet ownership, and meaning and purpose implications. Future interdisciplinary research should consider HAIs outside of pet ownership as frailty interventions for older adults, be mindful of population differences as they relate to intervention effectiveness, and work towards a universal, comprehensive definition of frailty that will aid in evaluating the frailty intervention effectiveness.

THE GIFT OF MUSIC: AN INTERGENERATIONAL CAMPUS-COMMUNITY PARTNERSHIP

Whitney Nesser, and Scott Buchanan, *Indiana State University, Terre Haute, Indiana, United States*

Intergenerational programs bring individuals together across a continuum of age to share experiences. This study was designed to engage university music students with residents at a senior living community. University music student groups performed monthly at a local senior living community and completed pre- and post- performance evaluations to assess performance expectations, level of interest in the performance, perception of factors determining performance success, and perception of performance importance for the senior residents. A total of 24 students participated in one of three musical ensembles (Choir=11; Flutes=5; Steel Drums=8) during the months of February, March, and April 2022. Across all three ensembles, 50% of the students had never performed for residents at a senior living community. On a scale of 1–5, with 1 being "Not at all" and 5 being "Very much", 21 students indicated a "4" or "5" as to the importance of the performance for the residents whereas 15 students indicated a "4" or "5" in response to the importance of the performance for themselves. Most students reported looking forward to the performance, and following the performance indicated it had been a success. Factors identified as determining performance success included comments such as: “How much the audience enjoyed themselves!” and “Performers and audience enjoyed the performance. We would love to come back!”. Our findings suggest that performing live music in an intergenerational campus-community setting is beneficial not only for students but also for senior living facility residents.

AGING DRAG QUEENS: RISKS, REWARDS, EXPRESSION AND PERFORMANCE

Laura Donorfio, Brian Chapman, and Kathleen Henneberry, *University of Connecticut, Waterbury, Connecticut, United States*

This poster presentation will share the exploratory findings of a qualitative research study examining the lived experiences of older drag queens, age 50+. Drag queens are an understudied and underrepresented population in the social science literature (Knutson, Koch, Sneed, Lee, & Chung, 2020; O’Brien, 2018). Older drag queens have yet to be studied in the social science literature. “Drag Queens possess unique characteristics as a subpopulation of the lesbian, gay, bisexual, and transgender (LGBT) community that warrant exploration” (Knutson, Koch, Sneed, & Lee, 2018). A comprehensive literature review identified approximately a dozen research driven articles from 2004 to the present, studying such areas as motivations, obstacles and stressors in becoming and being a drag queen (Hopkins, 2004; Knutson et al., 2021), depression, substance abuse, and resilience (Knutson et al., 2019; Tillewein & Kruse-Diehr, 2021) and the role gender plays via sexuality identities (Taylor & Rupp, 2004, Levitt et al. 2017). This research seeks to better understand how drag expression is integrated with one’s persona and how it interfaces with dragism, coping, and if drag expression can be used as a tool to foster resilience. Using a semi-structured interview protocol and thematic analysis, many themes emerged including the risks and rewards associated with drag expression, the relationship between aging and being a drag performer, and the shift in traditional versus 21st century drag. Lastly, we highlight the implications for gender and LGBTQIA+ theory and plans for future research.

THEMES FROM CONVERSATIONS WITH MEDICAL TRAINEES ON LGBTQ OLDER ADULTS

Shobhana Sandhu, Mackenzi Kim, Lynn Wilson, Nyann Biery, and Kimberly Infante, *Lehigh Valley Health Network, Allentown, Pennsylvania, United States*

Approximately 6–12% of the US population 65 or older self-identifies as LGBTQ. This population faces immense barriers when accessing care, including the bias from healthcare professionals. Efforts to combat this bias through formal education are minimal. Using a mixed methods study with one-group pretest-posttest design and focus groups, medical learners were included in sessions involving a showing of Gen Silent and a post-viewing discussion. Themes from discussion were extracted by two independent reviewers. Medical learners (Nf15) included residents and faculty of psychiatric and emergency medicine at Lehigh Valley Health Network. Themes included: recognition of the social isolation faced by LGBTQ older adults, recognition of barriers to care including stigma and bias, challenges supporting patients and enabling patients’ openness, a need for a community resource repository, opportunities for EMR optimization, and physicians as advocates. These results highlight the need for additional training for medical trainees as well as the efficacy of using a tool like Gen Silent to accomplish this.

THE IMPACTS OF DEPRESSION AND SUICIDE ATTEMPTS AMONG OLDER MEN WHO HAVE SEX WITH MEN

Alex Siu Wing Chan,[1] and Elsie Yan[2], *1. Hong Kong Polytechnic University, Hong Kong, Hong Kong, 2. The Hong Kong Polytechnic University, Hong Kong, Hong Kong*

Suicidality among older adults has attracted much attention due to their vulnerability. Older men who have sex with men (OMSM) have rarely been studied psychologically. Study examines factors that affect the mental health of OMSM, including depression, suicidal tendency, and suicide likelihood. OMSM in the United States are analyzed using descriptive statistics for correlations between depression and suicidal tendency. A literature review helped us select scales based on the regression model we constructed. Control variables were assessed for validity and relevance. A dependent variable was depression, and a dependent variable was suicidal tendencies. Depression and suicidal tendency scores significantly differed between men who have sex with men and the general population ($t = 67.084, 58.193$, $P < 0.01$). Suicidal tendencies and depression are significantly higher among homosexuals than among general groups. The regression analysis shows older men who have sex with men are more likely to suffer from depression and suicide ($P < 0.01$). Depression and suicide rates in OMSM are higher than those in the general population. The level of depression, in the intermediary test, mediates both the effect of OMSM on individual suicidal tendency and individual suicidal behavior ($P < 0.01$). Suicidal tendencies in OMSM can be reduced through depression intervention.

NAVIGATING DEMENTIA DURING COVID-19: THE EXPERIENCES OF GAY AND LESBIAN OLDER ADULTS

Laura Girling,[1] and Mike Splaine[2], *1. Towson University, Towson, Maryland, United States, 2. Splaine Consulting, Columbia, Maryland, United States*

By 2030, it is estimated that 30 million individuals worldwide will have Alzheimer’s disease or related-dementias (hereafter dementia). Described as a “modern epidemic of later life,” dementia research has begun to reflect the diversity of our aging society with greater attention to minority populations. Nonetheless, some marginalized dementia-affected populations remain understudied. Estimates suggest more than 1 million lesbian, gay, bisexual, and transgender older adults will have dementia by 2030. Despite sizeable predictions, dementia-affected gay and lesbian populations remain critically understudied particularly in relation to COVID-19. To date, there is scarce literature focusing on how community-dwelling gay and lesbian adults with dementia navigate the management of their condition during the COVID-19 pandemic. In order to identify how community-dwelling gay and lesbian adults manage their dementia during the COVID-19 pandemic, data were combined from two interview-based studies. Content analysis was conducted on the interview narrative of the subset of individuals with dementia identifying as gay or lesbian and their study partner(n=18). Thematic findings include: 1.triple marginalization (age, sexual orientation, cognitive status), 2.social isolation, 3.programming effects (e.g., adult day programming, ADRD support groups), 4.informal and formal care interruptions, and 5.symptom acceleration. While all members of the public have experienced difficulties since the onset of COVID-19, health threats vary depending on social circumstances and vulnerabilities. Analyses indicate community-dwelling gay and lesbians with dementia are uniquely impacted by COVID-19 and face unique challenges. Attunement to such issues are of special interest to community-level policy makers, health providers, and older LGBTQ adults themselves, requiring further attention.

LONELINESS IN LGBTQIA+ OLDER ADULTS: A SCOPING REVIEW

Katherine Bowers,[1] Joan Carpenter,[2] Marleen Thornton,[3] Hannah Fetting,[4] and Erin Johnson[5], *1. University of Maryland, Baltimore, Maryland, United States, 2. University of Maryland School of Nursing, Baltimore, Maryland, United States, 3. Notre Dame of Maryland University, Baltimore, Maryland, United States, 4. Johns Hopkins Bayview, Baltimore, Maryland, United States, 5. Johns Hopkins Hospital, Baltimore, Maryland, United States*

Loneliness in older adulthood is responsible for poor mental and physical health, cognitive decline, and early mortality. Older adults in the LGBTQIA+ community experience additional layers of vulnerability, such as discrimination, higher rates of childlessness, health inequity, and economic disparity that place them at high risk for loneliness. The purpose of this scoping review is to explore the existing literature on loneliness in LGBTQIA+ older adults and identify knowledge gaps to inform future research recommendations. Using the Arskey & O'Malley methodological framework, our team searched PubMed, Embase, CINAHL, PsychINFO, Scopus, and Google Scholar using keywords related to older adults, sexual and gender minorities, and loneliness. We identified 61 articles from 1980 to 2022. Most of the research in this literature reflected studies using descriptive and qualitative approaches. Intervention studies were the least reported. One opinion piece is included. Initial findings highlight associations between discrimination and loneliness, poor mental health and loneliness, the challenges of HIV in older adulthood and loneliness, and loneliness experienced in caregiving and end of life in LGBTQIA+ older adults. Importantly, many studies emphasized the protective nature of strong social support and community ties against loneliness. Equally, the literature suggests that limited social support is a significant risk factor for loneliness in this population. Older gender non-binary and LGBTQIA+ people of color were underrepresented in many studies. Future research should include intervention research that targets loneliness in this population as well as studies focused on understanding loneliness more comprehensively in underrepresented LGBTQIA+ older adults.

INTERNALIZED HOMOPHOBIA MEDIATING THE RELATIONSHIP OF SELF-CONCEALMENT ON DEPRESSION IN LGB OLDER ADULTS

Christopher Calzada, Carl St. Goar, Matthew Hollander, Vennisia Mo, Jamie Kiefer, Ben Hougaard, Nicole Carre, and Rowena Gomez, *Palo Alto University, Palo Alto, California, United States*

Previous research has demonstrated that self-concealment of sexual orientation may negatively affect the wellbeing of lesbian, gay, and bisexual (LGB) adults (Hu, Wang, & Wu, 2013). Additionally, studies have indicated that internalized homophobia significantly predicts depressive symptoms in LGB older adults (Sharma & Subramanyam, 2020). The present study examined how internalized homophobia may mediate the predictive relationship between self-concealment on depression symptoms in LGB older adults. As part of a larger study, participants (Nf301) responded to several questions and measures including the Sexual Orientation Self-Concealment Scale, The Internalized Homophobia Scale, and the Center for Epidemiological Studies Depression Scale. Using the Baron and Kenny's Method for Mediation (1986), the data analysis indicated that internalized homophobia fully mediates the relationship between self-concealment and depression severity (ps < .05). These results suggest that older adults who self-conceal their sexual orientation may experience an increase in depressive symptoms because of internalized homophobias. These findings may help clinicians better understand the mechanisms contributing to the high rates of depressive symptoms within the older LGB population. Furthermore, the findings suggest that cognitive restructuring of thoughts related to internalized homophobia and self-concealment may improve depressive severity in older LGB adults.

IMPACT OF COVID-19 ON THE MENTAL HEALTH OF OLDER SEXUAL MINORITY CANADIANS: A LONGITUDINAL ANALYSIS

Alexandra Grady, and Arne Stinchcombe, *University of Ottawa, Ottawa, Ontario, Canada*

The COVID-19 pandemic and related restrictions have had negative impacts on mental health. Sexual minorities (i.e., lesbian, gay, and bisexual; LGB people) have been shown to exhibit mental health disparities stemming from minority stress experiences. The purpose of this study was to examine the mental health trajectories of older sexual minority Canadians in comparison to heterosexual Canadians before and during the pandemic. We used data from the Canadian Longitudinal Study on Aging (CLSA), where data were collected from participants at baseline (2011–2015), first follow-up (2015–2018), and two time points during the COVID-19 pandemic (April-December 2020). General Estimating Equations (GEE) were used to model changes in depression symptoms (CESD-10; n=47,728) and loneliness (UCLA 3-item loneliness scale; n=41,698), adjusting for covariates (i.e., age, sex, income, race, education). Results showed that LGB participants reported more symptoms of depression (β=.595, p < .001) and loneliness (β=.313, p < .001) in comparison to heterosexual participants. Mental health outcomes worsened over time for all participants. These findings highlight the impacts of the pandemic on mental health and the need for tailored interventions for older lesbian, gay, and bisexual individuals.

HUMAN CENTERED DESIGN TO DEVELOP A LGBTQ+ COMMUNITY ADVISORY BOARD FOR SKILLED NURSING FACILITIES

Jennifer May,[1] Jason Wheeler,[1] Ames Simmons,[2] Mark Hensley,[3] Jerry O'Donnell,[4] Joseph Wheeler,[5] and Kirby Ellis[6], *1. Duke, Durham, North Carolina,* *United States, 2. Duke University, Washington, District of Columbia, United States, 3. AARP NC, Greensboro, North Carolina, United States, 4. Community Member, Greensboro, North Carolina, United States, 5. Carolina Aging Alliance, Inc., Raleigh, North Carolina, United States, 6. Liberty Healthcare, Pittsboro, North Carolina, United States*

Lesbian, gay, bisexual, transgender, queer (LGBTQ+) adults will require inclusive skilled nursing care as they age, but there is a paucity in LGBTQ+ specific training resources for skilled nursing facility (SNF) healthcare workers. Development of community advisory boards is becoming common in research studies as funders place emphasis on stakeholder engagement, but how advisory boards are created with community member involvement at the onset remains less clear. This presentation describes the creation of a community advisory board of LGBTQ+ community members, community organizations, and SNF administrators that work together to develop LGBTQ+ resources for 25 SNFs. Advisory board members were identified using a design thinking framework and the Field Guide to Human-Centered Design. Potential board members were identified through networking with community-based organizations, existing relationships with SNFs, and by word of mouth. The advisory board consists of 3 LGBTQ+ adults, 4 SNF administrators, 1 AARP community outreach and advocacy associate director, 1 advocacy coordinator for LGBTQ+ older adults, 1 SNF physician liaison, and 1 nurse scientist. To gain buy-in, individual interviews and focus groups with potential advisory board members were conducted. Meetings provided an opportunity to describe project goals and how potential member's expertise would guide development of resources. LGBTQ+ adult community members received compensation for their participation. The advisory board is meeting monthly and approaching the design phase. Community stakeholder involvement in early stages of development will help ensure that LGBTQ+ resources are relevant and applicable to enhance health and well-being of LGBTQ+ older adults in the future.

HEALTH INFLUENCES OF UNIQUE AND INTERSECTING IDENTITIES: AGE, SEXUAL ORIENTATION AND RACE

Laura Bernstein, and Julie Patrick, *West Virginia University, Morgantown, West Virginia, United States*

Lesbian, gay, and bisexual older adults are an understudied group with limited research using nationally representative samples. Although there are known physical health disparities based on age, sexual orientation, and race, the effects of intersecting identities have not been fully examined. We were interested in how these identities individually influence health and whether they interact to effect physical health. Using the 2020 Behavioral Risk Factor Surveillance System (M age = 54.30, SD = 17.52), we examined whether sexual orientation was related to the number of poor physical health days experienced and whether that relation was moderated by age and race. The overall model was significant (F (5, 223356) = 511.86, p < .001, R2 = .0113). Significant direct effects of sexual orientation and race emerged, but these were qualified by a significant sexual orientation by race interaction (b = -.09) A significant main effect emerged for age (b = 1.08) but the sexual orientation by age interaction failed to reach significance. There was a significant three-way interaction between age, race, and sexual orientation (F (2, 223356) = 6.34, p < .01). Investigation into the means found that multiracial adults tend to report more poor health days than White, Black, or Hispanic adults, except for bisexual older and younger adults. These results highlight the importance of examining intersecting identities when trying to understand health disparities across the lifespan. Understanding how these identities interact helps to identify specific barriers these groups face and ultimately improve health equity, specifically in an aging population.

RISKS FOR LATER-LIFE COGNITIVE IMPAIRMENT: DISENTANGLING CHILDHOOD AND EARLY FAMILY-LIFE PREDICTORS

Lindsey Mundy,[1] Kimson Johnson,[2] and Jacqui Smith[2], *1. University of Michigan, Tuscaloosa, Alabama, United States, 2. University of Michigan, Ann Arbor, Michigan, United States*

Observing later-life health outcomes using a life-course model uncovers critical periods of influence. We investigated the relationship between five multi-component measures of childhood disadvantage (determined by Morton et al., 2022) and risk of cognitive impairment (determined by the Langa-Weir Classification) in later life. Data from the Health and Retirement Study (n= 9,509) were used. We conducted a multivariable parametric survival analysis to examine the relationships between the early life predictors of low socioeconomic status (SES), childhood impairments, risky adolescent behaviors, risky parental behaviors, and childhood chronic illness and the risk of developing later-life cognitive impairment between 2006 and 2016. We found that each additional indicator of low SES, risky adolescent behavior, and impairment in childhood increased the risk of developing cognitive impairment over the 10 years studied (HR=1.14, p < .05; HR=1.15, p < .05; HR=1.19, p < .05). Additional indicators of risky parental behaviors, however, were related to a smaller risk of developing cognitive impairment over time (HR=0.96, p < .05). Childhood chronic illness was not significantly associated with the risk of developing cognitive impairment. These results show that early-life factors might have long-term implications for the development of cognitive impairment in later life and display differential relationships with risk when parsed into competing categories. Measures of disadvantage indicating smaller risk may point to the resilience and plasticity of the brain in early life and highlight the need for the study of multiple life stages in order to track predictors of cognitive impairment throughout the life course.

LIFECOURSE DETERMINANTS OF DEPRESSION AMONG OLDER MEXICAN ADULTS

Paige Downer,[1] John Prochaska,[2] and Rebeca Wong[3], *1. University of Texas Medical Branch, League City, Texas, United States, 2. University of Texas Medical Branch, Galeveston, Texas, United States, 3. University of Texas Medical Branch, Galveston, Texas, United States*

Older adults' exposure to poverty, poor health, and negative life events over their lifetime creates cumulative adversity, increasing their risk of depressive symptoms. We hypothesize that those with disadvantaged sociodemographic characteristics like household poverty, chronic health conditions, and negative lifecourse exposures will be more likely to report a high number of depressive symptoms in old age. Three sequential multivariable logistic regression models were estimated using Wave 3 (2012) of the Mexican Health and Aging Study (MHAS). The final sample included 5,610 respondents aged 50 and older, of which 34.3% reported depression measured by a modified 9-item CES-D scale. The sample was mostly female (63.3%) with a mean age of 69. Present-day conditions were measured by quality of the home, consumer durables, chronic health conditions, and health insurance. Early-life conditions were measured by the respondent's mother's education and exposure to poverty and illness during childhood. In 2012, older Mexican adults living in homes built with poor construction materials or homes that lack access to water and sanitation (OR=1.24) were more likely to experience high depressive symptoms. In addition, those living in homes without consumer durable goods (OR=1.23) were at increased risk. Older Mexican adults who experienced poverty (OR=1.16) or illness during childhood (OR=1.21) were more likely to report a high number of depressive symptoms in old age. In conclusion, we find evidence of a "long-arm" of childhood, whereas older Mexican adults' exposure to poverty and illness in childhood increases their likelihood of poor mental health outcomes, regardless of their present-day conditions.

GENDER DIFFERENCES IN RURAL-URBAN MIGRATION AND ITS IMPACT ON MENTAL HEALTH IN LATER LIFE

Jingwen Zhang, James Nazroo, and Nan Zhang, *The University of Manchester, Manchester, England, United Kingdom*

Although rural-to-urban migration has been well researched, how gender shapes processes and outcomes, including later life health outcomes, has not been thoroughly investigated. Guided by a life course perspective, this study explores gender differences in rural-urban migration patterns and its association with mental health in later life among Chinese older adults. Exploiting rich life history data from the China Health and Retirement Longitudinal Study, we employ sequence analysis to identify the typical migration trajectories of Chinese older adults. Moderated mediation analysis is then used to examine gender-specific health pathways linking migration trajectories and later-life mental health. The results indicate that: men and women follow different migration trajectories across the life course. Men are more likely to migrate between rural and urban areas, and to migrate multiple times. Rural migrants who settled in urban regions have better mental health in later life than return migrants or rural non-migrants; the gender gap in mental health is marginally smaller among early urban settlers than rural non-migrants. Household income and Hukou conversion mediate the relationship between migration trajectories and later-life mental health among older people of rural origin. Household income in later life has stronger mediation effects for migrant men than for migrant women. The study suggests that a life course perspective and awareness of gender dynamics should be incorporated in policymaking to reduce the rural-urban divide and gender-based inequality in mental health.

PERSPECTIVES OF THE FEMALE SPOUSE IN DEMENTIA CAREGIVING IN FORMAL CAREGIVING RESOURCE USE

Anna Satake, *Univerisity of California, Davis, American Canyon, California, United States*

The purpose of this qualitative descriptive study was to explore female spousal caregivers' decisions regarding the use of formal caregiving resources in caring for a partner with dementia. Participants included 11 female spouses who provided caregiving to their husbands with dementia in the home setting. Findings suggested that a caregiver's willingness or reluctance to use any resources were influenced by factors that related to them (e.g., assessment of their skills/abilities), their husband (e.g., his belief he didn't need help) and, to a lesser degree, the resource qualities (e.g., cost). Caregivers seemed to make the decision to use resources only after careful consideration of their husband's needs, his understanding of what he needed, and how well the resource would fit for him and whether he would accept that help. Interestingly, factors like cost and access were less germane to the caregiver's decision. This implies that the decision-making process for a wife caregiver in regards to the care for a partner with dementia is complex and involves their readiness and needs as the caregiver, the needs and readiness of the persons with dementia, and the qualities of the resources. These factors are all dynamic, and clinicians and formal caregiving services need to have ongoing conversations and assessments throughout the caregiving journey to assess both the caregiver's willingness and reluctance to start a specific service.

SESSION 9030 (POSTER)

LATE BREAKING POSTER SESSION IV

RISK OF HEART FAILURE AFTER CATHETER ABLATION VS. MEDICAL THERAPY FOR ATRIAL FIBRILLATION IN OLDER ADULTS

Ricardo Criado Carrero,[1] Andrew Crawford,[2] Ali Vaeli Zadeh,[3] Alan Wong,[2] Alexander Fleischhacker,[1] Elias Collado,[3] and Joshua Larned[4], *1. University of Miami/Holy Cross Hospital, Fort Lauderdale, Florida, United States, 2. Holy Cross Health-University of Miami, Fort Lauderdale, Florida, United States, 3. Holy Cross Health-Jim Moran Cardiovascular Research Institute, Fort Lauderdale, Florida, United States, 4. Holy Cross Health- University of Miami, Miami, Florida, United States*

Background: Age increases the risk of atrial fibrillation (AF). Catheter ablation (CA) proved being safer and superior to anti-arrhythmic drugs (AADs) in maintaining sinus rhythm and preventing readmissions. However, data on the risk of developing heart failure (HF) following each treatment in older adults is limited. Methods: A retrospective study was conducted using the PearlDiver database (PearlDiver Technologies, Fort Wayne, IN). Using ICD 9 and 10 codes, a cohort of patients without a history of HF, aged 65 to 75, with an Elixhauser Comorbidity Index (ECI) of >4 and new-onset AF (index event) was identified. The cohort was then divided into two groups based on treatment received following the index event and matched considering age, gender, ECI, and other cardiovascular diseases. Records from both groups were reviewed for the first episode of HF over 12 months following the initiation of treatment. Pearson's chi-squared test was used to compare groups. The strength of association was reported using Risk Ratios (RR). A p-value < 0.05 was deemed significant. Results: 6,446 were included in each group. The mean age, gender and ECI were indifferent. 958 (15%) of patients treated with AADs and 987 (15.3%) of patients treated with CA had a first episode of HF over a year after the treatment which was not significantly different between groups (RR=1.03, CI95% = 0.95- 1.11, p=0.49). Conclusion: The modality of treatment after the first episode of AF in older population doesn't significantly affect the risk of HF over the first year.

IMPACT OF OACS ON OUTCOMES OF COVID-19 INFECTION IN OLDER ADULTS WITH HISTORY OF ATRIAL FIBRILLATION

Ricardo Criado Carrero,[1] Andrew Carl Crawford,[1] Ali Vaeli Zadeh,[2] Alan Wong,[3] Ana De Diego Diaz,[4] Elias Collado,[2] and Joshua Larned[5], *1. University of Miami/Holy Cross Hospital, Fort Lauderdale, Florida, United States, 2. Holy Cross Health-Jim Moran Cardiovascular Research Institute, Fort Lauderdale, Florida, United States, 3. Holy Cross Health-University of Miami, Fort Lauderdale, Florida, United States, 4. University of Miami/Holy Cross Hospital, Fort Luderdale, Florida, United States, 5. Holy Cross Health- University of Miami, Miami, Florida, United States*

Background: Age, atrial fibrillation (AF), and COVID-19 infection predispose patients to hypercoagulability and poor outcomes. It is unclear if older adults with AF and COVID-19 infection would benefit from oral anticoagulants (OACs). Methods: A retrospective study was conducted using the PearlDiver database (PearlDiver Technologies, Fort Wayne, IN). Using ICD-10 codes, adults aged 65–75 and Elixhauser Comorbidity index(ECI) >4 with a history of AF admitted for COVID-19 were identified. The use of OACs for 6 months before the index event was used to split the cohort into two propensity score-matched groups considering age, gender, and ECI. Records from both groups were reviewed for multiple outcomes during the same admission. Pearson's chi-squared test was used to compare groups. The strength of association was reported using Risk Ratios (RR). A p-value < 0.05 was deemed significant. Results: We compared 16,967 individuals in both anticoagulated and non-anticoagulated groups. Anticoagulated patients had a lower risk of mortality (RR=0.11, p=0.026), and a higher risk of 30-day all-cause readmission(RR=1.12, p < 0.0001). However, there were no differences in ICU admission, gastrointestinal bleeding, intracranial hemorrhage, thromboembolic events, or length of hospitalization. Conclusion: Compared to non-anticoagulated patients, older adults with a history AF on chronic oral anticoagulants had a lower risk of all-cause mortality, and higher risk of 30-day all-cause readmission. This information would help clinicians decide whether to prescribe OACs to this population of patients.

GENDER AND AGE EFFECTS ON PTG EXPLAINED BY PSYCHOLOGICAL FACTORS IN CARDIAC PATIENTS

Amy Ai, and Crim Sabuncu, *Florida State University, Tallahassee, Florida, United States*

The present study explored the role of gender on posttraumatic growth (PTG) 30-months after cardiac surgery and mediation of preoperative psychosocial factors. Two previous meta-analyses found that woman tended to have more growth than men, and that PTG was associated with improved overall health, but most studies were cross-sectional and small-scale. Using a prospective design, we followed 262 patients undergoing cardiovascular operations with surveys and objectively measured medical indices from the Society of Thoracic Surgeons' (STS) national database. Participants completed a follow-up survey on PTG 30-month after surgery. Bivariate correlations related PTG with female gender, age, minority race, marriage, and faith-based factors, but no medical or other psychosocial factors. In hierarchical regressions, gender and age were linked with PTG, alongside other demographics in Step-1. These effects sustained after entry of STS indices, in Step-2, but the gender role diminished after adding medical comorbidities, preoperative depression, optimism, hope, and social support in Step-3. No other factor in these steps had an impact. The age effect vanished when faith factors were entered, but only positive spiritual coping (PSC) was related to PTG. Finally, the role of PSC on PTG was mediated by perceived spiritual support. The final model was significant, accounting for one-third of the variance [F (20, N = 215) = 4.896, p < .001, R2 = .334] in PTG. This suggests that more research should aim to explore the effect of gender and age on PTG in general. For cardiac patients, care providers may encourage positive faith-based coping prior to cardiovascular surgery.

EFFECT OF ASPIRIN IN COVID-19 OUTCOMES OF OLDER ADULTS WITH A HISTORY OF CORONARY ARTERY DISEASE

Ali Vaeli Zadeh,[1] Ricardo Criado Carrero,[2] Alan Wong,[3] Noah Mandile,[4] Marina Stukova,[5] German Lopez,[5] Elias Collado,[1] and Joshua Larned[6], *1. Holy Cross Health-Jim Moran Cardiovascular Research Institute, Fort Lauderdale, Florida, United States, 2. University of Miami/Holy Cross Hospital, Fort Lauderdale, Florida, United States, 3. Holy Cross Health-University of Miami, Fort Lauderdale, Florida, United States, 4. Jim Moran Cardiovascular Institute, Fort Lauderdale, Florida, United States, 5. University of Miami at Holy Cross, Fort Lauderdale, Florida, United States, 6. Holy Cross Health-University of Miami, Miami, Florida, United States*

Background: Advanced age and coronary artery disease (CAD) have been associated with a dismal prognosis in patients infected with COVID-19, most likely due to the virus's thrombogenic effects. Older adults with a history of CAD have routinely used low-dose Aspirin (LDA) as prevention due to their increased risk of cerebro-cardiovascular events. However, it is unclear if this population would benefit from LDA when infected with COVID-19. Methods: A retrospective study was conducted using the PearlDiver database (PearlDiver Technologies, Fort Wayne, IN). Using ICD codes, patients aged 65–75 and Elixhauser Comorbidity Score(ECI)>4 with a history of CAD admitted for COVID-19 were identified. The use of LDA for 1 month before the index event was used to split the cohort into two matched groups by age, gender, ECI, and other cardiovascular diseases. Records of groups were reviewed for multiple outcomes 30 days after admission. Pearson's chi-squared test was used to compare groups. The strength of association was reported as Risk Ratios (RR). Results: 4,017 patients with no difference in the mean age, gender, and ECI were

included in each group. No differences present in 30-days all-cause readmission(RR=1.04, CI95% =0.92–1.17, p=0.49), mortality(RR=0.63, CI95%=0.30–1.29, p=0.28), ICU admission(RR=1.01, CI95%=0.89–1.15, p=0.79), gastrointestinal bleeding(RR=1.09, CI95% = 0.85–1.40, p=0.51), and intracranial hemorrhage(RR=0.69, CI95%=0.26–1.83, p=0.62) between groups. Conclusion: LDA didn't improve the evaluated outcomes in older persons 30 days after admission. A plausible explanation is that COVID-19's thrombogenic mechanism is likely atypical.

COMORBIDITIES ASSOCIATED WITH RISK OF MYOCARDITIS IN HOSPITALIZED COVID-19 OLDER ADULTS

Andrew Crawford,[1] Andres Redondo,[2] Ali Vaeli Zadeh,[3] Alan Wong,[1] Ricardo Criado Carrero,[4] Alexander Fleischhacker,[4] Elias Collado,[3] and Joshua Larned[5], *1. Holy Cross Health-University of Miami, Fort Lauderdale, Florida, United States, 2. University of Miami, Fort Lauderdale, Florida, United States, 3. Holy Cross Health-Jim Moran Cardiovascular Research Institute, Fort Lauderdale, Florida, United States, 4. University of Miami/Holy Cross Hospital, Fort Lauderdale, Florida, United States, 5. Holy Cross Health- University of Miami, Miami, Florida, United States*

Background: Older adults are afflicted more severely by COVID-19. SARS-CoV-2 can be complicated by myocarditis (MC), and the incidence of MC has been shown to correlate linearly with severity. However, data on comorbidities associated with MC in this population is scarce. Methods: Data were obtained from the PearlDiver database (PearlDiver Technologies, Fort Wayne, IN). The study used ICD codes to include patients hospitalized with a primary diagnosis of COVID-19, aged 65–75, and Elixhauser Comorbidity index(ECI)>4. Within this cohort, we identified patients diagnosed with MC 60 days after admission and compared their baseline comorbidities upon admission to those without MC. Pearson's chi-squared test was used to compare groups. The strength of association was reported by Risk Ratios (RR). A p-value < 0.05 was deemed significant. Results: 412,582 patients admitted with COVID-19 as the primary diagnosis were identified. 0.12% of this cohort developed MC over the following 60 days. The MC group was more likely to be male(57%, p=0.0001), with similar mean age(70.4, p=0.86) and mean ECI(9.4, p=0.07) to the no-MC group. Patients who developed MC have significantly higher rates of prior heart failure(RR= 1.30, CI95%=1.07–1.57, p=0.008). There was no difference between groups in terms of history of arrhythmias(p=0.36), cerebrovascular disease(p=0.09), chronic kidney disease(p=0.13), CAD(P=0.19), diabetes(p=0.48), ischemic heart disease(p=0.06), tobacco use(p=0.39), alcohol use(p=0.17), HIV(p=0.79), and severe liver disease(p=0.14). Conclusion: A history of heart failure increased the likelihood of developing MC in older adults.

ASSOCIATION BETWEEN STATE AND TRAIT ANXIETY AND CARDIOVASCULAR DISEASE

Ruifeng Cui,[1] Montgomery Owsiany,[2] and Alaa Shalaby[3], *1. VA Pittsburgh Healthcare System, Morgantown, West Virginia, United States, 2. West Virginia University, Morgantown, West Virginia, United States, 3. VA Pittsburgh Healthcare System, Pittsburgh, Pennsylvania, United States*

Cardiovascular disease (CVD) consistently ranks among the top ten leading causes of death, with prevalence rates being the highest among middle aged and older adults. Research has found that CVD has a negative bidirectional association with anxiety. However, the literature is limited regarding what specific aspects of anxiety, i.e., state and/or trait, are associated with CVD. The present study investigated the association between state and trait anxiety and CVD in a national sample of 640 middle aged and older adults. Participants (M age = 56.2, SD = 11.8) were from the Midlife in the United States (MIDUS) Biomarker sub-project. State anxiety was assessed with the Mood and Anxiety Symptom Questionnaire-anxiety subscale and trait anxiety was assessed with the Spielberger Trait Anxiety Inventory. In a binary logistic regression model including both state and trait anxiety, only trait anxiety significantly predicted presence of CVD (p = .05). In particular, trait anxiety was significantly associated with circulatory disease (p = .05), heart murmurs (p = .03), and blood clots (p = .03). Among middle-aged and older adults, trait anxiety is associated with having several different CVDs. These findings support assessing and addressing trait anxiety among middle aged and older adults with CVD.

AGE DIFFERENCES IN DEPRESSION AND ANXIETY LEVELS OF OPEN HEART SURGERY PATIENTS

Crim Sabuncu, and Amy Ai, *Florida State University, Tallahassee, Florida, United States*

Age, as well as gender, are key demographic measures in cardiac patients. Further, depression and anxiety have been long established to be comorbidities of heart disease (HD). In this prospective study, to examine the impact of age and gender in preoperative depression and postoperative anxiety symptoms of HD patients receiving open heart surgery (OHS), we collected two waves of survey data along with medical indices from patients at a top-10 heart center in the USA (n = 481, mean age = 62.18 ± 12.04, female 42%). The collected survey data included socio-demographic information (age, gender, race), religious affiliation and other religious factors, general health and health behaviors, medical comorbidities, cardiovascular health indices, dispositional optimism, hope, social support, depression symptoms, and anxiety symptoms. Statistical analysis was carried out using hierarchical linear regression analyses. Findings support that higher age correlates with increased levels of cardiac symptoms. Further, younger age was associated with higher levels of postoperative depression, while older age was associated with higher levels of postoperative anxiety. Higher levels of dispositional optimism were consistently associated with lower levels of both postoperative depression and postoperative anxiety regardless of age. Female gender had an impact on depression scores but not on anxiety scores. Findings suggest that medical practitioners might benefit from being more attentive to non-medical conditions such as mood states, dispositional optimism, and general positive expectations about the future in post-OHS life. The findings also suggest that there might be age and gender differences in expected postoperative psychosocial symptomology for OHS patients.

THE ROLE OF MEDITERRANEAN DIET IN THE PRIMARY AND SECONDARY PREVENTION OF ATRIAL FIBRILLATION: A SCOPING REVIEW

Yan Su,[1] Kuan-Ching Wu,[2] Oleg Zaslavsky,[3] and Marilyn Prasun[1], *1. Illinois State University, Normal, Illinois, United States, 2. University of Washington, Seattle, Washington, United States, 3. Unversity of Washington, Seattle, Washington, United States*

Atrial fibrillation (AF) is the most common cardiac arrhythmia, especially in patients older than 65. The prevalence of AF increased 3-fold over the last 50 years. All treatments, such as cardioversion, ablation, and anticoagulation, are associated with risks and relapses. Besides, these strategies may not apply to all patients with AF. Adherence to the Mediterranean dietary pattern is assumed as an ideal nutritional model for AF. Yet, there is a gap on 1) how adherence to the Mediterranean diet prevents AF and 2) how the Mediterranean diet affects complications in patients with AF. A scoping review was performed in June 2022 to identify studies focusing on the Mediterranean diet and AF. A total of 334 articles were retrieved and 12 met inclusion criteria. Six studies were interventions (n=6) and six were observational studies (n=6). In the six intervention studies, five were nested within the PREDIMED (Prevención con Dieta Mediterránea) study. In AF occurrence (n=6), the results were inconsistent. The Mediterranean diet plus extra virgin olive oil was significantly and favorably related to AF, however, Mediterranean diet plus nuts was not, when compared with the low-fat diet; Mediterranean diet modified how long chain acylcarnitine affected development of AF but not how tryptophan or arginine metabolites affected AF. In patients diagnosed with AF (n=6), Mediterranean diet favorably related to adverse cardiovascular events, oxidative stress, and Mediterranean diet adherence, and did not affect anticoagulation for those taking anticoagulants. Further research is needed to examine how the Mediterranean diet affects the development of AF.

SHORT- AND LONG-TERM OUTCOMES AFTER HIP SURGERY IN OLDER ADULTS WITH AND WITHOUT HEART FAILURE

Sijia Wei,[1] Wei Pan,[2] Tingzhong (Michelle) Xue,[3] Hideyo Tsumura,[4] Chiyoung Lee,[5] and Eleanor McConnell[2], *1. Northwestern University Feinberg School of Medicine, Chicago, Illinois, United States, 2. Duke University, Durham, North Carolina, United States, 3. Duke University School of Nursing, Durham, North Carolina, United States, 4. University of Michigan School of Nursing, Durham, North Carolina, United States, 5. University of Washington Bothell, Bothell, Washington, United States*

Older adults with heart failure (HF) have a higher risk for adverse outcomes after hip fracture surgery than those without. Propensity score matching (PSM) reduces selection bias and makes a direct group comparison (older adults with and without HF) possible. Thus, this study aimed to assess the impact of HF on short-and long-term outcomes after hip fracture surgery in older adults living with and without HF. Electronic health records data of older adults (n = 1171) hospitalized for hip fracture surgery between October 2015 and December 2018 were extracted. Comparison groups (with and without HF) were identified using 1:1 ratio PSM to control for observed differences in baseline characteristics. Regression models were used to compare group differences in outcomes. Although in analyses without PSM, older adults with HF were more likely to have higher 90-day readmission, and 30-, 90-, and 365-day mortality, this association was not significant after controlling for selection bias. However, the associations between having HF with 30-day readmission and longer length of stay were significant before and after PSM. Additionally, if patients did not receive hip fracture surgery procedures within two days of admission, they had a 3.6-day longer inpatient stay (P-value < 0.0001) and were 47.8 times more likely to die during hospitalization (95%CI 4.9–482.0, P-value < 0.001). Being non-white was significantly associated with higher 90- and 365-day mortality. Future research should consider PSM approach on national representative datasets to rigorously evaluate the effects of HF on mortality and readmission following hip fracture surgery in older adults.

DECREASING THE USE OF BENZODIAZEPINES AND SEDATIVE HYPNOTICS IN POST OPERATIVE OLDER ADULTS

Amaka Opute, *UTSW Medical Center Dallas, Dallas, Texas, United States*

Purpose: The purpose of this project was to decrease the prescribing of benzodiazepines and sedative hypnotics in post-operative older adults Background: Routine prescribing of benzodiazepines and sedative hypnotics as first line choices for sleep medication is a known contributor to prolonged hospital stays, increased fall rates, increased development of delirium, higher health care costs, and long-term cognitive decline. Methodology: Practice changes included monthly provider and nursing staff education inservices, coupled with transparent monitoring of provider prescribing practices. The outcomes measure was to decrease the prescribing of benzodiazepines and sedative hypnotics by 5% within 90 days and increase the prescribing of melatonin by 10%. Results: When comparing six months of data pre and post implementation on the unit, there was a 33% decrease in the prescribing of benzodiazepines/sedative hypnotics and a 12% increase in the prescribing of Melatonin. There was also a 28% decrease in the hours of patient safety sitter use, a marker for delirium. Implications: This quality improvement project decreased the number of benzodiazepines and sedative-hypnotics prescribed by expanding provider and nursing knowledge, which ultimately led to fewer hours spent utilizing patient safety sitters, thereby lowering healthcare costs, while concurrently improving the quality of care delivered

DECREASING PAIN, ANXIETY, AND CONFUSION IN TERMINALLY ILL VETERANS

Denise Kresevic,[1] Muralidhar Pallaki,[2] Bridgette Wasil,[3] Marilyn Swanson,[3] and Christopher Burant[4], *1. VA Northeast Ohio Healthcare System, Sagamore Hills, Ohio, United States, 2. VA Northeast Ohio Healthcare System, Cleveland, Ohio, United States, 3. VA Northeast Ohio Healthcare System, Cleveland, Ohio, United States, 4. Case Western Reserve University, Parma, Ohio, United States*

Terminally ill patients often receive medications for pain and anxiety that result in sedation that may inhibit communication with their loved ones. Balancing comfort while maintaining meaningful communications is a common dilemma for patients, staff, and families. Many patients report confusion and a decreased ability to communicate with families and health care providers, resulting in fear, anger, and frustration. Additionally, family members (25 to 33%) also feel frustrated and angry not being able to communicate with their loved ones needs and wishes. Delirium, a distressing syndrome characterized by disturbed consciousness, reduced ability to focus attention, altered cognition is experienced by 62–88% of terminally ill patients. Unfortunately, it is often underdiagnosed and undertreated. While not all delirium can be prevented it is estimated that 50% of terminal delirium may be ameliorated. This project was designed to proactively identify terminally ill veteran preferences for nonpharmacological interventions to reduce pain, anxiety, and prevent delirium. In the sample of Veterans from an inpatient VAMC Hospice (n=31) the mean age was 79.46 (sd=10.69); 60.7% were Black and 39.3% were white; 60.9% had cancer and 27.6% had heart failure. The most common patient delirium related behaviors were verbal agitation, physical agitations, physical aggression, anxiety, and confusion. Veterans identified the following comfort priorities: decreased noise (82.6%) and lighting (82.6%), warm blankets (78.3%), music (65.2%), emotional support (73.9%), increased family involvement (43.5%) and (20.8%) going outdoors. Preventative individualized nonpharmacological interventions decreased disruptive delirium related behaviors over 95% of the time and should be incorporated into routine hospice care.

SERVED BY SYSTEMS: AGING WITH INTELLECTUAL AND DEVELOPMENTAL DISABILITIES AND INEQUITIES IN HEALTHCARE

Danielle Waldron,[1] Emily Hartford,[2] Jacquelin Sauer,[2] and Jeffrey Stokes[3], *1. Stonehill College, Taunton, Massachusetts, United States, 2. Stonehill College, Easton, Massachusetts, United States, 3. University of Massachusetts Boston, Boston, Massachusetts, United States*

Adults and older adults with intellectual and developmental disabilities (I/DD) often experience medical complexity, accelerated aging, and shortened life expectancy. This project explores health service utilization (HSU) of adults with I/DD receiving state services in the U.S. over the adult lifespan before and after the implementation of the Affordable Care Act (ACA). Three waves of cross-sectional data (2008–2019) from the National Core Indicators-In Person Survey were analyzed using multilevel mixed effects logistic regression (n=46,284). Older adults with I/DD were more likely to receive a physical exam, flu vaccine, eye exam, hearing test, and a dental exam compared to younger individuals, although these differences were small. Compared to non-Hispanic whites, non-Hispanic blacks were less likely to receive physical exams, flu vaccines, and dental exams; non-Hispanic other were less likely to receive eye exams and dental exams; and Hispanic persons were less likely to receive eye exams, flu vaccines, and dental exams. Individuals with I/DD living in states that expanded Medicaid were at 68% greater odds of receiving a physical exam than those who did not. Our research indicates that overall adults with I/DD are not yet reaching HSU of pre-ACA times, perhaps due to the oversaturation of existing providers. National and state policies, along with individual case management each play a role in ensuring healthy aging of individuals with I/DD. A call to action to better understand and integrate these three entities may help improve the potential for healthy aging of this group.

LOVE AMONG OLDER AFRICAN AMERICAN COUPLES: AN ACTOR PARTNER INTERDEPENDENCE MODEL ANALYSIS

Kadija Mussa,[1] and Chalandra Bryant[2], *1. University of Minnestoa, Falcon Heights, Minnesota, United States, 2. University of Minnesota, Minneapolis, Minnesota, United States*

Older women are often described as being asexual and uninterested in sex or intimacy (McHugh & Interligi, 2015). Thus, most research examining older couples describes those couples as primarily enjoying companionate or compassionate love – a type of love reflecting care and concern for another person (Allen et al., 2018). Unlike companionate or compassionate love, passionate love refers to a “state of intense longing for union with another” (Hatfield & Rapson, 1993, p. 67). Relatively little is known about passionate love and older couples (Hatfield & Rapson, 1993); moreover, far less is known about passionate love among African American older couples. Using data collected from African American couples (332 couples aged 20 to 39 and 90 couples aged 40 to 79), Actor-Partner Interdependence Models were used. For both age groups, 20 to 39 and 40 to 79, husbands’ and wives’ reports of marital quality were significantly associated with each other at Time 1. Husbands’ and wives’ reports of passionate love (assessed at Time 2) were not significantly associated with each other – for either age group under study. Cross paths (partner effects) were not significant for either of the two age groups; wives’ marital quality (Time 1) did not significantly predict husbands’ passionate love (Time 2), nor did husbands’ marital quality (Time 1) predict wives passionate love (Time 2). It is important to note that the older and younger age groups exhibited a similar pattern of results, suggesting that passion and physical intimacy may operate in similar ways for both.

IMPACT OF A DRIVING DECISION AID ON DECISIONAL CONFLICT AMONG OLDER ADULT DRIVERS AND THEIR STUDY PARTNERS

NIcole Fowler,[1] Rachel Johnson,[2] Ryan Peterson,[3] Matthew Schroeder,[4] Carolyn DiGuiseppi,[5] Duke Han,[6] Linda Hill,[7] and Marian Betz[8], *1. Indiana University School of Medicine, IU Center for Aging Research, Indianapolis, Indiana, United States, 2. Colorado School of Public Health, Aurora, Colorado, United States, 3. University of Colorado, Aurora, Colorado, United States, 4. Regenstrief Institute, Inc., Indianapolis, Indiana, United States, 5. University of Colorado Anschutz Medical Campus, Aurora, Colorado, United States, 6. University of Southern California, Alhambra, California, United States, 7. University of California San Diego, La Jolla, California, United States, 8. University of Colorado School of Medicine, Aurora, Colorado, United States*

Forty-four million US licensed drivers are ≥65 years old and at higher crash risk. Decision-making about stopping or continuing driving is difficult and often involves family and friends. This study examines if decision conflict about changing driving habits is associated between older adult drivers and their study partners (SPs) (i.e., family member or friend). Data were from a multi-site trial assessing a driving decision aid. Decision conflict about stopping or continuing driving for drivers and their SPs were measured with the Decision Conflict Scale (DCS). Dyadic associations between drivers' and SPs' DCS scores pre- and post-decision aid implementation were analyzed using an actor-partner interdependence model. Among 228 driver-SP dyads, driver mean (SD) age was 77.1 (5.1) years; 50.0% female; 98.7% non-Hispanic; 94.7% white; and 97.8% urban-dwelling. SPs mean age was 66.1 years (13.9); 65.8% female; 95.6% non-Hispanic; 92.1% white; and commonly the driver's spouse (54.6%) or adult child (21.1%). Most drivers (71.7%) and SPs (63.3%) had baseline DCS scores < 25 (drivers mean 18.5 (SD 12.3); SPs 20.5 (16.8)), suggesting low decision conflict. DCS was correlated within dyads at baseline ($r=0.18$, $p < 0.01$), and baseline DCS was associated with post-decision aid DCS ($p < 0.001$ for SPs [$\beta=0.73$] and drivers [$\beta=0.73$]). While SPs' baseline DCS was not associated with drivers' post-decision aid DCS, drivers' baseline DCS and SPs' post-decision DCS were ($\beta=0.10$; $p=0.036$). Higher decision conflict about driving felt by older drivers is frequently shared by their SPs, in whom decision conflict may persist even after a driving decision aid intervention.

EMPATHIC RESPONSE AND MARITAL QUALITY FOR SAME- AND DIFFERENT-SEX MIDLIFE COUPLES: MEDIATING ROLE OF DYADIC COPING

Susanna Joo,[1] Hye Won Chai,[2] Jihye Lee,[1] Hyoun K. Kim,[1] and Debra Umberson[2], *1. Yonsei University, Seoul, Seoul-t'ukpyolsi, Republic of Korea, 2. The University of Texas at Austin, Austin, Texas, United States*

Dyadic coping is a daily interpersonal process that married couples use to manage stress and maintain their marriage. However, little is known about its mediating role in the association between empathic response and marital quality among same-sex and different-sex couples. This study aimed to examine the extent to which dyadic coping mediates the association between empathic response and marital quality, focusing on middle-aged men and women in same-sex and different-sex marriages. We used dyadic data from the Health and Relationships Project (HARP), including 124 gay, 171 lesbian, and 124 straight couples. Results from the actor-partner interdependence mediation model (APIMeM) showed that dyadic coping within couples mediated the association between empathic response and marital quality for all couple types (i.e., gay, lesbian, and straight couples). More empathic response was associated with better dyadic coping, which led to higher marital quality. While such mediated paths did not differ significantly between gay and lesbian couples, direct associations between empathic responses and marital quality were only significant among lesbian couples. Additionally, there were gendered patterns within straight couples; while female spouses' empathic response was associated with their and their male spouses' marital quality through the couple's dyadic coping, such a mediated path was not significant for male spouses' empathic response. These findings suggest dyadic coping as an effective strategy for enhancing marital quality among same-sex and different-sex married couples, but the mediating role of dyadic coping is gendered in different-sex marriages.

PERCEIVED FINANCIAL VULNERABILITY, WEALTH, AND WEALTH CHANGE: THE HEALTH AND RETIREMENT STUDY

Madison Maynard,[1] Emily Flores,[2] Daniel Paulson,[1] and Peter Lichtenberg[2], *1. University of Central Florida, Orlando, Florida, United States, 2. Wayne State University, Detroit, Michigan, United States*

Financial vulnerability among older adults is an escalating social concern given all too frequent financial exploitation of this population. The 6-item Perceived Financial Vulnerability (PFV) was derived from the 56-item Lichtenberg Financial Decision Rating Scale to examine awareness and psychological vulnerability regarding finances. It was included as an experimental module in the Health and Retirement Study (HRS) in 2018. Prior findings have identified significant associations of PFV with wealth, demographics, and health status. The goals of the current study were to examine the relationship between wealth, changes in wealth, and perceived financial vulnerability. The sample included 1156 respondents to the HRS. Respondents were 57.5% female and 77.2% Caucasian. Average age was 68.28 (SD = 10.74) and average years of education was 13.11 (SD = 2.88). The PFV demonstrated adequate internal consistency ($\alpha = .60$). Total assets at baseline (2016) and change in total assets over two waves (2016 to 2018) were independently stratified into deciles and used as primary predictors of perceived financial vulnerability in 2018. A multiple linear regression model was conducted to examine these relationships. Consistent with previous findings, demographics ($R2=0.04$, $F(5,1150)=10.07$, $p < .001$) and baseline wealth ($B= -0.20$, $SE=0.02$, $p < .001$) predicted PFV scores. Subsequent addition of wealth change ($B=-0.06$, $SE=0.02$, $p=.002$) significantly contributed to overall variance accounted for ($p < .01$). Negative wealth change over two years and low baseline wealth related to higher PFV. These findings support the construct and the PFV measure as valid and informative.

INADEQUATE PHYSICAL ACTIVITY ON HEALTHCARE EXPENDITURES AMONG MIDDLE AGE AND OLDER WORKING ADULTS IN THAILAND

Katika Akksilp,[1] Wanrudee Isaranuwatchai,[2] Yot Teerawattananon,[2] and Cynthia Chen[3], *1. National University of Singapore, Singapore, Singapore, 2. Health Intervention and Technology Assessment Program, Muang Nonthaburi, Nonthaburi, Thailand, 3. National University of Singapore, Singapore, Singapore*

Physical inactivity is a significant risk factor for developing non-communicable diseases. This study estimates the additional health costs due to physical inactivity in Thai middle age and older working adults. We included participants aged 40 years and above from the Physical Activity at Work study, who had valid physical activity data from ActiGraph. Health costs were collected using the Health and Welfare Survey and the Work Productivity and Activity Impairment Questionnaire in Thailand. Direct and indirect costs (absenteeism and presenteeism) of the most recent illness in the previous month were collected. Active participants were defined as having at least 150 minutes of moderate-intensity equivalent activity per week. Two-part models were used to compare health costs between active and non-active participants. Data from 105 participants aged 40 to 63 were included in the analysis, where 42% of participants were active. Inadequate physical activity was significantly associated with increased direct health costs of 160.5THB (95%CI: 31.3 to 289.7THB) (~7.8 times higher in inactive). Further adjustment for sex, age, education, obesity, and cardiovascular condition yielded similar findings. After incorporating these indirect costs, the societal cost of having inadequate physical activity was 791.22THB (95%CI: 115.6 to 1466.8THB) (~1.3 times higher in inactive), even after adjusting for the covariates. Obesity and the female were also associated with higher societal costs (551.9THB and 342.9THB, respectively), although these results were not significant. Increasing physical activity in middle age and older working adults to meet the current guidelines may reduce Thailand's health costs.

FINANCIAL HARDSHIP AND INCOME SECURITY AND MENTAL HEALTH AMONG OLDER WORKERS: MULTI-CHANNEL SEQUENCE APPROACH

Oejin Shin,[1] Sojung Park,[2] Eunsun Kwon,[3] and Byeongju Ryu[4], *1. Illinois State University, Savoy, Illinois, United States, 2. Washington University in Saint Louis, Saint Louis, Missouri, United States, 3. Fairleigh Dickinson University, Florham Park, New Jersey, United States, 4. Washington University in St. Louis, St. Louis, Missouri, United States*

Drawing on the life course perspective and multi-channel sequence approach, this research identifies long-term financial hardship and income security patterns among older adults and examines their relationship with depressive symptoms. Data were from the 2010 to 2018 HRS with 3,077 older workers aged 62–71 in 2010. Four clusters of key sequences were identified: 1) High food and low medical insecurities with private pension plans (43%); 2) Moderate food and low medical insecurities with gradually acquired private pension plans (13%); 3) High food and low medical insecurities with both private and employment-based pension plans (40%); 4) High food insecurity with employment-based pension plans(3%). Regarding the association with depressive symptoms, a group of people who experienced high food and low medical insecurities with private pension plans ($b= 0.14$, $p < 0.1$) and those who experienced moderate food and low medical insecurities with gradually acquired private pension plans ($b= 0.32$, $p < 0.01$) were more likely to have depressive symptoms compared to those high food and low medical insecurities with both private and employment-based pension plans. These findings highlight the heterogeneity of long-term patterns of financial hardships and patterns of income security, including the limited accessibility for a pension plan through their occupation and that an individual pension plan may not be sufficient to ensure mental health in later life. The results imply the importance of dual security of private and employment-based pensions on their mental health and provide important insights for future tailored income support programs for older adults.

END-OF-LIFE HOSPITALIZATION SPENDING IN THE LAST SIX MONTHS OF LIFE AMONG CANCER PATIENTS

Katika Akksilp,[1] Vanessa Tan,[1] Julian Lim,[2] Keith Lim,[3] and Cynthia Chen[4], *1. National University of Singapore, Singapore, Singapore, 2. Saw Swee Hock School of Public Health, Singapore, Singapore, 3. National University Hospital, Singapore, Singapore, 4. National University of Singapore, Singapore, Singapore*

End-of-life care may constitute a vast proportion of health care expenditure globally. In the US, one-quarter of all medicare spending goes towards healthcare for people near the end of life. This is especially true for cancer patients. Our study aimed to estimate hospital spending in cancer patients in the last six months of life. Patients with cancer who died between June 2015 to December 2016 (n=653) were extracted from Singapore's electronic medical records. A two-part model was used to estimate hospitalization spending. In the last month of life, we found that 85% of the patients did not have chemotherapy, 43% had good quality care, and 31% had palliative care. The average total hospitalization spending in the last six months of life was S$59,180. Further analysis by month from death revealed that spending increased sharply by 62%, from $7,591 in the sixth month of life to $12,315 in the last month of life. Decedents who received chemotherapy in the last month of life spent $6,925 more on hospitalization expenditure than those who did not ($17,915 vs $10,990). Among decedents seen by a palliative doctor, hospital expenditures in the last month were $8,745 higher compared to those who did not ($16,119 vs $7,374). The study depicted the huge hospitalization spending during the end-of-life for cancer patients in Singapore. Expenditure on end-of-life care can be further reduced with investment in community-based services and integrated care across the community and acute sectors, where hospital-to-home services and earlier palliative care can provide potential cost-effective solutions.

A MODEL FOR STUDENT PARTICIPATION IN COMMUNITY-ENGAGED RESEARCH FOR OLDER ADULTS: THE ENROLL PROGRAM

Matthew Peterson,[1] Tina Newsham,[2] Alicia Sellon,[1] Madison Norris,[1] Leanza Sidey,[1] Christian Barnes,[1] William Holland,[1] and Jodi Rich[3], *1. University of North Carolina Wilmington, Wilmington, North Carolina, United States, 2. UNC Wilmington, Wilmington, North Carolina, United States, 3. New Hanover County Parks & Gardens, Wilmington, North Carolina, United States*

The current academic climate has left naturally occurring faculty-led student research experiences and mentoring a challenge. This is coupled with an already existing dearth of future scientists interested in aging-related research. The overarching goal of the Enhancing Research for OnLine Learners (EnROLL) Program is to facilitate research collaboration among undergraduate minoritized students, graduate distance learners, health sciences faculty, and academic partners. The program includes a variety of strategic initiatives, one of which includes building five inter-institutional research cores: epidemiology, preclinical, allied health, applied learning, and community engagement. Here, we present a community-based participatory project led by students and researchers in the EnROLL community engagement core in partnership with local government. Researchers at UNCW were contacted by New Hanover County Parks & Gardens staff to assist in wellness planning for area older adults. Two surveys were developed: Nf103 community members and Nf8 staff members completed separate surveys. Community respondents were 60.8 +/- 13.7 years old, 72% female, and 80% Caucasian. Approximately 58% of community respondents were at least somewhat likely to participate in wellness programming at County locations. Based on preferred days, times, and types of classes of the respondents, a comprehensive weekly schedule of wellness classes was developed and provided to County staff for implementation under the guidance of a UNCW masters student. This community engagement project, and the EnROLL program, can serve as a model for student-engaged, aging-related research in the health sciences, particularly as gerontologists work to diversify the demographics of researchers who focus on aging.

WORKING TOWARD AN AGE-FRIENDLY UINDY: EXAMINING THE PROCESS AS IT UNFOLDS

Lisa Borrero, and Heidi Ewen, *University of Indianapolis, Indianapolis, Indiana, United States*

Universities must adapt by expanding their understanding of inclusivity in higher education, acknowledging new aging-related career opportunities for students and their role as destinations for lifelong learning and community engagement for older adults. Accordingly, nearly 100 institutions have committed to age-inclusivity on their campuses by achieving Age-Friendly University (AFU) designation. For those interested in pursuing this designation at their institutions, an important part of the process is learning from one another about strategies used at other campuses that could be tailored to their own needs. With this in mind, this poster presentation will outline the initial strategies and resulting outcomes of the path to AFU designation at the University of Indianapolis (UIndy) via a preliminary “discovery” phase. Using GSA’s Tools for Advancing Age Inclusivity in Higher Education as a guide, AGHE members at the University of Indianapolis are in the beginning stages of their own process, characterized by discussions with various campus stakeholders during the recent spring semester. This “listening tour” has revealed strong support of the AFU principles and an eagerness to be part of an age-inclusive vision. These conversations have identified existing infrastructure and other strengths that support age-inclusivity, as well as current challenges to be managed and new opportunities to pursue. The authors will also describe the next phase of the process, including interviews with older UIndy alumni and retired faculty and staff about engagement with retired community members, as well as subsequent steps, such as working with colleagues to design viable age-friendly initiatives.

TECHNOLOGY-DRIVEN INTERGENERATIONAL PROGRAM IN THE PANDEMIC

Sheryl Groden, Matthew Carpenter, Jennifer Blackwood, and Allon Goldberg, *University of Michigan-Flint, Flint, Michigan, United States*

Intergenerational programs increase interaction among groups allowing both generations to share their beliefs, talents, knowledge, and wisdom. The Senior Programming Intergenerational College Experience (SPICE) Project was designed to deliver an 11-week long intergenerational program with college-aged and older adult participants and was provided virtually during the pandemic. The purpose of this study was to describe the participation characteristics and attitudes towards aging and technology of older adults who completed the SPICE program. Older adult recruitment occurred through paper fliers posted at senior centers/housing, libraries, faith-based organizations in Genesee County, Michigan and through a large statewide electronic study recruitment portal. Older adult participants were English speaking; aged 55+ years; able to participate in live Zoom sessions once/week; and were committed to complete >75% of the SPICE program. Online surveys were completed before/after SPICE to evaluate attitudes towards aging and technophilia. Results from 15 older adults who completed >75% of SPICE sessions indicated that they were able to cope with life as they got older (60%), viewed aging as a positive experience (85.7%), were not afraid to use new technology (68.6%) and believed technology was useful/fun (88.6%). Older adults were divided on willingness to try new technology and their ability to keep up with technological progress. These data indicate that for higher education institutions focused on designing age-inclusive online opportunities, older adults who possess a positive attitude toward aging and technology may be more likely to complete intergenerational programs.

GAUGING INTEREST AND NEEDS IN PROFESSIONAL DEVELOPMENT AND CONTINUING EDUCATION IN AGING IN MANITOBA, CANADA

Michelle Porter, William Kops, and Nicole Dunn,
University of Manitoba, Winnipeg, Manitoba, Canada

The Centre on Aging at the University of Manitoba in Canada conducted a needs assessment on continuing education (CE) and professional development (PD) in aging with people who work and connect with older adults. During winter and spring 2022, an online survey of 35 questions asked respondents about their own or their staff and volunteer topics of interest, as well as logistics of CE/PD workshop training. A total of 146 participants responded. Respondents were from different regions of Manitoba, with the highest proportion (42%) located in the Winnipeg region. About 86% were female and 12% male, ranging in age from 18 to 75: with most falling in the 35 to 64 age range. Respondents were asked to indicate their level of interest for topics on a five-point scale from Not Interested to Very Interested. The topics Aging Through the Lifespan and Wellness received the highest number of responses, while Indigenous Aging received the least. Across the 1,712 individual ratings of suggested topics, the highest proportion were rated as interested (35%) and very interested (31%); while 19% rated level of interest as moderate, 11% minimal, and 4% not interested. When asked about potential workshop formats, the majority (63%) preferred a mix of both in-person and online delivery formats with preference for 1–2-hour workshops and a certificate as proof of completion. About two-thirds indicated a requirement to complete CE/PD credits to maintain related credentials. These findings provide considerations for higher education institutions on CE/PD for those working and connecting with older adults.

AFRICAN-AMERICAN DEMENTIA CAREGIVER STRATEGIES INVENTORY (DCSI-A): INITIAL PSYCHOMETRIC EVALUATION

Nik Lampe,[1] Robert Glueckauf,[2] Benjamin Behers,[2] Yuxia Wang,[2] and Sarai Jean-Pierre[2], *1. Vanderbilt University, Nashville, Tennessee, United States, 2. Florida State University College of Medicine, Tallahassee, Florida, United States*

Recent studies have found promising evidence of the benefits of cognitive-behavioral interventions (CBIs) in improving depression and health status of African-American dementia caregivers (CGs). However, limited information exists about the specific CB strategies used in these investigations and which CB strategies were most effective in reducing caregiver distress and distress-related health problems. To address these shortcomings, Glueckauf and colleagues developed the African-American Dementia Caregiver Strategies Inventory (DCSI-A) using data from two CBI interventions (Nf129). The primary objectives of the current study were: (a) to identify the most frequently used categories of CBI strategies deployed by African-American CGs and (b) to conduct an initial evaluation of the psychometric properties of the DCSI-A. Descriptive statistics were calculated to assess strategy category frequency and percent of total responses. The two most frequently used strategies were: (1) CG Health-Related Intervention Strategies with 19 endorsements, 16.10% of total strategies and (2) Strategies for CG Social, Recreational, Personal Enhancement and Other Community Activities with 18 endorsements, 15.25% of total responses. These findings suggested that health-related and social, recreational, and personal enhancement strategies were the most commonly used by African-American CBI participants. Intercoder agreement was assessed across two one-month coding intervals, each of which contained 5 coding sessions. Mean percent of agreement and Kappa were .94 and .93, respectively. Both reliability measures fell within the highly acceptable range. Coder drift was minimal across the two time intervals. Future research will evaluate the psychometric properties of the DCSI-A with a larger sample of African-American CGs undergoing CBI.

ADVANCING DIVERSITY IN ADRD/AGING RESEARCH AND CLINICAL CARE: EDUCATIONAL AND CAREER TRAJECTORIES OF MSTEM MENTEES

Sheri Thompson, *UC San Diego, La Jolla, California, United States*

As an NIA-funded mentorship program, MADURA addresses the lack of diversity among Aging and Alzheimer's Disease & Related Dementia (ADRD) researchers and clinicians. Aims include improving retention and academic success of URM MSTEM undergraduates, and increasing rates of graduate/medical school applications and entry into Aging/ADRD clinical careers. MADURA offers paid research lab experience, weekly whole-cohort research skills training, guest seminars and presentations, and weekly faculty-facilitated small group supervision, advising and support. It served 23–29 undergraduates/quarter, in its initial five quarters. The Program accepts students at varying undergraduate educational levels, particularly because students from target populations often enter as Junior-level transfers from community colleges. Thus, although the Program just completed its second year, 17 MADURA trainees have already graduated. While ongoing data collection on Program, Mentor and Student Mentee performance is beneficial, outcomes data are of utmost importance to ensuring achievement of aims. This poster will present descriptive data on MADURA graduates' immediate employment and educational activities. Notable findings include a significant proportion of trainees who take a gap year before applying to graduate or medical school (for financial and personal reasons), and others taking internships, post-baccalaureate training or research jobs, to strengthen future medical and graduate school applications. Understanding the multiple pathways of recent graduates will enable mentorship programs to help current trainees critique and optimize preparations for their selected educational and career trajectories. These findings also suggest additional mentorship program outcomes of interest (beyond a sole focus on graduate program acceptance), and the need for longer-term alumni follow-up.

THE IHSS+ ADRD TRAINING PROJECT: BOLSTERING THE DEMENTIA CARE WORKFORCE IN CALIFORNIA

Jarmin Yeh,[1] Brittney Pond,[1] Matthew Beld,[1] Corinne Eldridge,[2] and Leslie Ross[1], *1. University of California, San Francisco, San Francisco, California, United States, 2. Center for Caregiver Advancement, Los Angeles, California, United States*

California's In-Home Supportive Services (IHSS) program provides vital home care to low-income consumers, some of whom live with Alzheimer's disease or related dementias (ADRD). Yet, most IHSS caregivers receive little or no training in dementia care. With the prevalence of ADRD among Californians age 55+ projected to increase 127% by 2040, reaching over 1.5 million people, the IHSS consumer population living with ADRD will likely increase at a similar rate, exacerbating the need for dementia-trained home care workers. This poster describes preliminary outcomes of the IHSS+ ADRD Training Project, a 10-week, competency-based training program, aiming to reach 600 IHSS caregivers in Alameda County, California, by 2024. All planned in-person activities switched to virtual strategies due to the COVID-19 pandemic. To date, 348 IHSS caregivers have been trained through 16 classes, with 9 classes offered in English, 3 classes in Spanish, and 4 classes in Cantonese. A quasi-experimental, longitudinal design was used to evaluate the project's impact through pre, post, and 3-month follow-up surveys. Caregiver outcome measures included the: 1) Dementia Knowledge Assessment Tool 2, 2) Fortinsky self-efficacy scale, 3) Caregiver Self-Assessment Questionnaire, and 4) Patient Health Questionnaire-2. Preliminary outcomes trend toward significant increases in caregivers' knowledge about ADRD and self-efficacy to maximize care they provide to consumers. While caregivers also reported slight increases in stress and depression, they expressed high levels of satisfaction with the training. Future analysis will include comparing IHSS caregiver outcomes to healthcare utilization patterns of IHSS consumers before and after their caregiver's participation in the training.

REVISITING THE TEACHING NURSING HOME: QUALITATIVE ANALYSIS OF NURSING STUDENTS' CLINICAL EXPERIENCE

Brianna Morgan,[1] Kierra Foley,[2] Nancy Hodgson,[1] Ann Kolanowski,[3] Kim Strauch,[4] Nancy Zionts,[5] Chelsea Dickson,[6] and Howard Degenholtz[7], *1. University of Pennsylvania, Philadelphia, Pennsylvania, United States, 2. Penn Nursing, Philadelphia, Pennsylvania, United States, 3. Penn State University, State College, Pennsylvania, United States, 4. Penn School of Nursing, Philadelphia, Pennsylvania, United States, 5. Jewish Healthcare Foundation, Pittsburgh, Pennsylvania, United States, 6. University of Pittsburgh School of Public Health, Pittsburgh, Pennsylvania, United States, 7. University of Pittsburgh, Pittsburgh, Pennsylvania, United States*

Revisiting the Teaching Nursing Home is a two-year pilot project to address the long-term care workforce shortage by introducing nursing students to geriatric nursing while also improving quality of care within nursing homes. The initiative has multiple components: enhanced clinical rotations for nursing students with partner schools of nursing, implementation of the Institute for Healthcare Improvement Age-Friendly Health System "4M" quality improvement model, and an online learning network. Undergraduate and graduate nursing students at three Schools of Nursing participated in clinical experiences at regional nursing homes. Students completed an "activity feedback" form after each clinical rotation at the nursing home or related activity, such as a session about the 4Ms or quality improvement/assessment. The activity feedback form asked students to share their most important takeaway and suggestions for improvement. Data from 340 feedback forms was coded qualitatively using conventional and directed content analysis using the American Association of Colleges of Nursing (AACN) Essentials for Professional Nursing Education. Multiple coders and audit trials were used to establish rigor. Students' takeaways encompassed 7 of 8 key concepts in the AACN Essentials; Knowledge for Nursing Practice, Person-Centered Care, and Interprofessional Partnerships were most frequently mentioned. Students provided numerous suggestions for improving their clinical experiences including facilitated learning from instructors and supported engagement with nursing home staff. In conclusion, the program addressed many of the core competencies designated by AACN. One recommendation that flows from these findings is to enhance the role of clinical preceptors in the nursing home setting to facilitate mentored training.

REVISITING THE TEACHING NURSING HOME: IMPACT ON NURSING STUDENTS' PERCEPTIONS OF WORKING IN LONG-TERM CARE

Howard Degenholtz,[1] Marie Boltz,[2] Donna Fick,[3] Nancy Hodgson,[4] Kim Strauch,[5] Jacob Kariuki,[6] Yurun Cai,[1] and Dawn Pajerski[6], *1. University of Pittsburgh, Pittsburgh, Pennsylvania, United States, 2. Penn State, State College, Pennsylvania, United States, 3. Penn State University, University Park, Pennsylvania, United States, 4. University of Pennsylvania, Philadelphia, Pennsylvania, United States, 5. Penn School of Nursing, Philadelphia, Pennsylvania, United States, 6. University of Pittsburgh School of Nursing, Pittsburgh, Pennsylvania, United States*

Revisiting the Teaching Nursing Home is a two-year pilot project to address the long-term care workforce shortage by introducing nursing students to geriatric nursing while improving quality of care within nursing homes. The initiative has multiple components: enhanced clinical rotations for nursing students with partner schools of nursing, implementation of the Institute for Healthcare Improvement Age-Friendly Health System "4M" quality improvement model, and an online learning network. Nursing students at three schools of nursing participated in the clinical rotations at regional nursing homes. The experience was limited to students in one specific course at each school of nursing. At the beginning and end of the spring 2022 semester, students rated their competence in: patient assessment, collaborating with the care team, gathering clinical information, medication review, eliciting resident values, and health promotion. Students also rated their preferences for working in long-term care and with older adults. Data from 85 responses at the start of semester and 64 responses to the end of semester survey were analyzed. Analysis of student responses found that students self-rated competencies improved in all areas except eliciting resident values. Prior to their clinical experience, students ranked working in long-term care and with older adults lower than other settings or populations. The rankings were unchanged after their clinical experiences. These initial findings suggest that although the Teaching Nursing Home Program is meeting the pedagogical goals, attitudinal shifts may require different strategies.

RE-AIM EVALUATION OF A VIRTUAL "AGING WITH PAIN" INTEGRATIVE HEALTH EDUCATION PROGRAM DURING THE COVID-19 PANDEMIC

Jennifer Brailsford,[1] Sophia Sheikh,[2] Jason Beneciuk,[3] Monika Patel,[2] Brittany Johnson,[4] Robin Moorman Li,[5] Phyllis Hendry,[2] and Natalie Spindle[2], *1. University of Florida, Jacksonville, Florida, United States, 2. University of Florida College of Medicine – Jacksonville, Jacksonville, Florida, United States, 3. University of Florida, Gainesville, Florida, United States, 4. UF Health Jacksonville, Jacksonville, Florida, United States, 5. University of Florida College of Pharmacy, Jacksonville, Florida, United States*

Literature suggests integrative pain management strategies reduce chronic pain and opioid use. However, many older adults are unaware of these options. The Aging and Integrative Pain Assessment and Management Initiative (AI-PAMI) launched in 2020, providing webinars and recorded presentations on integrative pain management for adults > age 50, caregivers and healthcare providers. The RE-AIM (Reach, Effectiveness, Adoption, Implementation, Maintenance) framework was used to evaluate AI-PAMI via the following measures: participant demographics, survey results, program elements and qualitative findings. Reach: There have been > 20,000 views of recorded content and 48% (885/1,859) of registrants attended a live webinar. Effectiveness: Survey results demonstrate 75%

of providers and 73% of older adults/caregivers reported new knowledge gain; and 80% of providers and 60% of older adults/caregivers reported changing their pain management practice/routine. Adoption: Presentations were delivered by 33 multidisciplinary experts from 12 different institutions. Six regional stakeholders promoted AI-PAMI using their dissemination networks. Implementation: The COVID-19 pandemic changed program delivery from an in-person model to virtual. To date, AI-PAMI has delivered 17 live webinars and 25 recorded presentations. Live webinars are delivered with a didactic, Q&A discussion and follow-up email. To refine AI-PAMI, 11 healthcare providers and 16 older adults participated in focus groups or in-depth interviews. Maintenance: AI-PAMI is in its third year and will be maintained under a long-standing institution-wide program. Website content will be sustained and remain free access. AI-PAMI is a valuable educational resource for older adults, caregivers, and healthcare providers. Virtual delivery is accommodating for a post-COVID environment.

PRACTICE CHANGE OUTCOMES OF POST-GRADUATE TRAINING IN ADVANCED CLINICAL DEMENTIA PRACTICES

Daniel Kaplan,[1] and Keith Chan[2], *1. Adelphi University, Cortlandt Manor, New York, United States, 2. Hunter College, City University of New York, New York City, New York, United States*

Neurocognitive disorder is common among older adults with often progressive symptoms impacting multiple domains of life and with major implications and challenges for family involved in care. Clinical providers including doctors, nurses, and social workers play instrumental roles in addressing health and mental health vulnerabilities associated with neurocognitive disorder as skillful interventions can effectively improve wellness and quality of life for patients and care partners. Yet, providers report needing expanded knowledge to deliver appropriate clinical dementia care. An advanced clinical dementia practice certificate program at a major university in the U.S. offers a 45-hour training that covers 35 clinical practices identified by an interprofessional advisory group. This study aims to test the learning impacts of the educational program. Since 2017, 74 participants have completed this training. Their self-reported frequency of use of each clinical practice was measured before and after the training using a 5-item rating scale ranging from "Never" to "Several times per day". Comparisons across two time periods demonstrate significant increases in overall use of clinical practices (mean difference: 0.45), with a large mean effect size (Cohen's $d = 0.8$). These increases were statistically significant in 30 of 35 practices ($p < 0.05$). The largest effects were observed for clinical practices emphasizing the teaching of practical care strategies and the application of person-centered interventions. Implications of this educational method for enhancing clinician practice behaviors and recommendations for quantitative evaluation of training outcomes will be presented.

VOCATIONAL ASSESSMENT AND INDIVIDUAL DEVELOPMENT PLANNING IN DIVERSITY-FOCUSED UNDERGRADUATE MENTORSHIP

Sheri Thompson, *UC San Diego, La Jolla, California, United States*

The UC San Diego MADURA Mentorship Program, funded the National Institute on Aging, strives to improve diversity in Aging/Alzheimer's Disease and Related Dementias (ADRD) research and clinical practice. Goals include improved academic success of undergraduate URM trainees, and facilitating graduate/medical school applications and entry into Aging/ADRD research or clinical careers. Mentees receive paid research experience, training, Program and lab-based faculty supervision, peer support, seminars, and professional development opportunities. To enhance educational and career planning, MADURA incorporated Individual Development Plan (IDP) use, in 2022. IDP training by a Career Services presenter was followed by interactive IDP completion during small group break-outs, with ongoing revisions occurring throughout the quarter. Further, all trainees were offered formal vocational assessment (Strong Interest Inventory®, College Edition). 21 trainees participated and some engaged in individual 30-minute feedback sessions. All mentors were asked to incorporate IDP and vocational assessment discussions into year-end professional development meetings with mentees. Data to be presented includes: Student evaluation of IDP training; prior vocational assessment access; student and mentor ratings of IDP and vocational assessment feasibility, utility and satisfaction; and cohort vocational profile characteristics. Discussion includes implementation challenges, benefits and limitations of IDP and vocational assessment use, and future research suggestions.

CHANGING AGING MYTHS AND READINESS FOR INTERPROFESSIONAL EDUCATION IN FAMILY NURSE PRACTITIONER STUDENTS

David Picella,[1] and Diana Lynn Woods[2], *1. Azusa Pacific University, Diamond Bar, California, United States, 2. Azusa Pacific University, Azusa, California, United States*

The preparation of Family Nurse Practitioner (FNP) students caring for the older adult population is inadequate. The design was a quasi-experimental pilot study ($N = 30$) to assess change in myths about aging and readiness for interprofessional education (IPE) in FNP students near graduation. The Woolf Aging Quiz (WAQ) containing 24 true-false myths about older adults, and the Readiness for Interprofessional Learning Scale (RIPLS) containing 19 items rated on a 5-point Likert scale (high score indicates more readiness), were completed at baseline and post-intervention. The intervention consisted of 4-weeks of education on normal aging, agism, age friendly healthcare, and IPE using online weekly brief video presentations and peer discussion. Thirty FNP students, mean age 43.5 years, 80.6% ($N = 25$) female, 19.4% ($N = 6$) male. A paired t-test showed no significant pre-post difference in the WAQ ($t = -1.388$, $p < .05$). McNemar crosstab analysis of the WAQ items indicated 14 aging myths where students chose the wrong answer pre and post intervention. In addition, the RIPLS showed no significant change (t = .793, p < .05) from pre-intervention (mean = 35.87) to post-intervention (mean = 34.42). FNP students near graduation held strong ageist beliefs, reflected in the WAQ, and were unprepared for IPE. Both of these results were resistant to change. The data suggests that FNP programs need to address aging and IPE content earlier and provide students with exposure to older adults that addresses myths about aging affords both theoretical and practical opportunities for interprofessional learning.

RELAXATION ELEMENTS WITHIN A HOME ENVIRONMENT AND OLDER ADULTS' SOCIOEMOTIONAL EXPERIENCES OF CHALLENGING TASKS

Shannon Mejía,[1] Jessie Chin,[1] Faith-Christina Washington,[1] Smit Desai,[1] Durga Ramesh,[1] Falguni Deshpande,[1] and Sungjae Hong[2], *1. University of Illinois at Urbana-Champaign, Champaign, Illinois, United States, 2. University of Illinois Urbana Champaign, Champaign, Illinois, United States*

Older adults protect their well-being under stressful experiences by carefully selecting their environments, social interactions, and tasks. This bias toward positive over negative experiences may reduce engagement in novel, intellectually challenging, or social complex activities that promote healthy aging over the long term. Environments that foster socioemotional well-being could provide older adults with the psychological resources to engage in novel and challenging tasks that support healthy aging. This study examined how relaxation elements within the environment, such as a fireplace, can support socioemotional experiences while engaging in complex cognitive tasks. The study employed a 2x2 (relaxation vs. not X stress vs. not) within-subject design and took place within the home office of a home simulation environment. Under each condition, 61 participants (age 50–82, 57% female) played a cognitive game on a tablet, reflected for 30 seconds, and described feelings while playing the game by telling a story and rating positive and negative adjectives. Relaxation and stress were manipulated via an electric fireplace and a modified Trier paradigm where game performance was observed remotely by a neurologist. The relaxation condition significantly differentiated the coupling of positive and negative sentiment and positive and negative affect. The negative correlation between positive and negative affect increased, whereas stories became more emotionally complex, with both positive and negative sentiment, when the fireplace was on. Our findings suggest that simple modifications to the environment can differentiate the socioemotional experiences of engaging in novel and challenging experiences. The implications for enrichment seeking in older adulthood are discussed.

THE SENIOR COMMUNITY SERVICE EMPLOYMENT PROGRAM: NEW DATA ON OLDER ASIAN WORKERS

Patrick Ho Lam Lai,[1] and Cal Halvorsen[2], *1. Boston College, Boston, Massachusetts, United States, 2. Boston College, Allston, Massachusetts, United States*

The Senior Community Service Employment Program (SCSEP) is the only federal employment program for people aged 55 and older. While 6% of the approximately 60,000 participants are Asian and federal funds are set aside to serve Asian workers, little is known about their personal characteristics and experiences in SCSEP. Using novel data from an online and paper-based Massachusetts survey of SCSEP participants from April to August 2022 offered in multiple languages, this study aimed to describe Asian participants' characteristics and experiences in SCSEP. Respondents (Nf39) ranged in age from 58 to 73. Almost all spoke a language other than English at home, and all respondents were born outside of the U.S. Nearly half reported a high school degree or less, and none reported "excellent" health. One-third reported feeling lonely occasionally or in specific situations. While two-thirds have made recent tradeoffs in paying for important goods and services (e.g., food and health care), most reported that their personal finances, social engagement, family life, and self-confidence have improved due to SCSEP. Further, 9 in 10 agreed that their supervisors understood the goals of SCSEP and were supportive. A quarter said separately that it was very likely they would search for a paid job or volunteer role after exiting SCSEP. These results contribute to the small amount of literature on older Asian American workers while informing the work of organizations that serve older Asian workers who have experienced multiple barriers to employment relating to nativity status, language abilities, and anti-Asian discrimination.

THE IMPACT OF RACE AND GENDER ON OVERALL CARE RATING AT THE END OF LIFE: APPLYING THE THEORY OF INTERSECTIONALITY

Zainab Suntai, *Baylor University, Waco, Texas, United States*

Research focused on the quality of care received at the end of life has advanced over the past few decades, but few studies have employed an intersectional lens to assess differences in care quality. The theory of intersectionality suggests that individuals with membership in two or more vulnerable groups may be at risk of experiencing increased hardships and stressors across the lifespan. To test the theory of intersectionality and fill the gap in research, this study aimed to assess the combined impact of race and gender on the quality of care received at the end of life among older adults. Data were derived from the combined Round 3 to Round 10 of the National Health and Aging Trends Study, an annual longitudinal panel survey of adults aged 65 and older in the United States. Chi-square tests were used for bivariate analyses and two multivariate logistic regressions were run. Results showed that White men were the most likely to have had excellent or good care at the end of life, followed by White women, Black men, and then Black women. This points to a significant disadvantage for Black women, who lag behind all other groups in other life domains such as income, education, and access to health insurance. Interventions may include intersectionality-focused cultural humility training, cultural matches between patients and providers, and the adoption of a universal health insurance plan to reduce the gaps in service quality caused by the dominance of employment-based health insurance in the United States.

SLEEP CHARACTERISTIC OF AN OLDER END OF LIFE (EOL) CAREGIVER: A SINGLE CASE STUDY

Hyeyoung Park,[1] Sunghoon Lee,[1] Amelia Bailey,[1] Yunda Liu,[1] and Cynthia Jacelon[2], *1. University of Massachusetts Amherst, Amherst, Massachusetts, United States, 2. University of Massachusetts Amherst College of Nursing, Amherst, Massachusetts, United States*

Background: Extensive caregiving work, psychological distress, and caregiving burdens put end of life (EOL) caregivers at great risk of sleep disturbances. Methods: A single case mixed method design was used to explore older EOL caregivers' sleep characteristics. Multi-dimensional data was collected through a series of methods including questionnaires (caregiver and care recipient demographics, care recipient symptom severity, caregiver caregiving strain, depressive symptoms, and sleep quality), 14 days of National Sleep Foundation (NSF) sleep diary, 28 days of daily sleep and activity measured by wearable personal sleep monitoring devices (Garmin vivofit 4), and a semi-structured interview. Data was analyzed using thematic content analysis. Findings: A 60 year old female taking care of her 85 years old mother with dementia, kidney cancer, and several other illnesses was recruited for this case study. She showed overall poor sleep quality measured by the Pittsburgh Sleep Quality Index (PSQI, total score: 8), and she slept 6.73 (±1.27) hours per day on average with 52.96% of deep sleep, 41.63% of light sleep, and 5.41% awake times. The caregiver reported that her daily sleep quality depended on her care recipient's health condition each night. She also described others supporting for her caregiving work as a "double-edged sword," because she needed to trade some privacy for the additional help. Conclusion: Further study is needed for EOL caregivers' poor sleep quality considering external factors and sleep intervention for EOL caregivers should be developed considering these external caregiving contexts.

MOTIVATING PATIENTS WITH PARKINSON'S DISEASE AND THEIR FAMILIES TO DISCUSS PREPARATION FOR END-OF-LIFE CARE

Jiayun Xu,[1] Susan Hickman,[2] Jessica Huber,[1] Rebecca Sudore,[3] Cleveland Shields,[1] Dilhara Moonesinghe,[1] Aubrey Parr,[1] and Taylor Kong[1], *1. Purdue University, West Lafayette, Indiana, United States, 2. Indiana University School of Nursing, Indianapolis, Indiana, United States, 3. University of California San Francisco, San Francisco, California, United States*

Parkinson's disease is the second most common neurological illness among older adults. Although most patients with Parkinson's face communication challenges in advanced illness, few talk about care preferences and are unprepared for worsening illness as a result. Thus, the purpose of the study was to explore the experience of making end-of-life decisions or the preparation of making end-of-life decisions among patients with Parkinson's, their family caregivers, and clinicians. The long-term goal of this study is to develop a medical decision-making resource for patients and families to better prepare for the end of life. We conducted one-hour semi-structured interviews with nine patients, 12 caregivers, and 12 clinicians to explore perceptions of whether end-of-life discussions may be difficult, the preferred timing of end-of-life information, and how to best motivate patients and their families to prepare. Descriptive thematic qualitative analysis methods were used to analyze the transcribed interviews. Participants were on average 59.7±15.3 years of age, 69.7% female, and 69.7% married. The predominant reasons for delaying end-of-life discussions were the unpredictability of Parkinson's disease, limited illness and prognostic awareness, and clinicians not initiating the discussion earlier in the disease course. There was a mismatch in preferences for timing of end-of-life information, with patients and family wanting end-of-life information presented earlier in the illness than clinicians. All participants desired a resource to help patients and caregivers cope emotionally, to guide future decisions, and to help prompt conversations. Findings indicate that despite provider concerns, patients and their families want early information about end-of-life issues.

INTERVENTIONS FOR FAMILY CAREGIVERS RECEIVING PALLIATIVE/HOSPICE CARE AT HOME: A SCOPING REVIEW.

Taeyoung Park,[1] Sulaiman Alshakhs,[1] Elisabeth Sweet,[1] Meghan McDarby,[2] Sara Czaja,[3] Cary Reid,[3] Ronald Adelman,[3] and Veerawat Phongtankuel[4], *1. Weill Cornell Medicine, New York, New York, United States, 2. Memorial Sloan Kettering Cancer Center, New York, New York, United States, 3. Weill Cornell Medicine, Ithaca, New York, United States, 4. Weill Medical College of Cornell University, New York, New York, United States*

With the growth of palliative and hospice care, patients with a terminal illness and their family caregivers have opportunities to pursue care focusing on alleviation of symptoms and optimizing quality of life in the home setting. However, caregivers are often overburdened with caregiving responsibilities leading to poor physical and mental health. Given the importance of family caregivers for patients who elect to receive hospice/palliative care at home along with the negative outcomes associated with caregiving, conducting a review of caregiver interventions is critical to understand what has been studied and identify gaps in the field. A scoping review was conducted to describe interventions focused on family caregivers providing care to terminally ill patients who receive palliative/hospice care in the home setting. Variables collected included intervention delivery details, study population, participant demographics, and measured outcomes. Our search yielded 14,527 articles, of which 70 articles on 54 unique interventions were included in the final analysis. Over three-quarters (77.8%) of the interventions were conducted in North America and Europe. Interventions commonly aimed to reduce the physical burden of caregiving (53.7%), educate the caregiver (53.7%), and improve psychological well-being (48.1%). The majority (58.6%) of the articles evaluated interventions for feasibility outcomes. The lack of studies in non-Western countries points to a cultural disparity in this field. Secondly, despite the variety of interventions, religious and spiritual needs in palliative care need to be further addressed. As palliative and hospice care is an emerging area of research, most studies are still implementing interventions and assessing feasibility.

HOW DOES THE INTERSECTION OF RACE AND GENDER AFFECT HOSPICE CARE AT THE END OF LIFE?

Zainab Suntai, *Baylor University, Waco, Texas, United States*

Research in the palliative and end-of-life-care field has shown that hospice care in the final months of life can improve outcomes such as pain, emotional well-being, and physical comfort. Yet, researchers often find significant disparities in the ability to access hospice care, with Black individuals being less likely to have hospice care at the end of life. The theory of intersectionality suggests that the combination of multiple vulnerable identities may add to the number of hardships and stressors that an individual experiences across the lifespan. To test the theory, this study aimed to access whether gender moderated the relationship between race and the receipt of hospice care at the end of life. Data were derived from Round 3 to Round 10 of the National Health and Aging Trends Study, and two multivariate regression models were used to assess the relationship between the race/gender interaction and hospice care at the end of life (Model 1: main effects, Model 2: interaction term). Results showed that the effect of race on hospice care was indeed dependent on gender, with Black women being the least likely to have hospice care at the end of life. This points to the combined disadvantages resulting from membership in two vulnerable groups (i.e., being a woman and being Black), including fewer hospice facilities in Black-populated areas, race and gender discrimination in hospice referrals, and other factors that combine to reduce hospice access for Black women. Implications for research, practice, and policy are provided.

AN EXAMINATION OF ADVANCED CARE PLANNING IN BLACK AMERICANS: DIRECTION TO IMPROVE ENGAGEMENT

Rachel Bassett, Daniel Paulson, and Nicole Valdes McClure, *University of Central Florida, Orlando, Florida, United States*

Past studies have found that older Black Americans are less likely to establish advance care directives (ACDs) than their White age peers, and medical distrust has been identified as one possible cause. Others have suggested the formulaic approach of ACD documentation which may conflict with the spiritual and cultural nature of these decisions. The Five Wishes ACD was developed partially to address this need. This study seeks to 1) replicate past findings regarding race and ACD adoption, and test the hypotheses that 2) Race will differentially predict Advanced Care Planning (ACP) engagement scores between conditions (Five Wishes vs State Directive), and 3) level of trust in physicians will relate to ACP engagement. The sample (N = 186) was recruited from Amazon Mechanical Turk and Prolific. Participants ranged from 50 to 77 years, were predominantly female (56.8%), White (51.61%), married (52.6%), and college-educated (70 .6%). ANCOVA results were a nonsignificant main effect of ACP engagement by race (F(1, 185) = 1.93, p = .166) and nonsignificant interaction of race by condition (F(1, 185) = 0.16, p < .69). Trust in physician scale scores predicted ACP engagement (F(1, 185) = 16.15, p < .001). The lack of an effect of race on ACP utilization may be explained by educational and SES characteristics of the sample by contrast to prior studies. The Five Wishes and State Directive ACD documents resulted in similar ACD engagement. These results suggest that trust in physicians is a primary barrier to ACP utilization.

VALIDATION OF THE ENVIRONMENTAL AUDIT SCORING EVALUATION (EASE) TOOL FOR LTC HOUSEHOLDS

Migette Kaup,[1] Margaret Calkins,[2] Adam Davey,[3] Robert Wrublowsky,[4] Ashlyn Zachgo,[1] Samantha Gibson,[5] and Madison Parker[6], *1. Kansas State University, Manhattan, Kansas, United States, 2. IDEAS Institute, Cleveland Hts, Ohio, United States, 3. University of Delaware, Newark, Delaware, United States, 4. MMP Architects, Inc., Winnipeg, Manitoba, Canada, 5. University of Kansas, Lawrence, Kansas, United States, 6. Wheat State Manor, Whitewater, Kansas, United States*

This poster will share the results from a research initiative funded by the National Institutes of Health to assess the validity of the Environmental Audit Scoring Evaluation (EASE) tool in its ability to distinguish between different types of skilled care models based on the environmental and operational practices that can be observed and documented. The EASE tool was compared against three existing tools; PEAP, TESS-NH, and EAT-HC. Twenty-eight living areas in nursing homes across the state of Kansas identified as a traditional, household, or hybrid model were observed. The scores of the EASE were compared against the scores of three existing tools in order to evaluate its construct validity. The EAT-HC was most closely related to the EASE, with an R-value of 0.8817. The PEAP and the TESS-NH were less correlated to the EASE, with R-values of 0.8175 and 0.7097, respectively. Results found that the EASE was able to distinguish between traditional and homelike settings, though it could not identify hybrid models with a high degree of certainty. The analysis of variance between homelike and traditional homes was significant at 0.016, while the variance between homelike and hybrid and between hybrid and traditional were not significant. Inter-rater reliability of the EASE was consistently high (.96 and above). The outcomes demonstrated the EASE tool was able to assess the homelike characteristics of the environment of nursing homes better than or equally as well as previously validated tools.

URBAN ENVIRONMENT AND AFFECTIVE STATES IN REAL TIME: AN ECOLOGICAL MOMENTARY ASSESSMENT STUDY OF OLDER ADULTS

Peichao Liang,[1] Yingqi Guo,[2] On Fung Chan,[3] Cheryl Hiu-Kwan Chui,[3] Yuqi Liu,[4] Shiyu Lu,[5] and Terry Lum[3], *1. The University of Hong Kong, Hong Kong, Hong Kong, 2. The Hong Kong Polytechnic University, Hong Kong, Hong Kong, 3. The University of Hong Kong, Hong Kong, Hong Kong, 4. South China University of Technology, Guangzhou, Guangdong, China (People's Republic), 5. City University of Hong Kong, Kowloon, Hong Kong*

Older adults are more dependent on their surrounding environment. Extensive research has demonstrated beneficial effects of both nature and built environment on mental health of older people. However, most previous research used cross-sectional designs failed to test the intraindividual variability between environment, behavior, and mental wellness in daily life. We used ecological momentary assessment (EMA), activity sensors, and GPS tracking to examine the association between real-time environment, mobility and activity, and momentary affect among older adults in Hong Kong. Data collection and data processing was conducted from December 2021 to May 2022. 168 older adults aged 65 to 84 received seven EMA prompts per day during a fifteen-day period, and completed a total of 17,345 momentary assessments of affective states, mobility, and activities. A set of GPS-derived indicators were used to measure the real-time environment. To disaggregate the between- and within-person effects, we used multilevel models to estimate three dimensions of affect, i.e., valence, calmness, and energetic arousal, in EMA observations, nested within individual participants. Preliminary results indicate significant concurrent associations between environmental attributes and momentary affect at the within-person level, while the between-person differences appear to be either null or modest. Being out of home is associated with higher valence ratings (b=0.04, p=0.0427), while exposure to green is associated with a lower level of energetic arousal (b=-0.03, p=0.0163). Greater walkability is consistently associated with higher momentary affect ratings in three dimensions, but these associations are not statistically significant. Implications of these findings for promoting healthy aging will be discussed.

IMPACT OF HOME AMBIENT TEMPERATURE ON SELF-REPORTED MOOD AND ATTENTION IN COMMUNITY-DWELLING OLDER ADULTS

Amir Baniassadi,[1] Wanting Yu,[2] Ryan Day,[3] Angel Wong,[3] Thomas Travison,[1] Lewis Lipsitz,[4] and Brad Manor[5], *1. Harvard Medical School, Boston, Massachusetts, United States, 2. Hebrew SeniorLife, Roslindale, Massachusetts, United States, 3. Hinda and Arthur Marcus Institute for Aging Research, Boston, Massachusetts, United States, 4. Hebrew SeniorLife, Brookline, Massachusetts, United States, 5. Hebrew SeniorLife/Harvard Medical School, Roslindale, Massachusetts, United States*

Background: Many older adults experience variations in daily mood and/or attention. Lab-based studies show that, among other variables, ambient temperature can influence both. The objective of this study was to determine if and how habitual home temperature influences self-reported mood and attention in this population. Methods: Ambient temperature and humidity data were collected from the homes of 41 community-dwelling older adults (age=78±7, 35 females) living in Boston from June 1st to Aug 15th. Participants received two time-stamped smartphone-based questionnaires each day to report their mood and attention. Results: On average, participants completed 86(±29) questionnaires. Those with most variations in subjective outcomes (top quartile of % of time reporting "feeling down/depressed" or "difficult keeping attention"), compared to the rest of the sample, tended to reside in homes with both higher mean ambient temperature (p=0.01) and greater deviation in temperature over time (p=0.10). Logistic regression analysis combining data from all participants revealed that ambient temperature at the time of response did not predict either self-reported outcome. However, within-subject analyses indicated that of the 17 participants who reported at least some variation in attention or mood, the likelihood of experiencing poor mood and/or attention was correlated with time-synced ambient temperature in six individuals. Gender, age, or housing type (affordable vs. private) did not predict the presence of such associations. Conclusion: Variations in self-reported mood and attention are at least partially explained by the home thermal environment in a non-trivial fraction of older adults.

GREENSPACE AND COGNITION: EXPLORING SPECIFIC GREENSPACE MEASURES

Aniruddh Ajith,[1] Sara Godina,[1] Xiaonan Zhu,[1] Alyson Harding,[2] and Andrea Rosso[1], *1. University of Pittsburgh, Pittsburgh, Pennsylvania, United States, 2. University of Minnesota School of Public Health, Minneapolis, Minnesota, United States*

Increased exposure to greenspace is potentially associated with lower risk of Alzheimer's disease and related disorders (ADRD) through increased physical activity, decreased stress, cleaner air, and social cohesion. Previous studies have primarily used global measures of greenspace, thus specific aspects of different types of greenspaces are overlooked. We assess how different measures of greenspaces associate with global cognitive functioning. We examined data from year 10 of the Pittsburgh site of Health, Aging, and Body Composition Study, a longitudinal cohort study of community-dwelling, Black and White adults aged 70–79 years at baseline. Measures derived from the National Land Cover Database (NLCD) use satellite imaging and include total greenspace, forests, and an index of greenspace diversity. Measures from Google Street View virtual neighborhood audits include dedicated greenspace that promotes physical activity, abandoned buildings, and undeveloped land. We measured global cognitive functioning using the Modified Mini-Mental State Examination (3MS). We conducted cross-sectional linear regression models. Covariates included race, education, and neighborhood socioeconomic status. Age was not included as a covariate because the range was narrow, and results did not vary by age. The sample (n=584) was 82.2 years old on average, 57% female, and 35% Black. Total greenspace (F=0.46, p=0.49), forests, and greenspace diversity, dedicated greenspace for physical activity (F=0.87, p=0.35), undeveloped land (F=1.49, p=0.22), and abandoned buildings (F=3.6, p=0.058) were not associated with 3MS, although the relation with abandoned buildings approached significance. We found no association between greenspaces and ADRD, although specific measures, such as abandoned buildings, may need further investigation.

AGE, PHYSICAL ACTIVITY AND MITOCHONDRIAL FUNCTION IN THE STUDY OF MUSCLE MOBILITY AND AGING (SOMMA)

Anne Newman,[1] Terri Blackwell,[2] Paul Coen,[3] Yujia Qiao,[4] Frederico Toledo,[5] Ezequiel Zamora,[6] and Nancy Glynn[4], *1. University of Pittsburgh, Pittsburgh, Pennsylvania, United*

States, 2. California Pacific Medical Center, San Francisco, California, United States, 3. AdventHealth, Orlando, Florida, United States, 4. University of Pittsburgh, School of Public Health, Pittsburgh, Pennsylvania, United States, 5. University of Pittsburgh, School of Medicine, Pittsburgh, Pennsylvania, United States, 6. Wake Forest University School of Medicine, Winston Salem, North Carolina, United States,

We studied whether lower physical activity (PA) in older adults may partly explain the age-related decline in muscle mitochondrial function in the SOMMA cohort of 879 men and women, aged 70+. PA was measured both subjectively (CHAMPS questionnaire) and objectively (wrist-worn ActiGraph Link) classifying PA levels as sedentary, light, or moderate to vigorous (MVPA, ≥3 METS). Muscle mitochondrial function was assessed ex vivo via respirometry in permeabilized fiber bundles and as in vivo by 31Phosphorus magnetic resonance spectroscopy (31P-MRS) of the maximal rate of muscle ATP regeneration (ATPMAX in the quadriceps after contraction. Of 809 with respirometry or 31P-MRS, mean age was 76.4, 58.3% were women, 12.7% Black, 85.2% White and 2.1% other race/ethnicity. Mean OXPHOS and ATPMAX values were 1.91 pmol/(s*mg) and 0.016 mM/sec lower per 5-year age increment. Men self-reported more MVPA than women, but women recorded more MVPA with actigraphy. For both self-reported and recorded activity, associations with maximal tissue oxidative phosphorylation (OXPHOS) as well as ATPMAX were stronger for MVPA than for sedentary or light activity. After adjustment for age, sex, and clinic site, OXPHOS was lower for each standard deviation) fewer minutes/week of MVPA [reported, SD=408 min/wk: -3.66 pmol/(s*mg) (95% CI -4.93, -2.39); recorded, SD=600 min/wk: -1.93 pmol/(s*mg) (95% CI -3.31, -0.55)]. Similar associations were noted for ATPMAX. MVPA attenuated the association of age with mitochondrial function by 31–50% for both OXPHOS and ATPMAX, suggesting that MVPA could offset the lower mitochondrial function with age or that lower mitochondrial function impedes MVPA at older ages.

THE ASSOCIATION BETWEEN FRAILTY AND PERCEIVED FATIGABILITY IN THE LONG LIFE FAMILY STUDY

Benjamin Schumacher,[1] Dustin Kehler,[2]
Alexander Kulminski,[3] Stacy Andersen,[4] Theresa Gmelin,[1]
Kaare Christensen,[5] Mary Wojczynski,[6] and
Nancy Glynn[7], *1. University of Pittsburgh, Pittsburgh, Pennsylvania, United States, 2. Dalhousie University, Halifax, Nova Scotia, Canada, 3. Duke University, Durham, North Carolina, United States, 4. Boston University School of Medicine, Boston, Massachusetts, United States, 5. Southern Denmark University, Odense, Syddanmark, Denmark, 6. Washington University, Saint Louis, Missouri, United States, 7. School of Public Health, University of Pittsburgh, Pittsburgh, Pennsylvania, United States*

Higher levels of frailty, quantified by a frailty index (FI), may be linked to fatigue severity as tasks become more physically and mentally demanding. However, the association between frailty and fatigability—quantification of vulnerability to fatigue in relation to specific intensity and duration of activities—has not been assessed. Using cross-sectional data from the Long Life Family Study Visit 2 (2014–2017; n=2,524; mean age +/- standard deviation 71.4+/-11.2 years; 55% women; 99% White), we examined the association between a 79-item FI (ratio of number of health problems reported (numerator) out of the 79 (denominator); higher percentage=greater frailty) and perceived physical and mental fatigability using the Pittsburgh Fatigability Scale (PFS) (range 0–50; higher scores=greater fatigability). Mean+/-SD FI scores were 0.08+/-0.06 and mean+/-SD PFS Physical and Mental scores were 13.7+/-9.6 (39.5% more severe, >=15) and 7.9+/-8.9 (22.8% more severe, >=13), respectively. Both PFS subscale scores were higher for each 0.10 increment in FI. Mean PFS scores were 10.7 and 34.2 (Physical) and 5.7 and 28.8 (Mental) for FI scores of < 0.10 (non-frail) and ≥0.30 (moderate-severely frail), respectively. In mixed effects models, a 0.03 higher FI score (accepted clinically meaningful increase in FI) was associated with 1.9-point higher PFS Physical (95% confidence interval (CI) 1.7–2.1) and 1.7-point higher PFS Mental (95% CI 1.5–1.9) scores after accounting for family structure and adjusting for age, sex, field center, body mass index, smoking status, education, and marital status. Individuals with higher FI scores may benefit from targeted interventions to mitigate further poor health outcomes.

DOES MOTIVATION PROMOTE PHYSICAL ACTIVITY IN OLDER ADULTS WITH CHRONIC MUSCULOSKELETAL PAIN?

Kailyn Witonsky, Xiaonan Zhu, Andrea Rosso, and
Caterina Rosano, *University of Pittsburgh, Pittsburgh, Pennsylvania, United States*

Chronic musculoskeletal pain is common and limits physical activity in older adults. Understanding why some older adults remain physically active despite chronic musculoskeletal pain, “pain resiliency”, may offer insights to promote physical activity. We investigated the cross-sectional association of three indicators of motivation or mood with physical activity in adults over the age of 65 with chronic musculoskeletal pain from the Cardiovascular Health and Cognition Study. Of 2,703 participants with brain scans, 919 (34%) reported at least one month of either foot, knee, hip, or back pain and 47% of those with pain had moderate to high levels of self-reported physical activity, defined as “pain resilient”. Indicators of motivation included: (1) self-reported motivation: a composite score of perceived effort, difficulty getting going in the morning, and difficulty concentrating, (2) social network score from the Lubben Social Network scale, and (3) a composite depression scale. Separate multivariable linear models estimated the association between physical activity and each indicator, controlling for gender, race, BMI, age, gait speed, number of medications, number of pain sites, cognitive function, as measured by the digit substitution symbol test, and brain integrity, as measured by level of white matter hyperintensities. Higher self-reported motivation (β=-0.11, p=0.02) and larger social networks (β=0.03, p=0.01) were associated with higher levels of physical activity. Better mood was not associated with higher levels of physical activity (β=-0.017, p=0.34). Albeit based on cross-sectional self-reported measures, our research suggests the need for further research investigating psychosocial contributions to pain resilience.

CT-DERIVED PARAVERTEBRAL MUSCLE RADIOMIC FEATURES ARE ASSOCIATED WITH MORTALITY IN THE MROS STUDY

Leon Lenchik,[1] Katey Webber,[2] Eric Orwoll,[3] Jane A Cauley,[4] Peggy Cawthon,[5] and Kristine Ensrud[6], *1. Wake Forest School of Medicine, Winston Salem, North Carolina, United States, 2. UCSF, San Francisco, California, United States, 3. OHSU, Portland, Oregon, United States, 4. School of Public Health, University of Pittsburgh, Pittsburgh, Pennsylvania, United States, 5. University of California, San Francisco, San Francisco, California, United States, 6. University of Minnesota Medical School and Minneapolis VA Health Care System, Minneapolis, Minnesota, United States*

The purpose was to determine if CT-derived radiomic features (biomarkers of muscle heterogeneity) are associated with all-cause mortality (independent of muscle size and density) in 2644 men (mean age 74.0) in the MrOS Study. Our fully-automated machine learning algorithm determined paraspinous muscle area and density. We also identified 75 radiomic features of muscle texture at the level of T12 vertebra. We used factor analysis to reduce the number of radiomic features into latent variables that explain the underlying data. Association of these factors, muscle cross-sectional area, and muscle density with all-cause mortality was determined using Cox proportional hazards models adjusted for CT-derived muscle area and density CT parameters (scanner model, slice thickness, tube current), participant age, height, total body fat, grip strength, walking speed, leg power, diabetes status, physical activity, self-reported health, and number of medications. Multiple comparisons were accounted for using false discovery rate testing. After a mean 13.3 ± 5.9 years of follow-up, 1945 (73.6%) men died. Muscle area and density and all 6 radiomic factors identified were significantly different in survivors compared with deceased. In fully adjusted models, 54 of 75 (72%) individual radiomic features were significantly associated with mortality. In fully adjusted models, low muscle density (HR/SD increment = 0.85; CI = 0.75,0.99), radiomic Factor 1 (HR/SD increment = 0.76; CI = 0.62,0.95), radiomic Factor 2 (HR/SD increment = 1.47, CI =1.23, 1.76) but not muscle area (HR/SD increment: 1.18, CI = 0.94, 1.48) or the other radiomic factors identified, were independently associated with mortality.

COMPUTING, DENTISTRY AND AGING: ORAL HEALTH, BIOLOGICAL AGE AND MORTALITY

Xin Zhong, *A*STAR Singapore, Singapore, Singapore*

Oral health is essential to general well-being across the lifespan. Recent study on number of natural teeth, denture use and mortality in non-Singaporean elderly indicated the importance of oral determinants. To the best of our knowledge, no study has envisioned the association between biological age and oral health among community-dwelling older Singaporeans. By leveraging the acquired knowledge from Singapore Longitudinal Ageing Study (SLAS), our aim is to examine the association between biological age, oral health, and mortality. Our hypothesis is that older adults with or without dental problems will have a significant difference in mortality and other health outcomes. Our methodology is to combine a more realistic AI approach and a hypothesis-driven multidisciplinary approach to examine the association between oral health and general health outcomes (mortality, hospitalization, etc). Cross-sectional data analyses were performed on 2844 community-living Chinese older adults of 65–80 years old in the Singapore Longitudinal Aging Study II (SLASII) cohort. The Keplan-Meier survival analysis showed statistically significant differences in survival time between the group with dental problems and the group without dental problems ($p < 0.001$) in an 8-year longitudinal study. Results also showed a significant difference between biologically younger, biologically older, and the intermediate group groups ($p = 0.0012$). Those groups were classified by the computed biological age. Our preliminary results will produce a plethora of new links between oral health, biological age, and mortality. The research outcome may serve as a baseline for policymakers to evaluate and promote subsidized oral health programs.

A COMPARATIVE STUDY OF FALL RISK ASSESSMENT IN COMMUNITY DWELLING OLDER ADULTS IN INDIA

Snehal Kulkarni, *Savitribai Phule Pune University, Pune, Maharashtra, India*

Falls in older adults can be prevented with early identification. Recent research investigates the use of wearable sensors to provide quantitative data on mobility parameters to assess risk of fall. However, the efficiency of these new methods in comparison to conventional fall risk assessment tools is unknown. Therefore, the current study compares the sensor-based fall risk assessment with conventional fall risk measures. The study included 659 community-dwelling older adults (>60 years) who were followed for 12 months after baseline. The American Geriatric Society Fall Risk Assessment tool was used to assess risk of fall conventionally and Kinesis QTUG was used to assess the fall risk using sensors. Receiver operating characteristics curve (ROC) was used to compare the sensor-based method and the conventional method of assessing fall risk. Out of the 659 community-dwelling older adults, 24% (163) of older adults reported a fall in 12 months. According to the sensor-based assessment, 23% of older adults had low risk, 50% had medium risk and 27% had high risk of fall and according to the conventional method 66.1% were in low risk, 27.1% were in medium risk and 6.8% were in high risk. The ROC analysis showed that the sensor-based methods (AUC-78%; sensitivity- 93.8% specificity – 56.3%) outperformed the conventional method (AUC – 61.2%; sensitivity – 82.8% and specificity - 67.2%) of identifying older adults at risk of fall. Therefore, use of simple wearable sensors can determine the risk of future falls.

THE MEANING OF EXPERIENCING FEAR OF FALLING AMONG OLDER ADULTS

Hanne Dolan,[1] and Natalie Pool[2], *1. Arizona State University, Phoenix, Arizona, United States, 2. University of Northern Colorado, Greeley, Colorado, United States*

Fear of falling (FOF) is prevalent among older adults. While the concept has been conceptually defined and factors associated with FOF has been extensively explored in nursing and other health sciences, the experience of this fear is often overlooked. The purpose of this study was to illuminate the phenomena of FOF using the rich descriptions elicited from four (Nf4) older adults. The meaning of these experiences was then interpreted in conjunction with the known and emergent FOF body of literature. Each participant was interviewed twice using videoconferencing as part of a larger study exploring the lived experience of being at risk for falling in the hospital. A total of eight interview transcripts were analyzed using van Manen's interpretive phenomenological methodology. The philosophical underpinning of this study is the philosophy of caring in nursing outlined by Kari Martinsen. Three major interpretive themes emerged: Loss of Self, Part of my Existence, and Remaining Safe Within the Boundaries of Fear. These themes describe how FOF is the fear of being suspended in time and space and losing connection with oneself both physically and mentally during a fall. The fear becomes a part of one's existence, ranging from worry to all-consuming panic, and the body becomes unpredictable. FOF means living within invisible boundaries of fear, where feelings of helplessness, uselessness, and isolation are common. Relationships with others can both temper and ignite the FOF, and caregivers must understand the meaning of this experience to improve support of older adults in managing this overwhelming experience.

PHYSICAL ACTIVITY AND SEDENTARY TIME ASSOCIATIONS WITH NON-FRACTURE FALL INJURY (NFFI) AND FRACTURE

Lily Bessette,[1] Andrea LaCroix,[2] Benjamin Schumacher,[1] Michael LaMonte,[3] John Schousboe,[4] Kristine Ensrud,[5] Jane A Cauley,[6] and Elsa Strotmeyer[6], *1. University of Pittsburgh, Pittsburgh, Pennsylvania, United States, 2. University of California, San Diego, La Jolla, California, United States, 3. University at Buffalo - SUNY, BUFFALO, New York, United States, 4. HealthPartners, Inc, Park Nicollet Clinic, Minnesota, United States, 5. University of Minnesota Medical School and Minneapolis VA Health Care System, Minneapolis, Minnesota, United States, 6. School of Public Health, University of Pittsburgh, Pittsburgh, Pennsylvania, United States*

Understanding fall injury risk factors and circumstances may lead to better prevention. However, many fall injury studies focus on fractures from hospitalizations or emergency events, rather than non-fracture fall injuries (NFFI), which comprise >50% of fall injuries in older adults. We hypothesized that risk factors were differently associated with NFFI vs. fracture fall injuries in a community-based cohort of ambulatory women with fall injuries in the Objective Physical Activity and Cardiovascular Disease Health in Older Women (OPACH) ancillary of the Women's Health Initiative Long Life Study. Women with daily fall calendars over 1-year follow-up completed telephone interviews regarding fall injury circumstances (Nf662; mean 79.6 + 6.7 years; 73.3% White). Risk factors and fall circumstances were assessed with first reported fall injury (NFFI vs. fracture) using univariate and multivariate logistic regression. Participants with NFFI vs. fracture were more likely to be non-white, less likely to seek clinical treatment or need help up from fall (all $p < 0.05$). Adjusting for age, race, and BMI, NFFI vs. fracture were more likely to report >=6 hours sitting (OR=1.72, 95% CI=1.07–2.73) and less likely to report weekly moderate exercise (OR=0.61, 95% CI=0.38–0.96), though total accelerometer-measured sedentary time and physical activity (PA) were not significant. Self-reported PA level at the time of fall (OR=1.31, 95% CI=0.82–2.09) and walking outside for >10 minutes >= 1/week (OR=1.24, 95% CI=0.77–1.98) were not different for NFFI vs. fractures. Older women with NFFI vs. fracture had more sedentary time and less moderate exercise, which may have implications for fall injury severity.

OLDER PRIMARY CARE PATIENTS' ENGAGEMENT WITH STEADI FALL PREVENTION RECOMMENDATIONS

Hiroko Kiyoshi-Teo,[1] Bryanna De Lima,[1] Debbie Cohen,[1] Kerri Winters-Stone,[2] and Elizabeth Eckstrom[1], *1. Oregon Health & Science University, Portland, Oregon, United States, 2. Oregon Health & Science University, Porltand, Oregon, United States*

The Stopping Elderly Accidents, Deaths, and Injuries (STEADI) initiative is a CDC-disseminated strategy to provide fall prevention recommendations to high risk patients. However, whether older patients engage with fall prevention recommendations is less clear. The aims of this study were to: 1) describe STEADI fall prevention recommendations provided to eligible older patients; and 2) understand patients' attitudes, confidence and adherence to recommendations. Fall prevention recommendations were identified by chart review (age ≥65 years old; STEADI score ≥4 (high risk); free of severe cognitive impairment). For those who consented to the study, questionnaires measured recollection (Yes/No), feelings (Positive/Negative), overall confidence to reduce fall risks through the recommendations (0–10 scale; 10 = most confident), and adherence to the specific recommendations (Yes/No). Results showed that 30% (n = 458) of eligible older adults received fall prevention recommendations. Among study participants (n = 182; 69% female, age 80.2 ± 7.7 years, STEADI score 7.0 ± 2.6), 73% reported positive reactions to recommendations. Overall confidence to reduce gait/balance-related fall risks through recommendations was 7.52 (n = 137) with adherence to physical therapy at 70% and tai chi at 38%. Overall confidence to reduce blood pressure-related fall risks through recommendations was 7.45 (n = 55) with adherence to adjusting medications at 89% compared to 69% for compression socks. Participants reported varying levels of adherence despite positive reactions and moderate confidence to reduce their fall risks. Additional research is needed to identify barriers and facilitators to improve adherence.

FEASIBILITY OF FALLS PREVENTION PROGRAMS IMPLEMENTATION BASED ON ACADEMIC-COMMUNITY PARTNERSHIPS

Uma Kelekar,[1] Cathy Elrod,[1] Patricia Heyn,[2] and Rita Wong[3], *1. Marymount University, Arlington, Virginia, United States, 2. Center for Optimal Aging, Marymount University, Fairfax Station, Virginia, United States, 3. Marymount University, Arlington, Virginia, United States*

The Northern Virginia (NoVa) region is diverse in age, race, ethnicity, economic status, health status, culture, and language. Based on state data, it is estimated that 28.7%

of the 75,000 older adults in NoVa will experience at least one fall annually. Since 2014, the Administration for Community Living (ACL) has sponsored implementation of evidence-based fall prevention programs (EBFPPs). The aims of this study are to 1) describe the EBFPP participants and delivery sites and 2) report initial effectiveness. Marymount University (MU) received two cooperative agreement grants (2016, 2018) from the ACL to implement in NoVa three EBFPPs: 1) Stay Active and Independent for Life (SAIL), 2) A Matter of Balance (MOB), and 3) Otago Exercise Program (OEP). The Northern Virginia Falls Prevention Alliance was formed and a Regional Training Office was built. The data source is the ACL national falls database. From 2016–2022, over 5,000 older adults were reached, over 400 EBFPP leaders were trained, and programs were delivered at 60 sites. Data analysis indicates that falls decreased from 20% to 15%. Those participating in MOB showed the greatest decline in falls (from 34% to 14%). Fall injuries declined from 11% to 7% and ED visits decreased from 3% to 1%. Preliminary analysis indicates beneficial impact: this academic-community partnership has reached people at low risk of falling (SAIL), and had an impactful decline in falls for individuals at moderate to high risk (MOB). Future research will investigate program outcome differences based on other demographics and delivery models.

FACTORS ASSOCIATED WITH FRID USE IN OLDER BLACK AND WHITE MEN AND WOMEN: THE HEALTH ABC STUDY

Jimmie Roberts, obert M. Boudreau, Lingshu Xue, Jane A Cauley, and Elsa Strotmeyer, *School of Public Health, University of Pittsburgh, Pittsburgh, Pennsylvania, United States*

Medications that increase falls, fall-risk increasing drugs (FRIDs), are common in older adults. Two FRID definitions, the CDC Steadi-Rx and Swedish National Board of Health and Welfare, are widely accepted. We hypothesized that FRID use risk factors vary by definition in 1,352 community-dwelling older adults in the Health, Aging, and Body Composition Study (Health ABC; 2007–2008 clinic visit; 83.4±2.8 years; 54.1% women; 34.9% Black). FRID use by either definition was associated with chronic health conditions, medical care including non-FRID use, higher BMI and depression scores, and less walking exercise (all $p < 0.05$). Steadi-Rx FRID use was also associated with more falls, ADL difficulty, and better cognitive scores. Using stepwise multivariate Poisson regression adjusting for demographics, lifestyle/behavior factors, and comorbidity, a 1-unit increase in BMI and depression score was associated with an approximately 2% mean FRID count increase for both definitions and 7% mean FRID count increase per 1-unit increase in non-FRID count. Both definitions had a 40% and 15% lower mean FRID count, respectively, with hypertension and cardiovascular disease (CVD) history. Better cognitive scores were associated with 1% mean increase in Steadi-Rx FRID count and a mean decrease of 13% and 33% FRID count, respectively, with cancer history and having primary healthcare. In identically adjusted logistic regression, FRID use (yes/no) was associated in a consistent direction with BMI, depression score, non-FRID count, hypertension, CVD, having primary healthcare, and also less likely with low-vs-high income (OR=0.18[0.06–0.50]). Risk factors differ by FRID definition, with Steadi-Rx identifying more predictors than the Swedish definition.

BURDEN OF FALL-RISK INCREASING DRUGS IN OLDER ADULTS PRESENTING WITH FALLS TO THE EMERGENCY ROOM

Martin Casey,[1] Joshua Niznik,[1] Greta Anton,[2] Michelle Meyer,[1] Casey Kelley,[3] Jan Busby-Whitehead,[1] Kathleen Davenport,[4] and Ellen Roberts[1], *1. University of North Carolina at Chapel Hill, Chapel Hill, North Carolina, United States, 2. University of North Carolina Medical Center, Chapel Hill, North Carolina, United States, 3. Unicersity of North Carolina at Chapel Hill, Chapel Hill, North Carolina, United States, 4. Univerisity of North Carolina at Chapel Hill, Chapel Hill, North Carolina, United States*

Prescribing of fall-risk increasing drugs (FRIDs) may be an important driver of falls in older adults. Understanding the types and frequencies of FRIDs prescribed to older adults presenting with falls to an emergency department (ED) may help identify opportunities for deprescribing. We performed a cross sectional analysis of data collected from a pharmacist-led fall-prevention program focused on older adults presenting with a fall to an academic ED in the southeastern United States between August 2020 – December 2021. ED pharmacists identified older adults (≥65 years old) presenting with a chief complaint of 'fall' and then performed a medication reconciliations to verify and obtain data on outpatient prescription drug use. FRIDs were identified in accord with the 2019 American Geriatrics Society Beers Criteria and the Centers for Disease Control and Prevention Stopping Elderly Accidents, Deaths, & Injuries (STEADI-Rx) list. The ED pharmacists performed medication reconciliations on 424 unique older adults presenting with a fall. The cohort had a mean age of 81.3 years and were mostly female (63.3%) and white (84.9%). Prescription use of FRIDs were identified in 45.8% (194/424) of older adults presenting with a fall. An estimated 25.5% (108/424) of the subjects were prescribed 2 or more FRIDs. The most common FRIDs identified were antidepressants (25.9%), anticonvulsants (18.6%), opioids (12.7%), benzodiazepines (8.5%), and antipyschotics (3.1%). . Prescription use of FRIDs, including use of 2 or more FRIDs, was common in older adults presenting with a fall to the ED.

THE IMPACT OF TECHNOLOGY USE ON CUSTODIAL GRANDPARENTS' DEPRESSION

Sarah Pace, Yanfeng Xu, and Theresa Harrison, *University of South Carolina, Columbia, South Carolina, United States*

During COVID-19, custodial grandparents experienced symptoms of depression due to social isolation, and technology use may reduce depression. This study examines the association between level of comfort of using technology and depression among custodial grandparents. Cross-sectional survey data (N = 287) were collected via multiple sources, including state agencies, local non-profit organizations serving kinship families, foster parent associations, schools, and Qualtrics Panels between March 2021 and March 2022. The average age of grandparents was 55 years. Over half were female (71.43%), had some college education (68.75%), and were White (55.12%). Depression was measured using the CES-D 10 scale. This variable was dummy coded using 8 as the cutoff score (Andresen et al., 1994). The level of comfort using technology was measured by combining four survey questions. Grandparent age, race, gender, marital status, home ownership, geographic area, disability, employment, education, physical health, telehealth, and telemental health were controlled. The logistic regression model revealed that those who had a higher comfort level with technology had significantly lower odds of having depression (OR = .543, p = < .001). Those with physical health had significantly lower odds of having depression (OR = .727, p = .044). Grandparents who needed telehealth (OR = 2.81, p =.005) and telemental health services (OR = 2.93, p =.003) had significantly higher odds of having depression. This research implies that custodial grandparents' use of technology, particularly their comfort levels with technology may reduce depression among grandparents. This will inform practice and policy for those who work with custodial grandparents.

THE RECIPROCAL RELATIONSHIP OF SELF-RATED HEALTH AND INSTRUMENTAL HELP FROM CHILDREN: EVIDENCE FROM GERMANY

Lisa Jessee, *University of Cologne, Cologne, Nordrhein-Westfalen, Germany*

Prior research suggests that receiving support from children may promote health among ageing parents. Poor health, however, often precedes the need for support. Yet, research linking instrumental support and self-rated health (SRH) has been deficient in two regards: First, little research has addressed the relationship between instrumental support and SRH simultaneously using longitudinal data. Second, only few studies, have accounted for unobserved confounders (e.g. within-person effects) and potential reverse causality. Recently developed dynamic panel models with fixed effects provide an opportunity to address these methodological issues. Using four waves of the German Ageing Survey (DEAS) among 4,496 adults aged 40 years and older, the current study investigates the potential bidirectional relationship between instrumental support and SRH. I find that prior receipt of instrumental support from children is not a significant predictor of future reported poor SRH. Similarly, previous poor SRH does not significantly predict the likelihood of receiving instrumental support from children at follow-up. Independent of older adults' SRH, however, prior receipt of instrumental support is a statistically significant predictor of receiving support at follow-up. Regardless of receiving children's instrumental support, poor SRH in the past predicts poor SRH in the future. The results shed new light on prior bidirectional associations between SRH and instrumental support in the German context. Previous results may be partly explained by a lack of controls for unobserved individual characteristics. The findings suggest that policy interventions may not exclusively rely on older adults' receipt of support from children in the event of health declines.

INTERGENERATIONAL RELATIONSHIPS OF RUSSIAN SPEAKERS IN ISRAEL IN THE SHADOW OF PROPAGANDA: FACEBOOK POSTS ANALYSIS

Ksenya Shulyaev, and Tova Band-Winterstein, *University of Haifa, Haifa, Hefa, Israel*

Part of the elderly Russian-speaking community in Israel is exposed to the TV channels of the Russian government. These channels are impacted by Russian propaganda and, as such, use false claims and manipulative techniques. The aim of this presentation is to shed light on the impact of Russian media on intergenerational relationships of Russian-speaker families in Israel. We conducted a preliminary qualitative study based on a thematic analysis of Facebook posts (Nf34) from March to June 2022. Analysis revealed four key themes: (1) "Tragedy of many families", the importance of unity of opinion and the problem of difference, a key element in the emotional well-being (or its lack) of Russian-speaking families at the moment; (2) "It's useless to explain something", the perception of older parents who support Putin as victims of "brainwashing", with comments on "zombies", totalitarian sects, and psychotropic drugs; (3) "The truth will destroy them", the perception of disbelief in war as a defensive reaction necessary for the elderly, because the reality may destroy them; (4) "A topic that is not talked about", a refusal to discuss Ukraine seen as the only way to save the relationship, speaking instead about health issues, daily life issues, and the weather. The findings underline that the Russian-Ukrainian war conflict impacts intergenerational solidarity and closeness, and calls for an intervention that provides support for both the elderly and their adult children.

GRANDPARENT-PARENT RELATIONSHIP, CAREGIVING MEANING AND FAMILY WELLBEING: AN APIM STUDY OF 200 DYADS

Xu Liao, *City University of Hong Kong, Hong Kong, Hong Kong*

While many older persons contribute to their families by providing care to their grandchildren (GC), the role transition could bring challenges to both grandparents (GP) and parents (P) especially for those who evenly share caregiving duties. Despite growing research on grandparenthood, a knowledge gap remains in the study of GP-P partnership; it is essential to examine GP and P as a unit and learn how the dyadic relationship influences their family. The purpose of this study is to gain a further understanding of GP-P relationship, meaning of caregiving, and family well-being (FWB). Data from 200 GP-P dyads in China were collected by a questionnaire survey. The study participants were chosen from families with one GC aged 0–8 who is cared for by GP and P together, and identified by the GC's teachers. The actor-partner interdependence model (APIM) was adopted in data analysis. Results showed that for co-(grand)parenting relationship and FWB, the actor effect was statistically significant for both GP and P; so was the partner effect from P to GP. Likewise, for meaning of caregiving and FWB, the actor effect was statistically significant for both GP and P; so was the partner effect from GP to P. The results advance knowledge about GP-P partnership and how feelings and actions could impact the overall family well-being. The findings can also guide the development of practices and services that enhance the function of GP-P collaboration and their family well-being.

FRAGMENTED FAMILIES OF OLDER FORCED UKRAINIAN MIGRANTS: PRELIMINARY DATA FROM A HELP CENTER IN NORTHERN ISRAEL

Ksenya Shulyaev,[1] Yulia Macarenko,[2] and Tova Band-Winterstein[1], *1. University of Haifa, Haifa, Hefa,* *Israel, 2. Volunteer Help Center for Refugees from Ukraine, Haifa, Hefa, Israel*

Since the beginning of the Russia-Ukrainian war, more than 50,000 people have come to Israel from Ukraine as “repatriates” (able to acquire citizenship) or “tourists” (with a right to live in Israel during the war, without citizenship), about 30% are older adults, for whom forced migration poses serious challenges. The aim of this presentation is to describe the socio-demographic characteristics of older migrants’ fragmented families, who turn to one of the Volunteer Help Center in Northern Israel. Descriptive statistics on older adults from the database of about 900 families who received support during April-June 2022 were performed. Data revealed: 189 migrants aged 55+ (M(SD)=69.7(8.2); range 55–89); 148 (78.3%) were female; 106 (56%) had Israeli citizenship or were in the process of receiving it; 75 (40 %) were “tourists”. Among “tourists”, about half (Nf30) came to visit their adult children. “Repatriates” and “tourists” did not differ in age (F(159)=1.574, p=ns). As a rule, older adults came with family members (Nf136(72.7%)). However among “tourists” 41.9% came alone and only 17.1% among “repatriates” (X=13.374, p < 0.001). Older adults were mostly accompanied by daughters (Nf80(58.8%)), usually without husbands, in 127 fragmented families (78.2%) were children under 18. Only 15% came with a spouse (half of the men, 5.5% of women), and five came with mothers. This preliminary data draws attention to the unique family fragmented structure of older displaced people, as this should be considered when developing an assistance program.

ACCEPTABILITY DATA OF A TECHNOLOGY-ENABLED CARE COACHING SERVICE FOR CAREGIVERS OF INDIVIDUALS WITH DEMENTIA

Katherine Judge,[1] Amelia Thomley,[2] Lauren Stratton,[3] Emily Silver,[2] Kerry Finegan,[3] Monica Moreno,[3] Sam Fazio,[3] and Joe Chung[2], *1. Cleveland State University, Cleveland, Ohio, United States, 2. Kinto, Cambridge, Massachusetts, United States, 3. Alzheimer’s Association, Chicago, Illinois, United States*

This poster presents acceptability data from the Kinto Care Coaching Intervention, an innovative technology-enabled care coaching service for caregivers of individuals with dementia. The 30-day program provides caregiver support and financial information through: 1) an initial one-on-one care coaching meeting; 2) interactive and on-going support and educational resources through an app; 3) access to support groups; and 4) if needed, additional meetings with their care coach. The solution is funded through the NIH’s Small Business Innovation and Research (SBIR) program, with the specific goals of developing mobile technology that is: 1) acceptable and usable for caregivers of all ages and 2) supports cost-effective deployment of the coaching intervention at scale. To assess program acceptability, participants completed a survey after their one-on-one care coaching meeting and after the 30-day program. On average, participants (n=32) were M=51.94 (SD=12.07) years old; 68.8% female; 71.9% White; 75% married; and 56.3% worked full-time. Using a 5-point Likert scale, nearly all participants (96.6%) indicated they ‘agreed’ or ‘strongly agreed’ that their care coach was: helpful in explaining the program; provided useful information; assisted with developing goals; and were supportive. Participants rated the program resources and technology as very helpful with mean ratings ranging from 4.41 to 4.69. When asked about the overall program acceptability, participants indicated they were extremely satisfied with the program (M=4.81; SD=.40), with 100% of participants ‘agreed’ or ‘strongly agreed’ that they were satisfied. Discussion will highlight key program components along with next steps in testing program efficacy.

A LATENT CLASS ANALYSIS OF STRESSORS AND RESOURCES AMONG SPOUSAL CAREGIVERS TO OLDER ADULTS IN THE UNITED STATES

Ruotong Liu,[1] Iris Chi,[2] and Shinyi Wu[2], *1. Oregon Health & Science University, Marina del Rey, California, United States, 2. University of Southern California, Los Angeles, California, United States*

Spousal caregivers to older adults experience differing intensities of co-occurring caregiving stressors and resources. Analyzing their heterogeneous profiles can improve recognition of spousal caregivers needing support and caregiving impact on their health. This study aims to identify latent classes among spousal caregivers to older adults and to explore the associated background characteristics and health outcomes. Using pooled data from Round 5 and Round 7 of National Study of Caregiving and the linked National Health and Aging Trends Study, eight indicators for stressors and three indicators for resources are included for latent class analysis to identify distinguishable spousal caregiver subgroups. ANOVA test or Chi-square test are used to understand the different characteristics across spousal caregiver classes. Multivariate regression is conducted to examine associations between class membership and health outcomes. Three latent classes are identified among the 793 included spousal caregivers: low-stress low-support class (39%), medium-stress high-support class (36%), and high-stress medium-support class (25%). Compared to the other two classes, high-stress medium-support class includes more female than male, medium-stress high-support class has greater portions of non-Hispanic Black individuals, and caregivers in low-stress low-support class have fewer comorbidities. In addition, compared to low-stress low-support class, spousal caregivers in high-stress medium-support class reported lower (0.42 unit) level of self-rated health and higher (1.87 unit) level of depressive symptoms. These results confirmed the heterogeneity among spousal caregivers, and highlighted the elevated needs to address the physical and mental health needs among spousal caregivers whose levels of resources could not offset the caregiving stress they experience.

THE RELATIONSHIP BETWEEN ATTACHMENT, RELATIONSHIP QUALITY, AND DAILY STRESS AMONG DEMENTIA CAREGIVERS

Paulina Wuestefeld, Paige Goodwin, and Robert Intrieri, *Western Illinois University, Macomb, Illinois, United States*

The current study assesses the relationship between attachment style, relationship quality, and daily stress among family caregivers of persons with dementia. The study incorporates a longitudinal burst design. In an initial meeting with the investigator, participants completed measures of attachment style (Experiences in Close Relationships Questionnaire Revised), past and current relationship quality (RQ), emotion regulation (Emotion Regulation Questionnaire), and caregiver burden (Zarit Burden Interview). For the next 14 days, participants were sent a link to a brief survey that included the Positive Affect and Negative Affect Schedule and the Perceived Stress Scale. They were also asked to estimate what proportion of their daily stress did they attribute to caregiving. There are significant positive correlations between caregiver burden and current negative RQ, r = 0.70, p = .008, as well as between attachment anxiety and current negative RQ, r = 0.60, p = .029. According to regression analyses, attachment anxiety predicts negative current RQ, R2 = .37, F(1, 11) = 6.32, p = .029. Current negative RQ predicts caregiver burden, R2 = .49, F(1, 11) = 10.55, p = .008. Additional analyses will explore the link between attachment style, emotion regulation, burden, relationship quality, and longitudinal assessments of daily stress and affect. Though preliminary, study results suggest that beyond caregiver burden, daily stress and well-being of caregivers is impacted by the relationship between attachment, relationship quality, and emotion regulation.

STUDENT CARE PARTNERING AMONG STUDENTS AT A HBCU: EXPLORING THE POTENTIAL IMPACT ON STUDENT PERSISTENCE

Claudia Thorne, *Coppin State University, Baltimore, Maryland, United States*

The number of students enrolled in higher education who are taking care of older adults, many of whom may be suffering from an illness, is expanding. The numerous factors in care partnering can compromise student success and persistence towards graduation. While most care partners experience challenges, the care partnering experience of Black students is magnified because Historically Black Colleges and Universities (HBCUs) have a higher enrollment of nontraditional and first-generation college students. Students may be primary care partners who provide most of the care, or they may provide supportive care as secondary, tertiary, and auxiliary care partners within an extended family or kinship network. Aging in place, within the context of family and community, emerges from African culture and tradition deeply grounded in filial loyalty. Care partnering is nuanced in the interaction of race, ethnicity, gender, family relationships, and student status; however, little is known about the lived experience of Black student care partners and how to support them to facilitate their persistence towards graduation. This poster describes initial efforts to understand Black student experiences in care partnering in the context of a Mid-Atlantic HBCU and suggests the next steps in a multi-year research program.

INCREASING MEDICATION SAFETY AWARENESS IN RURAL OLDER ADULTS

Kara Haughtigan,[1] Susan Jones,[2] Eve Main,[2]
Elizabeth Groves,[2] and Melinda Joyce[3], *1. School of Nursing and Allied Health, Western Kentucky University, Bowling Green, Kentucky, United States, 2. Western Kentucky University, Bowling Green, Kentucky, United States, 3. WKHL/Med Center Health Research Foundation, Bowling Green, Kentucky, United States*

Compared to urban populations, rural residents have a higher incidence of chronic diseases and poorer health outcomes. Most medications in the United States are consumed by older adults who are more susceptible to adverse drug events due to the presence of multiple chronic conditions and physiologic changes in the body. This community-based project evaluated the impact of an interdisciplinary medication education intervention on medication knowledge and adherence to medications and refills. The study was a quasi-experimental pretest/posttest design with a convenience sample. The project was marketed via a multi-media approach. Most participants reported learning of the event at a senior center. Each participant received a private educational session for their specific medications with a nurse practitioner, pharmacist, or pharmacy resident. Forty-nine older adults participated in the study with 48 (97.9%) completing both the pretest and posttest. The average age of participants was 71.4 years and the average number of medications per participant was 5.4. There was a statistically significant difference in the adherence to medication and refills subscale score (p = .003). There was no statistically significant difference in the medication knowledge subscale (p = .192), however, the scores did trend upward indicating an increase in medication knowledge. Forty-four (89.8%) participants reported they were more comfortable understanding their medication since participating in the program and 48 (98%) reported they would recommend the program to others. The results of this study suggest community-based outreach medication educational programs can increase adherence to medication and refills for older adults residing in rural areas.

RELATIONSHIPS AMONG ATTITUDES TOWARD DEMENTIA, QUALITY OF LIFE, AND MIDLIFE WOMEN'S SYMPTOMS IN FAMILY CAREGIVERS

Heejung Kim,[1] Seo Yun Kim,[2] Roger Yau,[2]
Glenna Brewster,[2] Wonshik Chee,[2] and Eun Ok Im[2], *1. Yonsei University, Seoul, Kyonggi-do, Republic of Korea, 2. Emory University, Atlanta, Georgia, United States*

Attitudes towards dementia and caregiving differ by family caregivers' racial/ethnic backgrounds. However, there is a gap in the literature on midlife women family caregivers' attitudes toward Alzheimer's Disease (AD) and family caregiving. The study purposes were to (1) explore racial/ethnic variations in midlife women family caregivers' attitudes toward AD and family caregiving and (2) examine the relationships among their attitudes towards dementia and caregiving, quality of life, and physical and psychological symptoms. This cross-sectional study was conducted through an online survey among 36 Whites, 41 African Americans, 40 Hispanics, and 55 Asians. The structured measures consisted of two types of attitudes (Attitude toward AD and Related Dementias Scale and Questions on Attitudes toward AD Caregiving), health-related quality of life (EQ-5D-5L), and multidimensional symptoms (Midlife Women's Symptom Index). The data were analyzed using one-way ANOVA and multiple linear regression analyses with SPSS 26. Asian caregivers perceived the care recipients' symptoms as more bothersome than White caregivers (p = .039). Asian caregivers reported lower levels of behavioral skills and shared responsibility compared with other racial/ethnic groups of caregivers (p < .01). African Americans showed more positive attitudes toward family caregiving compared with Hispanics and Asians (p = .001). The regression analyses indicated that more positive attitudes toward family caregiving were significantly related to a better quality of life and fewer symptoms (both physical and psychological symptoms; p < .05). Culturally tailored interventions that incorporate caregivers' attitudes are needed to improve midlife women family caregivers' quality of life and symptoms.

PRELIMINARY FINDINGS OF A STUDY ON LONGITUDINAL CHANGES IN EXPRESSED EMOTION IN FAMILY CAREGIVERS WITH DEMENTIA

Xiaoji Liu,[1] Reiko Kanaya,[1] Kazue Shigenobu,[1] Keigo Takiue,[2] and Miyae Yamakawa[1], *1. Osaka University, suita, Osaka, Japan, 2. Gifu University, Gifu, Gifu, Japan*

Purpose: The aim of this study was to explore and describe changes in expressed emotion (EE) among family caregivers of dementia and its associated factors at different time points over 3 months. Method: A longitudinal observation study using a 3-month survey was conducted in home care settings, Japan. We collected data on the demographic details of family caregivers currently providing care, which included care burden (Zarit Burden Inventory, ZBI), closeness of the caregiving relationship (Relationship Closeness Scale, RCS), depression (Geriatric Depression Scale, GDS). We used the validated Family Attitude Scale (FAS) to assess EE, in which higher scores indicate a greater intensity of emotional expression. Results: To date, 45 family caregivers completed the present study. FAS scores were 39.67 ± 24.90 at month 1 (T1), 38.64 ± 23.28 at month 2 (T2), and 39.69 ± 24.52 at month 3 (T3). The change in FAS scores did not show a statistical difference over the three-month period (p=0.816). Multiple regression analysis of FAS at T1 showed that the main influencing factors were gender, marriage, RCS, care burden, and depression ($R2=0.763$, $p < 0.001$); the main influencing factors at T2 were marriage and care burden ($R2=0.584$, $p < 0.001$); the main influencing factors at T3 were care burden and depression ($R2=0.674$, $p < 0.001$). Conclusions: Early identification of risk factors may help in the development of interventions to prevent high levels of EE in family caregivers. We plan to continue refining our analyses to test the validity of our hypothesis.

PREDICTING CARE-RECIPIENTS' WELLBEING BASED ON SPOUSAL CAREGIVERS' CO-OCCURRING STRESSORS AND RESOURCES

Ruotong Liu,[1] Iris Chi,[2] and Shinyi Wu[2], *1. Oregon Health & Science University, Marina del Rey, California, United States, 2. University of Southern California, Los Angeles, California, United States*

Besides caregivers, care-recipients' health outcomes can be impacted by caregiving as well. The aim of the current study is to explore whether care-recipients' longitudinal health outcomes differ by caregivers' profiles characterized by the co-occurring and relative intensities of caregiving stressors and resources. Data from Round 5 and Round 7 of National Study of Caregiving and Round 5 to Round 8 of the linked National Health and Aging Trends Study are utilized. After multiple imputation, sample characteristics are described and compared among the 639 unique care-recipients by caregivers' latent classes. Generalized estimating equations (GEE) with first-order autoregressive covariance are estimated to examine the differences in care recipients' health outcomes at baseline and rates of change across groups. The average self-rated health at baseline is 2.73 (SD=1.02), and the average baseline depressive symptoms are 2.65 (SD=2.76). GEE results indicate that compared to care-recipients cared by low-stress low-support spousal caregivers, those cared by medium-stress high-support and high-stress medium-support partners score 0.20 and 0.35 unit lower in self-rated health at baseline, respectively, and those cared by high-stress medium-support caregivers on average score 1.21 unit higher in depressive symptoms at baseline. No statistical differences in rate of change are detected for both self-rated health and depressive symptoms across groups. Despite different levels of health at baseline, our research does not find care-recipients' rates of change in health different across groups over one-year. Future studies are needed to further explore the longer-term differences in rates of change and to better understand the caregiving dyads.

OLDER ADULT CAREGIVERS' THOUGHTS ON WOUND CARE RESOURCES

Kristen Swartzell,[1] Janet Fulton,[2] and Jane Von Gaudecker[2], *1. IU School of Medicine, Indianapolis, Indiana, United States, 2. Indiana University, Indianapolis, Indiana, United States*

As healthcare increasingly shifts to home and community-based settings, informal caregiver responsibilities are increasing beyond assistance with activities of daily living to include complex care procedures previously performed by licensed caregivers in clinical settings. With an aging population, increasing numbers of older adults are assuming a caregiving role and these older adult caregivers are performing complex care procedures such as wound care. The negative physical and mental health consequences of caregiving for older adult caregivers are well documented in the literature. However, access to and use of resources are associated with better physical and mental health. Past research on caregiving resources has utilized pre-determined resource variables. Little is known about older adult caregivers' salient thoughts on resources important to caregiving and performing complex care procedures. This study utilized thematic analysis of qualitative interview data to identify themes and patterns related to resources as described by older adult caregivers. The following seven themes related to resources needed or utilized were identified: 1) expert guidance from healthcare professionals; 2) written instructions; 3) relationships with healthcare professionals for obtaining wound care supplies; 4) additional durable medical equipment; 5) financial resources; 6) coverage for caregiver personal time; and 7) select persons for social and emotional support. Older adult caregivers need and use a variety of resources when providing wound care. As increasing numbers of older adults choose to 'age in place', the importance of adequate resources to sustain care recipients and their caregivers in the home setting is critical.

INSOMNIA SYMPTOM TRAJECTORIES OF SPOUSE CAREGIVERS OF OLDER ADULTS WITH FUNCTIONAL LIMITATIONS

Dexia Kong,[1] and Peiyi Lu[2], *1. The Chinese University of Hong Kong, Hong Kong, Hong Kong, 2. Columbia University, New York, New York, United States*

Background: Studies have suggested older spouse caregivers experience burden-related adverse health outcomes compared to non-caregivers. However, potential causal inferences remain unclear. This study examined the effect of caregiving on insomnia symptoms of spouse caregivers over time, compared to non-caregiver samples matched by propensity score (PS). Methods: Longitudinal data from the Health and Retirement Study from 2006 to 2018 were used. Caregivers (Nf403) were respondents (aged 50+) who assisted their heterosexual spouses in performing (instrumental) activities of daily living at baseline. PS-matching was used to match non-caregivers based on sociodemographic, household, and health-related characteristics. Symptoms of insomnia were evaluated every four years for both groups. The link between caregiver status and number/severity of insomnia symptoms over time was assessed using a Poisson mixed-effects model. Results: The propensity-matched sample achieved a satisfactory covariate balance. There was no statistically significant difference between caregivers and non-caregivers in the number of insomnia symptoms at baseline (β_caregiver=0.092, 95% CI = -0.017, 0.201). However, caregivers reported a slower increase in insomnia symptoms compared to non-caregivers (β_caregiver×time = -0.012, 95% CI = -0.021, -0.003). Results were cross-validated in modelling the severity of insomnia symptoms. Conclusion: There is weak evidence that a spouse's role as a caregiver may be beneficial for his/her sleep health over time. The negative effects of caring on older individuals' sleep may vary depending on the caregiving context. The potential health benefits of informal spousal caring and their underlying mechanisms warrant further investigations.

INFORMAL CAREGIVING BURNOUT AMONG THE SANDWICH GENERATION

Erika Fenstermacher, Montgomery Owsiany, and Barry Edelstein, *West Virginia University, Morgantown, West Virginia, United States*

Twenty-nine percent of U.S. adults care for children. Of those adults, 12% are multigenerational caregivers who also provide unpaid care for one or more adults. Many multigenerational caregivers are considered members of the "sandwich generation," which is a term for multigenerational caregivers who provide care, financial support, and emotional support for both their children and parents. Approximately 71% of this generation is between the ages of 40 and 59, and approximately 10% are 60 or older. The sandwich generation is largely understudied and presents challenges including informal caregiving burnout and depression. Informal caregiving burnout is a syndrome that results from the stress of providing care. Researchers have not yet investigated burnout in the sandwich generation. The present study examined how sandwich generation caregivers differed from caregivers of children and caregivers of parents regarding depression and burnout. Two measures of burnout were used (non-caregiving burnout = degree of physical and psychological fatigue and exhaustion; informal caregiving burnout = degree of physical and psychological fatigue and exhaustion related to caregiving). We found that sandwich generation caregivers and caregivers of parents scored significantly higher than caregivers of children on informal caregiving burnout. Caregiving burnout and non-caregiving burnout were significantly correlated with depression ($r = .496$, $p < .001$ and $r = .773$, $p < .001$, respectively). Burnout is higher in sandwich generation caregivers and those who care for parents than burnout among those who care only for children. This study is unique in its investigation of informal caregiving burnout among the sandwich generation.

IDENTIFYING FACTORS ASSOCIATED WITH CAREGIVER NEGLECT IN OLDER PERSONS WITH DEMENTIA

E-Shien Chang,[1] Sara Czaja,[1] Tony Rosen,[2] and Jerad Moxley[1], *1. Weill Cornell Medicine, New York, New York, United States, 2. Weill Cornell Medical College / NewYork-Presbyterian Hospital, Pelham, New York, United States*

Caregiver neglect is common among older persons with dementia and is associated with significant morbidity and mortality. Despite this, little empirical research exists examining factors that contribute or prevent neglect. Our goal was to identify caregiving factors that may be associated with caregiver neglect. Data were drawn from the baseline information of 240 caregivers enrolled in the Caring for the Caregiver Network study who provided care to a family member with dementia. Caregiver depression, burden, social support, perceived mutuality with care-recipients, positive aspects of caregiving, and self-perceived caregiving preparedness, were measured using validated scales. To maximize sensitivity in our measure of caregiver neglect, we operationalized caregiver neglect as consisting of: 1) caregivers' failure to meet care-recipients' needs, using 8-item instrumental activities of daily living (IADL) and 6-item ADL scales, and 2) caregivers not receiving additional formal services (e.g., visiting nurses; home care aides) to address care-recipients' unmet needs. Selection of independent variables into multivariate regression models examining predictors of neglect was based on significance in bivariate analysis ($p < .10$). Caregiver neglect was found in 29.2% of caregivers. The caregiver being male was significantly associated with greater risk of neglect. In the final adjusted model, only caregiver preparedness was found to be a significant risk factor for neglect ($\beta = -.16$ $SE=.10$, $p < .05$). This analysis provides the first evidence of the association between caregiver preparedness and risk of caregiver neglect. Future research should examine possible psycho-social mechanism linking preparedness and neglect to inform neglect prevention and intervention programming.

HEALTHY CAREGIVER SELECTION AMONG DEMENTIA CAREGIVERS: THE ROLE OF SOCIAL SUPPORT

Hantao Jiang,[1] and Xueqing Wang[2], *1. Columbia University, Princeton, New Jersey, United States, 2. Princeton University, Princeton, New Jersey, United States*

As of 2019, more than 4 million older adults aged 65+ in the United States are cognitively impaired, including the diagnoses of mild cognitive impairment (MCI) and dementia.

Caregivers to these older adults bear significant burden, reflected as high prevalence of chronic stress and mental health problems among the caregiver population. It is thus crucial to understand the wellbeing of the caregiver population to design effective policies. Previous studies have documented survival advantage of dementia caregivers compared to non-caregiving individuals as well as other types of caregivers, namely caregivers to persons with MCI or other types of chronic conditions. However, it remains less clear how the role of social support explains dementia caregiver's survival advantage. In this paper, we directly compare the level and type of social support between different types of caregivers, and examine to what extent the difference in social support explains the survival and health advantage of dementia caregivers compared to caregivers to persons with MCI, non-cognitive impairment chronic conditions and non-caregiving individuals. We use the 12 waves of the Health and Retirement Study and apply multivariate and survival analysis to calculate difference in age-specific hazard ratios. Our preliminary results show that dementia caregivers tend to secure stronger support from family members than caregivers to persons with MCI. Our results have potential to shed light on the empirical puzzle of healthy caregiver selection effect and have direct implications for designing effective intervention to improve health of the caregiver population.

HEALTHCARE LITERACY AMONG INFORMAL CAREGIVERS: THE ROLE OF SOCIAL SUPPORT SYSTEM AND BURNOUT

Robyn Medcalf,[1] Jessika Dayrit,[2] Shirley Salom-Bail,[1] Cesz Islaya,[1] Shelly Foutz-Lowe,[1] and Renuka Alladi[1], *1. Department of Veterans Affairs, Palo Alto Health Care System, Palo Alto, California, United States, 2. Washington University in St. Louis, St. Louis, Missouri, United States*

Informal caregivers are integral components in the lives of individuals with health problems. However, little is known if the number of hours of informal care correlates with healthcare literacy levels. Thus, using the Center for Disease Control (CDC) Behavioral Risk Factor Surveillance (BRFSS) 2016 public dataset, the aim of this study examines the association between informal caregivers' hours of care and their health literacy level, by controlling their social/emotional support, type of care they provide, and socioeconomic level. Data was weighted for complex sampling design and logistic regression to examine the data (Nf3,249). The study's results show that being full-time or part-time caregiver has no association to healthcare literacy in verbal (OR=0.99, 95% CI=0.57–1.71) and written (OR=1.21, 95% CI=0.78–1.85) comprehensions. Further, caregiver's type of care does not correlate to healthcare literacy level in verbal (OR=0.87, 95% CI=0.58–1.32; OR=0.93, 95% CI=0.59–1.45) and written (OR=0.91, 95% CI=0.66–1.27; OR=0.81, 95% CI=0.57–1.16) comprehensions. However, caregivers who rarely-to-never receive social/emotional support are four times more likely to have difficulties understanding verbal health information than those who have always-to-usually receive social/emotional support (OR=4.02, 95% CI=2.45–6.61). Caregivers who rarely-to-never receive social/emotional support are two times more likely to have difficulties understanding written health information compared to those that have always-to-usually receive social/emotional support (OR=2.30, 95% CI=1.51–3.51). Caregivers with lower socioeconomic backgrounds are at higher probability of low healthcare literacy level. Our study suggests further longitudinal and qualitative research, to understand healthcare literacy level among informal caregivers, and how social support systems correlates to healthcare literacy level.

FACTORS ASSOCIATED WITH VOLUNTEERING AMONG FAMILY CAREGIVERS OF OLDER ADULTS

Sol Baik,[1] Rachel Coleman,[2] and Jennifer Crittenden[2], *1. University of Virginia Weldon Cooper Center for Public Service, Charlottesville, Virginia, United States, 2. University of Maine, Bangor, Maine, United States*

Family caregiving has been linked to an increased risk of poor mental health, poor physical health, and higher rates of perceived social isolation among caregivers. Despite the connection between caregiving and negative outcomes, or perhaps because of this connection, caregivers seek out and enjoy other life roles and activities including formal volunteerism. To explore the connection between informal caregiving and volunteering and establish the representative prevalence of formal volunteering among caregivers, descriptive and multivariate logistic regression analyses were carried out with data from 1,745 caregivers in the National Study of Caregiving (NSOC) (2017). Utilizing social capital theory four models were constructed with salient demographic characteristics associated with volunteering (model 1), caregiving context (model 2), caregiver physical and mental health (model 3), along with participation in informal and formal social networks (model 4). About a quarter of the sample participated in volunteering (26%). The average age was 60.5 years (SD = 14.3) and more than half consisted of female caregivers (67.11%). Non-Hispanic Whites (62.9%) were the majority of the sample, followed by non-Hispanic Blacks (28%), Hispanic (6.5%), and caregivers in other racial/ethic groups (2.6%). Gender, educational achievement, caregiving for a spouse, coresiding with care recipient, caregiving for multiple care recipients, quality of relationship with care recipient, caregiver psychological well-being, having emotional/physical support, attending religious services, and group activity participation were all significant indicators for caregiver volunteerism. Findings support the importance of both human and social capital in volunteering among caregivers.

EXERGAME INTERVENTION TO PROMOTE FAMILY CAREGIVERS' SOCIAL SUPPORT, PHYSICAL ACTIVITY, AND WELL-BEING

Xin Yao Lin, and Margie Lachman, *Brandeis University, Waltham, Massachusetts, United States*

Family caregivers often experience high stress, social isolation, poor mental and physical health, and have a sedentary lifestyle. The current study was a randomized trial (Nf76) comparing the effectiveness of Go&Grow (social vs non-social exergame app) to promote well-being through increased social support and physical activity for family caregivers over a 6-week intervention. Both groups received daily reminders to use the app. Findings showed the treatment group increased significantly more than the control group in well-being (management of distress) and social support (satisfaction with contact quality). There was an indirect effect of change in social support in which the treatment group increased more than the control group in satisfaction with contact quality, which in turn led to more positive affect and less loneliness. The increase in steps ranged from 3% to 12% across conditions. Social support moderated the relationship between condition and step changes, such that those in the treatment group who increased more in overall social support and knowing others' experiences increased steps more than those with less support, while change in steps for the control group was not related to support level. In the treatment group, those who used the social features of the app more frequently had a greater increase in steps compared to those who used the social features less often. These findings can offer new insights into implementing behavior change mechanisms using exergames for sedentary and socially isolated family caregivers to improve their health with modifiable behavioral factors such as physical activity and social support.

CAREGIVING BURDENS OF TASK TIME AND TASK DIFFICULTY AMONG PAID AND UNPAID CAREGIVERS OF PERSONS LIVING WITH DEMENTIA

Matthew Smith,[1] Chung Lin Kew,[1] Gang Han,[1] Lucas Wilson,[1] Shinduk Lee,[2] John Fitch,[1] and Marcia Ory[1], *1. Texas A&M University, College Station, Texas, United States, 2. University of Utah, Salt Lake City, Utah, United States*

Demands of caregivers of persons living with dementia (PLWD) are often influenced by the context of their caregiving situation. This study examines factors associated with caregiving burden in terms of task time and task difficulty among paid and unpaid caregivers of PLWD. Cross-sectional baseline survey data were analyzed from 110 paid and unpaid caregivers of PLWD participating in a larger NIH-funded study assessing the feasibility of using a novel in-situ sensor system. Oberst Caregiving Burden Scale constructs of task time and task difficulty served as dependent variables. Two least squares regression models were fitted, controlling for contextual items related to the caregiver, care recipient, and caregiving logistics. Caregivers whose care recipients were female (B=-0.29, P=0.006), had more chronic conditions (B=0.31, P=0.011), and had lower Mini-Mental State Exam scores (B=-0.20, P=0.015) reported higher task time burdens. Caregivers whose care recipients had other paid caregivers (B=0.30, P=0.031) and spent more months/years caring for their care recipients (B=0.28, P=0.004) reported higher task time burdens. Caregivers' task time burden was positively associated with their emotional stress level (B=0.30, P=0.020). Caregivers' task difficulty burden was positively associated with their emotional stress (B=0.30, P=0.029) and depressive symptomatology (B=0.32, P=0.002). Results reinforce the relationship between caregiver burden and mental health. While the care recipient's disease profile and needs were drivers of task time burden, which may also require coordination with other paid caregivers, task difficulty was emotionally driven. Findings highlight the importance of caregiver support services and programming for mental health.

THE ROLE OF PAID CAREGIVERS IN HOME-BASED DEMENTIA CARE: FAMILY, PAID CAREGIVER, AND GERIATRICIAN PERSPECTIVES

Deborah Watman, and Jennifer Reckrey, *1. Icahn School of Medicine at Mount Sinai, New York City, New York, United States*

Paid caregivers (e.g., personal care aides, home health aides, other direct care workers) provide essential care that allows people with dementia to remain living at home, yet little is known about the lived experience of this care. This project uses multiple perspective, qualitative longitudinal interviews to explore paid caregiver role in home-based dementia care. We conducted one-on-one interviews via telephone or zoom with the family caregiver, paid caregiver, and geriatrician of an individual person with moderate or severe dementia (n=9) living at home in New York City. After an initial interview, up to 2 additional interviews (at 3 and 6 month intervals) were also conducted for a total of 75 interviews with 29 unique respondents. Interviews were audio-recorded, transcribed, and analyzed using the framework method of analysis. Interviews revealed nuanced care arrangements, but paid caregiver role in care remained largely stable over time. Key findings include: (1) Family caregivers played a primary role in determining overall paid caregiver role in care, (2) Paid caregivers describe the emotional components of caregiving (e.g. being "like family", having patience) more frequently than families or doctors, and (3) Doctors rarely engage with paid caregivers unless family involvement is limited. The unique structure of each triad emphasizes the importance of person-centered dementia home care. Formal care plans may not reflect the nuances of care arrangements and responsibilities. Rather than prescriptive standards for home care, improved communication and clear expectation setting may help meet the complex needs of people with dementia and their families.

THE POTENTIAL CLINICAL AND ECONOMIC IMPACTS OF OVER-THE-COUNTER HEARING AIDS IN THE UNITED STATES

Ethan Borre,[1] Mohini Johri,[1] Judy Dubno,[2] Juliessa Pavon,[3] Evan Myers,[1] Howard Francis,[1] Osondu Ogbuoji,[1] and Gillian Sanders Schmidler[1], *1. Duke University, Durham, North Carolina, United States, 2. Medical University of South Carolina, Charleston, South Carolina, United States, 3. Duke University School of Medicine, Durham, North Carolina, United States*

Food and Drug Administration regulations (released 8/16/22) for over-the-counter (OTC) hearing aids (HAs) allow the purchase of OTC HAs for adults with perceived mild-to-moderate hearing loss. Given this new development, the quality-of-life benefits and costs of OTC devices are now relevant but also unknown. We sought to project the population-level costs and effectiveness of US OTC HA provision. We used a microsimulation of hearing loss (DeciBHAL-US) to simulate: 1) traditional HA provision validated to published estimates of HA uptake (10-year delay), and 2) OTC HA provision for persons with perceived mild-to-moderate hearing loss at increased uptake rates (5-year delay) across quality-of-life and cost combinations. Simulated adults experienced probabilities of hearing loss (0.1–10%/year), subsequent age- and severity-dependent HA uptake (traditional HAs: 0.5–8%/year; OTC HAs: 1–16%/year) and discontinuation (4–13%/year). Utility benefit for traditional HAs was +0.11, and was +0.05–0.11 for OTC HAs. Costs included traditional HA uptake ($3,690; maintenance=$1,000/year) and OTC HA uptake ($600-$2,000; maintenance=$220–500/year). Our model projected lifetime discounted quality-adjusted-life-years (QALYs) for traditional HAs of 18.140/person, and 18.139–18.174/person for OTC HAs varying with utility benefit (+0.05–0.11). As long as OTC HA utility benefit was >+0.05, increased access resulted in higher QALYs and was cost-effective ($4,000/QALY-$92,500/QALY, varying with HA cost and utility benefit). Our results were sensitive to variations in OTC HA uptake rates. In conclusion, OTC HAs may increase population health and access to hearing healthcare in a cost-effective manner, and our model may continue to explore the costs and benefits of OTC HAs as pricing and evidence evolves.

PERSONAL STRATEGIES FOR MANAGING EVERYDAY ACTIVITY CHALLENGES AMONG ADULTS AGING WITH VISION LOSS

Kara Mumma,[1] Elena Remillard,[1] and Wendy Rogers[2], *1. Georgia Institute of Technology, Atlanta, Georgia, United States, 2. University of Illinois Urbana Champaign, Champaign, Illinois, United States*

An estimated 6% of adults in the United States ages 65 and older are living with vision loss and may experience other age-related declines and conditions co-morbidly (e.g., arthritis, hypertension, hearing loss). As such, they are likely to experience challenges in performing everyday activities, but little is known about their personal strategies or innovative solutions for managing activity challenges. The Aging Concerns, Challenges, and Everyday Solution Strategies (ACCESS) study explored everyday activity challenges and strategies among older adults (Nf60; ages 60–79) with long-term vision loss (prior to age 50). The current analysis focused on understanding participants' own methods for managing activity challenges, or things they have come up with, beyond traditional methods, such as getting help from other people (e.g., caregiver) or using assistive devices (e.g., white cane, screen reader). We coded response strategies among participants' own methods, and the most frequently reported methods included: learning/familiarity/organization, planning ahead/prioritizing, and perseverance/patience/assertiveness. Response codes were classified using the Selection, Optimization, and Compensation model to better understand how these strategies are being used to adapt to losses. The most common strategies were classified as elective selection with optimization, which are strategies that entail continued performance of challenging activities through behavioral methods, without bringing in any new means to assist. Illustrative example quotes are featured to provide insight on the context of personal strategies. With greater understanding of solutions people aging with vision loss are employing to manage activity challenges, we can increase awareness about effective solutions and identify opportunities for supportive technology solutions.

USING THE COLLECTIVE IMPACT FRAMEWORK TO REFRAME AGING IN MISSISSIPPI

Kina White,[1] Kaye Bender,[2] and David Buys[3], *1. Mississippi State Department of Health, Ridgeland, Mississippi, United States, 2. Mississippi Public Health Association, Jackson, Mississippi, United States, 3. Mississippi State University, Ms State, Mississippi, United States*

Trust for America's Health (TFAH), the Mississippi State Department of Health (MSDH), and the Mississippi Public Health Association (MPHA) partnered to organize the Mississippi Age-Friendly Public Health System (AFPHS) Work Plan. Built on the foundation of Reframing Aging training offered by the Gerontological Society of America in May 2021, the Work Plan aims to reframe how Mississippi's public health system addresses aging using the AFPHS 6Cs. Developed by the MS AFPHS Advisory Committee using a collective impact framework, the Work Plan has now been opened for public comment prior to being finalized for adoption across partner agencies. An AFPHS focuses on promoting health; preventing injury; managing chronic conditions; optimizing physical, cognitive, and mental health; and facilitating social engagement for older adults. The Work Plan's purpose is to guide MSDH and partner agencies in implementing an AFPHS for Mississippi. This is Phase One of a comprehensive age-friendly movement for Mississippi, with the next phase being an age-friendly state. Much of the work that MSDH will accomplish under this plan lays the foundation for the state to then have many age and dementia friendly communities. This presentation will discuss how Mississippi is reframing aging through collective impact and AFPHS 6Cs frameworks; the results of the public vetting of the Work Plan; and the final Work Plan components based on the public vetting. The process and its results can be replicated in other rural states where resources for aging populations are limited and historical perspectives on healthy aging are open to change.

GLOBAL CLINICIAN PERSPECTIVES ON NON-OPERATIVE HIP FRACTURE MANAGEMENT DURING COVID-19

Lucille Xiang,[1] Mriganka Singh,[1] Lynn McNicoll,[1] and Iain Moppett[2], *1. Brown University, Providence, Rhode Island, United States, 2. University of Nottingham, Nottingham, England, United Kingdom*

There are currently no guidelines regarding clinician decision making in the type of hip fracture management among older adults. Cultural, social, structural and economic differences between global healthcare systems may result in differing approaches. This study's objectives were to identify possible factors influencing clinicians' decision to undertake a non-operative hip fracture management approach among older adults, and to determine whether there is global heterogeneity regarding these factors between high income countries (HIC), and low- and middle-income countries (LMIC) clinicians. A SurveyMonkey questionnaire was distributed to clinicians through the Fragility Fracture Network's Perioperative Special Interest Group and clinicians' personal networks between

May 24 and July 25, 2021. 406 respondents from 51 countries returned the questionnaire, of which 225 respondents came from HIC and 180 from LMIC. Clinicians from HIC reported a greater median [IQR] estimated proportion of admitted patients with hip fracture undergoing surgery (96% [95–99]) than those from LMIC (85% [75–95]) of mean (SD) at 94% (8) compared to 81% (16) among LMIC clinicians (p=2.94e-23). Several factors seemed to influence the clinician hip fracture management decision making process. Global heterogeneity seems to exist between HIC and LMIC clinicians regarding factors such as anticipated life expectancy, ability to pay, treatment costs, insufficient resources, and perception of risk in hip fracture management decision-making. This is the first international sampling of clinician perspectives regarding hip fracture management. Further research is necessary for the development of best practice guidelines to improve hip fracture management decision-making and quality of hip fracture care among older adults.

GIDDY UP! LESSONS LEARNED FROM INTRODUCING AN ONLINE, NATURE-BASED INTERVENTION TO ASSISTED LIVING

Megan Westmore,[1] Keith Anderson,[2] and Rebecca Mauldin[1], *1. University of Texas at Arlington, Arlington, Texas, United States, 2. University of Mississippi, Oxford, Mississippi, United States*

The processes involved with developing, funding, and conducting intervention studies in long-term care present a unique set of challenges for researchers. In this presentation, we explore the experiences of researchers evaluating an online nature-based intervention in assisted living. The first challenge lies in creating or finding a novel intervention specific to the setting and population. In this case, the researchers found and tailored an existing online, interactive program that focused on ranch life in rural Montana – Days at Dunrovin. In partnership with the developer of Days at Dunrovin, a group intervention was developed specifically for long-term care settings. The second challenge is finding a facility that has the desire, environment, and staffing to support the intervention. In this case, the researchers were able to partner with an assisted living facility that had an owner who was interested in research, an environment that matched the experimental design of the study, and a staff that was eager to find new ways for residents to engage with the world, particularly during the COVID-19 pandemic. The final challenge involves selecting a funding mechanism that best fits the needs of the study. In this case, the researchers targeted a private foundation that provided ample funding along with the latitude and flexibility that allowed the study to evolve and pivot as necessary. This presentation concludes with recommendations for both budding and seasoned researchers who seek to introduce creative interventions into long-term care settings.

BARRIERS AND STRATEGIES TO ENGAGE AND RETAIN DIVERSE RURAL DYADS IN PSYCHOSOCIAL INTERVENTIONS

Michael McCarthy, Y. Evie Garcia, Mara Cassady, Neshay Mall, Pamela Bosch, and Steven Barger, *Northern Arizona University, Flagstaff, Arizona, United States*

It is often challenging to engage and retain rural Latinx and Native Americans in psychosocial interventions after stroke, despite the fact that these populations tend to experience poorer health outcomes. Although strategies for effective patient-provider communication exist, few studies focus on the cultural aspects of engagement and retention of diverse dyads in a rural context. The aim of this study is to describe barriers to engagement and retention of diverse rural dyads in post-stroke psychosocial interventions, as well as to elucidate specific strategies to address these barriers. Semi-structured interviews were conducted with Nf14 clinical providers with extensive experience serving diverse rural couples and families. Qualitative data were analyzed using interpretive description methods. Seven key barriers were identified, grouped broadly into: 1. Those presented by providers (1a. Lack of time and attention given to dyads "telling their story"; 1b. Lack of culturally appropriate interpersonal skills; 1c. Incongruence between provider-patient values) and 2. Those existing within dyads themselves (2a. Low priority given to interpersonal and emotional issues; 2b. Concern about confidentiality in small communities and mistrust of those in power due to current or historical experiences with dominant cultures; 2c. Perception of stigma surrounding interpersonal and emotional issues; 2d. Tendency to be polite, accommodating, or feign investment). Providers offered specific culturally-informed strategies to overcome barriers which in turn may increase engagement and minimize attrition. Providers and researchers may benefit from these insights as they work to communicate with, build trust, and meet the unique needs of these populations.

LINKS BETWEEN LONELINESS AND SLEEP AMONG PARTNERED OLDER ADULTS: AFFECTIONATE TOUCH AS A MODERATOR

Carly Lawrence, and Christina Marini, *Adelphi University, Garden City, New York, United States*

Sleep problems and loneliness both increase with age and undercut older adults' health and well-being. Loneliness is a predictor of sleep problems, however, research in this area often fails to also consider the role of relationship quality. The current study therefore focuses on spousal relationship quality as it has been shown to have a proximal influence on sleep. We examined relative effects of physical and emotional facets of relationship quality–namely affectionate touch and emotional support (in addition to loneliness). We further examined the potential for relationship quality to buffer effects of loneliness on sleep. We utilized data from a nationally representative sample of older adults from the National Social Life Health and Aging Project (NSHAP). Participants were partnered (N = 559) and completed a novel sleep module that included subjective (i.e., insomnia symptoms) and objective (i.e., Wake After Sleep Onset; WASO) markers of sleep. Upon controlling for demographics and mental and physical health, a different pattern of findings emerged for each facet of sleep. For subjective sleep, older adults who were more lonely reported more insomnia symptoms, but only when spousal emotional support was low. For objective sleep, older adults who reported more affectionate touch experienced less WASO. These findings suggest that loneliness that occurs in the context of low emotional support from spouses is particularly damaging for older adults' subjective sleep quality. Further, affectionate touch from spouses may represent an important intervention target for promoting felt security that helps older adults stay asleep throughout the night.

FRAILTY AND DEPRESSIVE SYMPTOMS MEDIATE THE IMPACTS OF FOOD INSECURITY ON SLEEP DEFICIENCY AMONG OLDER FILIPINOS

Tuo-Yu Chen,[1] Grace Cruz,[2] and Yasuhiko Saito[3], *1. Taipei Medical University, Taipei City, Taipei, Taiwan (Republic of China), 2. University of Philippines, Diliman, Quezon, Philippines, 3. Nihon University, Chiyoda-ku, Tokyo, Japan*

Although research has shown that food insecurity may lead to sleep problems due to mental illness, it remains unclear whether physical health also mediates this relationship in addition to poor mental health. We investigated whether frailty and depressive symptoms mediated the association of food insecurity with sleep deficiency (i.e., inadequate and poor sleep) among community-dwelling older adults. We analyzed the baseline data of the Longitudinal Study of Ageing and Health in the Philippines, a study with national representative sample of adults aged 60 years or older (Nf5,187). Sleep deficiency was conceptualized as self-reported sleeping less than 6 hours, complaining about trouble with falling asleep and staying asleep, and/or having non-restorative sleep. Food insecurity was defined as being hungry and not having enough food in the past three months in the household. Frailty was operationalized using modified definitions under Fried's criteria. Depressive symptoms were assessed using the Center for Epidemiological Studies-Depression Scale. Covariates included socio-demographics (age,sex,education,wealth,insurance,living arrangement,urbanity), health (pain,chronic diseases), and lifestyles (smoking,drinking). Mediation analysis was performed using PROCESS macro. The results from bootstrapping showed that the indirect effects from food insecurity through frailty (b=.024,SE=.009,95%CI=.009-.043) and depressive symptoms (b =.118,SE=.022,95% CI=.078-.166) onto sleep deficiency were significant, but the direct effect from food insecurity to sleep deficiency was not (b=.243,SE=.134,95% CI=-.018-.505). The results suggested that the effects of food insecurity on sleep deficiency were fully mediated through frailty and depressive symptoms among community-dwelling older Filipinos. Preventing frailty and depression may help improve sleep health among individuals being food insecure.

USING STORYTELLING TO ASSESS NURSE'S KNOWLEDGE IN CARING FOR OLDER ADULTS

Michele Murphy-Boucher,[1] and Diana Lynn Woods[2], *1. Providence Holy Cross Medical Center/Azusa Pacfic University, Mission Hills, California, United States, 2. Azusa Pacfic University, Azusa, California, United States*

Continuing education, knowledge acquisition, and competence is required of all professional Registered Nurses. Remaining current in care delivery trends based on evidence practice is the responsibility of nurses supported by professional development specialists and educators. This project was conducted as a quality improvement project, using the evidence-based teaching modality of storytelling to educate practitioners in caring for older adults. This project addresses the question: For leaders of professional development and education focused on acute care and ambulatory practice, who have not had specialty geriatric training, how does using case-based/story-telling education for the care of patients 65 years and older affect confidence levels of the 4 M's (mentation, mobility, what matters and medication) of elder care? A convenience sample of 12 Directors of Professional Development participated, and a validated comparison of responses to the Gerontological Nursing Competence Questionnaire (GNCQ) and the Facts on Aging (2015 version) (FAQ) were used for collecting data of pre intervention and post intervention. An eight-minute video was the educational intervention. GNCQ responses for confidence in knowledge and confidence in teaching were statistically significant. Although an increase in the mean score for interest in additional training, it was not statistically significant. The FAQ showed no statistical significance for the pre and post results. Findings indicate that storytelling is a viable teaching modality for increasing nurse's knowledge of caring for older adults based on the concepts of the 4 Ms of age-friendly care. Keywords: storytelling, case studies, nurse education, professional development, narratives, and adult learning.

POSITIVE AGEING AND DEATH OR DYING: A SCOPING REVIEW

Robin Otto,[1] Noelle Fields,[2] Keith Anderson,[3] and Michael Bennett[1], *1. University of Texas at Arlington, Arlington, Texas, United States, 2. The University of Texas at Arlington, Arlington, Texas, United States, 3. University of Mississippi, Oxford, Mississippi, United States*

Ageing world populations and increases in life expectancy have facilitated an interest in developing ageing models that promote inclusivity and positive perceptions of ageing. This scoping review examines how and to what extent research that utilizes successful, active, productive, and healthy ageing framework(s) include death or dying. The study followed Joanna Briggs Institute's methodological standard for scoping reviews and PRISMA guidelines and conformed to Arskey and O'Malley's five-stage framework. A thematic analysis was used to identify how research utilizes the concepts of death and dying in the context of positive ageing models. The analysis identified five core themes: (a) the critique that death and dying dimensions in positive ageing models are absent; (b) older adults' outlooks on death and dying while ageing well; (c) religious and spiritual dimensions of ageing well; (d) negative consequences of positive ageing models without death and dying dimensions; and (e) the future of death and dying in positive ageing models. The results bolster support for a paradigm shift that redefines what it means to age successfully without denying death. Incorporating the topics of death and dying into ageing conversations encourages individuals to ponder their end-of-life preferences and proactively participate in their advanced care plans. Death and dying conversations help care providers support people to live and die in a manner that is meaningful to them and inspire those receiving care to live fully and deeply and to think about the legacy that they want to leave.

HOW TO ENGAGE SENIORS AS VOLUNTEERS IN SOCIAL CARE SECTORS: A CASE STUDY OF A TIMEBANK IN HONG KONG

Shiyu Lu, *City University of Hong Kong, Kowloon, Hong Kong*

Objective: Exploring the roles of older adults as volunteers in social care settings has attracted wide attention to facilitate healthy aging. However, knowledge of engaging older adults as volunteers in social care sectors remains scant. This study explores theoretical mechanisms for promoting volunteer engagement among older adults in the social care sector. Method: This study used a time bank program called Good Hands in Hong Kong as a case study. Good Hands was established in 2018 and engaged almost 200 older adult volunteers to provide buddying and accompany (e.g., home visits and medical escort services) to over 390 frail peers in the community. This study adopted a qualitative method. Three semi-structured focus group interviews with 18 participants, including senior volunteers and the timebank staff, were conducted in January – August 2021. The thematic analysis. Stakeholder checks were conducted in July 2022 to enhance the credibility of the findings. Results: Three emergent themes were identified as critical components to facilitate engagement among senior volunteers: (1) strong cross-sector collaboration, (2) meaningfulness in voluntary work comprising four subthemes, including capacity optimization, care capacity enhancement, belonging cultivation, and value recognition, and (3) a co-producing environment. In addition, this study also identified the challenges related to the sustainability of the timebank program. Conclusion. This study is the first to explore mechanisms for promoting volunteer engagement among older adults in the social care sector. The findings provide theoretical and practical implications for the roles of older adults in social welfare production for our society.

COPING AND LIFE SATISFACTION OF OLDER PEOPLE DURING THE COVID-19 PANDEMIC

Dongjuan Xu, Nasreen Lalani, and Gregory Arling,
Purdue University, West Lafayette, Indiana, United States

Covid-19 put older individuals at high risk for increased morbidity and mortality, isolation, reduced coping and life satisfaction. Optimism, sense of mastery and closeness with family and friends can enhance coping and life satisfaction among older adults. No such studies were found during the pandemic. Our study examined the associations between optimism, sense of mastery, closeness with spouse, family, and friends, physical and psychological functioning and its effects on coping and life satisfaction. A national representative sample of 1,890 community dwelling older adults was obtained from the 2020 Health and Retirement Study COVID-19 data during March 2020-June 2021. A structural equation modeling approach used to test the associations and their direct and indirect effects on life satisfaction. Coping was seen as a mediator affecting these relationships and their effects on life satisfaction. Optimism ($\beta = .318$, $p < .001$), mastery ($\beta = .195$, $p < .001$) closeness with spouse/partner ($\beta = .199$, $p < .001$), closeness with children (($\beta = .075$, $p < .010$), friends ($\beta = .086$, $p < .001$), had significant positive direct and indirect effects on life satisfaction. Frailty ($\beta = -.137$, $p < .001$), comorbidities ($\beta = -.057$, $p < .050$), and IADL limitations ($\beta = -.118$, $p < .001$) had negative direct effects on life satisfaction. Optimism, sense of mastery and closeness with family/friends promotes coping and life satisfaction whereas frailty and comorbidities negatively influence coping and life satisfaction of the older adults. Community interventions should target coping strategies that enhances optimism, mastery, and interpersonal closeness among older adults during pandemic.

A PILOT ASSESSMENT OF A TABLET-BASED INTERVENTION FOR HOMEBOUND OR SOCIALLY ISOLATED OLDER ADULTS WITH DEPRESSION

Caroline Galo,[1] Natalie Benda,[1] Isabel Olivia Rollandi,[2] Sara Czaja,[3] Marco Ceruso,[1] and Jo Anne Sirey[2], *1. Weill Cornell Medicine, New York, New York, United States, 2. Weill Cornell Medicine, White Plains, New York, United States, 3. Weill Cornell Medicine, Ithaca, New York, United States*

Older adults who are homebound or socially isolated have high rates of loneliness and depression with fewer opportunities for treatment. Our team extended an existing psychotherapy intervention (Engage & Connect) to improve access to mental health care for older adults who are homebound. We iteratively created a tablet-based application (Engage PRISM) leveraging a user-centered design approach to provide older adults, particularly those with limited technology experience, an easy-to-use application to support social reward. Engage PRISM connects clients with the psychotherapy intervention and additional features to increase social reward exposure virtually. All eligible participants received a K92 ZTE tablet, equipped with the Engage PRISM application, internet service, Zoom, and access to Selfhelp's Virtual Senior Center. Participants were then enrolled in the 9-week Engage & Connect intervention delivered by a licensed mental health counselor via Zoom on the tablet each week. We evaluated feasibility of the intervention and preliminary effect on depressive symptoms through a weekly PHQ-9. Feasibility was assessed through participants' ability to use the tablet to access mental health treatment. We provided tablets to eight participants ages 67 to 84; participants demonstrated 100% feasibility of use of the tablet intervention. We dropped two participants from the study due to a greater level of care needed. All participants were provided with referrals prior to ending the study. Preliminary evidence indicates that four of the six remaining participants had experienced a reduction in depressive symptoms (i.e., had lower PHQ-9 scores) three weeks into the study reporting over a 30% reduction on average.

IS THERE A CAUSAL RELATIONSHIP BETWEEN ONLINE HEALTH INFORMATION SEEKING AND ANXIETY AMONG OLDER ADULTS?

Shelia Cotten,[1] Reza Ghaiumy Anarsky,[1] and Amy Schuster[2], *1. Clemson University, Clemson, South Carolina, United States, 2. Clemson University, Seneca, South Carolina, United States*

The growth of the Internet has provided users unlimited access to an abundance of information, including health information. The Internet is typically the first source searched by U.S. adults (18 years and older) when seeking health information. Factors such as age and anxiety are associated with online health information seeking (OHIS). Older adults (65 years and older) are increasing their Internet use and OHIS, although OHIS decreases with age. Importantly, OHIS can lead to improved health outcomes for older adults. The relationship between OHIS and anxiety is less clear, with some studies finding individuals with higher anxiety are more likely to search for online health information while others find the reverse pattern. Anxiety affects up to 20% of older adults and is often unrecognized and untreated. Given the lack of research examining the relationship between OHIS and anxiety among older adults and the proportion of older adults who experience anxiety, we analyzed six waves (2015- 2020) of data from the National Health and Aging Trends Study to assess the causal relationship between anxiety and OHIS using a Random Intercept Cross-lagged Panel Model framework, a statistical approach to assess causal relationships. These results suggest that anxiety is leading to OHIS in the next wave, rather than the reverse; however, OHIS was not related to anxiety in the next wave. This suggests that OHIS is not capable of mitigating older adults' anxiety. Practitioners working with older adults should be aware that older adults may need additional support to manage their anxiety.

HOW TO PROMOTE INTERGENERATIONAL INTEGRATION THROUGH ONLINE COMMUNICATION: A MODERATED MEDIATION MODEL

Yeseul Lee, Miseon Kang, Susanna Joo, and Hyoun K. Kim, *Yonsei University, Seoul, Seoul-t'ukpyolsi, Republic of Korea*

The present study examined the extent to which online communication skills led to the degree of intergenerational integration mediated through loneliness, focusing on whether such a mediating path would be moderated by age groups. Intergenerational integration is a concept that emphasizes acceptance and flexibility to recognize diversity based on each other's values across multiple generations or groups of varying ages. The older group included 315 Koreans aged 65 or above, and the younger group included 322 Koreans aged 19 to 29. Both groups completed an online survey conducted from December 2021 through January 2022. The results showed loneliness significantly mediated the association between online communication skills and the degree of intergenerational integration among both older and young adults; the higher the level of online communication skills, the lower the level of loneliness, leading to high levels of intergenerational integration. However, the mediation path was moderated by age; the association between online communication skills and loneliness was stronger for young adults compared to older adults. Additionally, the direct path was moderated by age: the association between online communication skills and intergenerational integration was stronger for older adults compared to young adults. The findings indicate that programs aimed at improving online communication skills (e.g., SNS or video calls) can reduce loneliness and thus promote intergenerational integration in both younger and older adults. This study highlights the importance of promoting online communication ability to increase intergenerational integration of both older and young adults.

EXPANDING WORLDS: ASSESSING STRATEGIES TO IMPLEMENTING A VIRTUAL REALITY PROGRAM IN RESPITE CARE

Emily Quinones-Visot,[1] Louanne Bakk,[1] Katy Allen,[2] Mary Milnamow,[1] and Jason Dauenhauer[3], *1. State University of New York, University at Buffalo, Buffalo, New York, United States, 2. Lifespan of Rochester, Rochester, New York, United States, 3. SUNY College at Brockport, Brockport, New York, United States*

Virtual reality (VR) is an immersive experience that simulates real or imagined environments and provides an innovative solution to social isolation and loneliness. Implementation science was used to identify barriers and facilitators to implementing a novel VR intervention as part of a community-based participatory research project at Lifespan of Rochester within their Partners in Care (PIC) volunteer respite program. The VR intervention will be facilitated by PIC staff and volunteers with caregivers of community-dwelling persons living with dementia (PLwD) receiving respite services. A mixed-methods design was used to identify perceived barriers and facilitators to implementation. Focus groups and self-administered surveys were completed by PIC staff (Nf10) to assess their thoughts and concerns related to program implementation. Surveys included validated measures to assess self-rated ability to perform VR functional components, attitudes toward VR, beliefs on the acceptability, appropriateness, and feasibility of the VR program, effectiveness of improving comfort, confidence, and preparedness of facilitators. Identified barriers included lack of VR knowledge, skills, and confidence in capabilities; concerns related to safety, confusion, and triggers for PLwD; and the need to strengthen buy-in from staff. Implementation strategies were selected from the Expert Recommendations for Change project and tailored to support effective uptake and behavior change among PIC staff and volunteers. Identified evidence-based strategies included training and shadowing opportunities, identifying champions, and developing a trauma-informed approach manual. These findings illustrate the need to carefully examine organizational factors that can impede the implementation. The benefits of this approach and the lessons learned will be discussed.

BARRIERS AND FACILITATING FACTORS TO HEALTH MANAGEMENT TECH ADOPTION IN A RURAL MEALS ON WHEELS SAMPLE

David Wihry,[1] Jennifer Jain,[1] Jennifer Crittenden,[1] Lenard Kaye,[1] and Tabatha Caso[2], *1. University of Maine, Bangor, Maine, United States, 2. Eastern Area Agency on Aging, Brewer, Maine, United States*

Meals on Wheels clients served through the aging network represent a significant population of high need older adults who could benefit from health management technology. This poster presents the results of a study targeting Meals on Wheels clients in four rural U.S. counties on opportunities and barriers to adoption of technology-based health management interventions. Paper surveys were provided to 690 Meals on Wheels clients and 154 were returned (22.3% response rate). The mean age of respondents was 71.7 years and the sample was composed of 39% men and 61% women. When asked to select the most valuable features of home health management technology, 42% indicated vital signs monitoring, followed by remote access to classes and events at Area Agencies on Aging (21%), and video visits with medical providers (20%). When asked about current technology usage, 48% indicated never having engaged in a telehealth visit over a computer, smartphone or tablet. Top ranking barriers to health management technology utilization were affordability and privacy concerns. A majority (61%) of the sample disagreed or strongly disagreed that they have the money to afford a computer, smart phone, or tablet and 69% agreed or strongly agreed that they are concerned about privacy or scams when using the internet. Approximately four in ten (38%) are interested in using technology to manage their health. Additionally, 45% reported using a smartphone. The poster will also explore demographic differences in older consumer perceived barriers and opportunities and programmatic implications for expanding health management technology adoption.

USING DIGITAL TECHNOLOGIES TO IMPROVE READMISSION AND ADHERENCE AMONG OLDER ADULTS WITH HEART FAILURE

Melissa O'Connor,[1] Nilmini Wickramasinghe,[2] Vijay Gehlot,[3] Elliot Sloane,[4] Suresh Chalasani,[5] Ramona Wallace,[6] Patricia G Wisk,[7] and Stefan Gravenstein[8], *1. Villanova University, M. Louise Fitzpatrick College of Nursing, Villanova, Pennsylvania, United States, 2. Swinburne University of Technology & Epworth HealthCare, Hawthorne, Victoria, Australia, 3. Villanova University, Villanova, Pennsylvania, United States, 4. Villanova University, Villanova, Pennsylvania, United States, 5. University of Wisconsin-Parkside, Kenosha, Wisconsin, United States, 6. Western Michigan University, Kalamazoo, Michigan, United States, 7. University of Illinois at Chicago, Holland, Michigan, United States, 8. Brown University, Providence, Rhode Island, United States*

Heart failure (HF) affects approximately 26 million people globally resulting in morbidity, mortality, and rehospitalization. With 30-day rehospitalization rates ranging from 19% to 25%, HF is burdensome for patients and challenging for clinicians to manage. HF costs in the U.S. exceeded $30 billion in 2012, projected to exceed $70 billion by 2030, and produce estimated social care costs of 12 billion in 2020. Therefore, reducing HF readmissions should be a global priority. A technology-based platform may assist in the goal of reducing readmissions. This platform may accomplish this goal by providing several digital tools that can assist the clinician in the care process, while simultaneously enabling patients with self-care through more effective communication in all care settings. Digital twins (DT) and the nursing Avatar (NA) are two such tools. The DT is a virtual, real-time digital representation of a physical object/process. It originated from NASA to improve physical model simulation of spacecraft in 2010 (Wickramasinghe et al., 2021). It is possible to achieve similar benefits in healthcare by developing suitable DT of patients in specific clinical contexts (Wickramasinghe et al., 2021; Lui et al., 2019). So to, the NA was studied by Bickmore, et al (2209) and found ultimately to be the preferred discharge communication method. As such, we proffer the development of digital twins and NA for HF patients to support better provider decision and patient communication. This will result in HF care being more precise, consistent, reproducible, and personalized resulting in improved diagnosis, treatment, and care outcomes.

SIMPLE SOLUTIONS TO A COMPLEX PROBLEM: LISTENING TO DIRECT CARE WORKERS' PERCEPTIONS ABOUT RETENTION

Isha Karmacharya, and Leah Janssen, *Miami University, Oxford, Ohio, United States*

Direct care workers (DCWs) play a crucial role in delivering long-term services in nursing homes, assisted living, and in-home care. The work is physically and emotionally demanding and generally low-paid, which makes retaining and managing the workforce extremely challenging and has resulted in an unending workforce crisis. This study provides data on retention-promoting factors from the perspective of DCWs working in high-performing facilities and home care agencies that were identified through national and state retention data and reviews from case management agencies. Qualitative interviews were conducted in the spring of 2022 with a purposive sample of DCWs (n=16). Interviews were transcribed, checked for accuracy, and coded via thematic analysis. Three overarching themes emerged: work culture, appreciation, and monetary benefits. Retention was supported by a work culture that emphasizes person-centered care, family atmosphere, relationship building, staff empowerment, coaching supervision, participative leadership, effective communication, and flexible working conditions. DCWs experienced appreciation from employers, supervisors, and clients, which they perceived to promote retention. This theme includes valuing, respecting, recognizing, and acknowledging the efforts of DCWs. Monetary benefits promoting retention were seen as regular wage raises, employee assistance funds, gift cards, bonuses, paid time off, health insurance benefits, and travel reimbursement. This study demonstrates that while worker retention is a crisis, there are modifiable aspects of the job that can promote workers' retention. DCWs' retention can be impacted by work culture and appreciation practices. Study findings have implications for facility policy and practice pertaining to DCW's retention.

JOB CHARACTERISTICS ASSOCIATED WITH INTENT TO QUIT AMONG NURSING HOME EMPLOYEES AND MANAGERS

Katherine Kennedy,[1] and David Mohr[2], *1. Providence VA Medical Center, Providence, Rhode Island, United States, 2. VA Boston Healthcare System, Boston, Massachusetts, United States*

High turnover and recruitment challenges of nursing home employees and managers is an ongoing concern. This study's objective was to examine intent to quit among all staff and assess the roles of job characteristics and job satisfaction. Employees and managers within one nursing home chain working in direct patient care or nursing were compared. Data came from the Work, Family, Health Network 18-month follow-up survey in 2012 (Total = 1,000, Managers = 101, Employees = 899). A cumulative logit model controlling for demographics was estimated for lower intent to quit. Herzberg's Two-Factor Theory of Work Motivation guided the study. Employees scored significantly lower on family-supportive supervisor behaviors (FSSBs), schedule control (SC), and decision authority (DA) than managers. Employees and managers did not differ on job satisfaction, intent to quit, or job demands. Satisfied workers had 5.88 times greater odds of lower intent to quit compared to workers who were neutral or disagreed ($p < .0001$). DA (OR=0.29) and SC (OR=0.19) were related to higher intent to quit. In contrast, FSSBs (OR = 1.45), safety compliance (OR=1.41), and the combination of high DA with high SC (OR = 1.4) were related to lower intent to quit. Among nursing home staff, lower intent to quit may be achieved through improving job satisfaction, safety culture, the quality of supervision, and job enrichment through more schedule control and decision-making power. It is also imperative to develop strategies to retain those with more education through further research.

INTEGRATED FAITH BASED CURRICULUM FOR COMMUNITY-BASED OUTREACH WORKERS: ADDRESSING INEQUITIES AMONG OLDER ADULTS

Karen Bullock,[1] Kim Stansbury,[2] and Terrance Ruth[2], *1. Boston College, Chestnut Hill, Massachusetts, United States, 2. NC State University School of Social Work, Raleigh, North Carolina, United States*

Older Latino and Black Americans experience health inequities and a lack of culturally competent clinician may influence this outcome. Community-Based Outreach (CBO) has proven to be effective in addressing such challenges. CBO is an effective approach to engaging communities that have been historically marginalized and are less likely to utilize hospice and palliative than other racial/ethnic groups. Yet, few models and modules for training are available in the literature to prepare CBO workers. This presentation describes the development, coordination, content and implementation of an Interprofessional Educational (IPE) training and curricular innovation to meet needs of diverse older adults diagnosed with a serious illness.

Methods: A community-based outreach approach that integrated faith-based/spiritual care curriculum to train African American and Latino outreach workers to support older adults with serious illnesses, with a focus on advanced care planning (ACP) that explored potential barriers to equitable care. A collaboration with faith-based community representatives to design the intervention research protocol was essential. Results: The curriculum consisted of three parts: (1) a 36-hour classroom component delivered in three modules organized around eight themes: what is hospice and palliative care, spirituality and the meaning of death, understanding the dying process and decision making, goals of care, culturally responsive care; (2) weekly visits; and (3) field education/workforce development. At the end of the training, learners were able to: (a) express knowledge about culture differences; (b) demonstrate skills – listening, identifying meaning in the decision making, convey health information using patient-centered language; (c) understand cultural influencing decision making.

Participant Index

Arabic numbers refer to session numbers.
Duplicate numbers indicate the participant is listed as an author on multiple abstracts within a session.
