PANDEMIC CAREGIVING: A LONGITUDINAL ASSESSMENT OF THE TRAJECTORIES AND CORRELATES OF STRESS

Kristin Litzelman, Christina Kim, and Margaret Kerr, *University of Wisconsin-Madison, Madison, Wisconsin, United States*

In public health emergencies, caregivers are a crucial but often overlooked human resource. The purpose of this longitudinal study was to assess the well-being of caregivers and non-caregivers over the first 18 months of the COVID-19 pandemic. We used three waves of data from the Survey of the Health of Wisconsin's COVID-19 Community Impact Survey (Wave 1: May-June 2020; Wave 2: January-February 2021; Wave 3: June 2021; n=2,434 observations of 1,653 unique respondents). Caregivers were identified as those providing care for an adult with an illness or disability. Perceived stress (Global Stress Scale; mean=5.08, SD=4.81) was regressed on caregiver status and covariates in mixed models accounting for repeated measures. On average, caregivers had higher stress than non-caregivers (beta=2.10, p< 0.0001). Across the sample, stress increased between summer 2020 and winter 2021 (mean of 4.8 versus 5.8, p<.01), and lowered somewhat by summer 2021 (mean=5.0, p<.05); this trajectory was similar on average for caregivers and non-caregivers. Respondents who transitioned into a caregiving role during the pandemic had the highest stress (beta=2.55, p< 0.01 compared to non-caregivers). Other factors associated with higher stress (p<.01) include marginalized racial/ethnic identity (beta=1.74), being employed (beta=1.47) or female (beta=0.66), or caregiver having more health conditions (beta=0.22 per condition). Public benefits use and higher self-efficacy were associated with lower stress (betas=-1.18 and -0.30, respectively, p<.01). The findings emphasize the adverse outcomes experienced by caregivers and non-caregivers over the course of the pandemic and highlight potential factors that can inform risk stratification and interventions to support well-being in future crises.

REOPENING UNDER COVID-19: THE IMPACT OF REOPENING SOCIETY ON OLDER ASIAN AMERICAN'S DEPRESSIVE SYMPTOMS

Yifan Lou[1], Ethan Siu Leung Cheung[1], Jinyu Liu[2], and Bei Wu[3], *1. Columbia University, New York, New York, United States, 2. Columbia University, New York City, New York, United States, 3. New York University, New York, New York, United States*

Background:

The lockdown due to COVID-19 has influenced individuals' lives in many aspects. Yet, the impact of reopening under an ongoing pandemic is understudied. This study aims to investigate the impact of reopening policy on older Asian Americans' depressive symptoms and whether the impact varies by their sociodemographic characteristics.Method: We used interview data collected from 519 Chinese and Korean aged 60 and older in New York City between 5/23/2021 to 7/30/2021. Interrupted time series model was used to test whether there are significant level and slope changes in depressive symptoms (PHQ-9 scale) before and after the reopening on 7/1/2021 in NYC. We then ran the models in stratified sample by gender, education, income, self-reported health, and social connectedness through living arrangements, use of technology, and social interactions.

Results:

Older Asians' depression increased immediately following the reopening (ß=1.52, p< 0.05), and then slowly decreased then after (ß=-0.12, p< 0.001). A decrease in depression following reopening was significantly associated with the male gender, good health, higher income, living alone, having received or provided social support, daily texting, and no engagement in the discussions related to COVID-19 in social media. Discussions: While reopening may have long-term benefits on mental health, older Asians were anxious about their safety at the beginning of reopening under an ongoing pandemic. Older adults with worse health, lower SES, and limited social connectedness struggled to adjust to "back-to-normal" life. We discussed research, policy, and practice implications to support these disadvantaged older adults after reopening.

THE COMBINED EFFECTS OF SOCIAL ISOLATION AND LONELINESS ON PSYCHOLOGICAL WELL-BEING DURING THE COVID-19 PANDEMIC

Ke Li, and Fengyan Tang, *University of Pittsburgh, Pittsburgh, Pennsylvania, United States*

Social isolation and loneliness are related but distinct constructs. A number of studies have examined these two constructs separately; however, the combined and interactive effects of social isolation and loneliness on health outcomes have rarely been studied. Using the most recent data of the Health and Retirement Study (HRS 2020) collected during the pandemic, this study aimed to explore the latent classes of social isolation and loneliness among adults aged 60 and older (N=3,486) and to examine the associated psychological well-being. Social isolation was measured by five indicators, including living alone, no membership in any organizations, and less than once a month contact with children, relatives, and friends. Loneliness was measured by the 3-item UCLA scale. Four classes were identified by the Latent Class Analysis (LCA): neither isolated nor lonely (class 1, 35%), living alone and lonely (class 2, 25%), no social participation and lonely (class 3, 18%), and highly isolated and lonely (class 4, 23%). The results of multivariate regression indicated that compared to respondents who were neither isolated nor lonely, those who were in the class of living alone and lonely and the class of highly isolated and lonely had more depressive symptoms, stress, anxiety, worry, loneliness during the pandemic. The latent class of no social participation and lonely was associated with more depressive symptoms and covid-related stress. This study emphasizes the importance of specialized intervention strategies targeting the unique needs of older adults with different experiences of social isolation and loneliness.

SESSION 4241 (BIOLOGICAL SCIENCES INVITED SYMPOSIUM)

AGING-RELATED ADIPOSE REMODELING AND DYSFUNCTION

Chair: Qiong (Annabel) Wang

Aging is associated with insulin resistance, cardiovascular dysfunction, and many other chronic metabolic disorders, significantly shortening healthspan and lifespan. Fat (adipose) tissue, as the major site for energy storage, maintains whole-body energy homeostasis and insulin sensitivity. Adipose tissue has extraordinary plasticity, and it was not until recently that fat tissue remodeling during aging is considered to play an essential role in aging-associated metabolic disorders. Benefiting from recent technology advances, especially the single-cell technology and comprehensive genetic mouse models, we are beginning to unmask how adipose tissue remodels during aging cellularly and molecularly. This symposium features internationally-renowned aging research scientists whose work focuses on how aging remodels adipose tissues and how adipose tissue is vital for healthy aging and longevity. We will hear from Philipp Scherer from The University of Texas Southwestern Medical Center, who will present his research on the impact of adipocyte-derived factors on Healthspan and Lifespan; Hei Sook SUL from the University of California Berkeley will discuss “Aging dependent changes in adipose precursors”; Annabel Wang from the City of Hope will introduce her recent discovery of a new type of adipocyte progenitor cell that promotes aging-related visceral adiposity; and lastly, Gina Wade from the University of Wisconsin-Madison who will talk about “Regulation of aging energy expenditure by plasma lipid signaling”. Attendees will learn about the latest breakthroughs in adipose tissue aging, and the role of adipose tissue in maintaining and restoring metabolic health in aged individuals.

A UNIQUE ADIPOCYTE PROGENITOR POPULATION PROMOTES AGE-RELATED ADIPOSITY

Qiong (Annabel) Wang, *City of Hope, City of Hope, California, United States*

The average fat mass in adults increases dramatically with age, and older people often suffer from visceral obesity and related adverse metabolic disorders. Unfortunately, how aging leads to fat accumulation is poorly understood. It is known that fat cell (adipocyte) turnover is very low in young mice, similar to that in young humans. Here, we find that mice mimic age-related fat expansion in humans. In vivo lineage tracing shows that massive adipogenesis (the generation of new adipocytes), especially in the visceral fat, is triggered during aging. Thus, in contrast to most types of adult stem cells that exhibit a reduced ability to proliferate and differentiate, the adipogenic potential of adipocyte progenitor cells (APCs) is unlocked by aging. In vivo transplantation and 3D imaging of transplants show that APCs in aged mice cell-autonomously gain high adipogenic capacity. Single-cell RNA sequencing analyses reveal that aging globally remodels APCs. Herein, we identify a novel committed preadipocyte population that is age-specific (CP-A), existing both in mice and humans, with a global activation of proliferation and adipogenesis pathways. CP-A cells display high proliferation and adipogenesis activity, both in vivo and in vitro. LIFR serves as a functional maker of CP-A, which promotes CP-A proliferation. Together, these findings define a new fundamental mechanism involved in fat tissue aging and offer prospects for preventing and treating age-related metabolic disorders.

ADIPOCYTE-DERIVED FACTORS: IMPACT ON HEALTHSPAN AND LIFESPAN

Philipp Scherer, *The University of Texas Southwestern Medical Center, Dallas, Dallas, Texas, United States*

Adipocytes secrete numerous lipid and protein factors with profound effects on systemic energy homeostasis. One such adipokine that we first identified in the early 1990’s, adiponectin, has garnered significant attention as a potent mediator of insulin sensitivity and cell survival. FGF21 is another factor that is secreted by a number of cell types (including adipocytes), which has a beneficial effect on metabolism. Our group generated a novel mouse model that overexpresses, in an inducible fashion, physiological levels of FGF21 from adipocytes in the adult mouse. While comparable levels of constitutive overexpression of FGF21 from the liver do not have an impact on aging, adipocyte-derived FGF21 exerts a profound beneficial impact on health- and lifespan. This demonstrates that selective manipulation of adipose tissue per se has the potential to significantly reduce mortality and extend lifespan. The adipocyte-specific FGF21 transgenic animals have increased energy expenditure, weigh considerably less and exhibit an improvement in all systemic metabolic parameters examined to date. The mice further display unique immune-metabolic profiles of their adipose tissue depots, which defy the conventional changes associated with aging. Importantly, all these phenotypic alterations are achieved without a significant impact on adipose tissue beiging/browning. Moreover, at least some beneficial aspects of FGF21 appear to be mediated through a lowering of leptin, which leads to central leptin sensitization. Combined, these efforts shed additional light on the physiological effects of FGF21.

AGING-DEPENDENT CHANGES IN ADIPOSE PRECURSORS

Hei Sook Sul, and Frances Lin, *University of California, Berkeley, Berkeley, California, United States*

Adipose tissue mass and adiposity change throughout the lifespan. During aging, while visceral adipose tissue (VAT) tends to increase, peripheral subcutaneous adipose tissue (SAT) decreases significantly. Unlike VAT, which is linked to metabolic diseases, including type 2 diabetes, SAT has beneficial effects. However, the molecular details behind the aging-associated loss of SAT remain unclear. Here, by comparing scRNA-seq of total stromal vascular cells of SAT from young and aging mice, we identify an aging-dependent regulatory cell (ARC) population that emerges only in SAT of aged mice and humans. ARCs express adipose progenitor markers but lack adipogenic capacity; they secrete high levels of pro-inflammatory chemokines, including Ccl6, to inhibit proliferation and differentiation of neighboring adipose precursors. We also found Pu.1 to be a driving factor for ARC development. We identify an ARC population and its capacity to inhibit differentiation of neighboring adipose precursors, correlating with aging-associated loss of SAT.

HDL-LOCALIZED PLASMA CERAMIDES SUPPORT BODY TEMPERATURE REGULATION

Gina Wade, Judith Simcox, *University of Wisconsin - Madison, Madison, Wisconsin, United States*

As organisms age, the balance of energy expenditure is disrupted. One of the major ways in which this disruption is observed is in an inability to maintain body temperature. Our lab is interested in understanding the signals that regulate this energy balance, and we focus on lipids as energy substrates and signaling molecules to regulate this process. During cold exposure, plasma lipids produced by peripheral tissues are required to fuel and activate heat production in the brown adipose tissue. One of the lipid classes that increases with cold exposure is plasma ceramides. Beyond cold exposure, ceramide lipids are also elevated in aged individuals and are associated with increased cardiovascular disease risk and age-related diseases such as Alzheimer's disease where they are thought to signal inflammation. However, the functions of ceramides in non-disease states are unknown. To address this gap in knowledge, we have shown that ceramide production in 12-week-old C57Bl6/J mice is required for body temperature maintenance in the cold. Moreover, plasma ceramide levels in 2-year-old mice are unchanged in the cold, and these mice are unable to maintain their body temperature. In disease states, ceramides are transported through the plasma in LDL, but ceramides are enriched in the HDL plasma fraction in the cold. This differential plasma lipid transport suggests dynamic modes of lipid uptake and tissue targeting to regulate energy expenditure. This work will identify molecular mechanisms governing ceramide function in the mammalian response to cold and better our understanding of the systemic lipid metabolism dysregulated in disease.

SESSION 4250 (PAPER)

DISTRUPTING AGEISM AND STIGMA THROUGH EDUCATION

In this session, innovative and unique ways to combat ageism through educational efforts in varied classes are described.

”HOW OLD IS OLD?” ADDRESSING AGEISM AND UNCONSCIOUS BIAS AMONG MEDICAL STUDENTS DURING GERIATRICS CLERKSHIP

Ravishankar Ramaswamy, Stephanie Chow,
Noelle Marie Javier, Rosanne Leipzig, Gregory Hinrichsen, and Amy Kelley, *Icahn School of Medicine at Mount Sinai, New York, New York, United States*

Ageism (stereotyping, prejudice and discrimination based on age) has deleterious consequences on older adults' health. Medical students have variable attitudes and biases toward older people. We hypothesized that an embedded ageism curriculum within the Ambulatory Care-Geriatrics clerkship would increase ageism awareness and commitment to reduce ageism in the clinical environment for third year medical students. The 2021 curriculum included assigned pre-reading, videos, short didactics, expert-facilitated small group discussion of clinical vignettes, reflective journaling, and posting of personal commitments on a virtual messaging board. We surveyed students at the start and end of the clerkship to evaluate baseline awareness, change in UCLA Geriatrics Attitudes Scale, and satisfaction with curricular components. Of the 95 students who thusfar participated in the curriculum, we received 92 pre- and 48 post-curriculum survey responses. Pre-curriculum students reported the median age for “old” was 65 years (range 35-90) and 42% of students expressed preference for younger patients (33% neutral). Proportion of students with self-assessed ability to identify ageist remarks/actions increased from 52%(pre) to 92%(post), and ability to minimize own ageist biases increased from 23%(pre) to 83%(post). 86% of students found the curriculum useful; discussion with experts and viewing an ageism TED Talk were the most favorably scored components. Integrating an ageism curriculum with pre-work, didactic, guided discussion and reflection components in the Geriatrics clerkship increased medical student awareness and confidence in addressing ageism-related behaviors. This curriculum complements students' clinical interactions with older adults and has the potential to reduce the future impact of ageism in medicine.

IMPACT OF AN EDUCATIONAL INTERVENTION ON KNOWLEDGE AND ATTITUDES ABOUT MEMORY LOSS AND CARE ISSUES

Colleen Galambos[1], and Julie Ellis[2], *1. University of Wisconsin-Milwaukee, Milwaukee, Wisconsin, United States, 2. University of Wisconsin Milwaukee, Milwaukee, Wisconsin, United States*

While previous studies have evaluated the impact of education interventions on knowledge and attitudes about Alzheimer's disease and other dementias (Kaf, Barboa, Fisher, & Snavely, 2011; Kimzey, Mastel-Smith, & Alfred, 2016; Yamashita, Kinney, & Lokon, 2011), there is little research about the impact on knowledge and attitudes about issues related to caregivers of those with dementia. This paper reports on the results of an education intervention to increase college students' knowledge, and positive attitudes on memory loss, Alzheimer's disease and other dementias, and related caregiver issues. The intervention consisted of a series of lectures and readings, including a caregiver memoir. The intervention was conducted in social work and nursing classes over two semesters. A questionnaire, using established scales that measured knowledge and attitudes about dementia and caregiving issues, was administered to the students using a pretest-posttest design. The educational intervention tested successfully increased knowledge and positive attitudes about Alzheimer's disease, dementia, memory loss, and caregiving (p=.0001). This finding held across courses, grade levels, previous experience with older adults, knowledge of someone with memory loss, and relationships with caregivers and persons with memory loss. A memoir as a storytelling informational narrative, and structured lectures and readings served as effective learning tools that influenced both knowledge and attitude levels about Alzheimer's disease, dementia, memory loss, and caregiving. Gains made in knowledge and attitude changes were true for both face- to- face and online teaching venues. Implications for training, classroom teaching, and workforce development will be discussed.

WHAT AND HOW DID IT WORK? A SYSTEMATIC REVIEW OF THE INTERVENTION STUDIES OF CHANGING PERCEPTION TOWARD OLDER ADULTS

Yeonjung Lee[1], Lun Li[2], and Laxman Shrestha[3], *1. Chung-Ang University, Seoul, Seoul-t'ukpyolsi, Republic of Korea, 2. MacEwan University, Edmonton, Alberta, Canada, 3. University of Calgary, Calgary, Alberta, Canada*

Social workers are one of the major professionals serving for older adults. However, social work students often rank gerontology at the bottom of their future professional practice. Studies show that students have negative attitudes about, and perceptions of older adults and aging. Such stereotypes result in social work students considering practice areas other than gerontological social work. The objective of this study is to conduct a systematic review and identify any types of the intervention studies of changing perception and attitudes toward older adults and aging among social work students. This systematic review identified empirical research studies written in English that were published in a peer-reviewed journal before November 2021. Systematic search was carried out within four electronic databases (AgeLine, Education Research Complete, Social Work Abstracts, SocINDEX with full text) with the key words such as "social work student" and "aging or ageing or elderly or older adults or seniors or geriatrics or gerontology". A total of 470 abstracts were identified, and after careful review of 143 full articles yielded from the databases, 43 journal articles were included in this study. Analysis of the selected literature provides that major interventions have been tried include service learning, lecture, curriculum development, simulation, training program, and intergenerational program. This systematic review highlights the importance of the experiential learning, partnership development with community, and interprofessional collaboration to provide the best model of practice for changing perception toward aging and older adults among social work students.

SESSION 4260 (SYMPOSIUM)

EMBRACING OUR DIVERSITY: ENHANCING THE GEROFIT PROGRAM FOR PATIENT EXPERIENCE

Chair: Katherine Hall Co-Chair: Monica Serra

The Veterans Health Administration has long been at the forefront of telehealth development and advances. Gerofit to Home (GTH) is a novel, telehealth-based adjunct to a widely successful Gerofit facility-based program for Veterans ages 65 and older with multi-morbidities and functional limitations. Of note, participants are allowed to remain in the program as long as they wish, all of which enhances social engagement and camaraderie. Now disseminated to nearly 30 VA medical centers across the country, all of our sites transitioned within 6 weeks of the COVID-19 pandemic to group-based virtual classes, aptly called GTH. Because of the rapid and continuously evolving changes in telehealth, we had near daily Veteran feedback on what was working and what was not working. We cast a wide net and used multiple methods to obtain Veteran feedback. These were quite successful and allowed us to make ongoing improvements to our classes. The first presentation describes results from a telephone survey deployed to all patients who transitioned from facility-based Gerofit to GTH. The second presentation describes the development of a Gerofit Veterans Advisory Panel and the perspectives they provided in terms of scheduling, patient-requested content, feasibility and access. The third presentation explores patient satisfaction and retention in GTH participants, with an emphasis on rural vs non-rural settings. The fourth paper details an innovative approach to integrating student learners in to the Gerofit program, and explores the impact of these intergenerational interactions.

GEROFIT TELEHEALTH-DELIVERED GROUP EXERCISE IMPACTS SOCIAL SUPPORT AND HEALTH AMONG OLDER VETERANS

Lauren Abbate[1], Rebekah Harris[2], Sarah Jordan[3], Kathryn Nearing[4], Janet Prvu Bettger[5], Megan Pearson[6], Miriam Morey[7], and Katherine Hall[7], *1. Eastern Colorado Health Care System, Aurora, Colorado, United States, 2. VA Boston, Boston, Massachusetts, United States, 3. University of Colorado, school of Medicine, Aurora, Colorado, United States, 4. VA Eastern Colorado Geriatric Research Education and Clinical Center, Denver, Colorado, United States, 5. Duke University, Durham, North Carolina, United States, 6. Durham VA Healthcare System, Durham, North Carolina, United States, 7. Durham VA Health Care System, Durham, North Carolina, United States*

Group exercise provides social support, which is especially important among older adults. Gerofit conducted a telephone survey with participants (n=258) from 15 sites to learn about Veterans' experiences with transition to Gerofit-specific telehealth-delivered group exercise to guide continuous improvement of the program. One, open-ended question was asked at the end, inviting respondents to reflect on any other thoughts they had about the telehealth-delivered exercise sessions. This yielded robust qualitative responses which constitute the data analyzed in this qualitative descriptive study. Key themes that emerged from participant responses included: 1) telehealth-delivered group exercise provides structure, motivation, and accountability; and 2) transitioning from in-person to telehealth-delivered exercise has many beneficial impacts on health such as retaining strength and ability to recover from injury, weight management, and positive impacts on mental health and quality of life. Telehealth-delivered group exercise sessions provide social support and are associated with positive health impacts.

GEROFIT TO HOME: REDUCING BARRIERS TO GROUP EXERCISE TO RURAL AND NONRURAL OLDER ADULTS IN A SUCCESSFUL FASHION

Neil Gregor[1], Eva-Marie Christman[2], David Crivello[1], and Jamie Schukle[1], *1. Veteran Affairs, Martinez, California, United States, 2. Veteran Affairs, Redding, California, United States*

Transportation, scheduling and travel distance can present as barriers to participation in facility based exercise programs. Gerofit to Home(GTH) eliminates aforementioned burdens commonly associated with in-person programs. Understanding participant satisfaction and retention in rural(R) and non-rural(NR) groups assists in planning to better serve these populations with group exercise. This study aims to explore GTH participant satisfaction and retention in over 100 participants, through 3 months, for veterans over 65yo in rural and non-rural areas. Current results illustrate “Highly Satisfied” in majority of both R and NR groups. Retention at 3 months, in both groups, and factors associated with 3-month retention will be discussed in this presentation. Further research into the reasoning for participant stoppage prior to 3 months will aide in understanding how to better cater group exercise to these groups. Satisfaction scores in this study endorse further efforts for virtual group exercise in older adults.

GEROFIT STUDENT VOLUNTEERS: INTERGENERATIONAL APPROACH TO MOBILITY

Cathy Lee[1], Steven Castle[1], Katherine Hall[2], and Miriam Morey[2], *1. VA Greater Los Angeles, Los Angeles, California, United States, 2. Durham VA Health Care System, Durham, North Carolina, United States*

The Institute of Medicine (IOM) has reported that innovative models of care will need to be used to increase the workforce to care for an aging population and to encourage older adults “to be active partners in their own care” (IOM, 2008). Use of student volunteers in an intergenerational approach could be used to supplement the workforce to motivate older adults for self-care in clinical practice. Gerofit@UCLA is a student organization created to support Gerofit at the Greater Los Angeles VA. These students completed an Expectation Regarding Aging (ERA-12) Survey. ERA-12 is a 12-item survey that measures expectations regarding aging in physical health, mental health and cognitive function with scores ranging from 0-100, higher scores indicating higher expectations with aging. After volunteering in Gerofit, students indicated highest expectations for mental health (78.33 ± 5.9) compared to cognitive health (53.34 ± 5.3) and physical health (39.17 ± 3.7). Although these students recognize the physical changes with aging of this 80-102 year old group, they appreciate that group physical activity in a program like Gerofit has positive effects on mental health and cognition, for the patients and for themselves.

VETERANS VOICES: ACCEPTABILITY AND ENRICHING THE GEROFIT TO HOME EXPERIENCE FOR OLDER VETERANS

Cheryl Parham[1], and Janet Prvu Bettger[2], *1. Baltimore Gerofit Program, Baltimore, Maryland, United States, 2. Duke University, Durham, North Carolina, United States*

The pandemic helped us overcome many of the barriers we had struggled with for group based exercise. Within six weeks, all of our sites had transitioned to group-based virtual classes, aptly called Gerofit to Home (GTH). Because of the rapid and continuously evolving changes in telehealth, we had near daily Veteran feedback on what was working and what was not working. Part of this planning included retaining a smaller group of Veterans on a regular basis who would serve as an ongoing Gerofit Veterans Advisory Panel (VAP). The VAP is a racially and geographically diverse group of 12 men and women Veterans from 7 different sites, with varying levels and duration of participation in Gerofit (some exclusively remote, some in-person then transition to remote with the pandemic). This presentation will feature a moderated discussion with VAP representatives, summarizing the perspectives provided on Veteran preferences, needs, and motivators to engage in GTH.

SESSION 4270 (SYMPOSIUM)

ENRICHING OUR DISCOVERY BY TRAINING FOR ENGAGEMENT: METHODS FOR PATIENT/PERSON ENGAGEMENT IN RESEARCH

Chair: Rachel Lessem Co-Chair: Martina Roes Discussant: Katherine Abbott

There has been a recent movement towards greater involvement of the patient/person voice in aging research. However, many researchers embark on engaged research without adequate training or knowledge and without the skills or experience to train those they hope to engage. We define engaged research as research topics, designs, methods, analyses and/or dissemination strategies that have been informed through collaboration with or input from those who have a direct stake in research. This symposium explores education as a method of engaged research and is premised on the notion that engaged research enriches our discovery and ultimately leads to better outcomes in interventions as well as policy. There is an identified need for training of researchers as well as stakeholders in order to do successful engaged research. This symposium details educational methods for training those who utilize engaged research: student, researcher, and patient/person stakeholder, culminating in an examination of supporting patients in being trainers themselves. The first presentation investigates an overarching educational strategy to change the research paradigm. The second presentation explores a unique method for training researchers to engage older adults as advisory board members. The third presentation details a strategy for training a specific group of older adults to be active in engaged research. The symposium concludes by highlighting a method by which older adults engage in a research intervention as trainers. Attendees will be able to identify and evaluate the outcomes of the different educational methods and translate these methods to new settings.

TRAINING RESEARCHERS TO CREATE RESEARCH ADVISORY BOARDS WITH OLDER ADULTS

Rachel Lessem[1], and Rebecca Berman[2], *1. CJE SeniorLife, Chicago, Illinois, United States, 2. Leonard Schanfield Research Institute, Chicago, Illinois, United States*

The Sage Resource Project's goal was to prepare researchers to use the Sage Resources to create Sage Model boards in order to continue to expand and amplify the voice of older adults in aging PCOR/CER research. Training researchers is essential to amplify the voice of older adults in research. This project culminated in the creation of a training manual as well as critical lessons learned for the advancement of engaged research with older adults receiving Long Term Services and Supports (LTSS). After developing a series of webinars for national dissemination, 5 research centers were identified as potential sites for intensive and tailored training on The Sage Model and, ultimately, two research centers completed the training with quite different approaches and results. This session will review the training that was developed as well as the lessons learned from training researchers on creating research advisory boards with older adults.

BUILDING CAPACITY FOR PATIENT-CENTERED OUTCOMES RESEARCH IN AGING RESEARCH: TRAINING ACROSS THE CONTINUUM

Erin McGaffigan[1], and Marc Cohen[2], *1. UMASS Boston Gerontology Institute, North Reading, Massachusetts, United States, 2. University of Massachusetts Boston, Boston, Massachusetts, United States*

Patient-centered outcomes research (PCOR) models are increasingly used to ensure stakeholders inform evidence-based systems of care. Unfortunately, older adults are often left out of PCOR, leading to continued health and service disparities. The Aging PCOR Learning Collaborative was funded by the Patient-Centered Outcomes Research Institute in 2020 to conduct a series of training activities to change how older adults are viewed and engaged in research. Training was extended to Gerontology students, researchers new to engagement, established researchers, and to older adults to advance the strategies needed to infuse PCOR within aging research design and implementation. Project staff analyzed data relevant to these activities, which demonstrated the project's reach to over 300 older adults, researchers, funders, and academic leaders. This session will review the steps required to implement training, our project reach, outputs, and mid-term outcomes, providing one of the first glimpses into how to measure this shift in our research paradigm.

TRAINING LONG-TERM SURVIVORS OF HIV TO ENGAGE IN RESEARCH TO IDENTIFY PRIORITIES FOR AGING WITH HIV

Andy Rapoport[1], Rachel Lessem[2], and Margaret Danilovich[3], *1. Leonard Schanfield Research Institute, CJE SeniorLife, Chicago, Illinois, United States, 2. CJE SeniorLife, Chicago, Illinois, United States, 3. Leonard Schanfield Research Institute, Chicago, Illinois, United States*

With effective antiretroviral therapies, HIV has become a chronic disease. Currently, >50% of people living with HIV are 50+ years old, and they face dual challenges of aging and HIV management. Overall, <15% of published studies in HIV engage stakeholders in research. These rates are even lower for older adults with HIV. Thus, there is a critical need to engage long-term survivors in developing meaningful research questions for aging with HIV. To address this gap, we created the SHARE (Survivors of HIV Advocating for Research Engagement) board. Presenters will discuss the process for building the board's research capacity and results of a community needs assessment that board members designed and conducted to ascertain priorities for HIV-aging research. Presenters will discuss evidence-based educational strategies utilized to build member research knowledge, and pre-post training changes in knowledge, confidence, and understanding. Presenters will focus on novel training approaches implemented in the remote environment.

RECRUITING, FACILITATING, AND SUPPORTING PERSONS LIVING WITH DEMENTIA AS TRAINERS IN RESEARCH

Jen Hirsch[1], Fei Sun[1], Dan Cohen[2], Ha-Neul Kim[1], Steven Barbieri[3], and Brian LeBlanc[3], *1. Michigan State University, East Lansing, Michigan, United States, 2. Right to Music, Mineola, New York, United States, 3. National Council of Dementia Minds, Alma, Michigan, United States*

Research demonstrates that dementia education programs are effective in improving knowledge of dementia, but it takes more effort to change attitudes or skill sets. Empathy toward people living with dementia (PLWD) is low among college students due to lack of experience interacting with PLWD. Exposure to PLWD is recommended in training aimed to improve dementia literacy. We engaged PLWD from an active advocacy group, The National Council of Dementia Minds, to be co-trainers in an intervention with college students in health and social care professions to provide quality care for PLWD. Presenters will discuss the process for recruiting, engaging, and training PLWD successfully, including explanation of informed consent, preparation for training sessions, and structural support around communication and information processing needs. Emphasis will be on lessons learned directly from our co-trainers for successful support mechanisms, particularly in an online environment as all interaction occurred primarily over zoom and email.

SESSION 4280 (SYMPOSIUM)

EXCURSIONS INTO HEALTHCARE SYSTEMS TO HELP INFORMAL CAREGIVERS MANAGE DEMENTIA

Chair: Richard Fortinsky Discussant: Christopher Callahan

With the establishment in 2019 of the National Institute on Aging-funded IMPACT Collaboratory, the era of designing and implementing pragmatic clinical trials in partnership with health care systems to improve care and health-related outcomes for people living with dementia (PLWD) is well underway. An important focus for Collaboratory-funded work involves targeting and engaging family and other informal caregivers of PLWD across health care system settings. In this Symposium, we feature three Collaboratory-funded investigators who are partnering with health care systems to determine how to engage informal caregivers most pragmatically, with the goals of improving caregivers' capacity to manage dementia and provide sustained input into the clinical care of PLWD. Symposium presenters Quincy Samus and Hillary Lum are the first two Collaboratory-funded Health Care System Scholars and Richard Fortinsky is a pilot study awardee. Dr. Samus will present on her experiences and lessons learned in her multiple efforts to adapt and embed the MIND at Home family-focused care management model into health care systems, including her current work with a large managed care organization. Dr. Lum will explain ongoing capacity-building stakeholder engagement activities at a large academic health system in preparation for pragmatic clinical trials for PLWD and their caregivers. Dr. Fortinsky will present on experiences and lessons learned from ongoing efforts to identify caregivers of PLWD to join caregiver support programs, and store caregiver data electronically, in two health system outpatient care settings. Dr. Christopher Callahan, Leader of the Training Core for the Collaboratory, will serve as Symposium Discussant.

PILOT STUDY TO PRAGMATICALLY EMBED CAREGIVER DEMENTIA EDUCATION AND SUPPORT IN HEALTH CARE SYSTEMS

Richard Fortinsky, *University of Connecticut Center on Aging, Farmington, Connecticut, United States*

Evidence-based interventions offering meaningful benefits to informal caregivers of people living with dementia (PLWD) would be attractive to office-based practitioners if pragmatic linkages could be made between these interventions and outpatient care settings. This presentation will explain experiences and lessons learned in an ongoing pilot study in which we are: pragmatically identifying and inviting caregivers of PLWD to join online dementia education and support programs; collecting and storing caregiver outcomes data into electronic health records where these data are accessible to clinicians. Participating outpatient health care settings are a geriatrics practice at UConn Health and a memory care clinic at Emory Healthcare. Caregivers recruited at both sites participate in either Tele-Savvy or Caregiving During Crisis programs. Outcomes data will inform effects of program participation on caregivers' competence and stress, and help clinicians gain insights into caregivers' capacity to manage PLWD. Implementation evaluation strategies and results also will be discussed.

BUILDING CAPACITY FOR DEMENTIA CAREGIVER TOOLS AND PRAGMATIC TRIALS THROUGH STAKEHOLDER ENGAGEMENT

Hillary Lum, *University of Colorado Anschutz Medical Campus, Aurora, Colorado, United States*

Caregivers face challenges communicating and coordinating health-related needs on behalf of persons living with dementia (PLWD). This presentation will highlight capacity building activities at UCHealth, a large academic health system in Colorado and Wyoming, to prepare for pragmatic clinical trials to test integrated health informatics tools to improve the care of PLWD and their family caregivers. We will describe foundational activities of: 1) convening diverse patient and family caregivers to identify communication priorities and refine health informatics tools, 2) engaging health system leaders to develop a system-based value proposition, and 3) partnering with health informatics teams to adapt tools (i.e., dementia registry, refined patient portal tools) and implement reports of pragmatic outcomes. Through support as an NIA IMPACT Health Care System Scholar, we will discuss lessons learned related to highlighting the preferences of diverse caregivers, especially related to use of health informatics tools in the context of dementia care.

FLEXIBILITY MEETS COMPLEXITY: LESSONS FROM EMBEDDING A DEMENTIA CARE COORDINATION MODEL IN PRACTICE

Quincy Samus, *Johns Hopkins School of Medicine, Baltimore, Maryland, United States*

People living with dementia (PLWD) are among the highest-need and highest-cost individuals because of the complexity, duration, and range of medical, behavioral, environmental, and social needs. There is a growing evidence base showing that family-centered active management approaches that include activation and empowerment of care partners are well suited to improve care quality and health-related outcomes, and have potential to curb high ADRD-related healthcare costs. This presentation will outline key experiences and lessons learned after a decade of work developing, adapting and embedding a comprehensive family-focused care management model called MIND at Home into practice. The work, supported in part by the IMPACT Collaboratory Health Care System Scholars Award to partner with Centene Corporation, a large managed care organization, illustrates two overriding principles: (1) the necessity of "meeting people and health systems where they are" (literally and figuratively), and (2) the importance of effectively matching intervention to outcome and context.

SESSION 4290 (PAPER)

FRAILTY AND PHYSICAL AGING

ABNORMALITIES IN THE CITRATE CYCLE METABOLISM ARE ASSOCIATED WITH DECLINED INTRINSIC CAPACITY IN OLDER ADULTS

Yiming Pan, Pan Liu, Yun Li, and Lina Ma, *Xuanwu Hospital Capital Medical University, Beijing, Beijing, China (People's Republic)*

Background:

Aging is accompanied by a decline in physical and mental functions, manifested as the declines in intrinsic capacity. However, there is still a lack of understanding about the metabolic mechanisms underlying the declining intrinsic capacity. Objective: To explore the metabolic characteristics and pathways of the declines in intrinsic capacity with the assistance of metabolomics methods.

Methods: Our study recruited 38 participants in total. The Short Physical Performance Battery, Mini-Mental State Exam, 30-item Geriatric Depression Scale, self-reported hearing/visual impairment and Mini Nutritional Assessment were used to assess the five domains of intrinsic capacity respectively. The untargeted liquid chromatography-mass spectrometry-based metabolomics was performed on the serum of participants. Multivariate statistical analysis and pathway analysis were then implemented.

Results: Among the 38 participants aged 66.50±15.20 years, 22 were with the declines in at least one domain of intrinsic capacity. In the 349 identified metabolites, 35 were candidate biomarkers for declining intrinsic capacity with variable importance in the projection > 1.5 and $p < 0.05$. Citrate cycle, tryptophan metabolism, phenylalanine and tyrosine metabolism, and Arginine biosynthesis were significant pathways associated with the declines in intrinsic capacity.

Conclusions: Decreased intrinsic capacity is an age-related change with characteristic metabolomics features. Many pathways, especially the dysregulation of the citrate cycle metabolism, may be involved in the pathogenesis of intrinsic capacity decline.

ARE INTRINSIC CAPACITY AND MULTIMORBIDITY ASSOCIATED TO FRIED'S FRAILTY REVERSIBILITY?

Emmanuel Gonzalez Bautista[1], Aarón Salinas Rodríguez[2], Ana Rivera Almaraz[2], and
Betty Soledad Manrique Espinoza[2], *1. Institute of Aging. Toulouse University Hospital (CHU Toulouse)., Toulouse, Midi-Pyrenees, France, 2. National Institute of Public Health, Cuernavaca, Morelos, Mexico*

Our objective was to characterize older adults with reversible frailty in their baseline intrinsic capacity and multimorbidity status. MethodsWe used data from the most recent waves of the SAGE Mexico study (3 and 4), representative of older adults at a national level. Study n=749. We objectively measured gait speed and grip strength based on Fried's frailty criteria. Weight loss exhaustion was self-reported and physical activity (using the IPAQ). Reversible frailty was defined as going from frailty to pre-frail or robust and from pre-frail to robust. Worsening and stable frailty were coded similarly. Intrinsic capacity was measured using a summary index (0-100) based on five domains: cognition, locomotion, sensory, nutrition, and psychological. Multimorbidity was coded yes/no if the participant self-reported two or more chronic conditions. We compared the odds of being in the reverse group versus not in it according to baseline intrinsic capacity score and multimorbidity status, adjusting for age, sex, rural/urban, and wealth. ResultsReversible frailty=33% of those pre-frail or robust at baseline. Intrinsic capacity was higher in the reverse group than in those with worsening frailty but not significantly higher than those with stable frailty.Having multimorbidity significantly decreased the chances of frailty reversibility, adjusting for covariates. ConclusionsAs an expression of lifecourse damage to the physiological reserve, multimorbidity limits the chances of reversible frailty in Mexican older adults. High levels of intrinsic capacity did not characterize frailty reversibility in our study. Yet, low intrinsic capacity levels are a marker for older adults prone to frailty worsening.

PATTERNS OF AGING CHANGES IN BODY WEIGHT AND BMI MAY PREDICT CHANCES OF ALZHEIMER'S DISEASE AND LONGEVITY

Svetlana Ukraintseva, Konstantin Arbeev, Hongzhe Duan, Rachel Holmes, Igor Akushevich, Arseniy Yashkin, Heather Whitson, and Anatoliy Yashin, *Duke University, Durham, North Carolina, United States*

Background: Lower bodyweight/BMI was previously linked to AD and frailty; however, the role of long-term changes in the bodyweight/BMI in both AD and longevity is not well understood, as is the role of APOE polymorphism in such changes.

Methods: Using longitudinal data from the Framingham Heart Study (FHS) and the Health and Retirement Study (HRS), we estimated trajectories of the weight and BMI at ages 40 to 75, and compared them between individuals who did and who did not develop AD at ages 75+. We also evaluated associations between APOE4 carrier status and key characteristics of the age-trajectories of weight/BMI, including the age at peak value of the bodyweight/BMI (AgeMax), and slope of the decline in bodyweight/BMI after reaching the maximum.

Results: Women with late-onset-AD had lower bodyweight/BMI values up to three decades before AD diagnosis. They reached the peak of bodyweight in their 50s, about 10 years earlier than AD-free women. Younger AgeMax was associated with lower survival chances after age 80 in women. APOE4 carriers showed earlier/faster declines in weight and BMI than non-carriers; however, relevance of this to AD was unclear.

Conclusion: Younger age at peak value of the bodyweight/BMI indicates higher chances of late-onset-AD, while older age can predict better survival later in life and may favor longevity in women. The earlier start of the decline in bodyweight/BMI values could be sign of accelerated aging, which may contribute to AD. Relevance of APOE4 effects on age-trajectories of weight/BMI to AD warrants further investigation.

THE ROLE OF SYSTEMIC INFLAMMATION IN HEALTH NOW, LATER, AND CHANGE OVER TIME: EVIDENCE FROM MIDUS

Julie Ober Allen, *University of Oklahoma, Norman, Oklahoma, United States*

Systemic inflammation is theorized to be a biological pathway through which chronic stressors (e.g., discrimination, social marginalization) contribute to adverse health outcomes and disparities among older adults. Cross sectional research documents associations between inflammation and a broad array of health outcomes. Less is known about whether and how inflammation may influence health longitudinally. This study investigated whether a composite measure of inflammatory burden predicted physical health: a) concurrently, b) approximately 7 years later, and c) changes during that time. Data derive the National Survey of Midlife in the United States (MIDUS) participants who provided inflammatory biomarker data (2004-2009 Biomarker study) and health data in MIDUS 2 (2004-2006) and MIDUS 3 (2013-2014) (N=931, Mage 57, 45% male, 91% White). Inflammatory burden reflected the number of inflammatory biomarkers in the highest risk quartile, out of five: C-reactive protein, interleukin-6, fibrinogen, E-selectin, and intracellular adhesion molecule. Three general indicators of physical health were examined: number of commonplace chronic physical health conditions, out of 7; functional limitations; and self-rated physical health. Multivariate regression analyses indicated that inflammatory burden predicted all three concurrent physical health outcomes and the same health outcomes seven years later (p-values <.02). Inflammatory burden was unrelated to changes in these outcomes over time. This study adds to the literature on stress-related biological mechanisms of health and identifies a potential clinical indicator of enduring health problems. It also suggests that while inflammatory burden may demonstrate consistent relationships with physical health over time, other mechanisms may account for health changes and deterioration.

SESSION 4300 (SYMPOSIUM)

INNOVATIVE CARE ENVIRONMENTS FOR PEOPLE WITH DEMENTIA

Chair: Hilde Verbeek Co-Chair: Bram de Boer Discussant: Marie Boltz

As part of the ongoing culture movement within long-term care several innovative care concepts for people with dementia are developing. These concepts radically change their physical, social and/or organizational environment in order to align care services with needs and demands of people with dementia, and providing meaningful activities. The current symposium will discuss the effects and possible working mechanisms of innovative caring environments for people with dementia across three European countries and the US. The symposium will start with a presentation describing the Homestead care model in the Netherlands, which is a care model that was developed following a co-creation study focused on translating scientific knowledge on nursing home care environments into practice. This is followed by three presentations about the effects of three types of innovative care environments for people with dementia: (1) farm based day care in Norway, (2) shared housing arrangements in Germany, (3) green care farms providing 24-hour nursing care in the Netherlands. The three studies on the effects of innovative care environments present a variety of designs (case study, cluster randomized controlled multi-center intervention study, and a qualitative study with semi-structured interviews) to study the effects on various outcomes (activities, physical effort, social interaction, mood, the number of hospital admissions for people with dementia, quality of life, challenging behavior, risk of falls, stabilization of cognitive abilities, daily life). The symposium will conclude with a reflection on these innovative care concepts from a US perspective.

TRANSLATING SCIENCE INTO PRACTICE TO DEVELOP AN INNOVATIVE DEMENTIA CARE MODEL: THE HOMESTEAD CARE MODEL

Bram de Boer, *Maastricht University, Maastricht, Limburg, Netherlands*

This study reports on a participatory research approach to translate a scientific conceptual framework on innovative dementia care into practice. This led to the development of the Homestead care model. Results indicate that achieving positive outcomes for people with dementia, (in)formal caregivers, and the community is dependent on how well the physical, social and organizational environment are congruently designed. Physical aspects are related to interior design, outdoor areas, architecture and sensory elements. Social aspects include interactions with others in the environment, such as residents, staff, family, and the wider community (local entrepreneurs, societies, schools). Organizational aspects are related to the organizational culture and leadership of a care facility. These theoretical underpinnings of the conceptual model have been translated into three main pillars of the Homestead care model: activation, freedom, and relationships. The Homestead care model has a unique physical, social and organizational environment, which can affect daily life of residents.

TURNING THE ORDINARY INTO THE EXTRAORDINARY: EXPERIENCES OF PROVIDING FARM-BASED DAYCARE FOR PEOPLE WITH DEMENTIA

Ingeborg Pedersen, *Norwegian University of Life Sciences, Ås, Akershus, Norway*

This study gives a deeper understanding of how service providers think and work when offering farm-based days care (FDC) services for people with dementia. Seven semi-structured interviews with service providers, analyzed using text condensation, resulted in the five main themes; “On fertile ground”; “The foundation”; “Activities with rippling effects”, “Positive social and emotional environment” and, “Making room”. The theme “On fertile ground”, reflects the ordinary aspect of the farm context; closeness to nature and the home-like atmosphere. “The foundation” describes the extraordinary aspect of FDC; the service providers relentless effort to tailor all aspects of the service to the attendees. These two themes lay the foundation for the activities, the social setting, and possibilities for having a personal focus, reflected in the three remaining themes. The study gives an enhanced understanding of the key role of the service provider and how they offer person-center care in the farm context.

RISK REDUCTION OF HOSPITAL ADMISSIONS FOR PEOPLE WITH DEMENTIA IN SHARED-HOUSING ARRANGEMENTS: THE DEMWG STUDY

Karin Wolf-Ostermann[1], Susanne Stiefler[2], Annika Schmidt[2], Anna-Carina Friedrich[2], Elmar Gräßel[3], Carolin Donath[3], Jennifer Scheel[3], and André Kratzer[3], *1. University of Bremen, Bremen, Bremen, Germany, 2. Institute of Public Health and Nursing Research, University of Bremen, Germany, Bremen, Bremen, Germany, 3. Universitätsklinikum Erlangen, Department of Psychiatry and Psychotherapy, Center for Health Services Research, Erlangen, Bayern, Germany*

People living with dementia (PlwD) have an increased risk of hospital admission which may result in severe consequences. The DemWG-study therefore aims to investigate whether a complex intervention in shared housing arrangements (SHA) for PlwD reduces the number of hospital admissions. Furthermore, quality of life, risk of falls, and stabilization of cognitive abilities are assessed. The intervention includes motor and cognitive training for PlwD and education of caregivers and general practitioners. The study is conducted in 88 SHA in Germany with a total of 330 PlwD and a 6 months intervention. Data are collected up to 18 months after baseline, including quantitative and qualitative data. Results from caregivers’ perspectives on the intervention designate a perceived improved social interaction, which in turn has a positive effect on living together in the SHA. Based also on the results of the ongoing quantitative assessments recommendations for better care and support will be derived.

HOW DO GREEN CARE FARMS FOR PEOPLE LIVING WITH DEMENTIA SUCCESSFULLY INTEGRATE OUTDOOR SPACES?

Katharina Rosteius, Bram de Boer, and Hilde Verbeek, *Maastricht University, Maastricht, Limburg, Netherlands*

Green Care Farms (GCFs) are an innovative care environment for vulnerable groups. This study explores the design, and the successful integration of the natural environments of GCFs. By actively integrating outdoor spaces into daily care, they may encourage residents to participate in meaningful activities. A case study was conducted on a Dutch GCF using mixed ethnographic methods. 129 hours of observations of daily life were combined with 24 semi-structured interviews with residents, family, volunteers, staff and management, and a focus group with staff. The physical environment was assessed quantitatively. Data was analyzed thematically and triangulated. Results indicate that some factors supported the integration of the outdoor spaces into daily care. First, the physical environment was specifically designed to stimulate residents. Second, the outdoors was easily and openly accessible for residents. Third, residents' security was supported in several ways. Lastly, staff members creatively motivated residents to use the outside spaces.

SESSION 4310 (SYMPOSIUM)

LESSONS FROM CAPABLE: DRIVERS, IMPLEMENTATION EXPERIENCE, AND MARKET READINESS CONSIDERATIONS

Chair: Deborah Paone Co-Chair: Sarah Szanton

External, organizational, and individual factors which drive or restrain adoption, implementation, and scaling of CAPABLE provide lessons for other programs to move from research to practice and promote sustainability. Lessons are offered for policymakers, payers, consumers, and communities to support evidence-based programs that improve function and reduce disability for older adults. This symposium presents results from a 3-year study of implementation of CAPABLE by 40 organizations, an analysis of the drivers and restrainers of CAPABLE dissemination, and a 1-year pilot study on engaging unpaid care partners in CAPABLE. We will explore the lessons from each--finding synergy and unique insights. CAPABLE is a case example to guide efforts at the organizational, system, and societal levels.

CAPABLE IMPLEMENTATION: PROGRESS AND BARRIERS

Deborah Paone[1], and Sarah Szanton[2], *1. Johns Hopkins University, Baltimore, Maryland, United States, 2. Johns Hopkins University School of Nursing, Baltimore, Maryland, United States*

CAPABLE is an evidence-based 4-to-6-month program that improves daily function and the home environment based on the older adult's goals. Study aims were to: (1) understand context and readiness factors in implementation, (2) identify barriers and facilitators, and (3) examine the utility of two frameworks. The unit of analysis was the organization. We employed the CFIR and RE-AIM frameworks for this qualitative study, using multiple data sources and traced the implementation of 40 organizations over 3 years. Leadership support, perceived value of the program, initial funding, strategic importance, and program champion were common supportive factors. Common challenges included difficulty with recruitment, staffing and infrastructure readiness and sustainability of funding. This study indicates readiness, technical support, and resources needed for implementation and sustainability of CAPABLE and suggests external environmental supports needed. It offers a practical way to monitor, evaluate, and report on ongoing implementation of evidence-based programs.

DRIVERS AND RESTRAINERS OF CAPABLE DISSEMINATION

Sarah Szanton[1], and Deborah Paone[2], *1. Johns Hopkins University School of Nursing, Baltimore, Maryland, United States, 2. Johns Hopkins University, Baltimore, Maryland, United States*

Using the technique of Force Field Analysis, the co-developer of CAPABLE examined drivers and restrainers of dissemination for the CAPABLE program. This generated 19 distinct drivers including robust research findings, demonstrated clinical and economic utility, and high value to older adults. The environmental shift toward value-based approaches in Medicare and Medicaid also increased the perceived value of CAPABLE. In addition, there were 8 restrainers, including component complexity, siloed health and housing sectors, and the operational lift needed to build the program. Lessons are offered from this case study to move from research to embedded practice.

UNDERSTANDING POTENTIAL INVOLVEMENT OF CARE PARTNERS IN CAPABLE

Beth Fields[1], and Pamela Toto[2], *1. University of Wisconsin-Madison, Madison, Wisconsin, United States, 2. University of Pittsburgh, Pittsburgh, Pennsylvania, United States*

This qualitative study focused on understanding how to involve unpaid care partners ('family members or friends') of older adults who are participating in CAPABLE. Using field notes, focus groups, and key informant interviews, the study revealed considerations for involving care partners, including providing choices, defining roles, sharing information in a collaborative manner, and reinforcing knowledge and skills training. These findings can help guide organizations interested in involving care partners in their older adult programs.

SESSION 4320 (PAPER)

MEASURES AND PROFILES OF FRAILTY AND FUNCTION

ASSOCIATION BETWEEN COGNITIVE FRAILTY AND ORAL HEALTH IN COMMUNITY-DWELLING OLDER ADULTS IN KOREA

Yoonjung Ji[1], Jane Chung[2], and TaeWha Lee[1], *1. Yonsei University, Seoul, Seoul-t'ukpyolsi, Republic of Korea, 2. Virginia Commonwealth University, Richmond, Virginia, United States*

Cognitive frailty(CF) is a condition where physical frailty and mild cognitive impairment (MCI) co-exist without dementia. CF is related to adverse health outcomes, such as functional disability, hospitalization, depression, and mortality. Studies suggest that poor oral health is also associated with a greater risk of frailty, a significant healthcare challenge in aging populations. However, no previous studies have investigated the association between oral health and CF. This study aimed to assess the prevalence and its association with oral health. A secondary analysis was conducted using the 7th wave dataset from the Korean Longitudinal Study of Aging collected in 2018. Individuals aged ≥65 years, without dementia and pre-frailty were included (N=750, mean age 73.2 years). Participants were classified into either robust (n=635) or CF (n=115) based on the presence or absence of CF. Oral health was assessed using the Geriatric Oral Health Assessment Index (GOHAI). Poor oral health was prevalent in both robust and CF groups (58.6% and 95.7%, respectively). Logistic regression analyses were conducted to investigate the associations of CF with oral health. CF was significantly associated with GOHAI scores ($B = -0.153$, 95% CI: 0.833-0.884, $p < 0.001$). The association remained significant after adjusting for age, sex, educational level, smoking, drinking, comorbidities, and body mass index ($B = -0.140$, 95% CI: 0.836-0.904, $p < 0.001$). The presence of oral health problems was associated with greater risks of developing CF in older age. The identification and management of poor oral health is critical to preventing cognitive frailty in older adults.

CREATION AND VALIDATION OF A POLYSOCIAL SCORE FOR PHYSICAL FRAILTY AMONG COMMUNITY-DWELLING OLDER ADULTS IN THE US

Chenkai Wu, and Junhan Tang, *Duke Kunshan University, Kunshan, Jiangsu, China (People's Republic)*

The interrelatedness between social determinants of health impedes researchers from identifying important social factors for health investment. A new approach is needed to quantify the aggregate effect of social factors and develop person-centered social interventions. Data are from the Health and Retirement Study; 6,075 older adults initially not frail (non-frail or prefrail) were included. Frailty was assessed by slowness, weakness, exhaustion, inactivity, and shrinking. Persons were classified as "nonfrail" (0 criteria), "prefrail" (1–2 criteria), or "frail" (3–5 criteria). We included 24 social factors from five categories (economic stability, neighborhood environment, education, community/social context, and healthcare system) and used forward stepwise regression to screen for important ones. Polysocial score was created using 15 social factors and was classified as low (0-29), intermediate (30-42), and high (43+). We used the Poisson regression to estimate the risk of incident frailty by three polysocial score categories. We found that 444 (34.5%), 651 (17.9%), and 108 (9.4%) cases of incident frailty at the 4-year follow-up among participants with a low, intermediate, and high polysocial score, respectively. In the multivariable-adjusted Poisson model, the risk of frailty among participants in the intermediate and high polysocial score categories was 35% and 59% lower than those in the low polysocial score category, respectively. We found a universal association between polysocial scores and frailty across race/ethnicity and sex subgroups. The polysocial approach may offer possible solutions to monitor social environments and suggestions for older people to improve their social status for specific health outcomes.

DISTINCT PROFILES OF SEDENTARY BEHAVIORS IN OLDEST OLD ADULTS

Katelyn Webster[1], and Weijiao Zhou[2], *1. Indiana University, Indianapolis, Indiana, United States, 2. University of Michigan, Ann Arbor, Michigan, United States*

Sedentary behavior (SB) is a significant health risk. Emerging research suggests that mentally active SB (such as computer use and reading) were associated with better health than mentally passive SB (such as watching TV). However, this has not been examined among the oldest old (age ≥80). The aims of this study were to (1) identify distinct profiles of oldest old adults based on six domains of SB (watching TV, using a computer/tablet, talking to friends or family members, doing hobby or other activities, transportation, and resting/napping); and (2) compare health-related outcomes across identified profiles, using the National Health and Aging Trends Study (NHATS) dataset. Latent profile analysis was used to identify distinct profiles of SB. Design-based linear and logistic regressions were used to examine associations between different profiles and health outcomes, accounting for sociodemographic characteristics. We identified four profiles and named them based on total sedentary time (ST) and passive/active pattern (n=852, "Low ST", "High ST-passive", "Medium ST-TV", "High total ST-mentally active"). Compared to the "High ST-passive" group, "Low ST" group was associated with fewer difficulties with activities of daily living, fewer problems limiting activities and higher cognitive function; "High ST-mentally active" group was associated with the above outcomes, as well as lower anxiety and depression. This study, with a national representative sample of the oldest old population, suggests that both total ST and SB pattern matter when evaluating health outcomes of being sedentary. Interventions should encourage oldest old adults to reduce ST and especially target mentally passive ST.

FRAILTY AND CARDIOVASCULAR DISEASE EVENTS IN COMMUNITY-DWELLING HEALTHY OLDER ADULTS

A R M Saifuddin Ekram[1], Sara Espinoza[2], Joanne Ryan[3], Michael Ernst[4], Andrew Tonkin[3], Christopher Reid[5], John McNeil[3], and Robyn Woods[3], *1. Monash University, Nunawading, Victoria, Australia, 2. Sam and Ann Barshop Institute, UT Health San Antonio, San Antonio, Texas, United States, 3. Monash University, Melbourne, Victoria,* *Australia, 4. The University of Iowa, Iowa City, Iowa, United States, 5. Curtin University, Perth, Western Australia, Australia*

BACKGROUND: Frailty is associated with adverse outcomes, but whether it independently increases cardiovascular disease (CVD) risk requires clarification.

METHODS: This study examined the association between frailty in a cohort with no previous CVD events and subsequent CVD outcomes in 19,114 community-dwelling older people from the ASPREE trial. Frailty was assessed using the modified Fried phenotype, comprising weakness, exhaustion, low body mass index (BMI), slowness and low physical activity, and a deficit accumulation frailty index (FI) of 66 items. CVD event was defined as a composite of CVD death, non-fatal myocardial infarction, non-fatal stroke and hospitalization for heart failure.

Results: Over a median 4.7-years of follow-up (interquartile range: 3.6 to 5.7 years), pre-frail/frail participants were more likely to develop CVD events (Hazard ratio (HR): 1.33; 95% Confidence Interval (CI): 1.16, 1.53 for pre-frail and HR: 1.68; 95% CI: 1.19, 2.38 for frail participants) according to Fried phenotype. Subtypes of CVD (fatal/non-fatal myocardial infarction and heart failure hospitalization) similarly increased HRs except fatal or non-fatal stroke. These effect sizes were more prominent when frailty was assessed using the FI than that assessed by Fried phenotype.

CONCLUSION: Pre-frail and frail participants were at significantly increased risk of developing CVD and its subtypes (particularly fatal/non-fatal myocardial infarction and hospitalization for heart failure). Addressing pre-frailty and frailty in older people could contribute to CVD prevention strategies.

TRANSLATION OF A MEDICARE CLAIMS-BASED FRAILTY ALGORITHM FROM ICD-9-CM TO ICD-10-CM

Keturah Faurot[1], Emilie Duchesneau[1], Shahar Shmuel[2], Jihye Park[1], Til Stürmer[2], Michele L. Jonsson-Funk[1], and Jennifer L lund[1], *1. University of North Carolina at Chapel Hill, Chapel Hill, North Carolina, United States, 2. Gillings School of Global Public Health, Chapel Hill, North Carolina, United States*

Clinical trials often have insufficient power to estimate drug effects in older adult populations. Medicare claims data are a valuable resource for studying healthcare delivery for older adults. The Faurot frailty index (FFI) is a validated algorithm that uses demographic, enrollment, and ICD-9-CM-based claims information to predict ADL dependency as a proxy for frailty. The original FFI consists of 20 constructs, including those related to geriatric syndromes, of which 16 are based on ICD-9-CM diagnosis codes (e.g., arthritis, dementia). In October 2015, the US healthcare system transitioned to ICD-10-CM. In this study, we updated and validated the FFI for the ICD-10-CM era . We used General Equivalence Mapping (GEM) to translate the ICD-9-CM codes to ICD-10-CM. For each construct, we manually reviewed the ICD-10-CM codes after GEM, assessed the suitability, and plotted the monthly prevalence before and after the transition (2013-2017). Code lists for all but 1 construct required editing after translation using GEM (adding and/or removing codes). We observed increasing monthly prevalence for several constructs, although trend lines were consistent across the ICD-9-CM and ICD-10-CM eras: bladder dysfunction (1.8-2.5%), weakness (2.7-3.9%), and psychiatric illnesses (6.9-9.1%). Rehabilitation services did not translate well using diagnosis codes, however, adding CPT codes improved capture. The updated FFI was strongly associated with frailty-related geriatric outcomes (1-year mortality, hospitalization, SNF admission). Studies of drug effects in older adults should use validated indices, such as the FFI, to reduce bias. Thorough evaluation of claims-based algorithms is essential to support healthcare services research using these measures.

SESSION 4330 (SYMPOSIUM)

MOVING, THINKING, AND SLEEPING: NOVEL INSIGHTS INTO PHYSICAL AND COGNITIVE HEALTH FROM ACCELEROMETRY DATA

Chair: Jennifer Schrack Discussant: Amal Wanigatunga

Physical activity and sleep are well-established predictors of health and longevity with aging. Wrist accelerometers, that produce high-frequency time series data, capture multiple aspects of daily physical activity and sleep 24-hours/day. Historically, the majority of accelerometry-based activity research has employed summary metrics to understand the associations of total daily physical activity and sleep with physical and cognitive health. Although these measures are important for understanding conformity with physical activity and sleep recommendations, they underutilize the potential of these data. Further, the summary metrics may differ by accelerometer type/brand, making it difficult to translate results across device types and studies. This symposium will examine the associations between accelerometry-derived physical activity and various aging-related health outcomes, and compare the measurement properties of two commonly used accelerometers for measuring sleep. Ms. Marino will discuss the association of physical activity volume and fragmentation with the presence of the Apolipoprotein-ε4 genotype in the Baltimore Longitudinal Study of Aging (BLSA), overall and by time of day. Dr. Wanigatunga will present evidence on the association of physical activity patterns with beta amyloid plaques in the BLSA. Dr. Schrack will present the association of physical activity fragmentation and diurnal patterns with peripheral artery disease in the Hispanic Community Health Study/Study of Latinos (HCHS/SOL). Finally, Ms. Liu will compare measurement of sleep variables derived from two commonly used accelerometers. Collectively, these presentations highlight ways to utilize the richness of accelerometry data to illuminate more sensitive associations between movement and health outcomes to advance prevention science and promote health aging.

ANKLE BRACHIAL INDEX (ABI) AND ACCELEROMETER PATTERNS OF DAILY PHYSICAL ACTIVITY IN HCHS/SOL

Jennifer Schrack[1], Venus Chiu[2], Amal Wanigatunga[1], Daniela Sotres-Alvarez[3], Shoshana Ballew[2], Matthew Allison[4], Robert Kaplan[5], and Kunihiro Matsushita[2], *1. Johns Hopkins Bloomberg School of Public Health, Baltimore, Maryland, United States, 2.*

Johns Hopkins University, Baltimore, Maryland, United States, 3. University of North Carolina, Chapel Hill, North Carolina, United States, 4. University of California San Diego, La Jolla, California, United States, 5. Albert Einstein College of Medicine, Bronx, New York, United States

The benefits of routine engagement in physical activity (PA) on vascular health are well established; lesser known is whether vascular health associates with accelerometry-based daily patterns of PA in mid-to-late life. Using linear regression models adjusted for demographics and comorbidities, we modeled the cross-sectional associations between ankle brachial index (ABI) and PA patterns (diurnal activity and activity fragmentation) in 7,848 HCHS/SOL participants (45.5% men, 56.4±0.2 years). Compared to those with normal ABI (1.0-1.4), those with low ABI (≤0.9) had more fragmented daily activity (B=1.0%, SE=0.4, p=.04); primarily between 12 and 8 PM (B=1.66%, SE=0.55, p<.01). Similarly, those with low ABI had lower daily activity throughout the day (B=-0.09 log-counts, SE=0.05, p<.05) also mainly between 12 and 8 PM (B=-0.16 log-counts, SE=0.55, p<.01). Results suggest a diminished, less favorable PA profile patterns in those with low ABI. Future longitudinal studies should consider whether patterns of PA assist in determining PAD risk.

OBJECTIVELY MEASURED PHYSICAL ACTIVITY PATTERNS OVER 24-HOURS BY APOE-Ε4 CARRIER STATUS

Amal Wanigatunga[1], Francesca Marino[2], Fangyu Liu[1], Eleanor Simonsick[3], Qu Tian[4], Jennifer Deal[5], Susan Resnick[3], and Jennifer Schrack[1], *1. Johns Hopkins Bloomberg School of Public Health, Baltimore, Maryland, United States, 2. Johns Hopkins Bloomberg School of Public Health, Washington, District of Columbia, United States, 3. National Institute on Aging, Baltimore, Maryland, United States, 4. National Institutes on Aging, Baltimore, Maryland, United States, 5. Johns Hopkins University, Baltimore, Maryland, United States*

The Apolipoprotein-ε4 (APOE-ε4) genotype is associated with earlier onset and greater risk of β-amyloid deposition, but whether APOE-ε4 status is associated with physical activity amount or fragmentation remains unclear. In 563 BLSA participants aged 55-97 years with APOE-ε4 and ≥3 days of wrist accelerometry data, multivariable linear regression models were fitted to estimate differences in activity amount (daily or by 6-hour time blocks) or fragmentation by APOE-ε4 status and to test whether age modifies these effects. Overall, daily activity amount and fragmentation did not differ by APOE-ε4 status (p=0.28 and p=0.93, respectively). Yet, age significantly modified the APOE-ε4 effect. Per each additional year of age, APOE-ε4 carriers had less activity during early morning (12:00-6:00AM) than non-carriers (p=0.035). This association was non-significant among the oldest-old (p=0.697 at age 80 years, p=0.347 at age 90 years), suggesting possible decreases in the predictive power of APOE-ε4 with increasing age.

DIFFERENCES IN PHYSICAL ACTIVITY AMOUNT AND FRAGMENTATION OVER 24 HOURS BY Β-AMYLOID STATUS AND AGE

Francesca Marino[1], Fangyu Liu[2], Eleanor Simonsick[3], Qu Tian[4], Jennifer Deal[5], Amal Wanigatunga[2], Susan Resnick[3], and Jennifer Schrack[2], *1. Johns Hopkins Bloomberg School of Public Health, Washington, District of Columbia, United States, 2. Johns Hopkins Bloomberg School of Public Health, Baltimore, Maryland, United States, 3. National Institute on Aging, Baltimore, Maryland, United States, 4. National Institutes on Aging, Baltimore, Maryland, United States, 5. Johns Hopkins University, Baltimore, Maryland, United States*

β-amyloid is a hallmark of Alzheimer's disease and can be measured in vivo by PET imaging. Whether PiB+ (elevated β-amyloid) individuals exhibit distinct physical activity patterns throughout the day (i.e., activity amount or fragmentation) is unknown. Using data from 125 BLSA participants (56-95 years) with PET imaging and ≥3 days of wrist accelerometry, we examined associations between PiB status and activity patterns daily and during 6-hour time blocks using multivariable linear regression models. Modification by age was also examined. Daily total activity counts and activity fragmentation did not differ by PiB status (p=0.34 and p=0.70, respectively). Yet, per each additional year of age, PiB+ individuals were more active during early morning (p=0.04) and evening (p=0.029) but trended towards less active in mid-morning (p=0.069) than PiB- individuals. Though replication of findings is needed, older PiB+ participants appeared more active in the late evening/early morning, possibly reflecting altered sleep-time, agitation, or restlessness.

COMPARISON OF SLEEP PARAMETERS FROM WRIST-WORN ACCELEROMETERS IN OLDER ADULTS

Fangyu Liu[1], Jennifer Schrack[1], Sarah Wanigatunga[2], Jill Rabinowitz[1], Linchen He[1], Amal Wanigatunga[1], Eleanor Simonsick[3], and Adam Spira[4], *1. Johns Hopkins Bloomberg School of Public Health, Baltimore, Maryland, United States, 2. Johns Hopkins, University, Baltimore, Maryland, United States, 3. National Institute on Aging, Baltimore, Maryland, United States, 4. Department of Mental Health, Johns Hopkins Bloomberg School of Public Health, Baltimore, Maryland, United States*

Researchers often prefer different accelerometers for measurement of sleep and physical activity (PA) in older adults, but wearing multiple accelerometers increases costs and participant burden. We tested the hypothesis that the Actiwatch-2, commonly used to measure sleep, and the ActiGraph GT9X Link, commonly used to measure PA, yield comparable sleep parameters among 331 participants (aged 71+/-14 years, 50.5% women) who wore them simultaneously for 7+/-1.6 nights in the BLSA. Compared to the Actiwatch-2, the ActiGraph estimated 50% greater wake after sleep onset, 89% longer wake bout length, 18% lower sleep fragmentation index (SFI), 5% lower total sleep time (TST) and 5% higher sleep efficiency. Yet, despite yielding different absolute values of TST and SFI, the devices generated similar between-person (relative) differences in TST and SFI. These devices may only be interchangeable for measurement of some relative sleep parameters in older adults. Studies with both devices and gold-standard polysomnography are needed.

NOVEL INSIGHTS INTO GAIT, MOTOR CONTROL, AND THE BRAIN: IMPLICATIONS FOR COGNITIVE AGING

Andrea Rosso[1], Sarah Fraser[2], Roee Holtzer[3], Talia Salzman[2], Caterina Rosano[1], Emma Baillargeon[1], Briana Sprague[1], and Qu Tian[4], *1. University of Pittsburgh, Pittsburgh, Pennsylvania, United States, 2. University of Ottawa, Ottawa, Ontario, Canada, 3. Yeshiva University and Albert Einstein College of Medicine, New York, New York, United States, 4. National Institutes on Aging, Baltimore, Maryland, United States*

What can muscles, gait, and brain activity tell us about cognitive decline? Are there certain markers we can track that are early predictors of cognitive status years later? In the current symposia, our goal is to address these questions with recent pilot, longitudinal and cross-sectional studies that measure potential markers of cognitive decline in different older adult cohorts. The first speaker will present findings on changes in skeletal muscle adiposity and 10-year change in global cognition from the Health Aging and Body Composition (Health ABC) study. The second speaker explores cross-national comparisons of gait speed and its association with cognitive function from the Cohort Studies of Memory in an International Consortium (COSMIC). The third speaker investigates changes in brain activity with functional near infra-red spectroscopy (fNIRS) from single to dual-task walking and its relation to changes in several gait quality parameters. The fourth speaker presents pilot work that examines dual-task gait and tapping with fNIRS and compares the dual-task performance and brain activity of older adults who report experiencing subjective cognitive decline to those that do not. The final speaker presents findings from the Baltimore Longitudinal Study on Aging (BLSA) that demonstrate that early markers of slow gait and metabolic dysfunction could identify those at risk of progression to dementia 7 years prior to onset. Taken together, the findings from this symposium present novel markers of changes in cognitive function in older adults and ultimately targets for prevention or slowing of cognitive declines in older adults at risk for dementia.

WHAT CAN DUAL-TASK WALKING AND TAPPING TELL US ABOUT SUBJECTIVE COGNITIVE DECLINE? AN FNIRS STUDY

Talia Salzman[1], Hannah Perreault[1], Farah Farhat[1], Diana Tobon Vallejo[2], and Sarah Fraser[1], *1. University of Ottawa, Ottawa, Ontario, Canada, 2. Universidad de Medellin, Medellin, Antioquia, Colombia*

Older adults who pass standard cognitive tests but report subjective cognitive decline (SCD) may be identifying early changes in cognition at a stage when intervening can prevent further declines. Changes may be subtle highlighting the need for novel approaches, such as divided attention tasks, to distinguish between those with and without SCD. This pilot study examined 15 older women (9 SCD, 6 non-SCD) completing dual-task walking and tapping. Brain (cerebral oxygenation) and behavioural (gait and tap speed, accuracy, and vocal response) measures were assessed during single and dual-tasks. Older adults with SCD were marginally less accurate during dual-task tapping ($p < .06$) and had greater cerebral oxygenation than the non-SCD group ($p = .01$). SCD did not moderate gait speed from single to dual-task while non-SCD did ($p = .02$). Findings suggest that challenging dual-task paradigms may help identify different behavioural and brain activity markers of SCD and intervention targets.

INTERMUSCULAR ADIPOSITY: A NOVEL RISK FACTOR FOR COGNITIVE DECLINE IN A BIRACIAL COHORT OF OLDER ADULTS

Caterina Rosano[1], Anne Newman[1], Xiaonan Zhu[1], Adam Santanasto[2], Bret Goodpaster[3], and Iva Miljkovic[1], *1. University of Pittsburgh, Pittsburgh, Pennsylvania, United States, 2. School of Public Health, University of Pittsburgh, Oakmont, Pennsylvania, United States, 3. AdventHealth, Orlando, Florida, United States*

Skeletal muscle and brain health both decline with age. Poorer skeletal muscle characteristics may be early markers of cognitive decline. The Health ABC study obtained repeated measures of thigh intermuscular adiposity via CT (IMAT, Years 1 and 6) and Mini-Mental State Exam (MMSE, Years 1 through 10), in 1634 adults (69-79 years, 48% women, 35% black). Linear mixed effects models accounted for change (Years 1 and 6) in weight, muscle (strength, area), and adiposity characteristics (abdominal subcutaneous, visceral, total fat mass) and for dementia risk factors (education, APOE4, diabetes, hypertension, physical activity). IMAT increased by 0.97 cm2/year (SD:1.16), and MMSE declined by 0.4 points/year (0.02). Each SD of IMAT corresponded to a MMSE decline of 0.22 points/year ($p<0.0001$), similar in adjusted models and stratified by race or gender. Aging-related IMAT increase may be a novel predictor of cognitive decline beyond traditional risk factors, with potential implications for muscle-brain cross talk.

DUAL-TASK CHANGES IN PREFRONTAL ACTIVATION AND GAIT QUALITY IN OLDER ADULTS

Emma Baillargeon[1], Anisha Suri[2], Theodore Huppert[1], Ervin Sejdic[3], and Andrea Rosso[1], *1. University of Pittsburgh, Pittsburgh, Pennsylvania, United States, 2. Swanson School of Engineering, University of Pittsburgh, Pittsburgh, Pennsylvania, United States, 3. University of Toronto, Toronto, Ontario, Canada*

We compared the impact of performing dual-task walking on gait quality and prefrontal cortical activation assessed by functional near-infrared spectroscopy (fNIRS). We hypothesized a greater increase in fNIRS averaged over the left prefrontal cortex during dual-task walking would be associated with a greater decrease in gait quality (increased step-time variability; decreased gait speed, cadence, smoothness, and adaptability). In older adults (n=60, 75±5.8 years, 57% female), we quantified the change in fNIRS and gait metrics from single-task walking (even surface) to walking with attentional (reciting every-other letter of the alphabet) and physical (uneven surface) dual-task challenges using four 15m repetitions of each task. Gait metrics were computed from a tri-axial accelerometer at the lower-back. Changes in fNIRS from single to dual-task walking were not associated with changes in gait quality for both attentional and physical challenges (Spearman correlations, all $p>0.08$). Variability in response across individuals may contribute to our findings.

COGNITIVE CORRELATES OF GAIT SPEED AMONG OLDER ADULTS FROM SIX COUNTRIES: FINDINGS FROM THE COSMIC COLLABORATION

Briana Sprague[1], Xiaonan Zhu[1], Andrea Rosso[1], Joe Verghese[2], Kim Delbaere[3], Darren Lipnicki[4], Perminder Sachdev[4], and Caterina Rosano[1], *1. University of Pittsburgh, Pittsburgh, Pennsylvania, United States, 2. Albert Einstein College of Medicine, Bronx, New York, United States, 3. Neuroscience Research Australia, Randwick, New South Wales, Australia, 4. Centre for Healthy Brain Ageing (CHeBA), Sydney, New South Wales, Australia*

Using data from population-based cohorts of older adults 65+ from six countries across three continents (N=6472), we aimed to (1) describe and (2) identify predictors of usual and rapid gait speed from studies participating in the Cohort Studies of Memory in an International Consortium (COSMIC) collaboration. We investigated whether clinical (BMI, hypertension, stroke, APOE status), psychological (cognition, mood, general health) and behavioral factors (smoking, drinking, physical activity) predicted gait speed similarly across cohorts; we used regression models controlling for demographics. Unadjusted usual gait speed ranged from 0.52-1.09 m/s and rapid gait speed ranged from 1.20-1.68 m/s. Lower BMI and better cognitive function consistently predicted faster usual and rapid gait speed in all cohorts. These patterns were not attenuated by demographics. Other psychological and behavioral factors were less consistently associated with gait. Taken together, gait speed is variable across ethnogeographic regions, but the influence of cognitive on gait is remarkably consistent.

EARLY CHARACTERISTICS AND BIOMARKERS OF COGNITIVE IMPAIRMENT AND DEMENTIA WITH PRIOR MOTOR IMPAIRMENT

Qu Tian[1], Susan Resnick[2], and Luigi Ferrucci[2], *1. National Institutes on Aging, Baltimore, Maryland, United States, 2. National Institute on Aging, Baltimore, Maryland, United States*

Motor impairment is one early feature of preclinical Alzheimer's disease and strongly predicts future dementia. Whether older persons with dementia who had prior motor impairment present specific characteristics is less clear. In the Baltimore Longitudinal Study of Aging, we compared characteristics of participants with cognitive impairment or dementia who had slow gait on average 6 years before symptom onset (<1.0m/sec)(n=65,81±7 years,35%women,25%black) to those who did not (n=93,77±7 years,61%women,16%black). Early cognition and key biomarkers on average 7 years before onset were compared between groups using multivariable linear regression, adjusted for demographics. Those with prior slow gait had early unfavorable metabolic panel (higher fasting glucose,higher 2hr-OGTT insulin,lower HDL,higher triglyceride,higher BMI and waist,higher blood pressure), lower manual dexterity and processing speed, and lower lysophosphatidylcholine 18:1 and 18:2, critical in the synthesis of cardiolipin-an essential component of mitochondrial membranes. Strategies to prevent metabolic dysfunction at an early stage may slow down dementia progression.

SESSION 4350 (SYMPOSIUM)

NURSING FACILITY QUALITY, CLOSURES, AND STAFFING

Chair: Denise Tyler

The quality of care provided in nursing facilities has long been a societal concern and an important focus of policy at the federal and state level. The COVID-19 pandemic has drawn increased attention to nursing facilities due to high infection and mortality rates as well as increased media attention on staffing shortages that have occurred in the wake of the pandemic. The Office of the Assistant Secretary for Planning and Evaluation (ASPE) and RTI International have recently completed a series of studies focused on nursing facility quality and staffing. This symposium will present the results of four of those studies. First, we will report the results of a study exploring states' use of value-based payment (VBP) programs as part of their nursing facility Medicaid payment systems. Second, we will present the results of a study examining inappropriate discharges from nursing facilities. Third, we will report findings from a study that examined the factors associated with nursing facility closures. Finally, we will present findings from a study that explored the effect of the pandemic on nursing facility staffing. Together these studies provide important information about the state of nursing facilities in the wake of the COVID-19 pandemic and suggest key areas of focus for policymakers.

STATE USE OF VALUE-BASED PAYMENT IN NURSING FACILITIES

Denise Tyler[1], Kristie Porter[2], Melissa Hunter[2], Iara Oliveira[3], Marie Squillace[4], and Judith Dey[3], *1. RTI International, Waltham, Massachusetts, United States, 2. RTI International, Durham, North Carolina, United States, 3. Office of the Assistant Secretary for Planning and Evaluation, Washington, District of Columbia, United States, 4. ASPE, Washington, District of Columbia, United States*

Some states use value-based payment (VBP) programs as part of their nursing facility Medicaid payment systems. The purpose of this study was to determine which states use these programs, their goals, the measures used and other elements of these programs. An environmental scan was conducted to identify states that have VBP programs for nursing facilities, the key design elements of those programs, and the goals that states are aiming to achieve. Interviews with seven stakeholders were also conducted. We found that 20 states and the District of Columbia use VBP for nursing facilities with the goals of improving quality and increasing efficiency. However, due to lack of evaluation, it is not known if these programs are achieving their goals. Additional research is needed to determine which state programs are most successful. The results of such research would help in the development of future VBP programs.

ASSESSING THE FACTORS ASSOCIATED WITH NURSING HOME CLOSURES

Kelly Hughes[1], Qinghua Li[2], Zhanlian Feng[3], Iara Oliveira[4], and Judith Dey[4], *1. RTI International, Research Triangle, North Carolina, United States, 2. RTI International, Waltham, Massachusetts, United States, 3. RTI International, Research Triangle Park, North Carolina, United States, 4. Office of the Assistant Secretary for Planning and Evaluation, Washington, District of Columbia, United States*

The media has reported recent increases in nursing home closures. This study examined closures from 2011-2019, identified facility and market characteristics associated with closures, and assessed the impact of closures on quality and access. We identified closures using termination dates and gaps in certification surveys and conducted descriptive and multivariate analysis. We identified 1,220 closures, with large increases in closure rates in 2018 and 2019 and geographic clusters. Chain facilities, urban facilities and smaller facilities were more likely to close, as were facilities with higher percentages of non-white and Medicaid residents. Staffing and quality five-star ratings had a nonlinear relationship with closure, which suggests Medicaid funding may impact closures rates. We found both the number of beds per 1,000 elderly and occupancy rates decreased, including in high-quality facilities. Closures should be examined further in the context of the COVID-19 pandemic.

THE COVID-19 PANDEMIC MAY HAVE EXACERBATED NURSE STAFFING DISPARITIES IN NURSING FACILITIES

Kristie Porter[1], Angela Gasdaska[2], Marie Squillace[3], Judith Dey[4], Iara Oliviera[4], Zhanlian Feng[2], and Micah Segelman[5], *1. RTI International, Durham, North Carolina, United States, 2. RTI International, Research Triangle Park, North Carolina, United States, 3. ASPE, Washington, District of Columbia, United States, 4. Office of the Assistant Secretary for Planning and Evaluation, Washington, District of Columbia, United States, 5. Research Triangle Institute, Washington, District of Columbia, United States*

Nursing facilities (NFs) have historically struggled to maintain adequate nurse staffing. We used PBJ data linked with other publicly available sources and conducted stakeholder interviews to understand nurse staffing between 2019 and 2020. We found large declines in the population of NF residents and in staffing hours. Measured in hours per resident day (HPRD) to account for the size of the NF resident population, there were slight increases in staffing. Staffing was nonetheless a major challenge for NFs because they required increased staffing due to the impact of the pandemic. NFs in higher quartiles of percentage of minority residents lost nurse staffing HPRD relative to NFs in the lowest quartile of minority residents. Stakeholders explained that NFs with more minority residents were likely to employ staff who live in more vulnerable communities with a greater concentration of minorities, who were more impacted by COVID.

FACTORS ASSOCIATED WITH HIGH-RISK DISCHARGES FROM NURSING FACILITIES

Kelly Hughes[1], Zhanlian Feng[2], and Iara Oliveira[3], *1. RTI International, Research Triangle, North Carolina, United States, 2. RTI International, Research Triangle Park, North Carolina, United States, 3. Office of the Assistant Secretary for Planning and Evaluation, Washington, District of Columbia, United States*

Although some nursing facility discharges are appropriate or an individual's choice, others may be facility-initiated discharges (FIDs) that are potentially inappropriate. Since FIDs cannot be observed directly in available data, this study focused on live discharges of residents with risk factors for FIDs from 2011-2017. We defined risk factors as characteristics identified in prior literature that were more prevalent among residents discharged live than residents not discharged in our analysis. We found the following risk factors: severe behavioral symptoms; impairments requiring more staff time; and transition to Medicaid eligibility. Psychiatric and mood disorders were not identified in prior literature but also associated with live discharge. Risk factors were consistent across years but varied by state and facility type. For-profit, chain, and government facilities were most likely to discharge residents with risk factors. Furthermore, the rates of post-discharge acute care use were highest among residents with risk factors.

SESSION 4360 (SYMPOSIUM)

PROGRAMS TO IMPROVE QUALITY OF LIFE AND HEALTH: WHAT DO OLDER ADULTS AND PRACTITIONERS THINK?

Chair: Ashley Ritter Co-Chair: Allen Glicksman Discussant: Robyn Stone

Numerous programs and services are designed to help older adults improve their health and quality of life. Impact evaluations typically focus on health outcomes. Often, less attention is paid to the opinions of professionals tasked with administering these efforts or the older persons and caregivers about the need for the program or the way the program is administered. This panel addresses the question with four presentations, each of which uses data collected from practitioners and/or older adults to gain their perspectives on programs to help maintain quality of life and health. Sweeny examines the experience of older LTBTQ adults as they navigate the care and social service systems. Dictus and colleagues will describe a community level effort to develop a master plan for aging in one county. The method for including the views of the older adults in the process can be a model for other communities. Corpora and colleagues report on efforts to ensure that staff are aware of important preferences of nursing home residents, with a focus on the predictors of successful implementation. Glicksman and colleagues examine the impact of migration on the attitudes and perceptions of older Spanish speaking migrants toward the formal long-term care system. Finally, Stone will address the question of how these types of data can be used to help shape policy and practice, using research to help older adults and professionals at all levels to support older persons in community and facility care.

COMING OUT AND GOING BACK IN: AGING AND STRATEGIC IDENTITY DISCLOSURE AMONG LGBTQ ADULTS

Brian Sweeny, *Long Island University, Brookville, New York, United States*

In addition to facing social, economic, and health disparities, LGBTQ older adults face prejudice and discrimination across various social domains, leading some to re-enter the closet. When might older adults openly identify as LGBTQ, and when might they conceal this identity? Based on participant observation and interview data collected in two naturally occurring retirement communities in New York City, this paper examines LGBTQ identity and coming out in relation to aging processes, especially changing care networks and family structures, decreasing autonomy, and increasing engagement with health and social services. The older LGBTQ adults in the study feel the benefits of broad social changes and increasing cultural competencies regarding LGBTQ issues, yet they also speak of unsafe spaces, experiences of exclusion, and uncertainties. I analyze three specific identity disclosure strategies older LGBTQ adults use as they navigate prejudice and discrimination and work to affirm identities as aging gender and sexual minorities.

ENGAGING OLDER ADULTS AND STAKEHOLDERS TO DEVELOP A COMMUNITY MASTER AGING PLAN: A CASE EXAMPLE

Cassandra Dictus[1], Sallie Allgood[2], Ryan Lavalley[3], Janice Tyler[4], and Cherie Rosemond[5], *1. University of North Carolina - Chapel Hill, Chapel Hill, North Carolina, United States, 2. Center Of Innovation To Accelerate Discovery And Practice Transformation (ADAPT), Health Services Research And Development, Durham VA Health Care System, Durham, North Carolina, United States, 3. Occupational Science And Therapy, University of North Carolina - Chapel Hill, Chapel Hill, North Carolina, United States, 4. Orange County Department on Aging, Chapel Hill, North Carolina, United States, 5. Partnerships in Aging Program, University of North Carolina - Chapel Hill, Chapel Hill, North Carolina, United States*

As our population ages, communities are creating policies and programs to support older adults. Yet, there is a lack of input from older adults about which policies and programs meet their needs. This case example describes how one community in North Carolina (NC) engaged community stakeholders (older adults and organizational leaders) in all phases of their Master Aging Plan (MAP). Community stakeholders participated in a community assessment through surveys (n=860), focus groups (n=13, 63 participants), key stakeholder interviews (n=34), and two community-wide listening sessions. Organized by the WHO's age-friendly framework domains, community stakeholders formed workgroups to create, implement, and track the MAP. An evaluation was completed using the tracking documents, ripple effect mapping, and workgroup leader interviews. Orange County, NC's experience with collaborative community engagement can serve as a guide for other communities seeking to involve community stakeholders in the development and evaluation of their own MA

THE INFLUENCE OF NURSING HOME CHAMPIONS ON THE IMPLEMENTATION OF A PERSON-CENTERED QUALITY IMPROVEMENT PROJECT

Miranda Kunkel[1], Kamryn Kasler[1], Alexandra Heppner[1], Kimberly VanHaitsma[2], and Katherine Abbott[1], *1. Miami University, Oxford, Ohio, United States, 2. The Pennsylvania State University, University Park, Pennsylvania, United States*

Preferences for Activity and Leisure (PAL) Cards are a communication tool designed to alert nursing home staff to important resident preferences. This study explored the role of nursing home provider champions implementing (PAL) Cards in their community. Champions (n=35) created PAL Cards for 15-20 residents. A total of 88 monthly interviews were audio-recorded, transcribed, checked for accuracy, and coded using the domain "Characteristics of the Individual" from the Consolidated Framework for Implementation Research. Each construct was assigned a general valence rating based on consensus. Four constructs received the highest positive valence ratings and were identified as important facilitators to implementation success, and one construct received a neutral valence. Champions who anticipated the benefits of PAL Cards for their community and recruited a supportive team exhibited high implementation success. Additionally, the champion's perception of help from staff seemed to increase their own self-efficacy to achieve their goals.

PAST AS PRESENT: HOW LIVED EXPERIENCE INFLUENCES INTERACTION WITH LTSS AMONG OLDER SPANISH SPEAKERS

Allen Glicksman[1], Misha Rodriguez[2], Lauren Ring[3], and Michael Liebman[4], *1. NewCourtland, Haverford, Pennsylvania, United States, 2. APM, Philadelphia, Pennsylvania, United States, 3. Private, Philadelphia, Pennsylvania, United States, 4. IPQ Analytics Inc, Kennett Square, Pennsylvania, United States*

Older persons who migrated to the mainland United States bring with them their experiences and culture from their homelands and the process of migration and settlement in their new communities. The attitudes, values and assumptions that emerge will contribute to the interaction of the individual with the formal Long Term Care Services and Support (LTSS) system. Our research focused on better understanding of that process among older Spanish speakers. Data from four focus groups (# of participants) conducted in Spanish about the participants experience with LTSS was used in this analysis. Findings demonstrate the importance of understanding the ways in which the worldview of these persons shape their expectations and use of the formal LTSS system. The findings will facilitate the development of a Social Interaction Model to enable planners, policy makers and practitioners in LTSS to more effectively work with older migrants.

SESSION 4370 (PAPER)

SOCIAL DETERMINANT OF HEALTH, UNMET NEEDS, AND DISCRIMINATION

A MIXED-METHOD SOCIAL NETWORK ANALYSIS OF LOW-INCOME DIVERSE OLDER VOLUNTEERS

Katy (Qiuchang) Cao[1], Holly Dabelko-Schoeny[2], Keith Warren[3], and Mo-Yee Lee[3], *1. The Pepper Institute on Aging and Public Policy and The Claude Pepper Center, Florida State University, Tallahassee, Florida, United States, 2. Ohio State University, Columbus, Ohio, United States, 3. The Ohio State University, Columbus, Ohio, United States*

Although the health benefits of volunteering among older adults are well established in gerontology, older migrants' abilities and interests in social participation are hardly recognized. To address the gap, we collected focus groups and survey information in Russian, Khmer, Somali, Nepali, and English to understand the volunteering experiences, social networks, and feelings of loneliness among low-income diverse volunteers in the Senior Companions Program (SCP) in Columbus, Ohio (N=41). The grounded theory approach informed the qualitative analysis. Exponential Random Graph Modeling (ERGM) was utilized to identify statistically significant structural features in the volunteers' network. Five major themes emerged from the focus groups: (1) Expanding and strengthening social networks through volunteering; (2) Experiencing and coping with loneliness; (3) Experiencing and managing the social impact of COVID; (4) Exploring and loving the program; (5) Social connections outside of the program. Graphs and preliminary ERGM results demonstrate that participants tend to form homophily-based relationships with other volunteers of the same gender (β=2.45, p< 0.001) and from the same country (β=4.86, p< 0.001). However, participants tend to form friendships with people from different racial (β= -1.12, p< 0.001) and different educational backgrounds (β = -0.88, p< 0.001). The tendency to reciprocate (β= 0.96, p< 0.001) and to form triads (β= 9.90, p< 0.001) are both positively significant in the networks. Findings imply that practitioners should attend to within- and cross-cultural relationships in programs for diverse older adults. Addressing language barriers and other sources of homophily may facilitate cross-cultural friendships.

DIFFERENCES IN HEALTH AMONG LOW-INCOME OLDER IMMIGRANTS: DOES ETHNICALLY HOMOGENEOUS ENVIRONMENT MATTER?

BoRin Kim[1], ByeongJu Ryu[2], Jihye Baek[3], Sojung Park[3], Chung Hyeon Jeong[1], and Jina Park[3], *1. University of New Hampshire, Durham, New Hampshire, United States, 2. Chuncheon Hyoja Social Welfare Center, Chuncheon-si, Kangwon-do, Republic of Korea,*

3. Washington University in St. Louis, St. Louis, Missouri, United States

Older immigrants comprised 14% of the US older population, which is predicted to continue to rise. Despite the importance of ethnic attachment in older immigrants' well-being, little is known how ethnically homogeneous housing environment affect older adults' health. This study aims to fill the gaps in knowledge on low-income older immigrants living in subsidized senior housing and to explore the associations between immigrant status, senior housing environments, and self-rated health among this population. Our survey data was collected from 18 subsidized senior housing communities in IL, MO, and NH (N=459). Bilingual surveyors fluent in Chinese, Russian, and Korean were also available for the participants with limited English proficiency as the sampled housings were the multi-ethnicity properties. Hierarchical Linear Modeling was employed for our analysis to address our participants were clustered within senior housing.More than a half (56%) of our sample lived in ethnically homogeneous senior housing (either all immigrants or all non-immigrants). Immigrants consist of 53% of our sample, and 48% of them lived in ethnically homogeneous housing. Our finding showed that immigrants were more likely to report low level of self-rated health (OR=0.885, p< 0.01). However, ethnically homogeneous senior housing environments positively influence the association between immigrant status and self-rated health (OR=1.219, p<.05).This study highlights the importance of ethnically homogeneous living environment for low-income older immigrants in senior housing. Although ethnic diversity may be beneficial in broader society, concentration of ethnic minority older immigrants could play an important role in terms of social support and service delivery.

MENTAL HEALTH IMPACT OF DISCRIMINATION: THE PROTECTIVE FUNCTION OF SOCIAL CAPITAL IN DIVERSE GROUPS OF OLDER ADULTS

Mengzhao Yan, Yuri Jang, and Kathleen Wilber, *University of Southern California, Los Angeles, California, United States*

Discrimination occurs in complex social contexts leading to various levels and types of outcomes. Although the negative health impact of discrimination is well-documented, there is a need to investigate patterns among discrimination, social factors, and health outcomes in diverse racial/ethnic groups of older adults to inform interventions. For example, social capital, such as social cohesion, social ties, and safety, is anticipated to be directly associated with mental health and also to modify the impact of discrimination. In the present study, we examined (1) racial/ethnic differences in perceived discrimination, social capital, and depressive symptoms and (2) the direct effect of perceived discrimination and social capital, as well as their interactions, on depressive symptoms among different racial/ethnic groups. Data were drawn from the National Social Life, Health, and Aging Project (NSHAP) Round 3 (2,988 non-Hispanic Whites, 719 non-Hispanic Blacks, and 499 Hispanics; 68 mean age). Compared to non-Hispanic Whites, non-Hispanic Blacks had a significantly higher level of perceived discrimination, lower social capital, and more depressive symptoms. Findings from multivariate linear regression models demonstrated that, in all racial/ethnic groups, frequent experiences of discrimination and low levels of social capital were associated with increased symptoms of depression. A significant interaction between discrimination and social cohesion was observed in non-Hispanic Whites and Hispanics. In both groups, the negative impact of discrimination was lower among those with higher levels of social cohesion. Our findings support efforts such as improving well-being for older adults by promoting age-friendly communities to build greater social cohesion.

NEIGHBORHOOD CHARACTERISTICS AND QUALITY PERFORMANCE OF HOME HEALTH AGENCIES: A COHORT STUDY

Chenjuan Ma, *New York University, New York, New York, United States*

Home health care (HHC) is a core source of home- and community-based services to older adults "aging in place'. This study examined variation in HHC quality by neighborhood characteristics in the US by using 5 years (2014-2019) of national Home Health Compare data linked to Providers of Services (POS) files and Area Health Resources Files (AHRF). HHC quality was measured by agency rates of timely initiation of care, hospitalization, and ED visits. We examined 7,487 HHC agencies (37,435 agency-years) in 1,760 counties. At baseline, the mean rates of timely initiation of care, hospitalization, and ED visit were 91.5%, 15.8%, and 12.5%. On average, county percentage of Blacks, Hispanic, individuals with college degree, unemployment, and being in poverty were 12.9% (range: 0.1% – 76.0%), 20.6% (0.4% - 95.8%), 30.4% (7.3% - 77.6%), 5.4% (2.1% - 24.0%), and 14.4% (3.1% - 38.0%) respectively in 2015. Estimates from multivariate regressions showed that neighborhoods with higher proportion of Blacks (β= -0.04, p=0.000) and Hispanics (β= -0.02, p=0.000), higher rate of unemployment (β= -0.07, p=0.035) were less likely to have HHC agencies providing timely initiated care; neighborhoods with higher proportions of Blacks (β= 0.01, p=0.000) and higher poverty rates (β= 0.02, p=0.027) were more likely to have HHC agencies with higher hospitalization rates; and neighborhoods with higher poverty rates (β= 0.04, p=0.000) were more likely to have HHC agencies with higher ED visit rates. Our findings indicate that racial/ethnic minorities in neighborhoods with low socioeconomic status were less highly to access high quality HHC.

UNMET NEEDS AMONG ADULTS AND OLDER ADULTS IN BRAZIL, ELSI-2019

Flavia Andrade[1], and Xiayu Chen[2], *1. University of Illinois--Urbana-Champaign, Urbana, Illinois, United States, 2. University of Illinois at Urbana-Champaign, Urbana, Illinois, United States*

Many older adults in Brazil struggle to receive adequate assistance in later life. To better understand this issue, this study examines the prevalence and characteristics of unmet needs of adults ages 50 and older with difficulties performing activities of daily living (ADL), instrumental activities of daily living (IADL), the caregiving patterns, and the consequences of unmet needs in Brazil. We use data from the second wave of the Brazilian Longitudinal Study of Aging (ELSI-Brazil) study conducted in 2019-2021 (N=9,949). Results indicate that the prevalence rate of ADL was 8.9% (95% CI 7.6 – 10.5), and the prevalence of IADL was 15.6% (95% CI 13.1 – 18.5). Among those with ADL difficulties, 11.5% (95% CI 8.2 – 16.0) reported having unmet needs. Among those with IADL difficulties, 8.8% (95% CI 6.1 – 12.4) reported having at least one activity with unmet needs. Unmet needs were higher among younger adults, those living alone, Black or mixed race, or the Northeast region. Most of the care (87%) was provided by family members, primarily daughters, and wives. About 20% of caregivers had to stop working or studying to provide the needed care. Those with ADL unmet needs were less likely to visit friends or family, whereas IADL unmet needs were associated with lower odds of visiting a doctor. Our study provides the first glimpse of the characteristics of those with currently unmet needs among adults in Brazil and of caregivers. Unmet needs are associated with social isolation and worse healthcare use.

SESSION 4380 (SYMPOSIUM)

HOUSING, AGING, AND HEALTH: NEW FINDINGS AND FRAMEWORKS FROM HOUSING-FOCUSED RESEARCH IN THE CONTEXT OF COVID-19

Chair: Nancy Berlinger

Older adults have been the most vulnerable population to severe illness, hospitalization, or death from COVID-19. During the pandemic, housing became a site of health and safety for some, while reinforced inequities for others due to underlying problems of affordability, accessibility, safety, and service access. This symposium showcases five housing-focused studies reflecting the pandemic context, including research by early-career investigators. The first speaker will present findings from a study of materials preserving promising practices and policy ideas generated by housing-focused pandemic responses to middle-income and low-income community-dwelling older adults. The second speaker will discuss narrative lessons from "avoidance hotels" – an infection-reduction strategy that transferred older adults from shelters to hotel rooms – with potential to guide planning for the needs of older adults facing homelessness and serious illness. The third speaker will analyze findings from multi-city research on the pandemic housing experiences of lower-income Black women, who faced severe intersectional threats to housing security. The fourth speaker will share data from a qualitative study of a Medicare-financed home care program for residents of HUD housing, including recommendations for improving experiences of participants and providers. The fifth speaker will describe the evolution of the pandemic-response roles of HUD service coordinators, based on findings from surveys in 2020 and 2021. We will conclude with audience discussion about ways for age-focused researchers to collaborate in crafting policy solutions and effective public narratives about housing equity in America's aging society.

SEEING THROUGH A HOUSING LENS: STUDYING HOUSING-FOCUSED RESPONSES TO THE NEEDS OF OLDER ADULTS DURING THE PANDEMIC

Nancy Berlinger, *The Hastings Center, Garrison, New York, United States*

This paper draws on a study of unindexed literature produced by local and state policymakers, Area Agencies on Aging, nonprofit organizations, for-profit companies, age-friendly initiatives, affordable housing providers, and other groups responding to the needs of older adults at home during the COVID-19 pandemic. By collecting and analyzing descriptions of how service providers pivoted or improvised to meet urgent challenges, we sought to identify promising practices and policy ideas preserved in reports, newsletters, websites, and other communications. This paper reviews study methods and recommendations, and explores a concept that emerged from this research: recognizing services and support for older adults at home as "housing-focused" care that relies on the affordability, accessibility, and safety of a person's home. The applications of the "housing lens" to future research on housing, aging, and health and to making progress on better integrating housing policy and health policy in aging societies will be discussed.

TEMPORARY ADDITIONS TO TEMPORARY HOUSING: LESSONS FROM HEALTH EXPERIENCES OF COVID AVOIDANCE HOTEL RESIDENTS

Ian Johnson[1], Michael Light[2], Tam Perry[3], and Terri Lewinson[4], *1. University of Tennessee, Knoxville, Tennessee, United States, 2. University of Washington Palliative Care Training Center, Seattle, Washington, United States, 3. Wayne State University, Detroit, Michigan, United States, 4. The Dartmouth Institute for Health Policy and Clinical Practice, Lebanon, New Hampshire, United States*

COVID-19 amplified system burdens and health risks within the housing care continuum, in which older adults with chronic serious illness are disproportionately represented. We present retrospective chart review data about the health experiences of older adults with serious illness living in and moving through temporary avoidance hotels during the COVID-19 pandemic. Through narratives of fourteen residents, we illustrate trends across two nine-month phases. Trends illustrate how avoidance hotels created opportunities for continuity of care, connection to services, and health-affirming relationships with place. We also identified challenges in catering to diverse medical, behavioral, and psychosocial-spiritual needs of older and seriously ill residents, as well as negative consequences to the geographic dispersion caused by de-congregating homeless shelters. Avoidance hotels present important lessons in considering future housing and healthcare intervention and implementation for older people facing homelessness while seriously ill.

BRINGING HOME CARE TO HUD HOUSING: AN EVALUATION OF NEW JERSEY'S ASSISTED LIVING PROGRAM

Karen Zurlo, *Rutgers, The State University of New Jersey, New Brunswick, New Jersey, United States*

The Assisted Living Program (ALP) in New Jersey provides home care services, financed by Medicaid and self-pay, to older adults living in low-income HUD housing. Because the program had attracted few providers and had low uptake, we designed a qualitative study aimed at understanding experiences of ALP participants compared to non-participants. After pandemic-related postponements, the study began in June 2021, collecting data from 63 respondents. Findings revealed differences in the demographics and needs of older New Jerseyans as well as differences between participants and non-participants in ALP. This paper will review the study and discuss investigators' conclusions about how to strengthen this highly viable model of home-based care and better serve low-income older adults in New Jersey. Opportunities for improvement include modifications to regulations and financing; marketing of services, and collaboration among ALPs and housing providers.

BRIDGING THE GAP: SERVICE COORDINATION IN HUD HOUSING DURING COVID-19

Samara Scheckler, and Jennifer Molinsky, *Harvard University, Cambridge, Massachusetts, United States*

Older HUD residents were vulnerable to COVID-19 due to their age, health, income, race, ethnicity, and resources. In combination, these factors increased risk to health and housing stability. While many HUD properties employ a service coordinator, this role is not universally adopted and impacts of these services are not well understood. This research surveyed service coordinators in mid-2020 and late-2021 to characterize older adult experiences living in public housing during the pandemic and ways service coordinators helped manage disruptions. Surveys were disseminated to 3,500 service coordinators. Findings identified needs in transportation, personal care, sociality, mental and physical healthcare, and food. Interventions included resource procurement, benefits management, technology access improvement, and linking residents to services. Tools included information dissemination, needs assessments, and partnership development. This work offers insight into the role of a service coordinator to mitigate health and housing risk. It becomes increasingly salient as HUD residents trend demographically older.

SESSION 4390 (SYMPOSIUM)

THE IMPLEMENTATION OF GERIATRIC EMERGENCY DEPARTMENT ACCREDITATION (GEDA) IN RURAL CRITICAL ACCESS HOSPITALS

Chair: Ellen Flaherty Discussant: Kevin Biese

The largely rural setting of Northern New England offers unique challenges to implementing improved acute care for the growing geriatric population. Northern New England is one of the United States' most rapidly aging regions, with Vermont and New Hampshire being the second and third oldest US states respectively by median age (U.S. Census 2017). There is a need to expand innovations in geriatric emergency medicine to reach older adults in rural areas such as Northern New England. Dartmouth-Hitchcock Medical Center and the West Health are collaborating on a project leveraging telehealth to extend the reach of a GED to rural hospitals, as well as investigate the opportunities for scaling and sustaining this concept to other rural facilities across Northern New England and throughout the country. This symposium will focus on our experience implementing a hub and spoke model to achieve our goal of improving the care of older adults in rural emergency departments.

LEVERAGING THE STRENGTH OF UNIQUE PARTNERS TO IMPROVE GERIATRIC EMERGENCY CARE IN RURAL CRITICAL ACCESS HOSPITALS

Scott Rodi, *Dartmouth-Hitchcock Medical Center, Lebanon, New Hampshire, United States*

Developing a level 1 accredited geriatric emergency department during the pandemic was challenging. The greater challenge has been to support rural critical access hospitals on their journey of becoming level 2 accredited geriatric emergency departments. This has been accomplished through a novel collaborative approach between the level 1 accredited emergency department, a newly established Geriatric Center of Excellence at Dartmouth-Hitchcock Health and a HRSA funded Geriatric Workforce Enhancement Program. This talk will focus on bringing together system partners and funders who have a history of success through: (a) development, testing and dissemination of tool kits and implementation guides; (b) boot camp training that includes interprofessional team training, QI and specific geriatric content training; (c) implementation support and coaching using data and QI methodology through learning collaboratives; (d) scaling successful models of evidence based geriatric care; (e) expertise in implementation science; (f) expertise in evaluation and (g) disseminating findings to achieve our goals.

ALIGNING GERIATRIC EMERGENCY CARE WITH THE 4MS OF THE AGE-FRIENDLY HEALTH SYSTEM FRAMEWORK

Jennifer Raymond, *Dartmouth-Hitchcock Medical Center, Lebanon, New Hampshire, United States*

In 2019 Dartmouth-Hitchcock Medical Center (DHMC) was recognized by the Institute for Healthcare Improvement as a level 2 Age Friendly Health System (AFHS). Over the past two years DHMC leveraged the strengths of the AFHS to become a level 1 American College of Emergency Physicians (ACEP) accredited geriatric emergency department. Leveraging the paradigm of 4M care including: What Matter's Most, Mobility, Medication and Mentation, DHMC achieved alignment between the geriatric emergency department accreditation and the AFHS framework. Pathways focusing on the 4Ms have been identified as a model to improve transitions of care post ED. This talk will focus on lessons learned and outcome data specific to the creation of the 4M pathways and transitions of care,

SAFE TRANSITIONS: POST-ED DISCHARGE FROM A RURAL CRITICAL ACCESS HOSPITAL

Kristie Foster, *Alice Peck Day Memorial Hospital, Lebanon, New Hampshire, United States*

This talk will focus on leveraging the strengths of small rural communities to improve transitions of care post ED discharge. We moved beyond post discharge telephone calls, and partnered with already existing community based organizations. These collaborative partnerships enabled the use of standardized bundles of interventions targeting specific risks such as falls, depression, polypharmacy and the lack of documentation around goals of care.

ENHANCED COMMUNICATION BETWEEN A RURAL CRITICAL ACCESS HOSPITAL, A RESIDENTIAL CARE FACILITY, AND PRIMARY CARE

Lee Morissette, *Mount Ascutney Hospital, Windsor, Vermont, United States*

A need to improve the transitions of care between a small rural emergency department, a residential care facility and a primary care practice emerged early on in our work to become a level 2 accredited emergency department. One challenge is bringing together 3 partners all with distinct types of health records, unique foci of care and a variety of disciplines and workforce. This paper will focus on our journey of creating an individualized plan of care to help mitigate problems of poor communication with a focus on the 4Ms framework including: What Matters Most, Mobility, Medication and Mentation.

SESSION 4400 (SYMPOSIUM)

TRAINING THE NEXT GENERATION OF GERONTOLOGICAL LEADERSHIP: WHO AND HOW?

Chair: Neil Charness Co-Chair: Patricia Heyn Discussant: James Appleby

Knowing how to train the next generation of gerontological leaders involves understanding where we are now and where we want to be in the coming decades. We outline the results of a survey of the membership of Directors of Aging Centers. The Directors of Aging Centers interest group in GSA has representation from the USA, Canada, and Europe. A survey was sent to the membership in late December with reminders in January and had 31 respondents. We discuss the results of the survey, highlighting the demographics of the current leadership (Neil Charness), perceived need for training by current leaders (Peter Lichtenberg), and consensus content of leadership training programs (Patricia Heyn). Patricia D'Antonio provides a perspective on GSA's approach to professional development programs and avenues for soliciting funding for leadership training. Our discussant (James Appleby, CEO of GSA) will reflect on the need for training in the context of building the next generation of gerontological leadership. We plan to devote significant symposium time to solicit audience input on next steps for supporting the effort to improve the quantity, quality, and diversity of the gerontological leadership workforce.

CHARACTERISTICS OF LEADERS OF AGING CENTERS

Neil Charness, *Florida State University, Tallahassee, Florida, United States*

In December of 2021 and January of 2022, current leaders of Centers on Aging belonging to the GSA Age Directors interest group were invited to fill out a survey inquiring about their backgrounds, training for leadership, and perceived needs for training via an online Qualtrics survey. Thirty-one responses were received though a few responses were missing for most questions. The sample mostly resided in the USA (86%), and identified mainly as female (63% female, 37% male). Most were married (90%). The average age of a respondent was 58 years (SD=9; range 37-74). Respondents were not diverse: 97% White. Most had doctoral level education (1 Master's level). The results indicate that there is a need to enhance and develop leadership skills in diverse mid-career gerontologists in order to provide replacements for an aging cohort of directors. Results are also consistent with prior National Academies' recommendations for training the gerontological workforce.

GSA R13 DIVERSITY WORKSHOP: THE CAREER JOURNEY OF A THOUSAND EXPERIENCES BEGINS WITH ONE STEP

Patricia Heyn[1], and Keith Whitfield[2], *1. Center for Optimal Aging, Marymount University, Fairfax Station, Virginia, United States, 2. University of Nevada, Las Vegas, Las Vegas, Nevada, United States*

After 23 years, since the NIH recognized the need to increase the contribution of underrepresented minority (URM) scientists in the biomedical sciences, modest gains have been made to address the significant under-representation in biomedical sciences. By the time URM scholars have gained the necessary research skills to succeed as scientists, they have overcome many social and professional barriers, yet they still experience the social burdens of disadvantage and discrimination. In an effort to increase representation, the GSA has been successfully delivering Diversity Mentoring and Career Development Technical Assistance Workshops (GSA DMCDTAW) since 2018 with support from grants from the NIH/NIA. Many trainees and faculty from diverse backgrounds participated in DMCDTAW. The program promoted peer mentoring opportunities, professional training, and networking engagements and underwent a series of evaluations and focus group discussions. The program framework, curriculum, and evaluation will be presented. Recommendations for future mentoring development and evaluation will be discussed.

WHAT LEADERSHIP SKILLS ARE NEEDED TO DIRECT GERONTOLOGY PROGRAM: SURVEY RESULTS FROM LEADERS ACROSS THE COUNTRY

Peter Lichtenberg, *Wayne State University, Detroit, Michigan, United States*

Gerontology programs across the country, including Centers, Institutes and Departments play a key role in promoting the field and the careers of the scientists they connect with. A recent survey of 30 Gerontology leaders from the GSA interest group found that 60% of them received no leadership training before becoming a Director or Chair in their program. Only 50% of those who received some generic leadership training found that it prepared them for their current role. This presentation will highlight some of the potential areas of focus for leadership training more specific to Gerontology programs. Among the topics most highly valued by the Gerontology Program leaders include budgets, managing people, negotiating difficult situations, understanding different leadership styles, teamwork, ethics and diversity, equity and inclusion. This session will frame some of the key aspects of leadership training including a deeper understanding of universities as organizations; and negotiating for resources.

GSA ACTIVITIES TO SUPPORT CAREER DEVELOPMENT: RELEVANCE TO DIRECTORS OF AGING CENTERS

Patricia D'Antonio, *The Gerontological Society of America, Washington, District of Columbia, United States*

GSA continues to support our members through career development activities. These activities are designed to empower members to develop the necessary skills to advance their careers as leaders in the field of aging. Through activities like the GSA NIA R13 Diversity, Mentoring, and Career Development Technical Assistance Workshop, we strive to support, promote, and advance the training of diverse students in aging. This presentation will discuss how the experiences with this R13 project and other career development efforts inform additional activities of the Society through a well-framed aging lens. We also discuss the process of soliciting funding to support leadership training and the role that GSA can play in the application process.

SESSION 4410 (SYMPOSIUM)

UPDATE IN GEROSCIENCE FOR NONBIOLOGISTS

Chair: George Kuchel Co-Chair: Steven Austad

Geroscience began as a result of discoveries made by biologists in aging cells, simple organisms and animal models. Such advances, the discovery of strategies for modifying rate of aging, and appreciation of aging as a shared risk factor for chronic diseases led to the Geroscience Hypothesis. It states that interventions modifying aging biology can slow its progression, resulting in the prevention or delay of onset of multiple diseases. However, for these discoveries to truly impact human health, nonbiologists – scientists in other disciplines and clinicians, must also engage in geroscience. An obstacle to a wider engagement by disciplines and GSA members other than basic biologists in geroscience has been the fact that varied fields engaged in aging issues tend to use language (jargon), methods and scientific approach that can make their work less accessible and understandable to other disciplines. To that end, speakers have been selected not only for their scientific contributions, but also for their ability to overcome such barriers. Steve Austad (UAB) will discuss the range of animal models and experimental approaches that led to the Geroscience Hypothesis. Anne Newman (U Pittsburgh) will review evidence that these findings are relevant to and might be translatable to humans. John Newman (UCSF/Buck) will seek to frame these considerations in terms of broader societal discussions regarding aging while providing a framework by which nonbiologists may critically evaluate discoveries and actual products claiming benefits in terms of aging. (Sponsored by Nathan Shock Coordinating Center U24AG056053; Geroscience Education and Training Network R25AG073119).

ANIMAL MODELS AND THE EMERGENCE OF GEROSCIENCE

Steven Austad, *University of Alabama at Birmingham, Birmingham, Alabama, United States*

Aging, meaning the generalized deterioration in physical and mental function with time, influences nearly all living species. Moreover, many underlying biological mechanisms of aging appear to be conserved. At the same time, there appear to be great differences in the rate at which different species age. Research using both traditional and nontraditional animal species, employing both laboratory and field studies has offered important insights into the discovery of underlying causes of aging. Also, a variety of studies using well-established animal models of aging have now identified both repurposed medications and new compounds and other approaches that appear to slow biological aging with potential improvements in lifespan and healthspan. It is these findings, when framed in the context of the emergence of multiple chronic diseases with aging, that have led to the Geroscience Hypothesis.

STUDYING BIOLOGICAL AGING AND GEROSCIENCE IN HUMANS

Anne Newman, *University of Pittsburgh, Pittsburgh, Pennsylvania, United States*

For geroscience to impact human health, its scientific underpinnings observed in animal models must also be relevant to humans, and therapies grounded in geroscience principles must be translatable to humans. Given the heterogeneity of human aging, chronological age alone is not a sufficient indicator of susceptibility to specific diseases, disabilities, or death, nor does it provide insights into the likelihood of benefiting from specific geroscience-inspired approaches. Bringing these metrics to large epidemiological studies and clinical trials has provided a number of important insights. For example, indices developed from aggregates of biomarker, physiological and clinical data have been shown to perform well in terms of predicting healthy aging, specific aging-related traits and mortality. Functional or composite outcomes have been favored for capturing health span in translational trials.

ASSESSING PURPORTED AGING THERAPIES IN THE CLINIC

John Newman, *Buck Institute and UCSF, Novato, California, United States*

Aging is a universal human experience that looms large in popular and commercial culture. It can be difficult for patients and providers alike to sort fact from unproven plausibility and from potentially harmful fiction. Geroscience is an emerging field, and while some interventions involve repurposed or over-the-counter drugs with early clinical data, it is important to note that none yet have a specific aging-related indication and none have a consensus recommendation for clinical use in an aging context. Even highly plausible links to mechanisms of aging do not ensure that an intervention will be effective or risk-free, and not all purported therapies align with preclinical science. Finally, some purported therapies fall into potentially problematic regulatory gaps. With all of these considerations in mind, attendees will gain insights into applying their existing skills to evaluate this field, and new tools for critically evaluating geroscience literature to assist in patient-centered decision making.

SESSION 4420 (SYMPOSIUM)

US RACIAL AND ETHNIC DISPARITIES IN DEMENTIA LIFE EXPECTANCY, RISK/PROTECTIVE FACTORS, AND CAREGIVING STRESSORS

Chair: Maria Aranda

The health, emotional, and economic impacts of dementia are far-reaching and impossible to fully calculate. Late-life dementia is not equitably distributed across population subgroups including older people and racial/ethnic minorities. Clear evidence underscores disparities in social/personal resources, environmental exposures, racism/discrimination, increased burden of caregiving, and uneven access to quality care especially for Blacks and Hispanics and caregivers. Each paper in this symposium addresses high-priority, disparity research areas highlighted in the recent NASEM Decadal Survey of Behavioral and Social Science Research on ADRD: characteristics of population groups that influence disease ascertainment and dementia life expectancy; quantification of mid- and late-life risk/protective factors; pesticide exposure and cognition, and caregiving stressors among racial/ethnic minorities. All presentations utilize nationally representative data on older people in the US. Garcia et al. utilize HRS data to create dementia life expectancy estimates using four competing algorithmic classifications of dementia status by race/ethnicity (Blacks, Whites), nativity status (US-, non-US-born Latinos), and gender. Applying the Lancet Commission Dementia Prevention framework to HRS data, Ferdows and Aranda examine risk/protective factors and quantify the relative contribution of individual variables in explaining racial/ethnic dementia disparities. Chanti-Ketterl et al. elucidate the association between organochlorines pesticides (total scores, specific type) and cognition based on NHANES data to ascertain racial/ethnic differences. Based on NHATS, Moon et al. explore differences in primary stressors by dementia care and race (Blacks, Whites) during COVID-19. Findings provide evidence of potential multi-level targets for interventions and public policies. All primary authors are early-career scholars dedicated to mitigating ADRD health disparities.

DEMENTIA LIFE EXPECTANCIES: NEW KNOWLEDGE AND CONSIDERATIONS FROM THE HEALTH AND RETIREMENT STUDY

Marc Garcia[1], Wassim Tarraf[2], Chi-Tsun Chiu[3], Joseph Saenz[4], and Adriana Reyes[5], *1. Syracuse University, Syracuse, New York, United States, 2. Wayne State University, Detroit, Michigan, United States, 3. Institute of European and American Studies, Taipei City, New Taipei, Taiwan (Republic of China),*
4. University of Southern California, Los Angeles, California, United States, 5. Cornell University, Ithaca, New York, United States

Alzheimer's disease and related dementias (ADRD) are a growing public health crisis. Estimates on the prevalence and incidence of ADRD across and within population-based studies have varied in part due to competing measures to assess dementia status. Disentangling these inconsistencies is crucial for understanding dementia disparities among racial/ethnic, and nativity groups among older adults. Based on the Health and Retirement Study we examined across (Whites, Blacks) and within-group differences (US- and non-US-born Latinos) in estimates of dementia life expectancy, using four competing algorithmic techniques (i.e., the Langa-Weir, Expert, Hurd, and Lasso) for the classification of dementia ascertainment. Estimates of dementia life expectancy across algorithms largely point to dementia disparities in the prevalence of the disease across racial/ethnic, and nativity groups, regardless of the algorithmic technique utilized. Elucidating algorithms that can be utilized with different racial/ethnic groups may reduce bias in dementia assessment in the future.

RACIAL/ETHNIC DISPARITIES IN RISK AND PROTECTIVE FACTORS OF DEMENTIA: A LIFESPAN APPROACH

Nasim B. Ferdows[1], and Maria Aranda[2], *1. Northeastern University, Boston, Massachusetts, United States, 2. University of Southern California, Los Angeles, California, United States*

We examined risk and protective factors associated with dementia and decomposed racial/ethnic disparities in factors associated with dementia. We performed a retrospective analysis of 3,495 individuals 65+ who participated in the 2016 Harmonized Cognitive Assessment Protocol, linked to Health and Retirement Study. Using the MMSE score, individuals were classified as having dementia vs cognitively normal. Risk factors included cardiovascular factors and hearing loss in midlife, current smoking, depression, and physical inactivity. Protective factors included educational attainment and wealth. Using Oaxaca-Blinder decomposition we quantified the relative contribution of individual variables in explaining racial/ethnic disparities. We found that Blacks and Hispanics have higher dementia risk compared to Whites. Accounting for demographics, mid-and later-life risk and protective factors explained one-third of the difference in Blacks and Whites' cognitive functioning, and two-thirds of the difference in Hispanics and Whites. The findings highlight disparate dementia rates, and the need to elucidate other factors beyond race/ethnicity.

ORGANOCHLORINE EXPOSURES AND COGNITIVE FUNCTION IN OLDER LIFE: THE ROLE OF RACE/ETHNICITY

Marianne Chanti-Ketterl[1], Maria Aranda[2], and Brenda Plassman[1], *1. Duke University, Durham, North Carolina, United States, 2. University of Southern California, Los Angeles, California, United States*

Organochlorines (OCs) are persistent pesticides that remain in the environment and body for extended periods after exposure. Little is known about their long-term impact on cognition in later life. Some studies, but not all, have shown that higher levels of selected OCs are associated with lower cognitive function (CF). Using weighted linear generalized estimating equations, we explored whether the association between lipid-adjusted levels of 8 OCs and global CF is modified by race/ethnicity in 985 adults age 60+ from the National Health and Nutrition Examination Surveys (2011-2014). Adjusting for covariates, results indicated that higher levels of grouped-OCs are not associated with lower CF (p=0.121), but higher levels of specific OCs were associated with lower CF: Mirex[p=0.029]; Oxychlordane[p=0.036]; p,p'-DDE[p=0.009]; p,p'-DDT[p=0.003]; and trans-Nonachlor[p=0.023]. These associations did not differ by race/ethnicity. Disentangling the complex impact of OCs on late-life cognition—whether in combination or singularly—may lead to more equitable environmental health policies.

IMPACT OF CAREGIVING DURING THE COVID-19 PANDEMIC: COMPARISON BETWEEN DEMENTIA AND NONDEMENTIA CAREGIVERS BY RACE

Heehyul Moon[1], Sunshine Rote[1], Jeanelle Sears[2], and Stacey Schepens Niemiec[3], *1. University of Louisville, Louisville, Kentucky, United States, 2. Bowling Green State University, Bowling Green,, Ohio, United States, 3. University of Southern California, Los Angeles, California, United States*

Despite evidence of increased caregiving intensity, stress, and burden during the COVID-19 crisis and clear racial disparities in COVID-19, there is a lack of research on the impact of dementia (vs. non-dementia) care provision on caregivers' (CGs) quality of life by race. The current study used the National Health and Aging Trends Study COVID-19 Family Members and Friends data (N=1,462, 15% Black and 85% Non-Hispanic White CGs) to explore differences in primary stressors (changes in the provision of help with ADL and IADL tasks and emotional support) by dementia care and race during COVID-19. Most respondents were adult children. Dementia CGs in particular reported increases in stressors (ADL and IADL provision) during the pandemic. Black dementia CGs reported significantly more provision of help with ADL tasks before and after the COVID-19 onset and a significantly higher level of emotional support to their care recipients compared with the other three groups (Black non-dementia, White dementia, and White non-dementia CGs). Black dementia CGs also reported the highest care burden and worst psychological well-being and self-rated health during COVID-19. Findings revealed significant differences in the magnitude and nature of the changes in CG help provision before and amidst the pandemic, by race and dementia care status. Future studies should examine the longitudinal impact of the pandemic on the well-being of CGs from other racial and ethnic minority groups.

SESSION 4430 (PAPER)

USING QUALITATIVE METHODS TO GAIN A DEEPER UNDERSTANDING INTO AGEISM, HOMELESSNESS, AND DEATH EXPERIENCES

AGING IN PLACE: THE REALITIES OF OLDER HOMELESS WOMEN NAVIGATING URBAN STREETS AND SHELTERS

Judith Gonyea[1], and Arden O'Donnell[2], *1. Boston University, Boston, Massachusetts, United States, 2. Boston University, Medfield, Massachusetts, United States*

Older homeless women have often been an invisible population; however, this is changing as their numbers grow. Today, women age 50 and older represent 30% of the shelter population. In this qualitative study, we explored the question, What does "aging in place" mean to women in their fifties who are navigating the urban streets and shelter system?" Our study's purpose was to gain a deeper understanding of the impacts of daily displacement and migration and, through the women's accounts, engage in a critical analysis of the shelter system's practices and policies. Fifteen older chronically homeless women were recruited via a flyer posted at a city's women's day shelter to participate in an onsite interview about their homelessness experiences. Using a phenomenological approach, in depth semi-structured interviews were conducted, recorded and transcribed verbatim. Our analysis process was inductive and iterative with the culminating phases being theme generation and interpretation. Participants identified challenges centered on six themes: 1) loss of a sense of control, self-determination, and independence, 2) lack of physical security, 3) worsening physical and emotional health, 4) lack of comfort, familiarity, and routine, 5) weakening or loss of social connections, and 6) a diminished sense of self-worth. The findings highlight the links between place, sense of belonging, and identity. The data underscored that shelters were dehumanizing places that further diminished women's sense of self. We discuss reforms needed to disrupt shelter and housing systems' practices that further disempower and stigmatize the women and fail to support pathways out of homelessness.

DEEP AGING: THE CONNECTION THAT SURVIVES DEATH AND ITS ROLE IN INCREASING HUMAN–NONHUMAN RELATIONSHIPS

Hong-Jae Park, *Western Sydney University, Penrith, New South Wales, Australia*

Ageing is part of life, and so is death. Although death will involve all of us over time, it is often regarded as a taboo topic, and bonds with the dead are seldom acknowledged in contemporary times. The aim of this paper is to present selected insights on the connection that survives death and its role in increasing human/non-human relationships, learned from two indigenous knowledges—whakapapa (genealogical connections in Maori) and filial piety (respect/care for parents and ancestors). Data were collected from semi-structured interviews with 49 key informants (Maori=25; Korean=24) between 2019 and 2021 in New Zealand and South Korea. A modified thematic analysis method was used to analyse the data obtained in a bilingual research context. The research findings show that the connectedness with ancestors or deceased loved ones is a significant part of the participants' mental and social lives, emphasised in both whakapapa and filial piety/ancestor veneration traditions. Maori participants were likely to consider their natural environment (for example, land and water) as a common good for all generations, while Korean counterparts viewed it (for example, a mountain) as the place where ancestors were remembered and venerated. Participants' awareness of the post-mortem relationships was associated with their connection with nature and spiritual practices. Overall, this study suggests that there are several possible ways that older people could do 'something' prior to death for their remaining families and friends, ranging from activities concerning death talk, end-of-life preparation, legacy building and after-life planning, to connectedness with nature and non-human beings.

EXPLORING THE LIVED EXPERIENCE OF RACIALIZED AGEISM AMONG OLDER ADULTS: A PHENOMENOLOGICAL STUDY

Andrew Steward[1], Carson De Fries[2], Annie Zean Dunbar[2], Miguel Trujillo[2], Yating Zhu[3], Nicole Nicotera[2], and Leslie Hasche[2], *1. University of Wisconsin-Milwaukee, Milwaukee, Wisconsin, United States, 2. University of Denver, Denver, Colorado, United States, 3. University of Denver, Dener, Colorado, United States*

Ageism is a prevalent, insidious social justice issue which has harmful effects on the health of older adults. Preliminary literature explores the intersectionality of ageism with sexism, ableism, classism, and ageism experienced among LGBTQ+ older adults. To our knowledge, the intersection of ageism with racism, or racialized ageism, is largely absent from the literature. This qualitative study explored the following research question from a phenomenological perspective: "What is the lived experience of racialized ageism among diverse older adults?" Twenty participants 60+ years of age (M=69) in the U.S. Mountain West identifying as Black, Latino(a), Asian-American/Pacific Islander, Indigenous, or White engaged in a one-hour interview between February and July 2021. A three-cycle coding process used constant comparison methods. Five coders independently coded interviews, engaging in critical discussion to resolve disagreements. An audit trail, member checking, and peer debriefing enhanced credibility. Six umbrella themes and 20 sub-themes were identified. In this paper, the following six sub-themes are highlighted with direct implications for practice:1) compounding oppression, 2) being avoided or categorized due to others' discomfort, 3) increased disrespect, 4) microaggressions, 5) acts of hate, and 6) cultural values/respect for elders as a protective factor. Implications include informing how practitioners may enhance support for older adults in preventing and coping with experiences of racialized ageism. Enhanced understanding of racialized ageism should also inform existing anti-ageism initiatives at the community level. Future research should focus on the experience of racialized ageist microaggressions and the relationship between racialized ageism and specific health outcomes.

MID- AND LATER-LIFE COMMUNITY COLLEGE STUDENTS: OFF-TIME EDUCATION AND THE SIGNIFICANCE OF INTRACOHORT DIVERSITY

Kathryn McGrew[1], Phyllis Cummins[2], and Oksana Dikhtyar[3], *1. Miami University Scripps Gerontology Center, Oxford, Ohio, United States, 2. Miami University, Oxford, Ohio, United States, 3. Miami University, Oxford, Ohio, United States*

Workers ages 45 and older make up about 45% of the U.S. labor force. To meet labor market demands in the U.S., employers will need to rely on mid- and later-life (MLL) (age 40 and older) workers. Through a gerontological lens, using both qualitative and quantitative data, we investigated the "off-time" enrollment of MLL community college students to explore how their enrollment decisions and academic goals are situated in the timing and intersection of life events and transitions, such as the responsibilities of work and family. We conducted 12 focus group interviews with MLL community college students (n=68) in Ohio and conducted a quantitative analysis of the distribution of academic goals by age group. We conclude that the foremost characteristic of MLL students as a group is its within-group heterogeneity and the greatest barrier to serving MLL students is in how we have been thinking—or failing to think—about them. We take a first slice at disaggregating "adult" students and turn away from deficit narratives to identify opportunities and assets among MLLs. Finally, we offer a theory to explain how especially wide within-group diversity of MLL academic goals is produced by cohort divergence of life events, transitions and trajectories; diverse enrollment precipitants; and individual point-of-time appraisals of lifetime elapsed and lifetime remaining. We suggest that community colleges, already leaders in adult education, are in a unique position to effectively serve MLL students by recognizing and accommodating their diversity. We present implications and strategies for colleges, policymakers and researchers.

SESSION 4440 (SYMPOSIUM)

WHAT NEEDS TO BE DONE TO PREVENT ELDER ABUSE IN JAPAN?

Chair: TsuAnn Kuo Discussant: Georgia Anetzberger

This symposium first introduces the Japanese Act on the Prevention of Elder Abuse, including its elder abuse definitions and trends in elder abuse in both institutional and domestic settings. It then describes a recent amendment to operational standards made by ministerial ordinance, which aims to reduce elder abuse. Second, it presents analysis of elder abuse data (N=497) from Matsudo-City in Chiba prefecture, which found that only about 65% of reported elder abuse cases were deemed to meet the legal definition of elder abuse and the rest were excluded due to how the law defines abusers. Findings suggest the definitions in the Act be broadened to encompass a wider set of abuse situations. Third, it presents analysis using the same data, of characteristics of abusers. Findings indicate that about 24% of abusers were caregivers with disabilities, suggesting the importance of supporting caregiver health and welfare to help prevent abuse. The symposium concludes by presenting findings from a longitudinal survey of older adults aged 75+ (N=769) indicating that physical restraints use is associated with "having been diagnosed as intractable neurological diseases," "unstable general condition or at the terminal stage," "higher levels of care-need," "having medical treatment," and "family members' long-term care burdens."

A NEW STEP TO PREVENT ELDER ABUSE IN JAPAN

Noriko Tsukada[1], Naoki Ikeda[2], and Asako Katsumata[3], *1. Nihon University, Tokyo, Tokyo, Japan, 2. Kamihonnmachi sougou houritsu jimusyo, Tennouji-ku, Osaka, Japan, 3. Rehabilitation Institution, Chiba, Chiba, Japan*

This paper first introduces major aspects of the Japanese Act on the Prevention of Elder Abuse, including trends in substantiated elder abuse cases in both institutional and domestic settings, definitions of elder abuse, and abusers and reporting systems. It then introduces the recent amendment of operational standards in institutional settings made by ministerial ordinance. The amendment includes a requirement to develop a committee to prevent occurrence and recurrence of elder abuse and to appoint a designated individual to establish guidelines and implement training. It is hoped to further prevent elder abuse in Japan.

DETECTION OF ELDER ABUSE IN JAPAN NOT COVERED BY THE ELDER ABUSE PREVENTION LAW IN COMPARISON WITH WHO DEFINITION

Tadashi Wada[1], Hitoshi Suda[2], and Kana Satoh[3], *1. Irahara Primary Care Hospital, Matsudo City, Chiba, Japan, 2. SEITOKU University, Matsudo city, Chiba, Japan, 3. Teikyo University of Science, Adachi, Tokyo, Japan*

The Elder Abuse Prevention Law mainly defines “elder abuse” inflicted by caregivers. Elder abuse by non-caregivers is therefore rarely covered by the law. We investigated domestic elder abuse reported in Matsudo City, Chiba, Japan, to determine the number of domestic elder abuse cases excluded from legal protection but constituting elder abuse defined by WHO. From April 2017 to March 2020, the municipal elder protection services agency received 525 reports of domestic elder abuse. We studied the effective records of 497 of these cases. 299 cases were confirmed elder abuse cases defined by the law, with 198 excluded. However, 176 out of the 198 excluded cases constitute elder abuse defined by WHO. In these 176 cases, abuse was perpetrated by non-caregivers. Due to the current formation of the law, this abuse went undetected and unprotected. We think amendment of the law is required to protect these excluded cases.

NEED FOR SUPPORT FOR PERSONS WITH DISABILITIES IN ELDER ABUSE

Hitoshi Suda[1], Tadashi Wada[2], and Kana Satoh[3], *1. SEITOKU University, Matsudo city, Chiba, Japan, 2. Irahara Primary Care Hospital, Matsudo City, Chiba, Japan, 3. Teikyo University of Science, Adachi, Tokyo, Japan*

Among the elder abuse cases reported to Matsudo City, Chiba Prefecture (population 487,091 as of April 1, 2017) from fiscal year (FY) 2017 to FY 2019. Of the 525 reported cases, 497 for which records could be judged to be accurate were included in the study. There were 119 cases (23.9%) in which the abusers were presumed to have a disability. Out of these 119 cases, the abusers of 86 (72.3%) cases were not involved with health and welfare policies for people with disabilities or such involvement had been suspended. If the abuser had received support in the field of health and welfare for the disabled or as a person in need at an early stage, the elder abuse might not have occurred. Support for people with disabilities and support for persons in financial need are required before they become abusers.

PHYSICAL RESTRAINTS AT HOME AND THEIR FACTORS: A ONE-YEAR LONGITUDINAL SURVEY AMONG HOME CARE SERVICE USERS IN JAPAN

Noriko Yamamoto-Mitani, Hanako Numata, and Chie Fukui, *The University of Tokyo, Tokyo, Tokyo, Japan*

We conducted a one-year survey of homecare service users aged 75 years and older. Data from 769 clients were examined. Altogether 47 (6.1%) received physical restraint at least once among the five survey points conducted over a one-year period. Among them, 27 (57.4%) received restraint only at one point, and only 2 received restraint in all five points. In the bivariate analyses, the factors associated with the use of physical restraint were: diagnosis of neurological disease, unstable general condition or terminal stage, high level of care required, medical treatment, and family burden. When those who were released from the restraint at 12 months (n=30) were compared with those who were not (n=17), not having stroke, not receiving suctioning, and not having home-visit medical care were significant factors. Physical restraints at home were not common but we must be careful when we serve clients with significant factors of prolonged restraints.

SESSION 4450 (SYMPOSIUM)

EAST MEETS WEST: MODELS OF "AGING IN COMMUNITIES": DEMENTIA, CAREGIVING, AND ACTIVE AGING BETWEEN THE US AND TAIWAN

Chair: TsuAnn Kuo Discussant: Fernando Torres-Gil

As countries around the world are entering the super aged societies, aging in place will need to be planned not only as an individual but also as a multi-disciplinary and age-friendly community. Many models are built based on the concept of "Aging in communities" in order to consider the multi-levels of needs and interests that older adults face when living in the same area. With Asia being the next fastest aging continent, innovative models and programs are also developed in Taiwan as it tries to promote healthy aging, combating dementia and supporting family caregivers. This symposium will include 4 papers by introducing a national program for frailty prevention, a community friendly model for people with dementia and a collaborative network to prevent family caregivers from being burned out. In addition, the village model developed in the U. S. will be compared to show how east meets west to demonstrate communities meeting the needs of older adults.

FOSTERING MULTIPARTNERSHIP IN DEVELOPING A DEMENTIA-FRIENDLY COMMUNITY WITH AN OPEN DEMENTIA DAY CENTER IN TAIWAN

Ling-Hui Chang[1], Men-An Pan[2], Li-Xue Wu[2], Chi-pang Lu[3], Liwen Sung[4], and Pai--Chuan Huang[5], *1. National Cheng Kung University, Tainan City, Tainan, Taiwan (Republic of China), 2. Pingtung County Government, Pingtung City, Pingtung, Taiwan (Republic of China), 3. Research Center For Humanities And Social Sciences, Tainan City, Tainan, Taiwan (Republic of China), 4. Department of Architecture, Tainan City, Tainan, Taiwan (Republic of China), 5. Occupational Therapy, College of Medicine, Tainan City, Tainan, Taiwan (Republic of China)*

Introduction. Supporting persons with dementia without increasing the demands of formal care is an issue that many countries face today. Pingtung County proposed an innovative practice of an open dementia day center situated in a dementia-friendly community (DFC), where people with dementia in the center can freely go outside and enjoy community living. This presentation examines the experience of an university academic team in fostering a municipality-academic-community partnership as we tried to “flip” the care of a traditional dementia day center to adopt an “open” care model and concurrently to make the nearby community dementia-friendly. Method. A pragmatic research paradigm was adopted to address the socially situated situation in which we encountered when building a dementia-friendly community and the strategies we adopted to respond to the problem. Results/Discussion. Three themes: (1) Partnering with local government, e.g. to reduce the cognitive and physical barriers for outdoors activities and to increase the competence of local officials in DFC. (2) Partnering with local community and business: e.g. to increase the DFC awareness of community volunteers and to initiate a DFC business project, (3) building an academic team: e.g. to engage faculties who were motivated to pioneer an innovative practice, to fulfill their social responsibility, bridge the gap between theory, research, and practice. Conclusion. Significant changes were made in the community and the day center towards DFC. Community stigma towards dementia and community inertia was major obstacles. The allocation of city resources, personal drive towards DFC, and regular communication were key, despite the process was fraught with compromise, power dynamics, and conflicts of interests.

AGING IN COMMUNITY MODELS IN THE US: FRAMEWORKS FOR COMMUNITY SUPPORTIVE NETWORK DIALOGS BETWEEN WEST AND EAST

Su-I Hou, *University of Central Florida, Orlando, Florida, United States*

Aging in Community (AIC) is the preferred way to age. This session shares promising AIC models in the U.S. and analyzed model characteristics. Four models were identified with the potential to achieve person-environment (P-E) fit, including village, naturally occurring retirement community (NORC), cohousing, and university-based retirement community (UBRC). Empirical studies show these AIC models enhance social support and improving older adult's well-being, remain independence at homes, and community social and civic participation. Each model has a unique way to help community-dwelling older adults with their aging needs. This session aims to stimulate dialogs on opportunities and challenges of forming AIC supportive networks considering Eastern versus Western cultural and societal differences. Promising U.S. AIC models shared will serve as conceptual frameworks to facilitate discussions on various model's strengths and weakness and how they might be adapted in Taiwan's society considering eastern cultural values, societal norms, and healthcare system. Examples of Taiwan versions of these similar promising U.S. AIC models will be shared. Continued research is needed to address the challenges of engaging older adults with lower socio-economic status, meeting older adults' diverse and dynamic needs, and conducting comparative studies to share lessons learned across the globe.

THE ESTABLISHMENT OF A COMMUNITY NETWORK TO SUPPORT FAMILY CAREGIVERS

Tsuann Kuo, *Chung Shan Medical University, South District, Taichung, Taiwan (Republic of China)*

In 2021, 114 Caregiver Resource Sites were established in Taiwan to provide case management and services for family caregivers who may experience caregiving burnout due to long-term care. Each Caregiver Resource Site is responsible for serving 60-100 caregivers. An effort was made to recruit volunteers and gather resources so caregivers can be surrounded in the care-friendly community network, including care counseling, support groups, caregiving skill classes, relaxation activities, caregiver café, and in-home coaching for hard-to-care moments. By forming this community network to support caregivers, it has reduced caregiver burnout and avoided possibly negative tragedies due to caregiving.

SESSION 4460 (SYMPOSIUM)

BEREAVEMENT ACROSS THE ADULT LIFE COURSE: VARIATIONS IN EFFECTS ON HEALTH AND WELL-BEING

Chair: J Jill Suitor Co-Chair: Megan Gilligan

This symposium considers the consequences of deaths of family members across the life course on psychological well-being, physical health, and mortality in the middle and later years. The first two papers focus on intergenerational losses, using data from the HRS. Donnelly, Lin and Umberson examine the ways in which the impact of parental death on adult children's health in later life are shaped by children's ages at loss, social isolation, and race/ethnicity. Next, Huo and Kim investigate the extent to which the effect of child loss on parents' well-being in mid- and later-life is moderated by volunteering. The third and fourth papers focus on the role of spousal loss in health and well-being. Rodin and colleagues use HRS data to explore whether the association between widowhood and mortality differs depending on the cognitive health of the surviving spouse. Next, Vedder and colleagues provide a systematic review of variations in patterns and predictors of loneliness by marital status in middle and later life. Finally, Miles and Olsen examine the association between recent loss and binge drinking among spouses and adult children who had served as caregivers to the deceased, using data from the Georgia Behavioral Risk Factor Surveillance Survey. This diverse set of studies reveals how the impact of the death of family members on survivors' health and well-being is shaped by a complex set of structural and socioemotional factors, shedding new and important light on health disparities by sex/gender and race/ethnicity in the middle and later years.

RACIAL/ETHNIC DISADVANTAGE IN PARENTAL DEATH ACROSS THE LIFE COURSE, SOCIAL ISOLATION, AND HEALTH IN LATER LIFE

Rachel Donnelly[1], Zhiyong Lin[2], and Debra Umberson[3], *1. Vanderbilt University, Nashville, Tennessee, United States, 2. University of Texas at San Antonio, San Antonio, Texas, United States, 3. The University of Texas at Austin, Austin, Texas, United States*

Prior research has not considered how exposure to parental death across the life course may contribute to lasting social isolation and, in turn, poor health among aging adults. The present study uses longitudinal data from the Health and Retirement Study (HRS; 1998-2016) to consider linkages of parental death, social isolation, and health (self-rated health, functional limitations) for Black, Hispanic, and White older adults. Findings suggest that exposure to parental death before later life is associated with higher levels of isolation, greater odds of fair/poor self-rated health, and more functional limitations in later life. Moreover, social isolation partially explains associations between parental bereavement and later-life health. Racial disparities in bereavement are central to disadvantage: Black and Hispanic adults are more likely to experience parent death early in the life course and this differential exposure to bereavement has implications for racial and ethnic disparities in social isolation and health throughout life.

LONG-TERM PSYCHOLOGICAL CONSEQUENCES OF PARENTAL BEREAVEMENT PRIOR TO MID-LIFE: VOLUNTEERING HELPS

Meng Huo[1], and Kyungmin Kim[2], *1. University of California, Davis, DAVIS, California, United States, 2. Seoul National University, Seoul, Seoul-t'ukpyolsi, Republic of Korea*

Losing a child prior to midlife may be a uniquely traumatic event that continues to compromise parents' well-being in later life. This study compared psychological well-being between bereaved and non-bereaved parents, and examined whether volunteering protects bereaved parents. We analyzed a pooled sample of parents aged 50+ (N = 12,023) from the Health and Retirement Study, including parents who lost a child prior to 50 and those who never lost a child. Bereaved parents reported more depressive symptoms and lower life satisfaction than non-bereaved parents, which was more evident among parents with fewer children alive. Among bereaved parents, volunteering, particularly volunteering 100+ hours/year, was associated with better well-being at baseline; yet, volunteering 1–99 hours/year led to a larger increase in life satisfaction over time. This study adds to our understanding of lasting effects of parental bereavement and suggests volunteering as a potential intervention aimed at helping bereaved older parents.

THE WIDOWHOOD EFFECT IN COMPLEX SERIOUS ILLNESS: THE IMPACT OF SPOUSAL DEATH ON MORTALITY IN DEMENTIA

Rebecca Rodin[1], Alex Smith[2], Edie Espejo[2], W. John Boscardin[2], Siqi Gan[2], Lauren Hunt[2], Katherine Ornstein[3], and Sean Morrison[1], *1. Icahn School of Medicine at Mount Sinai, New York City, New York, United States, 2. University of California, San Francisco, San Francisco, California, United States, 3. Johns Hopkins, University, Baltimore, Maryland, United States*

Numerous studies suggest that there is an association between widowhood and mortality. This "widowhood effect" may be heightened in patients with dementia, who have high support needs and for whom spouses typically provide extensive caregiving support. Yet there are limited data on widowhood and mortality that account for dementia status. To determine the relative mortality risk of widowhood among those with and without dementia, we conducted a retrospective cohort study among community-dwelling, married/partnered persons, ≥65 years, enrolled in the Health and Retirement Study, 2000-2018. Among the 12,308 persons (n=390 with dementia), widowhood was not associated with increased mortality, after adjusting for age and dementia status, in men or women (adjusted HR 1.04; 95%C.I.(0.95-1.13); HR 0.96; 95%C.I.(0.87-1.95), respectively). These findings suggest that dementia, age, or other unmeasured confounding variables may account for the previous finding of increased mortality following spousal death. Further research is needed to confirm these findings in diverse populations.

THE LONG-TERM LONELINESS OF WIDOWHOOD: A SYSTEMATIC REVIEW OF MARITAL STATUS DIFFERENCES

Anneke Vedder[1], Jeffrey Stokes[2], Kathrin Boerner[2], Henk Schut[3], Paul Boelen[3], Bibi Schut[3], and Margaret Stroebe[4], *1. Faculty of Social & Behavioural Sciences, Utrecht, Utrecht, Netherlands, 2. University of Massachusetts Boston, Boston, Massachusetts, United States, 3. Utrecht University, Departement of Psychology, clinical psychology, Utrecht, Utrecht, Netherlands, 4. University of Groningen, Experimental Psychopathology, Department Clinical Psych. & Exp. Psychopathology, Groningen, Groningen, Netherlands*

Loneliness can be prominent in bereavement, possibly leading to compromised mental and physical health. We systematically reviewed the extent of loneliness across marital status groups, examining the prevalence, intensity, risk factors, and correlates of loneliness in widowhood, compared to other marital statuses. Studies that met predefined criteria as well as investigated marital status (comparisons) were included in the review. For reporting, we followed the PRISMA statement. Thirty-eight studies were included. Widowhood was associated with a greater likelihood and intensity of loneliness when compared to other marital statuses, and especially the divorced. Widowers were on average lonelier than widows. Findings suggest that , widowed persons are uniquely vulnerable to loneliness, and that, in the long-term, loneliness may be more pronounced among the widowed than the divorced. However, methodological shortcomings (e.g., heterogenous samples, different measures of loneliness) of available studies must be considered, and future research should aim to overcome these limitations.

NEW BEREAVEMENT IS A RISK FACTOR FOR BINGE DRINKING, SMOKING, AND POOR MENTAL HEALTH (2019 GEORGIA BRFSS)

Toni Miles, *Rosalynn Carter Institute, Athens, Georgia, United States*

This presentation advances studies of population health by estimating the association between new bereavement and binge drinking rates among adults aged 50 years and older. In other reports, bereavement is associated with significantly higher rates of binge drinking among older adults. In 2019, the state of Georgia used an optional module in the Behavioral Risk Factor Surveillance Survey (BRFSS) to measure the prevalence of new bereavement. This is the first effort to capture population-level data on bereavement in Georgia. 45% of adults (4 million persons) aged 18 and older were newly bereaved in the 24 months prior to survey. Highest bereavement rates: adults aged 55 to 64 years (51%), unemployed (49%), and Black respondents (60%). Binge drinking rate for bereaved was 31 % (versus 23.6% not bereaved). Combined bereavement and binge drinking increased risk for poor mental health (OR = 2.83) and smoking (OR = 4.54).

SESSION 4461 (BIOLOGICAL SCIENCES INVITED SYMPOSIUM)

NEUROBIOLOGY OF AGING

Chair: Jasmin Herz

MENINGES HARBOR IMMUNE MEMORIES OF LIFE EXPERIENCES

Jasmin Herz[1], Khalil Alves de Lima[2], Andrea Francesca Salvador[2], Mackenzie Lemieux[2], Taitea Dykstra[2], Igor Smirnov[2], and Jonathan Kipnis[1], *1. Washington University in St. Louis, School of Medicine, St. Louis, Missouri, United States, 2. Washington University in St. Louis, St. Louis, Missouri, United States*

The adaptive immune system relies on formation of the memory of past microbial challenges to accelerate protective immune responses in the event of reinfection. This memory is accomplished in part by the retention of antigen-specific B and T cells within barrier tissues. As the healthy central nervous system parenchyma is virtually devoid of adaptive immune cells, the meningeal spaces carry out the vital function of coping with environmental threats during aging. We conducted an extensive molecular and functional analysis of meningeal T cells to test the hypothesis that the meninges in the brain sense and respond to internal and external cues throughout life, and that alterations in the meningeal T cell repertoire alter brain function. We found presumably self-reactive tissue-resident T cells in the meninges of naive mice. Using models of pathogen exposure, we describe a neuroimmune axis in which antigen experienced resident Tcell subsets dynamically record immune perturbations, which resulted in behavioral abnormalities that were exacerbated with aging. Our findings elucidate molecular properties of T cells that survey the brain borders under both homeostatic and pathological conditions and provide insights linking CNS immune privilege with memory.

REGULATION OF NEURONAL MITOCHONDRIAL BIOENERGETICS BY LIPID METABOLITES UPREGULATED IN DEMENTIA

Stephanie Heimler,[1] K. Allison Amick,[2], Jaclyn Bergstrom,[1] Mohit Jain[1], Anthony J. Molina[1], *1. UC San Diego School of Medicine, San Diego, California, United States*
2. Wake Forest School of Medicine, Winston Salem, North Carolina, United States

Mitochondrial dysfunction occurs early in Alzheimer's disease (AD) progression and is evident in the Central Nervous System (CNS) and peripheral circulating cells. While there is evidence indicating that bioenergetic decline can drive the early pathogenesis of AD, little is known about the extracellular factors that alter neuronal bioenergetic capacity. We hypothesized that circulating metabolites contribute to neuronal bioenergetic decline associated with AD. Using a cohort comprised of participants with normal cognition, mild cognitive impairment, and dementia, we show that human serum harbors circulating, non-cellular factors capable of mediating neuronal bioenergetic differences according to the cognitive status of the serum donor. We developed a novel screening-based approach to identify candidate "mito-active" lipid metabolites in human serum that could mediate differences in bioenergetic capacity. Among these, Nervonic Acid and 15-epi-PGA1 were predicted to be mitochondrial inhibitors upregulated in participants with dementia. Neurons exposed to physiologically-relevant ranges of these molecules in-vitro exhibited a dose-dependent reduction in maximal mitochondrial respiration. We found that 500ug/mL of Nervonic Acid and 9ug/mL of 15-epi-PGA1 reduced maximal mitochondrial respiration by 62.3% and 63.3%, respectively, thereby validating our screening and prediction approach. Future experiments may be directed towards investigating if and how these and other mito-active metabolites of interest cross the blood-brain barrier to meaningfully affect AD. Furthermore, identified mito-active molecules can be investigated in other clinical cohorts to examine their role/s in multiple age-related or neurological conditions. This work expands our mechanistic understanding of how extrinsic factors associated with age and cognitive status contribute to neuronal bioenergetic decline.

R1P DISPERSION IN WHITE MATTER CORRELATES WITH COGNITIVE IMPAIRMENT IN OLDER ADULTS

Fatemeh Adelnia, Taylor Davis, Lealani Mae Acosta, Amanda Puckett, Feng Wang, Zhongliang Zu, Kevin Harkins, John Gore, *Vanderbilt University Medical Center, Nashville, Tennessee, United States*

Alzheimer‘s disease is the most frequent form of dementia in older adults and has a total estimated worldwide cost that rises to $2 trillion by 2030. Much previous neuroimaging research in AD has focused on the roles of amyloid and tau proteins using PET, but there have also been several studies that have implicated microvascular changes as an early indicator of damage related to later dementia. Here, we developed and refined a non-invasive 3D-R1ρ dispersion imaging technique using different locking fields to quantify microvasculature changes within brain tissues in persons with mild cognitive impairment (MCI) compared to healthy controls. The fractional difference in R1ρ comparing different locking fields provides a unique way of characterizing changes in the geometry and structure of microvasculature. After providing informed consent, 40 adults aged 62 to 82 years (n=17MCI) underwent cognitive assessments and MRI scan at 3T. We found the fractional change in R1ρ of the whole brain white matter is significantly greater in persons with MCI, and the correlation remained significant (ß=-0.4, p-value=0.01) after introducing age (ß=0.2, p-value=0.2) and sex (ß=-0.1, p-value=0.5) as covariates. The white matter hypertonicity lesion volume measured from conventional MRI was also correlated with the health status (p-value < 0.05); however, the size of the regression coefficient was substantially smaller (53% lower), and it was no longer significant (p-value=0.14) after adjusting for age and sex. This work establishes a new non-invasive method that can potentially characterize changes in microvasculature anatomy with the progression of cognitive impairment regardless of an age effect.

SESSION 4465 (SYMPOSIUM)

REIMAGINING DISASTER AND EMERGENCY PREPAREDNESS IN LONG-TERM CARE: EXAMPLES FROM FLORIDA AND TEXAS

Chair: Lindsay Peterson Co-Chair: Ross Andel Discussant: Sue Anne Bell

A thread common to all disasters is the effect on human health that results when the health care infrastructure and delivery of health services are disrupted. This view has reinforced the importance of an all "all-hazards approach" to preparedness, whereby disaster response planning incorporates principles common to all events and can be adapted to specific contingencies. Preparing for and responding to a disaster in long-term care (LTC) requires a broad view of multiple events that can disrupt daily life and needed services for LTC residents (e.g. hurricanes, pandemics). This symposium will examine the effects of varied emergency events on older adults residing in nursing homes (NHs) and assisted living communities (ALCs) using quantitative and qualitative methodologies. The first presentation will discuss morbidity and mortality of NH residents exposed to Hurricane Harvey (Texas). The second is an investigation of NH direct care staffing during the recent Winter Storm Uri (Texas). The third presentation qualitatively explores the challenges of providing care to residents living with dementia during the COVID-19 pandemic, based on interviews with Florida NH and ALC administrators. The fourth quantitatively and qualitatively explores issues related to resident-to-resident contact restrictions in Florida ALCs. Finally, we will discuss the application of the 4Ms Age Friendly framework (What Matters, Medication, Mentation, and Mobility) to disaster preparedness in LTC. This symposium will provide information that can be used to develop or revise public policies to improve preparedness for and response to a range of emergency events in NHs and ALCs.

ASSOCIATION BETWEEN EXPOSURE TO HURRICANE HARVEY AND MORTALITY AMONG NURSING HOME RESIDENTS

Cassandra Hua[1], Kali Thomas[2], Sweta Patel[2], David Dosa[2], Dylan Jester[3], and Ross Andel[4], *1. Brown University School of Public Health, Providence, Rhode Island, United States, 2. Brown University, Providence, Rhode Island, United States, 3. University of California San Diego, La Jolla, California, United States, 4. University of South Florida, Tampa, Florida, United States*

Hurricane Harvey made landfall in Southeast Texas in August 2017, causing catastrophic flooding. We examined the association between exposure to Hurricane Harvey and rates of 30-and 90-day mortality among Texas nursing home residents. Using Medicare data, we compared a cohort of residents exposed to the storm in 2017 (n= 18,693) to a cohort of residents not exposed to the storm in 2015 (n=19,688). We fit generalized estimating equations with a sandwich estimator, adjusting for resident demographic and clinical characteristics. Exposure to Hurricane Harvey was not associated with 30-day rates of mortality. However, it was associated with a 15% increase in the odds of dying at 90 days holding resident characteristics constant (adjusted odds ratio: 1.15 [95% Confidence interval: 1.06, 1.25). Health effects due to severe flooding, such as those related to decreased ability to manage chronic conditions, may not be apparent until several weeks after the storm.

TEXAS NURSING HOMES INCREASED DIRECT-CARE STAFFING LEVELS DURING WINTER STORM URI

Dylan Jester[1], Lindsay Peterson[2], Ross Andel[2], and David Dosa[3], *1. University of California San Diego, La Jolla, California, United States, 2. University of South Florida, Tampa, Florida, United States, 3. Brown University, Providence, Rhode Island, United States*

Prior work suggests that nursing homes (NHs) increase their registered nurse (RN), licensed practical nurse (LPN), and certified nursing assistant (CNA) staffing levels in anticipation of a major hurricane. However, less is known about NHs' ability to increase staffing levels during a winter storm. We examined RN, LPN, and CNA staffing levels in 1,170 Texas NHs during Winter Storm Uri from February 13-20, 2021. This storm was characterized by cold temperatures and snow/ice accretion that affected the Texas power grid. Linear mixed effects models were adjusted for profit status, continuing-care retirement community status, resident census, overall star rating, a weighted deficiency score, number of citations for infection control, number of substantiated complaints, and county fixed-effects. After adjustment, Texas NHs decreased RN (β=-0.005;b=-0.002;p=.004) but increased LPN (β=0.022;b=0.009;p<.001) and CNA (β=0.044;b=0.026;p<.001) staffing levels. NHs face unprecedented challenges during winter storms, including maintaining adequate staffing levels to meet the needs of their residents.

WE DID MORE DAMAGE: HOW COVID-19 COLLAPSED THE CONVOYS OF CARE FOR RESIDENTS LIVING WITH DEMENTIA

Sara Hackett, Lindsay Peterson, Carlyn Vogel, and Debra Dobbs, *University of South Florida, Tampa, Florida, United States*

COVID-19 has posed a multitude of challenges for nursing homes (NHs) and assisted living communities (ALCs). However, little information is known about how the pandemic impacted residents living with dementia. Using the convoys of care framework, we conducted a qualitative descriptive study to gain insight regarding administrators' perceptions of how care for residents living with dementia was altered. Forty-two participants, representing 16 NHs and 43 ALCs in Florida, participated in one 60-minute semi-structured interview. Thematic analysis revealed that the convoys of care for those living with dementia were strained by the competing demands associated with maintaining residents' social and medical care. Explicitly, participants emphasized how diminished family involvement, the increasing responsibilities of staff, and the climate of the industry, contributed to disrupted convoys of care. Consequently, this study may help inform policy and practice as it details which care strategies worked, which did not, and considerations for moving forward.

RESTRICTIONS ON RESIDENT CONTACT IN ASSISTED LIVING DURING COVID-19: A MIXED-METHODS STUDY

Lindsay Peterson, Sara Hackett, Kallol Kumar Bhattacharyya, and Debra Dobbs, *University of South Florida, Tampa, Florida, United States*

Efforts to protect assisted living residents from COVID-19 by limiting contact warrant attention. Assisted living was developed as a social model where care is provided in a home-like environment. Given the social dimensions of assisted living, we sought to better understand the effects of COVID-19-based restrictions in assisted living. We surveyed (online) assisted living community (ALC) administrators (N=130) between October 2020 and March 2021 as part of a larger project on COVID-19 in Florida. We then interviewed a subset of participants (N=26). Administrators of chain-affiliated ALCs (compared to non-chain) were 2.7 times more likely to report resident-contact limitations had disrupted care (p=0.02). Larger ALCs (25 or more beds) were marginally more likely to report care disruptions (p<0.10). Three main themes emerged from our qualitative interviews

– varying interpretation of COVID-19 guidelines, effect of precautions on residents, assisted living as a home. Policy implications of these findings will be discussed.

USING THE INSTITUTE OF HEALTHCARE IMPROVEMENT'S 4M FRAMEWORK TO IMPROVE DISASTER PREPAREDNESS FOR NH POPULATIONS

David Dosa[1], Dylan Jester[2], Lindsay Peterson[3], Debra Dobbs[3], Lisa Brown[4], and Kathy Black[5], *1. Brown University, Providence, Rhode Island, United States, 2. University of California San Diego, La Jolla, California, United States, 3. University of South Florida, Tampa, Florida, United States, 4. Palo Alto University, Palo Alto, California, United States, 5. University of South Florida, Sarasota-Manatee, Florida, United States*

Prior studies have repeatedly demonstrated that exposure to natural disasters such as hurricanes, earthquakes, and flooding events have profound effects on nursing home (NH) residents. Previous efforts to improve disaster preparedness have often been predicated on the decision to evacuate or shelter in place from a disaster. Unfortunately, evacuation of NH residents is often not possible and nursing homes are often required to make difficult decisions to protect the lives of their residents without data. Recognizing that healthcare systems increasingly provide care for complex individuals; the Institute of Healthcare Improvement (IHI) and the John H. Hartford Foundation introduced a framework for evaluating age-friendly healthcare systems based on 4 evidence-based core elements that matter to older adults. We believe that this 4 M's paradigm: What Matters, Medication, Mentation, and Mobility, provides a step off point for defining a practical approach to disaster preparedness for nursing homes exposed to future disasters.

SESSION 4470 (PAPER)

COMMUNICATION AND LANGUAGE

Paper

AGING COUPLES' SATISFYING RELATIONSHIPS AND WE-TALK PROMOTE CARDIOVASCULAR HEALTH DURING CONFLICT

M. Rosie Shrout[1], Stephanie Wilson[2], Megan E. Renna[3], Annelise A. Madison[4], and Janice K. Kiecolt-Glaser[4], *1. Purdue University, Lafayette, Indiana, United States, 2. Southern Methodist University, DALLAS, Texas, United States, 3. University of Southern Mississippi, Hattiesburg, Mississippi, United States, 4. Ohio State University, Columbus, Ohio, United States*

Marital conflict poses health risks that intensify as couples grow older. Dyadic stress theories suggest spouses' marital satisfaction and communication patterns alter cardiovascular function, a key pathway from troubled relationships to poor health. Despite these risks, older spouses are more likely to have a strong couple identity where they think and talk in relational terms. This communication pattern, termed we-talk, is shown when spouses use words like "we" rather than "you" or "me," reflecting that they are thinking about resolving conflict as a couple rather than as two separate individuals. We examined how both spouses' relationship satisfaction and we-talk reduced conflict's cardiovascular toll, and if the health benefits were greatest when both spouses were satisfied and used we-talk. Married couples (n=107) ages 40-87 engaged in a 20-minute conflict discussion while wearing heart rate monitors to assess heart rate variability (HRV), a measure of cardiac flexibility. Couples' conflicts were transcribed to measure we-talk, or the proportion of first-person plural pronouns, such as we, us, and our. Results showed a person's HRV was higher and thus healthier when both spouses were satisfied and their partner used we-talk more often. In contrast, HRV was lower and less healthy when neither or only one spouse was satisfied and their partner used we-talk less often. Thus, a couple's mutually satisfying relationship along with a partner's we-talk provided a health advantage during conflict. Talking in relational terms may help reduce conflict's biological toll in aging couples, particularly when their relationships are satisfying.

LANGUAGE-BASED DISCRIMINATION RELATES TO MEMORY COMPLAINTS AMONG LATINX/HISPANIC OLDER ADULTS

Elizabeth Soto[1], Silvia Chapman[2], Indira Turney[3], Laura Zahodne[4], Stephanie Cosentino[3], Adam Brickman[5], Jet Vonk[6], and Jennifer Manly[6], *1. Columbia Medical Center, New York City, New York, United States, 2. Columbia University Irving Medical Center, New York City, New York, United States, 3. Columbia University Medical Center, New York, New York, United States, 4. University of Michigan, Ann Arbor, Michigan, United States, 5. Columbia Medical Center, New York, New York, United States, 6. Columbia University, New York, New York, United States*

Memory Complaints (MCs) are a risk factor for dementia, but research in this area has largely been limited to non-Latinx White adults. Previous studies have shown that Latinx/Hispanic individuals are at higher risk for Alzheimer's Disease and Related Disorders (ADRD). The mechanisms underlying this disparity in ADRD are multidimensional and can include negative social stressors such as discrimination. Language discrimination can be a source of stress in this population and might be an important contributor to MCs. We examined if MCs varies as a function of language-based discrimination in a total of 495 Latinx/Hispanic older adults without dementia from the community-based Washington Heights Inwood Columbia Aging Project. Language-based discrimination was measured with a dichotomous item that inquired if individuals had been discriminated against because they do not speak English well (yes or no). A linear regression was conducted to examine the cross-sectional association between language-based discrimination and MCs adjusted for age, education, sex/gender, socioeconomic status (income), and depressive symptoms. The experience of language discrimination was independently associated with MCs (B= 0.83, 95% CI=0.13, 1.54, SE= 0.36, p= .021). Results demonstrate a relationship between negative stressors and the expression of MCs. Future studies should comprehensively examine other discriminatory stressors which may also impact the expression of MCs and the risk for progression to ADRD. Identifying language-based and other discriminatory stressors that negatively affect Latinx/Hispanic communities will allow us to develop models that aim to assess and prevent discrimination, as a protective mechanism for the development of MCs and ADRDs.

LINGUISTIC STRATEGIES FOR AGE-INCLUSIVITY: ANALYSIS OF HAIKU-BASED INTERGENERATIONAL INTERACTION

Harumi Maeda[1], Emily Wan[2], and Yoshiko Matsumoto[2], *1. Stanford University , Stanford, California, United States, 2. Stanford University, Stanford, California, United States*

Many studies have examined communicative and linguistic strategies helpful to the interactional inclusion of persons living with dementia (PLwD) and the promotion of an age-inclusive society (e.g., Wray, 2020; Stickle, 2020). Building on this existing body of research, our study examines question-answer sequences in conversations (Schegloff & Sacks, 1973) among younger adults and PLwD using discourse analysis methodology to illuminate effective communicative practices for facilitating more inclusive and meaningful interactions between these individuals. Findings from this methodology are complemented by analysis of post-interaction interviews. The data set for this study consists of audio-video recordings of (1) intergenerational conversations around haiku poetry in English between older adults with mild cognitive impairments (MCI) and college students, and (2) post-interaction interviews that assess participants' feelings about the experience. The data was collected as part of a larger study designed to promote social inclusion of individuals of all ages and cognitive conditions, particularly during the pandemic, via an online intergenerational haiku-making activity. The audio-video recordings were transcribed for qualitative analysis. Findings from the analysis demonstrate the effectiveness of open and emotion-focused questions (Matsumoto, Liao, Xue, 2020; Worley, 2005) in encouraging persons with MCI to express themselves on their own terms and promoting their interactional participation. By presenting the benefits of this type of question and related linguistic strategies, this study hopes to provide a basis for developing more inclusive communicative environments for people of all ages and PLwD to help improve quality of life and well-being across all stages of life.

MAPPING BARRIERS AND FACILITATORS OF ACCESS TO HEARING HEALTHCARE RESOURCES TO THE COM-B FRAMEWORK

Debra Schutte[1], Thomas Templin[1], and Brian Schutte[2], *1. Wayne State University, Detroit, Michigan, United States, 2. Michigan State University, East Lansing, Michigan, United States*

Age-related hearing impairment (ARHI) affects 20-40% of older adults. However, many people with hearing impairment fail to seek professional evaluation and treatment, delay seeking treatment, or abandon treatment. The purpose of this study was to identify barriers and facilitators of access to hearing healthcare resources in a rural setting and to characterize these barriers within the COM-B (capability, motivation, and opportunity) framework. Survey packets were handed out following services at a rural community church; 72 completed surveys were returned. The mean age of participants was 54.4 years. Thirty-one percent of respondents reported moderate to severe hearing impairment; of these individuals, 7 (31%) were currently using a hearing aid. Rates of hearing protection use fell below the Healthy People 2020 target of 53% across occupational and leisure noise exposure. Forty-eight percent (N=34) of participants had never had their hearing tested as an adult. Overall perceived barriers were significantly correlated with age (r= .260, P = .034) and perceived hearing loss (r=-.277, P= .025). Barriers were identified across all domains and subdomains of the COM-B framework. Barriers clustered in the reflective motivation domain, in which participants undervalue the significance of hearing loss. Barriers also clustered within the social and physical opportunity domains, suggesting a lack of access to providers and an undervaluation of hearing loss by others (family and health care providers). These findings provide evidence regarding the accessibility of hearing healthcare services in rural settings and will serve as a foundation for the design of a community-tailored hearing health intervention.

SESSION 4480 (PAPER)

DEATH, DYING, AND END OF LIFE

DEATH FEARS AND ANXIETY ACROSS THE LIFE COURSE: IMPLICATIONS FOR DEATH REFORM

Amber Thompson[1], and Rebecca Utz[2], *1. University of Utah, Sandy, Utah, United States, 2. University of Utah, Salt Lake City, Utah, United States*

Western culture is experiencing a movement for death reform which includes aspects such as death acceptance and supporting individual choice concerning how one wishes to experience end-of-life (EOL). The underlying goal of this reform is to foster natural curiosity about death and dying in order to soothe death fears and anxiety. Over the past few decades in the U.S. there has been an increase in public support for the EOL option of medical-aid-in-dying (MAID), or legally prescribed pharmaceuticals intended to cause death. There have been mixed findings regarding the effects of age on attitudes and perspectives towards death and dying. The aim of this study was to determine the relationship between age, death fears and anxiety, values and perspectives, demographic characteristics, and approval of MAID at EOL in a U.S. nationally representative sample (N = 1994), using a partially latent structural equation model (SEM). Results show that age has a curvilinear effect on death fears and anxiety, and that as death fears and anxiety increase support for MAID decrease. This suggests that the ability to provide person-and-family-centered care at EOL must address the biopsychosocial aspect of death fears and anxiety across the life course. These findings demonstrate the need for more research documenting changes in attitude and perspectives towards EOL for different populations (i.e., ages). The potential benefits of this approach provide a basis for expanding education and awareness of both death and dying in general, and EOL needs and wants for older adult populations.

FAMILY DECISION-MAKING IN SERIOUS ILLNESS SCENARIOS: ACCURACY AND PERCEIVED ACCURACY OF ADULT CHILD SURROGATES

Jessica Hahne, and Brian Carpenter, *Washington University in St. Louis, St. Louis, Missouri, United States*

Adult children often help older adults make important decisions in serious illness situations, but previous research suggests adult children are not uniformly accurate in predicting parents' preferences. In this project we examined the accuracy with which adult children (N= 68; M age= 45; 69.1% female) were able to predict medical preferences of their parents (N= 34; M age= 75; 94.1% female). Parents expressed their preferences in four serious illness scenarios, and children predicted parents' preferences. Parents and children also estimated the accuracy of children's predictions and the frequency of communication about medical care. On average across all scenarios, children predicted parents' preferences accurately 42.3% of the time. Parents were willing to take more risk with treatment for more severe disease, as their children predicted, although children generally overestimated parents' willingness to live with increasing disability (M difference = 9.77%). Overall, children were poor at predicting their own accuracy (Rs = -.017, p= .893). Parents were slightly more insightful about their children's accuracy (Rs= .261, p=.034), but there was no association between accuracy and parent or child estimate of frequency of conversations about medical preferences (Parent Rs= .067, p=.586 ; Child Rs= .164, p= .182). These findings suggest that neither are adult children highly accurate at predicting parents' medical preferences, nor do they or their parents have a precise sense of their accuracy. Results from this study may inform interventions to help families communicate about advance care planning.

PERSONALITY TRAITS AND END-OF-LIFE ATTITUDES AND BEHAVIORS IN OLDER ADULTS: EVIDENCE FROM SHARE

Valerie-Anne Ryser[1], Sarah Vilpert[2],
Gian Domenico Borasio3, and Jürgen Maurer[2], *1. Swiss Centre of Expertise in the Social Sciences, Lausanne, Vaud, Switzerland, 2. University of Lausanne, Lausanne, Vaud, Switzerland, 3, Lausanne University Hospital and University of Lausanne, Lausanne, Vaud, Switzerland*

Personality traits (PTs) - Neuroticism, Extraversion, Openness to experience, Agreeableness, Conscientiousness - are related to decision-making styles, as well as to specific end-of-life (EOL) healthcare preferences. Building on this knowledge, our study aims to explore the association of PTs with attitudes and behaviours towards the EOL in general and EOL care planning in particular. Our analyses are based on a paper-and-pencil self-completion questionnaire (n=1'524) administered as part of wave 6 and 7 of SHARE in Switzerland. PTs are measured with the Big-Five inventory ten (BFI-10). Attitudes and behaviours related to EOL are: outlook –avoid thinking about death, think about and discuss EOL preferences–, administrative arrangements –testament, power of attorney–, approval and completion of advance care planning. Results show that older adults with higher scores on openness are more likely to think, plan and discuss EOL, as well as to have made arrangement in advance such as a testament, and a power of attorney. Higher scores on extraversion are linked with having a testament. Individuals who express higher scores on neuroticism more often think about their wishes for EOL, whereas those scoring higher on agreeableness are less likely to be in favour of advance care planning. To conclude, older adults in Switzerland remain unfamiliar with EOL topics, since only individuals with higher openness to experience are more prone to prepare for the EOL. PTs should be taken into account when educating and encouraging people to plan for their EOL.

UNEQUAL LOSS: DISPARITIES IN RELATIONAL PROXIMITY TO A COVID-19 DEATH AMONG US OLDER ADULTS

Alicia Riley, *University of California, Santa Cruz, Santa Cruz, California, United States*

The COVID-19 pandemic has devastated communities of color in the U.S. at disproportionate rates. Racial-ethnic and language disparities in COVID grief may be even more extreme than those in individual mortality. We drew on the National Social Health and Aging Project (NSHAP) COVID Study, a supplement to the nationally-representative longitudinal survey. The analytic sample consisted of 2,554 community-dwelling older adults in the U.S. interviewed between September 2020 and January 2021. We used descriptive analysis to evaluate disparities by race/ethnicity/language subgroups in relational proximity to a COVID-19 death (aquaintaince < friend/family member < household member < spouse) and multiple logistic regression to evaluate disparities in experiencing at least one COVID-19 death in one's social network. English-speaking, Non-Hispanic Black and Latino older adults were over-represented in every category of proximity to a COVID-19 death, but overrepresentation in proximity to a COVID-19 death was greatest among Spanish-speakers of any race. Although Spanish-speaking respondents were only 4.6% of the full sample, half of the respondents who lost a spouse to COVID-19 were Spanish-speakers. Disparities by language and race/ethnicity persisted even with the inclusion of controls for age, sex, marital status, education, and nativity. The most extreme disparities in closeness to COVID-19 death were experienced by Spanish-speakers of any race/ethnicity. It is unclear if this disparity is driven by language alone or the intersection of language and nativity and associated systemic vulnerabilities. Observed disparities could also reflect variation by language and immigrant identity in network size and structure, including connections to relatives in other countries.

WORKING MEMORY MODERATES DEPRESSIVE SYMPTOMS AFTER PARTNER MORTALITY: HEALTH AND RETIREMENT STUDY

David Brush[1], Daniel Paulson[2], and Robert Dvorak[3], *1. University of Michigan, Ann Arbor, Michigan, United States, 2. University of Central Florida, Maitland, Florida, United States, 3. University of Central Florida, Orlando, Florida, United States*

Grief is conceptualized as a process after which the individual becomes better adapted to changed living conditions after a loss. The Selection, Optimization, and Compensation with Emotion Regulation (SOC-ER) model posits that working memory may be necessary for mitigation and resolution of grief. This study examined the hypothesis that working memory facilitates successful grieving following the loss of an intimate partner. Participants include 3,599 respondents of the longitudinal Health and Retirement Study (HRS) who experienced spousal mortality between 1994 and 2014. Working memory was measured assessed using Serial 7's, and depressive symptoms were assessed using the 8-question CES-D. Latent-growth models were used to estimate rate of change in depressive symptoms up to loss-of-spouse (baseline event), and then subsequent to that loss. Missing data were handled using full-information maximum likelihood. Sample participants had an average age 78.04 (SD = 7.32) at the time of their spouse's death and were disproportionately female (69.10%), White/Caucasian (82.30%), non-Hispanic (92.37%), and completed an average of 11.61 (SD = 3.42) years of education. The hypothesized level 2 model fit the data very well: $\chi2(56)=61.323$, p=.29 RMSEA=0.005 [0.000 0.012]; CFI=0.998, SRMR=0.028. Initial depressive symptom endorsement was significantly related to working memory ability. Working memory also moderated the relationship between depressive symptom endorsement and time, where individuals with better working memory tended to report lower depressive symptoms and demonstrated a lesser increase in depressive symptoms. In conclusion, working memory may be one determinant of successful bereavement. Findings support application of the SOC-ER model to the study of grief.

SESSION 4490 (PAPER)

DIVERSE GERIATRIC SYNDROMES ISSUES

ASSOCIATION OF LIVER STIFFNESS BY TRANSIENT ELASTOGRAPHY WITH MOBILITY DIFFICULTY IN OLDER ADULTS WITH NO CIRRHOSIS

Paulo H Chaves, *Florida International University, Miami, Florida, United States*

Growing experience with non-invasive ultrasound transient elastography (TE) offers now a major opportunity to improve understanding about the functional impact of non-advanced, asymptomatic liver dysfunction. We assessed the relationship of liver stiffness measurement (LSM) and controlled attenuation parameter (CAP) obtained by TE, surrogates for liver fibrosis and steatosis, respectively, with mobility difficulty, an early stage of the disablement process. Cross-sectional study utilizing National Health and Nutrition Examination Survey 2017-2018 data. Analytic sample (n=1,203) included participants aged 60 years and older without known cirrhosis with available LSM and CAP. Logistic regression assessed the odds of mobility difficulty (walking ¼ mile or climbing stairs) according to LSM and/or CAP, with adjustment for demographics, diseases, metabolic syndrome, body mass index, aminotransferases, gamma-glutamyl transferases, albumin, and platelets. LSM and CAP were linearly, positively associated with the probability of mobility difficulty. In the fully adjusted model, LSM, though not CAP, remained strongly associated with mobility difficulty. Those with LSM in the top (>7 kilopascals [kPa]) and intermediate quintiles (4-7 KPa) had higher odds of mobility difficulty; i.e., odds ratio (OR): 1.81; 95% confidence interval (CI): 1.15-2.86; p=0.01) and OR:1.45; 95%CI: 1.01-2.08; p=.046), respectively. LSM was independently associated with early mobility disability in older adults without known cirrhosis. A direct effect through sarcopenia promotion pathways might be speculated. Whether TE screening could be useful to identify adults with non-advanced liver fibrosis who might benefit from preventive interventions – e.g., diet and exercise for non-alcoholic fatty liver disease patients vis-à-vis mobility disability prevention remains to be tested.

DEMOGRAPHIC DIFFERENCES IN THE LONGITUDINAL EFFECTS OF SYMPTOMS ON FALLS AND FALL-RELATED OUTCOMES

Wenting Peng[1], Christina Miyawaki[2], Cen Mo[1], Yuqian Luo[1], Siyuan Tang[1], and Minhui Liu[1], *1. Central South University, Changsha, Hunan, China (People's Republic), 2. University of Houston, Houston, Texas, United States*

Research has shown an association between symptoms and falls and fall-related outcomes among older adults. However, this association was primarily drawn from cross-sectional studies or studies with a single symptom. Using the 2011-2018 waves of the National Health and Aging Trends Study, we examined whether 1) prior-wave common co-occurring symptoms predicted later-wave fall-related outcomes and 2) demographics moderated the longitudinal effects of symptoms on fall-related outcomes among community-dwelling older adults. Falls and fall-related outcomes were self-reported falls, multiple falls, fear of falling (FOF), and FOF limiting activity. The number of symptoms (from 0 to 6) was calculated based on the presence of pain, insomnia, breathing difficulty, depressive symptoms, anxiety, and fatigue. Binomial logistic regression was used for data analyses. Our sample consisted of 9,060 participants who contributed 34,327 observations. These observations were aged between 65 and 79 years old (57.7%), female (58.4%), and non-Hispanic White (70.5%). Each additional symptom was associated with an increased risk of falls (Adjusted Odds Ratio [AOR]: 1.13, 95% CI: 1.11-1.15), multiple falls (AOR: 1.15, 95% CI: 1.12-1.18), FOF (AOR: 1.21, 95% CI: 1.18-1.24) and FOF limiting activity (AOR: 1.25, 95% CI: 1.21-1.29). Age, race/ethnicity, education, and living arrangement significantly moderated the relationships between symptoms and falls and fall-related outcomes. However, gender did not moderate the effects of symptoms on any outcomes. These findings suggest that symptoms longitudinally predict falls and fall-related outcomes. Common symptoms assessment and individual demographics should be incorporated into fall risk assessments and interventions.

HOME-BASED TRANSCRANIAL DIRECT CURRENT STIMULATION AND CLINICAL PAIN IN OLDER ADULTS: A RANDOMIZED CLINICAL STUDY

Hyochol Ahn[1], Geraldine Martorella[1], Kenneth Mathis[2], and Hongyu Miao[1], *1. Florida State University, Tallahassee, Florida, United States, 2. University of Texas Health Science Center at Houston, Houston, Florida, United States*

Knee osteoarthritis (OA) is one of the leading causes of pain in older adults. Previous studies indicated clinic-based transcranial direct current stimulation (tDCS) was effective to reduce pain in various populations, but no published studies have reported the efficacy of home-based self-administered tDCS in older adults with knee OA using randomized clinical study. Thus, the purpose of this study was to evaluate the efficacy and safety of tDCS on clinical pain intensity in adults with knee OA pain. One hundred twenty participants aged 50–85 years with knee OA pain were randomly assigned to receive fifteen daily sessions of 2 mA tDCS for 20 min (n = 60) or sham tDCS (n = 60) over 3 weeks with remote supervision via telehealth. Clinical pain intensity was measured by asking participants to rate their knee pain using a numeric rating scale from 0 (no pain) to 100 (worst pain imaginable). Participants (68% female) had a mean age of 66 years and the mean body mass index in the sample was 32.59 kg/m2. There have been no adverse events. Active tDCS significantly reduced pain intensity compared to sham tDCS after completion of the fifteen daily sessions ($t = 6.57$, $df = 110$, $p < .001$). We demonstrated that home-based self-administered tDCS was safe and reduced clinical pain intensity in older adults with knee OA, which can increase its accessibility. Future studies with multi-site randomized controlled trials with various populations are needed to validate our findings.

THE ASSOCIATION BETWEEN MEDITERRANEAN DIET ADHERENCE AND ALLOSTATIC LOAD IN OLDER ADULTS

Alexandra Fiocco[1], Anik Obomsawin[2], and Danielle D'Amico[3], *1. Toronto Metropolitan University, Toronto, Ontario, Canada, 2. X (Ryerson) University, Toronto, Ontario, Canada, 3. Toronto Metropolitan University, York, Ontario, Canada*

Allostatic load (AL) is a multisystemic index of biological wear and tear which is associated with poor health outcomes. In recent years, researchers have examined the association between dietary pattern intake and AL; however, no studies to date have examined the relationship between AL and consumption of a Mediterranean diet. Blood and urine samples were collected from 201 community-dwelling older adults who completed a Food Frequency Questionnaire (FFQ). A Mediterranean Diet Score (MDS) was calculated based on previous recommendations and a sex-based AL index was calculated using a count-based approach for 16 biomarkers associated with neuroendocrine, immune, cardiovascular, or metabolic function. It was hypothesized that a higher MDS would associate with lower AL, and that this association would be particularly robust for the immune and metabolic subcomponents of the AL index. In support of the study hypotheses, generalized linear models revealed a significant inverse relationship between MDS and AL (ß = -0.03, P = 0.037). Furthermore, higher MDS was significantly associated with lower immune (ß = -0.06, P = 0.38) and metabolic (ß = -0.05, P = 0.039) subsystem scores, but was not associated with cardiovascular or neuroendocrine subsystem scores. Exploratory analyses further showed that the association was more robust in male than female participants. The current findings are interpreted with caution given the study design and sample characteristics. However, these findings contribute to the literature supporting the Mediterranean diet as an important lifestyle behavior that may support healthy aging.

SESSION 4500 (SYMPOSIUM)

RACIAL AND ETHNIC VARIATIONS IN DEMENTIA DIAGNOSIS, SURVIVAL, AND END-OF-LIFE CARE QUALITY

Chair: Olga Jarrín Co-Chair: Zahra Rahemi Discussant: Michael Gusmano

In the United States most adults have a preference to die at home and is an indicator of good end-of-life care. In the context of dementia, family members and caregivers are decision makers and part of good and equitable care involves understanding cultural variation in attitudes and social norms related to dementia, death and dying, and the meaning of a good death. This symposium explores racial and ethnic variation in lifetime dementia diagnosis and end-of-life care quality indicators. The first presentation examines racial, ethnic, and geographic variation in the rarely discussed lifetime prevalence of dementia and survival time from dementia diagnosis to death using national Medicare data. The second presentation describes the relationship between end-of-life care planning and satisfaction with end-of-life care using data from the Health and Retirement Study. The third presentation describes variation in place of death, a key indicator of end-of-life care quality, by dementia diagnosis and race/ethnicity using national Medicare data. The fourth presentation examines variation in hospice use, another indicator of end-of-life-care quality, and place of death by dementia diagnosis, race, and ethnicity using national Medicare data. The symposium concludes with a presentation examining the relationship between place of death and satisfaction with care received using data from the Health and Retirement Study. The Institute for Healthcare Improvement's Triple Aim (improving the experience of care, improving the health of populations, and reducing per capita costs of health care) serves as a lens for discussing policy and practice implications of the major findings from each presentation.

SURVIVAL AFTER DEMENTIA DIAGNOSIS: VARIATION BY RACE/ETHNICITY AND GEOGRAPHIC FACTORS

Haiqun Lin[1], Olga Jarrín[2], Bei Wu[3], Paul Duberstein[4], Anum Zafar[2], and Maria Lopez[2], *1. Rutgers University, Newark, New Jersey, United States, 2. Rutgers, The State University of New Jersey, New Brunswick, New Jersey, United States, 3. New York University, New York, New York, United States, 4. Rutgers School of Public Health, Piscataway, New Jersey, United States*

This study describes racial and ethnic variation in dementia diagnosis and survival time between diagnosis and death for Medicare beneficiaries aged 50 years and older who died in 2018 (n=1,998,282). The prevalence of diagnosed dementia was higher among non-Hispanic white (45.7%), Black (45.5%), and American Indian/Alaska Native (44.1%) decedents compared to Asian American/Pacific Islander (42.7%), and Hispanic (38.5%) decedents. Median survival time in years was shorter for American Indian/Alaska Native (2.51, IQR 0.7-6.0) and white (2.85, IQR 0.8-6.3) beneficiaries, and longer for Asian American/Pacific Islander (3.36, IQR 1.0-7.3), Black (3.38, IQR 0.9-7.4), and Hispanic (3.83, IQR 1-8.2) beneficiaries. Median survival time also varied by geography and was shortest for Hispanic decedents in Arizona (2.37, IQR 0.6-6.0) and New Mexico (2.92, IQR 0.8-7.0) compared to New Jersey (4.85, IQR 1.5-8.9) and Puerto Rico (5.45, IQR 1.1-12.8). Among Black decedents, survival was longest in New Jersey (3.80, 1.1-7.9) and Arkansas (4.22, 1.0-8.5).

END-OF-LIFE CARE PLANNING AND SATISFACTION AMONG THE HEALTH AND RETIREMENT STUDY DECEDENTS

Zahra Rahemi[1], Ayse Malatyali[2], Tom Cidav[3], Olga Jarrín[4], Cheryl Dye[5], and Christopher McMahan[5], *1. Clemson University, Greenville, South Carolina, United States, 2. University of Central Florida, Orlando, Florida, United States, 3. Johns Hopkins University, Baltimore, Maryland, United States, 4. Rutgers, The State University of New Jersey, New Brunswick, New Jersey, United States, 5. Clemson University, Clemson, South Carolina, United States*

The frequency and timing of advance care planning among individuals living with cognitive impairments vary by race/ethnicity and other sociodemographic factors. This study examined relationships between advance care planning and end-of-life care satisfaction among participants in the Health and Retirement Study (Exit files 2002-2018). Among decedents with cognitive impairment (n=3,102), Black and Hispanic participants were less likely to have a living will (OR=0.22, 0.19) and less likely to discuss end-of-life care (OR=0.422, 0.544) compared to White and non-Hispanic participants, respectively. Black and Hispanic participants were more likely to prefer all possible end-of-life care (OR=3.29, 3.34) and less likely to refuse extensive-care measures (OR=0.34, 0.48) compared to White and non-Hispanic participants. Participants dissatisfied with end-of-life care were 48% less likely to have a living will. End-of-life care planning disparities among racial/ethnic groups can inform interventional and educational programs to improve equity in end-of-life care.

PLACE OF DEATH AMONG MEDICARE BENEFICIARIES: VARIATIONS BY DEMENTIA DIAGNOSIS AND RACE/ETHNICITY

Olga Jarrín[1], Haiqun Lin[2], Bei Wu[3], Anum Zafar[1], Maria Lopez[1], and Paul Duberstein[4], *1. Rutgers, The State University of New Jersey, New Brunswick, New Jersey, United States, 2. Rutgers University, Newark, New Jersey, United States, 3. New York University, New York, New York, United States, 4. Rutgers School of Public Health, Piscataway, New Jersey, United States*

Death at home is preferred by most people and has become a key indicator of the end-of-life care quality; however cultural attitudes about death and dying may vary by race and ethnicity. This study describes racial and ethnic variation in place of death among Medicare beneficiaries aged 50 years and older who died in 2018 with a dementia diagnosis (n=902,208) and without a dementia diagnosis (n=1,096,074). Among those with dementia, 60% died at home, with the highest percentage for non-Hispanic white (62%) beneficiaries, followed by Black/African American (55%), Hispanic (61%), Asian American/Pacific Islander (58%), and American Indian/Alaska Native (58%) beneficiaries. Among those without dementia 61% died at home, with the highest percentage for non-Hispanic white (60%) beneficiaries, followed by Black (57%), Hispanic (65%), Asian American (65%), and American Indian (60%) beneficiaries. Among those who died at home, about half without dementia received hospice care compared to the majority with dementia.

HOSPICE UTILIZATION AND PLACE OF DEATH BY DEMENTIA DIAGNOSIS AND RACE/ETHNICITY

Olga Jarrín[1], Haiqun Lin[2], Bei Wu[3], Paul Duberstein[4], Maria Lopez[1], and Anum Zafar[1], *1. Rutgers, The State University of New Jersey, New Brunswick, New Jersey, United States, 2. Rutgers University, Newark, New Jersey, United States, 3. New York University, New York, New York, United States, 4. Rutgers School of Public Health, Piscataway, New Jersey, United States*

Timing of hospice referral is critical to patient's and family's quality of life and satisfaction with hospice care. This study examined racial/ethnic variation in hospice use and factors associated with death at home among Medicare beneficiaries aged 50 years and older who died in 2018 (n=1,998,282). Hospice use was most frequent among non-Hispanic white beneficiaries (55.8%) followed by Hispanic (46.2%), Asian American (44.5%), Black (42.7%), and American Indian (42.1%) beneficiaries. Among decedents diagnosed with dementia, initiation of hospice prior to the last day of life was significantly associated with death at home among all racial/ethnic groups: non-Hispanic white (OR=2.62), Black (OR=2.04), Hispanic (OR=2.17), Asian American (OR=2.54), and American Indian (OR=2.76). Among decedents not diagnosed with dementia, initiation of hospice prior to the last day of life was less strongly associated with death at home: white (OR=1.33), Black (OR=0.83), Hispanic (OR=1.32), Asian American (OR=1.69), and American Indian (OR=1.56).

PLACE OF DEATH AND CARE SATISFACTION AMONG THE HEALTH AND RETIREMENT STUDY DECEDENTS

Ayse Malatyali[1], Zahra Rahemi[2], Tom Cidav[3], Cheryl Dye[4], Olga Jarrín[5], and Christopher McMahan[4], *1. University of Central Florida, Orlando, Florida, United States, 2. Clemson University, Greenville, South Carolina, United States, 3. Johns Hopkins University, Baltimore, Maryland, United States, 4. Clemson University, Clemson, South Carolina, United States, 5. Rutgers, The State University of New Jersey, New Brunswick, New Jersey, United States*

The place of care at the time of death can influence the satisfaction, type, and cost of end-of-life care. This study investigated factors associated with place of death among older adults in the Health and Retirement Study (Exit files 2002-2018) with cognitive impairment (n=3,102). Black and Hispanic participants were more likely to die in the hospital (OR=1.80, 1.47) and less likely to die in a nursing home (OR=0.54, 0.37) than white and non-Hispanic participants. Hispanic participants were also 50% more likely to die at home than non-Hispanics. Compared to other places, participants who died at home were 43% more satisfied, and participants who died at nursing homes were 32% less satisfied with the care they received. There was no significant effect of ethnicity on the relationship between place of death and satisfaction with care. Investigating the moderating role of other demographic factors can shed more light on this relationship.

SESSION 4510 (PAPER)

ECONOMIC AND EMOTIONAL COSTS OF FAMILY CAREGIVING

FINANCIAL DISTRESS OF ADULT CHILDREN TAKING CARE OF AGING PARENTS

Mengya Wang, and Suzanne Bartholomae, *Iowa State University, Ames, Iowa, United States*

Providing care to parents is often a rewarding experience for adult children, however, one trade-off is the toll it takes on the caregiver's own financial security. Using the framework of life course theory, the current research examines the sources of support (family, community and the government) that may reduce parental caregivers' financial distress. In this study, we examine whether intensive parental caregivers are experiencing financial distress and whether the association between caregiving and financial distress is ameliorated by the presence of having siblings, community support, and government policy supportive of caregiving. This study utilizes data provided by the fifth wave of the survey of health and retirement in Europe (SHARE). Preliminary analyses are consistent with previous studies, that providing intensive care to parents is associated with an increased risk of experiencing healthcare hardship. Moreover, the findings align with life course theory as having support from family members and the government is associated with lower levels of financial distress. However, the effect of community support is not significant. This study suggests that adult children, especially adult daughters, sacrifice their own financial security for the benefit of caring for their parents. In addition, having a broad support network, such as caregiving support groups and caregiving educational programs, can reduce adult children's financial distress, and enable them to provide care longer, which avoids or delays the need for costly institutional care. Ongoing analyses examine the potential long-term consequences of caregiving.

LATINO FAMILY CAREGIVERS' EXPERIENCES COVERING OUT-OF-POCKET COSTS WHEN CARING FOR SOMEONE LIVING WITH DEMENTIA

Susanna Mage[1], Donna Benton[2], Alexander Gonzalez[3], Gabriela Zaragoza[4], Kathleen Wilber[2], Reginald Tucker-Seeley[5], and Kylie Meyer[6], *1. University of Southern California, Leonard Davis School of Gerontology, Los Angeles, California, United States, 2. University of Southern California, Los Angeles, California, United States, 3. University of Southern California, LOS ANGELES, California, United States, 4. UTHSCSA, San Antonio, Texas, United States, 5. University of Southern California, Los Angele, California, United States, 6. Case Western Reserve University, Cleveland, Ohio, United States*

Family caregivers to persons living with dementia spend an average of $11,293 annually out-of-pocket on caregiving costs. Costs include home modifications, medications, and other daily expenses. Financial strain from caregiving affects caregiver mental and physical health and is unequally distributed across race/ethnicity groups. While other caregivers spend approximately one-quarter of their income on caregiving, the cost for Latinos family caregivers comprises nearly half of annual income. To gain insight into this disparity, eleven 1-hour in-depth qualitative interviews were conducted with Latino caregivers of persons living with dementia living in California and Texas. Interview transcripts were thematically coded, guided by the Tucker-Seeley Material–Psychosocial–Behavioral Model of financial strain. We identified four themes: 1) caregivers were concerned with meeting the daily needs of care recipients and would incur additional costs, such as credit card interest, to address immediate needs; 2) high levels of psychological distress were expressed regarding caregivers paying for the care of loved ones and themselves in the future; 3) caregivers wanted to use community resources that help older adults and their families but described stressful barriers accessing support. Further, Latino culture affected spending. For example, caregivers incurred shared living costs given reluctance to place loved ones in a nursing facility, exemplifying the concept of familismo. By understanding the factors contributing to high caregiving costs for Latino caregivers and the challenges met when addressing these costs, we can build approaches at both the individual- and policy-levels and develop culturally relevant interventions to help Latino families to lower care costs.

RESOURCE UTILIZATION AMONG FAMILY CAREGIVERS: INDIVIDUAL AND NEIGHBORHOOD CHARACTERISTICS

Hyojin Choi[1], Kristin Litzelman[1], Autumn Harnish[1], and Maija Reblin[2], *1. University of Wisconsin-Madison, Madison, Wisconsin, United States, 2. University of Vermont, Burlington, Vermont, United States*

Resources in the community play a pivotal role in increasing well-being of both care recipients and caregivers and ensuring equitable access to needed resources is a crucial priority for policy and practice. Drawing on the Andersen Behavioral Model, this study explored the longitudinal relationship between individual and neighborhood factors and social resource utilization (i.e., paid caregivers, respite care, support group, training, financial help, or transportation) among family caregivers. Unpaid family caregivers for community-dwelling older adults were identified using data from the National Study of Caregiving and National Health and Aging Trends Study (Time 1: 2015, Time 2: 2017; n=616). Neighborhood characteristics were indicators of the Social Vulnerability Index and provider density at the census-tract level. Poisson regression was used to assess predictors of greater resource use (interpreted as incident rate ratios [IRR] with 95% confidence intervals [CI]). Nearly two-thirds of the sample reported using one or more services at each timepoint. Enabling factors were key predictors of resource use at Time 2, including income above 400% federal poverty level (IRR[CI]=1.53 [1.11,2.09]), better self-rated health (IRR[CI]=1.11 [1.01,1.22]), and resource use at Time 1 (IRR[CI]=1.64 [1.29,2.08]). Need-based predictors included greater frequency of personal care (IRR[CI]=1.13 [1.05,1.22] and longer care duration (IRR[CI]=0.99 [0.98,1.00]). Neighborhood factors were not associated with resource use in this analysis, nor were other need factors including caregiving burden. The findings highlight potential disparities in resource use by income, health status, or experience with systems navigation, with implications for policy and outreach.

THE MASON CARES RANDOMIZED STUDY: ASSESSING CAREGIVER BURDEN FOLLOWING A STRESS MANAGEMENT PROGRAM

Gilbert Gimm[1], Harveen Pantleay[2], Emily Ihara[2], Megumi Inoue[2], Shannon Layman[2], and Catherine Tompkins[2], *1. George Mason University, Vienna, Virginia, United States, 2. George Mason University, Fairfax, Virginia, United States*

OBJECTIVE: The Mason CARES study examines the impact of a virtual stress management program and personalized music intervention on the stress of family caregivers of older adults with dementia. This study presents early findings on 31 participants (Cohort 1) who enrolled in January 2022.

METHODS: Using primary data, we analyzed caregiver stress levels among 31 participants in Weeks 1 and 5 of a stress management program. Caregiver stress was measured using the Zarit Burden Interview (ZBI) score with a range from 0 to 48 (Bédard, 2001). Higher values (ZBI >=17.0) are associated with higher levels of stress.

RESULTS: Among the 31 caregivers, 51.6% were spouses and 48.4% were non-spouses (e.g., adult children, nephew, etc.). While mean ZBI scores in Week 1 were similar for spouses and non-spouses (24.2 vs. 24.9), caregiver stress was higher when older adults had advanced versus moderate dementia

(26.2 vs. 23.2). Between Weeks 1 and 5, spouses reported a greater decrease in stress (-2.6 vs. -2.2) compared to non-spouses. However, caregivers of older adults with advanced dementia experienced less of an improvement (-1.5 vs. -3.0).

CONCLUSION: Findings show that all caregivers had high stress levels in Week 1 (ZBI score of 17 or more) with no difference between spouses and non-spouses. Between Week 1 and 5, spouses reported greater stress improvement than non-spouses. However, caregivers of older adults with advanced dementia had less improvement in stress. Future research will examine caregiver stress levels after random assignment to a Phase 2 music intervention group and control group.

TIME-USE AND WELL-BEING IN FAMILY AND OTHER UNPAID CAREGIVERS OF OLDER ADULTS

Sol Baik[1], Amanda Lehning[2], Paul Sacco[2], John Cagle[2], and Nancy Kusmaul[3], *1. University of Virginia Weldon Cooper Center for Public Service, Charlottesville, Virginia, United States, 2. University of Maryland, Baltimore, Baltimore, Maryland, United States, 3. University of Maryland Baltimore County, Baltimore, Maryland, United States*

Due to the intensive time commitment for caregiving, caregivers report limited freedom to engage with others, participate in physical activities, pursue leisure activities, and have adequate time for sleep. Few studies have focused on caregivers' time-use across different activities, particularly how different patterns of time-use are associated with well-being. This study aimed to: (1) identify time-use profiles of family caregivers of older adults and (2) examine associations between identified time-use profiles and caregiver well-being. We analyzed 1,640 family caregivers of community-dwelling older adults by combining secondary data from Round 7 (2017) of the National Study of Caregiving and the National Health and Aging Trends Study. We conducted latent profile analysis to estimate time-use profiles including covariates and outcomes. Three classes of caregivers emerged based on time-use patterns. The High Committed class (20%) spent the longest time in non-eldercare related committed activities, such as household activities and paid work. The High Discretionary class (49%) spent the highest amount of discretionary time, including social activities, physical activities, and other free-time activities. They also spent the least amount of non-eldercare committed time compared to the other two caregiver types. Lastly, the Balanced class (31%) allocated time relatively evenly in all activities. When comparing well-being outcomes between time-use profiles, caregivers in the High Discretionary class had worse self-rated health but lower levels of anxiety than the Balanced class. Research on time-use and caregiver well-being may help identify at-risk caregiver groups based on lifestyle profiles and develop targeted policies to promote better caregiver well-being.

SESSION 4520 (SYMPOSIUM)

EVOLVING AGE-FRIENDLY UNIVERSITIES: ENHANCING STUDENT SUPPORT SERVICES AND PROMOTING SKILL DEVELOPMENT

Chair: Allyson Graf Co-Chair: Katherina Terhune
Discussant: Heidi Ewen

Students in higher education face numerous challenges, many of which have been exacerbated by the pandemic. Globally, universities have capitalized on age-friendly programs and practices to respond to rapid changes in age demographics, build more age-inclusive and intergenerational programming, and create new forms of support campus-wide. This symposium features campus leaders representing universities that have drawn on the Age-Friendly University (AFU) principles to generate new and creative forms of support and skill-building for students of all ages. These initiatives represent the diverse ways that AFU-based programs and practices can be utilized to respond to opportunities and challenges in higher education. Graf et al. will discuss how age and age-related bias impact adult learners' experiences in the classroom, and ways to inform training programs for students, faculty, and staff. Felsted and Eaton will describe a GSA/AARP-funded grant initiative aimed at increasing access, inclusion, and support for older adult learning at the university, resulting in a partnership with Emeritus faculty to pursue the AFU designation. Hancock and Kutcher will describe how service-learning and intergenerational learning opportunities provide a meaningful space for students to develop realistic notions of their own aging experiences. Newsham et al. will discuss a virtual intergenerational mentoring project designed to improve social connectedness and well-being, to improve expectations regarding aging, and to decrease ageism. Terhune et al. will discuss campus-wide data used to assess the prevalence and impact of unpaid caregiving on students and will explore community and campus connections to better support students in caregiving roles.

HOW AGE-FRIENDLY UNIVERSITIES CAN COMBAT AGEISM

Allyson Graf[1], Heather Han[2], Will Phillips[2], and Jessica Wiley[2], *1. Northern Kentucky University, Florence, Kentucky, United States, 2. Northern Kentucky University, Highland Heights, Kentucky, United States*

At a time of growing enrollment among adult learners, student bodies are increasingly age diverse. Identifying and reducing age-related bias on campus may be multipurpose in supporting those who experience ageism while promoting professional skills to combat ageism in students' future careers. The extant literature has primarily focused on ageism in the workplace and ageism experienced by faculty and staff in higher education while less has focused on ageism experienced by adult students and the possible disruption this creates to feeling included as part of the campus community. We present data from a mixed methods study of adult learners assessing the extent to which they experience and are impacted by age-related bias on campus. Data are used to justify faculty and student training to improve intergenerational contact in the classroom and beyond under the broader umbrella of DEI initiatives.

UNDERSTANDING AND RESPONDING TO THE NEEDS OF STUDENT CAREGIVERS THROUGH THE AGE-FRIENDLY UNIVERSITY LENS

Katherina Terhune[1], Allyson Graf[2], Kate Wade[3], and Faith Greer[3], *1. Northern Kentucky University, Lexington, Kentucky, United States, 2. Northern Kentucky University, Florence, Kentucky, United States, 3. Northern Kentucky University, Highland Heights, Kentucky, United States*

Caregiving has steadily increased over the years, with approximately 44 million individuals in the U.S. providing over 37 billion hours of unpaid, informal care for adult family members and friends with chronic illnesses or conditions that impact their functionality and daily activities. While much caregiving research has been completed over the years, research on student caregivers is scant, and less is known about the experiences and the needs of students in caregiving roles. This presentation examines data from a campus-wide survey to assess the prevalence and impact of unpaid caregiving on students. Utilizing the Age-Friendly University framework, this study aims to identify sources of unmet caregiving need, as well as community and campus connections to better support students in caregiving roles. Recommendations for assessing student caregiver needs and ways to generate and enhance caregiver support through the AFU lens will be highlighted.

INTERGENERATIONAL CONVERSATIONS AS GOOD AGE-FRIENDLY UNIVERSITY PRACTICE

Cynthia Hancock, and Katie Kutcher, *UNC Charlotte, Charlotte, North Carolina, United States*

Service-learning is an established practice in gerontological education. At UNC Charlotte, our service-learning is embedded in our foundational gerontology course which is open to students across the University. Students engage in 10 hours of conversations utilizing topic prompts that align with course content to engage in comfortable conversations with an older adult they have never before met. Students then complete five reflective writings to process the experience. Our model aligns with the AFU principles of promoting "intergenerational learning" and increasing "the understanding of students of the longevity dividend and the increasing complexity and richness that aging brings to our society." Through a qualitative analysis of student reflective writings, the authors will share how this service-learning model leads to increased student gerontological literacy and in particular a better understanding of their future aging selves.

IMPLEMENTING A VIRTUAL, AGE-FRIENDLY INTERGENERATIONAL PROGRAM

Tina Newsham[1], Elizabeth Fugate-Whitlock[2], Natalie Quinn[2], and Sky Bergman[3], *1. UNC Wilmington, Wilmington, North Carolina, United States, 2. University of North Carolina Wilmington, Wilmington, North Carolina, United States, 3. Cal Poly, San Luis Obispo, San Luis Obispo, California, United States*

As the University of North Carolina Wilmington (UNCW) seeks to become more age-friendly and stakeholders pursue endorsement of the Age-Friendly University principles, a virtual intergenerational mentoring project was implemented. The aim was to connect the community's older adults, including retired faculty, with current students. Older adults and students were paired and asked to engage in a series of conversations, watch a documentary, and attend a Q&A with the filmmaker. The goals were to improve social connectedness and well-being, improve expectations regarding aging for members of both groups, and to decrease ageism. Impacts of the project were assessed through the Expectations Regarding Aging scale prior to any interactions between partners and again at the end of the project along with an open-ended questionnaire about their experiences. Expectations regarding aging improved on 75% of the items, and participants indicated qualitatively that their experiences with the intergenerational interactions were positive.

PAVING THE WAY FOR AGE-FRIENDLY UNIVERSITY DESIGNATION: ACCESS AND SUPPORT FOR OLDER ADULT LEARNING INITIATIVES

Katarina Friberg Felsted[1], and Jacqueline Eaton[2], *1. University of Utah, Salt Lake City, Utah, United States, 2. University of Utah College of Nursing, Salt Lake City, Utah, United States*

Through a GSA/AARP funded grant, the University of Utah implemented an initiative to promote awareness of a state bill which provides reduced tuition for residents 62 and older. The initiative provided tuition waivers to older adult students, which enhanced enrollment and increased engagement with key age-friendly stakeholders. Implemented over four semesters, student use of tuition waivers increased 875%. This initiative was a crucial step in seeking Age Friendly University (AFU) designation, as it led to mentorship from members of the AFU global network and a partnership with our university's Emeritus Faculty Board. Strategic planning guided the preparation of a four-step plan towards designation: 1) complete a cross-campus AFU inventory and inform campus stakeholders, 2) report progress to the Council of Deans, 3) present to Academic Vice Presidents, and 4) obtain AFU endorsement from the University President. During this presentation we will present lessons learned as we progress towards designation.

SESSION 4530 (SYMPOSIUM)

EXISTING DATA SETS FOR FAMILY CAREGIVING AND BEREAVEMENT RESEARCH: HIGH-VALUE APPLICATIONS AND KEY CONSIDERATIONS

Chair: Djin Tay Discussant: Rebecca Goodwin

Aging and the end of life is marked by greater reliance on others to address increasingly complex care needs. At the end of life, nine in 10 caregivers are family members. Reliance on family caregivers will continue to increase as the home outpaces hospitals and nursing facilities as place of death. As the population ages and dependence on family caregivers increases, it is critical to examine the impact of family on aging and end-of-life experiences and conversely, the impact of end-of-life caregiving and bereavement on families' health and well-being. Population-based data, such as registries that link administrative, health and vital records or nationally representative datasets, minimize the challenges of selection bias, low response rates, and underrepresentation of racial and ethnic minority groups that are common in prospective clinical research. However, few population-based datasets exist that can facilitate research on family caregiving. This symposium includes five presentations focused on the use of population-based data for family caregiving research-- the first examines the social and caregiving network of adults who age solo using the National Health and Aging Trends Study data. The next two presentations examine how family characteristics are associated with place of death and end of life treatment utilization among nursing home decedents using linked statewide data. The final two examine how family caregivers are impacted by different death and dying experiences in Utah and Denmark. Leveraging population-based data to understand the end-of-life dynamics within a family system has the potential to advance family caregiving research, clinical practice, and policy.

INFORMAL CARE NETWORKS AMONG ADULTS AGING SOLO

Jane Lowers[1], Duzhi Zhao[2], Evan Bollens-Lund[2], Dio Kavalieratos[1], and Katherine Ornstein[3], *1. Emory University, Atlanta, Georgia, United States, 2. Icahn School of Medicine at Mount Sinai, New York, New York, United States, 3. Johns Hopkins, University, Baltimore, Maryland, United States*

More than 20% of older adults lacks proximal family caregivers. Yet is it unclear who provides support for this growing population. Using 2015 National Health and Aging Trends Study data for 2,998 community-dwelling Medicare beneficiaries who received help with at least one task (e.g., bathing, shopping, insurance help) in the past month, we identified individuals aging solo (no spouse/partner or children residing in the same state) and determined social and caregiving network size and composition. Compared to married peers with nearby children, adults aging solo (7.6% of sample) had social networks of similar size but greater diversity (i.e., more friends, neighbors). Adults aging solo were significantly more likely to rely on paid help and a wider network of informal caregivers, including distal family, and friends. Social networks can anchor interventions to help adults aging solo prepare for future care needs and inform policies to support informal caregiving.

FAMILIAL AND SOCIODEMOGRAPHIC DETERMINANTS OF PLACE OF DEATH: A RETROSPECTIVE STUDY OF THE UTAH POPULATION DATABASE

Brenna Kelly[1], Heidi Hanson[1], Huong Meeks[1], Michael Hollingshaus[1], Djin Tay[1], Lee Ellington[2], Caroline Stephens[1], and Katherine Ornstein[3], *1. University of Utah, Salt Lake City, Utah, United States, 2. University of Utah and Huntsman Cancer Institute, Salt Lake City, Utah, United States, 3. Johns Hopkins, University, Baltimore, Maryland, United States*

Consistent with preferences, home deaths in the US increasing — yet most Americans still die in hospitals or other healthcare facilities. Although declining health has been considered the primary factor influencing place of death, few studies have examined how family support and sociodemographic factors influence place of death. This study examined a population-based cohort of 205,932 decedents aged 50+ who died in Utah between 1998 and 2016. Using multivariate logistic regression models, we found that having a living spouse or child was associated with decreased odds of a healthcare facility death (spouse: AOR= 0.62, CI 0.65-0.59; child: AOR = 0.80, CI 0.79-0.82). Additionally, educational attainment (graduate degree: AOR = 0.95, CI 0.91-0.99) and non-Hispanic/Latinx ethnicity (AOR = 0.81, CI 0.79-0.85) were associated with decreased odds of a home death. Our findings highlight the importance of families in place of death and suggest that sociodemographic and economic disparities persist even in death.

UTILIZING POPULATION DATA TO CHARACTERIZE NURSING HOME DECEDENTS AND THEIR FAMILIES AT THE END OF LIFE

Caroline Stephens[1], Michael Hollingshaus[1], Brenna Kelly[1], Djin Tay[1], Katherine Ornstein[2], Ken Smith[1], and Rebecca Utz[1], *1. University of Utah, Salt Lake City, Utah, United States, 2. Johns Hopkins, University, Baltimore, Maryland, United States*

Over 2/3 of nursing home (NH) residents are eligible for palliative care (PC), but do not receive it. Utilizing the Utah Population Database, we examined EOL characteristics for 39,672 NH residents who died in Utah between 1998-2016. Dementia was the leading cause of death (36.6%), followed by cardiovascular disease (23.9%) and COPD (16.7%). Women were more likely than men to die in a NH (21.0 vs 15%) and more likely to die in a NH with heart disease (20.0% vs. 11.7%) or cerebrovascular disease (25.9% vs. 21.0%), compared to men. Use of PC, hospice, and life-sustaining treatments was low within this NH sample, particularly among persons with dementia. First-degree family characteristics varied at EOL with presence of a spouse exerting the greatest influence on EOL care utilization. Understanding population-based NH resident EOL life characteristics can help inform the development of resident- and caregiver-centered PC interventions and health policies.

HEALTH AND WELL-BEING OF FAMILY CAREGIVERS FOLLOWING HOSPICE USE

Rebecca Utz[1], Michael Hollingshaus[1], Katherine Ornstein[2], Djin Tay[1], Caroline Stephens[1], and Ken Smith[1], *1. University of Utah, Salt Lake City, Utah, United States, 2. Johns Hopkins, University, Baltimore, Maryland, United States*

Some patterns of hospice use are potentially disruptive and stressful for both patient and family. Using a decedent sample of 17,320 hospice users from the Utah Population Database, linked to the health records of spouse and first-degree relatives (child, parent, sibling, Mean=3.36 per decedent). Stroke decedents had higher odds of delayed admission (i.e., <7 days of hospice), while those with dementia and COPD had higher odds of extended use (i.e., >6 months of hospice), compared to cancer decedents. Family members, especially spouses, who experienced delayed admission or extended use had higher odds of hospitalization and increased use of antidepressants, both prior to and following the death, compared to those with more normative hospice use (6 months or less, typical of cancer patients). The hospice experience has both immediate and lasting consequences on the family; eligibility criteria for the hospice benefit may need to be modified by admitting diagnosis.

SERIOUS MENTAL ILLNESS EXACERBATION POST-BEREAVEMENT: A POPULATION-BASED STUDY OF PARTNERS AND ADULT CHILDREN

Djin Tay[1], Lau Thygesen[2], and Katherine Ornstein[3], *1. University of Utah, Salt Lake City, Utah, United States, 2. University of Southern Denmark, Odense, Syddanmark, Denmark, 3. Johns Hopkins, University, Baltimore, Maryland, United States*

The death of a family member may trigger exacerbations among individuals with serious mental illness (SMI). We hypothesized that bereavement would be associated with SMI exacerbations among bereaved partners and adult children diagnosed with SMI. Using linked population-based registries in Denmark, we identified partners and adult children diagnosed with schizophrenia, schizoaffective disorder, bipolar disorder, and major depression in the five years preceding the family member's death. Generalized estimating equations were used to estimate the odds of SMI exacerbation two years after decedent death. Partners had increased odds of SMI exacerbation at 3 months into bereavement compared to 9-12 months prior to partners' death (AOR=1.43, [1.13-1.81]). Children with a history of SMI had lower odds of SMI exacerbation in the second year of bereavement. Sociodemographic characteristics and co-occurring alcohol and substance abuse disorders were associated with higher odds of SMI exacerbations. These findings have implications for targeted bereavement support.

SESSION 4540 (SYMPOSIUM)

FOSTERING SOCIAL CONNECTIVITY AND RESILIENCE IN SEXUAL AND GENDER MINORITY OLDER ADULTS

Chair: Hyun-Jun Kim

While social connectedness and engagement are key aspects of well-being over the life course, sexual and gender minority (SGM) older adults are found to experience elevated risks of social isolation and limited social connectivity, which have been linked to loneliness. Social isolation and loneliness have been significant health concerns, increasing risk of premature death, cognitive decline, and poor health and well-being, yet SGM older adults are resilient populations. To address the strengths and challenges found in evidence-based intervention development, it is critical to understand how they have managed to build and maintain their social resources and reduce social isolation and loneliness. To this end, this symposium will analyze and incorporate the results using data from both Aging with Pride: National Health, Aging and Sexuality/Gender Study (NHAS), the first longitudinal study of SGM older adults in the United States and Innovations in Empowerment and Action (IDEA) Café, the first clinical trial pilot study addressing social isolation among SGM older adults living with dementia. Dr. Kim and colleagues with present a factor analysis suggesting a multi-dimensional construct of social resources unique to SGM older adults. Dr. Fredriksen Goldsen and colleagues will identify sexual and gender diverse older adults at heightened risk of loneliness and examine risk and protective factors. Dr. Emlet and colleagues will present findings from a pilot study, IDEA Café, designed to enhance social connectedness, physical functioning, and quality of life among socially isolated SGM older adults with cognitive impairment.

UNDERSTANDING THE DIMENSIONS OF SOCIAL RESOURCES AMONG SEXUAL AND GENDER MINORITY OLDER ADULTS

Hyun-Jun Kim, Karen Fredriksen Goldsen, and Meghan Romanelli, *University of Washington, Seattle, Washington, United States*

Despite the growing number of recent studies on the positive role of social resources on health and well-being among SGM older adults, the multi-dimensional construct of social resources has not been examined due to a lack of adequate measures and data. This study describes the rationale behind the measurements of social resources used in the National Health, Aging, and Sexuality/Gender Study (NHAS). We analyze NHAS data collected in 2014 (N = 2,450) to assess the reliability of these social resource measurements. Out of 28 indicators of social resources ($\alpha = .82$), three distinct factor structures emerged: relational social connectedness ($\alpha = .71$), collective social connectedness ($\alpha = .82$), and perceived social connectedness ($\alpha = .79$). All item-rest correlations for each scale were moderate to strong. The scales could be used to understand various aspects of social resources and its role in enhancing health and well-being in the historically marginalized populations.

LINKING LIVES: DISRUPTING THE CYCLE OF SOCIAL ISOLATION

Karen Fredriksen Goldsen[1], Hyun-Jun Kim[1], Charles Hoy-Ellis[2], and Christi Nelson[1], *1. University of Washington, Seattle, Washington, United States, 2. University of Utah, Salt Lake City, Utah, United States*

Loneliness has been found to be associated with increased risk for early mortality and dementia, with sexual and gender diverse older adults at elevated risk of both social isolation and loneliness. Based on the Health Equity Promotion Model and Iridescent Life Course, we examine factors associated with increased risk of loneliness over time, utilizing 2014 to 2016 data from the Aging with Pride: National Health, Aging, Sexuality/Gender Study, a longitudinal national study of LGBTQ+ midlife and older adults. The findings illustrate that sexual and gender diverse older adults had nearly double rates of loneliness compared to the general population, with those living alone and having cognitive decline at increased risk. We found that higher mastery, LGBTQ+ community engagement, larger network size, and being partnered/married were associated with less loneliness over time. Loneliness is ripe for the development of interventions; additional longitudinal data is needed to further assess trajectories in loneliness.

REACHING THE SOCIALLY ISOLATED OLDER ADULTS IN DEMENTIA RESEARCH

Charles Emlet[1], Karen Fredriksen Goldsen[2], Hyun-Jun Kim[2], Linda Teri[2], Hailey Jung[2], and Brittany Jones[2], *1. University of Washington, Tacoma, Washington, United States, 2. University of Washington, Seattle, Washington, United States*

Sexual and gender minority (SGM) older adults are at greater risk for dementia and social isolation compared to their heterosexual peers. Lack of an available caregiver is of major concern. Yet, most dementia interventions to date have been designed primarily for caregiver-care recipient dyads or solely caregivers. A pilot study evaluated a 9-session virtual program designed to address social isolation, physical functioning and quality of life among SGM older adults living with dementia without a caregiver. Participants in the experimental group (n = 14) showed high attendance (75%) and retention rates. Social support was associated with intervention adherence. Compared to controls, the experimental group showed a significant increase in physical functioning and quality of life and decrease in depressive symptomatology and perceived stress. To meet the needs of this population without adequate social resources, research must address the different configurations of resources to better serve socially isolated SGM older adults.

SESSION 4550 (SYMPOSIUM)

IMPROVING DEMENTIA CARE IN CO-CREATION BETWEEN SCIENCE, PRACTICE, AND EDUCATION

Chair: Simone de Bruin Discussant: Simone de Bruin

Long-term care is transitioning from a medical-somatic model of care to a psychosocial model of care. This transition requires new ways of working, and thus different competences of health and social care professionals. Innovative learning environments of multiple stakeholders in long-term care are increasingly being created in the Netherlands to foster co-creation between science, practice (including persons with dementia) and education of current and future health and social care professionals. In this symposium, we will share experiences from the Netherlands. The first presentation describes the challenges current and future health and social care professionals are facing with regard to innovation in dementia care. We will further explain how these experiences were used to set up a learning community 'living well with dementia'. The second presentation is dedicated to a participatory action research to develop new collaboration practices to address the often under-addressed theme of meaning in life among community dwelling older adults. The third presentation will focus on a co-creation project dedicated to a care innovation for migrants with dementia, being a guideline for managing challenging behaviour at home. In the plenary discussion after the three presentations, participants are invited to share experiences from their own countries and discuss the lessons learned.

WORKING TOWARD A LEARNING COMMUNITY ENABLING LIVING WELL WITH DEMENTIA

Simone de Bruin, and Franka Bakker, *Windesheim University of Applied Sciences, Zwolle, Overijssel, Netherlands*

Health and social care professionals play an important role in enabling to live well with dementia. Supporting living well from a psychosocial approach to care requires new ways of working and different competences compared to a medical-somatic approach to care. Interviews and group meetings with future (i.e. students) and current health and social care professionals organized in 2021, however, revealed that training to develop such competences and adopt these new ways of working receive little attention in the curricula of existing training programs. They further experience that their organisations insufficiently facilitate them (e.g. in terms of time, creating a positive learning climate) to actually use these competences and innovate their ways of working. Therefore, there is a need for creating innovative learning environments in the form of learning communities. These collaborations of stakeholders from science, practice, and education aim to accelerate innovation in dementia care based on lifelong learning and development.

MULTISTAKEHOLDER COLLABORATION TO BETTER ADDRESS MEANING IN LIFE: PARTICIPATORY ACTION RESEARCH

Franka Bakker[1], and Theo van Leeuwen[2], *1. Windesheim University of Applied Sciences, Zwolle, Overijssel, Netherlands, 2. Department of Theology and Philosophies of Life, Windesheim University of Applied Sciences, Zwolle, Overijssel, Netherlands*

Meaning in life of older adults is related to a good life. Health and social care professionals are expected to address tensions in finding meaning in life among their clients. From 2020 to 2022, we conducted a 24-month participatory action research to discover how professionals in spiritual care, social workers, and volunteers can collaborate to better recognize, address and support questions regarding meaning in life. Four groups of co-researchers were composed, each consisting of a social worker, professionals in spiritual care, older adult, volunteer, students and researcher. They had monthly meetings to discuss actions and findings. In-between, collaboration activities were shaped and qualitative data were gathered about e.g. experiences. Results show that collaboration can be shaped by activities like providing workshops, expert consultation, coaching-on-the-job, jointly shaped interventions for clients, dialogue sessions, and multidisciplinary meetings. Thereby, for realising sustainable collaboration and ongoing mutual learning, structural and person-independent encounters should be realised.

CO-CREATING A GUIDELINE FOR MANAGING CHALLENGING BEHAVIOR OF MIGRANTS WITH DEMENTIA AT HOME

Leontine Groen-van de Ven[1], Serena van der Kaaij[2], Geraldine Visser[1], Judith Huis in het Veld[2], Robbert Gobbens[2], and Simone de Bruin[1], *1. Windesheim University of Applied Sciences, Zwolle, Overijssel, Netherlands, 2. InHolland University of Applied Sciences, Amsterdam, Noord-Holland, Netherlands*

Challenging behaviour is common in people with dementia at home. Nurses guide people with dementia and their informal caregivers managing challenging behaviour. However, common nursing guidelines for challenging behaviour in home care are unsuitable to the situation of migrants with dementia. We started a co-creation project with home care nurses, dementia case managers, informal caregivers of migrant background and student nurses as co-researchers that aims to develop an appropriate guideline. Semi-structured interviews at the start explored the current experiences with challenging behaviour. Interview results informed several working sessions where we discussed the results and used creative working methods such as role play to develop a first prototype of the guideline. The prototype was implemented in the daily practice of six home care teams and followed up during reflection meetings with our co-researchers. Our guideline puts special attention to getting familiar with each other before taking steps in managing challenging behaviour.

SESSION 4555 (BSS FLASH POSTERS)

BSS FLASH POSTER SESSION 2: THE POWER OF PURPOSE AND PERSONAL TIES IN LATE LIFE

PURPOSE IN LIFE, STRESS REACTIVITY, AND COGNITIVE AGING: A LONGITUDINAL INVESTIGATION

Niccole Nelson, and Cindy Bergeman, *University of Notre Dame, Notre Dame, Indiana, United States*

This study examined (1) the time-varying relationship between purpose in life and perceived stress reactivity, (2) the trajectory of perceived stress reactivity as it relates to both within- and between-person purpose in life, as well as (3) the predictive utility of perceived stress reactivity and its rate of change on cognitive ability and allostatic load. The sample comprised 933 participants from the Notre Dame Study of Health & Well-being, a 10-year study of annual questionnaire packets and biennial daily diary bursts. Analyses included three-level multilevel models from which random effects were extracted and used to predict allostatic load and cognitive ability. Results indicated that individuals were affectively reactive to perceived stress, and that perceived stress reactivity declined over time. Considering the effects of purpose in life on these processes, there were two cross-level interaction effects indicating (1) more purposeful individuals were less stress reactive than less purposeful individuals, and (2) more purposeful individuals declined less in negative affect over time than less purposeful individuals. There was also preliminary evidence for a within-person interaction effect between yearly purpose in life and daily affective reactivity such that when individuals felt particularly purposeful, they also tended to be less stress reactive. Finally, higher perceived stress reactivity, as well as less decline in this construct, was predictive of better cognitive ability. These findings indicate purpose in life buffers against environmental and maturational effects on negative affect, and that perceived stress reactivity may indicate a different, more adaptive process than affective reactivity to experienced stressors.

OLDER ADULTS SHARE CHALLENGES IN THEIR LIFE STORY: SENSE OF PURPOSE AS A RESOURCE FOR RESILIENCE

Semper Habib[1], Ameesha Narine[1], Susan Bluck[2], and Shubam Sharma[1], *1. Kennesaw State University, Kennesaw, Georgia, United States, 2. University of Florida, Gainesville, Florida, United States*

Maintaining a sense of purpose promotes mental and physical well-being in older adults (Musich et al., 2018). Drawing on one's sense of purpose is thus important for late life resilience. How older adults' sense of purpose manifests in their everyday lives remains understudied. This study used qualitative methods to amplify older adults' voices regarding purpose and resilience through analysis of their life stories. This study 1) explored what factors contribute to maintaining purpose in older adulthood, and 2) identified how older adults draw on their purpose during major challenges, particularly in the context of the COVID-19 pandemic. Eighteen older men and women (Mage = 79.1; including the young-old, old-old, and oldest-old) participated in semi-structured life story interviews that asked about participants' individual interpretations of purpose in their lives and their experiences navigating the COVID-19 pandemic. Thematic analysis was conducted using established methods (Braun & Clarke, 2012). To address the first research question, analyses revealed that older individuals largely maintain their purpose through engaging in acts of service to others, fostering connections with close others, and actively setting and achieving goals. Regarding the second question, older adults described how drawing on purpose through acts of service and connections with others fostered resilience through the COVID-19 pandemic. Overall, older adults' own expressions of their life stories illuminated how they are guided by purpose. Findings demonstrate the functionality of purpose in late life and how purpose can be practically fostered, specifically within the context of universally challenging experiences such as the COVID-19 pandemic.

BLACK GREEK LETTER ORGANIZATIONS: FACILITATING HEALTH PROMOTION FOR AFRICAN AMERICANS ACROSS THE LIFECOURSE

Chivon Mingo, *Georgia State University, Atlanta, Georgia, United States*

African Americans remain underrepresented in accessing and utilizing evidenced-based health promotion interventions (EBIs). Challenges with dissemination and implementation of EBIs further corroborate existing racial/ethnic health/healthcare disparities. Therefore, there is a need to identify effective ways to increase the widespread adoption of health promotion behaviors among African Americans across the life course. It is plausible that engaging in non-traditional partnerships (i.e., community groups or organizations valued in the community with the capacity and infrastructure) could result in greater adoption and improved utilization of EBIs among African Americans. Although frequently overlooked as a study variable in empirically sound public health research, Black Greek Letter Organizations (BGLO) could be an innovative and practical approach to advancing health in the African American community. It is necessary to gain preliminary evidence of feasibility (e.g., motivation, target population reach, acceptability,). Therefore, the purpose of this study was to conduct a content analysis to identify the intentions and communication trends of BGLOs as it pertains to public health and the African American community and assess population reach and perceptions by evaluating responses to communication specific to health promotion.We assessed health promotion patterns of four BGLOs in a ten-county metropolitan area. Coded content included communication via the organization's webpage, Facebook, Twitter, YouTube, Instagram, and LinkedIn from a five-year time period. Findings confirm that BLGOs are invested in the health and well-being of the community, place emphasis on mitigating health inequities, and are uniquely positioned to serve as stakeholders for the translation of EBIs to end-users.

THE ROLE OF EDUCATION AND LITERACY SKILLS ON MIDDLE-AGED AND OLDER VOLUNTEERS BY RACE AND ETHNICITY IN THE US

Donnette Narine[1], Takashi Yamashita[2], Wonmai Punksungka[3], Abigail Helsinger[4], Jenna Kramer[5], Rita Karam[6], and Phyllis Cummins[7], *1. University of Maryland, Baltimore, Baltimore, Maryland, United States, 2. University of Maryland, Baltimore County, Baltimore, Maryland, United States, 3. University of Maryland - Baltimore County, Baltimore, Maryland, United States, 4. Miami University, Oxford, Ohio, United States, 5. RAND Corporation, Arlington, Virginia, United States, 6. RAND*

Corporation, Santa Monica, California, United States, 7. Miami University, Oxford, Ohio, United States

Volunteer participation is a form of civic engagement that benefits both the individual and society over the life course. Although education, basic skills (e.g., literacy), and race/ethnicity are individually associated with volunteering, detailed interrelations are yet to be explored. Guided by the integrated theory of volunteer work and the notion of productive aging, the goal of this study was to examine the roles of education and adult literacy in the context of volunteering in later life across racial and ethnic groups (Whites, Blacks, Hispanics) in the U.S. Using the nationally representative sample of middle-aged and older adults (age 45+; n = 3,770) from the 2012/2014/2017 Program for International Assessment of Adult Competencies (PIAAC), structural equation modeling was constructed to evaluate mediation relationships among education, literacy, and volunteering by racial and ethnic groups. Results show no statistically significant mediation (a.k.a., indirect) effect of education on volunteering through literacy, nor was there statistically significant difference in the mediation effect across racial and ethnic groups. However, there were statistically significant differences in the direct effect of education on volunteering between Black adults and White adults [b(Black) = 0.44 versus b(White = 0.24), $p < 0.05$], as well as Black adults and Hispanic adults [b(Black) = 0.44 versus b(Hispanic) = 0.08, $p < 0.05$]. These findings indicate that higher education was more strongly associated with volunteering among older Black adults, compared to White and Hispanic counterparts. Suggested policy implications include support for the promotion of volunteer participation through culturally and socioeconomically sensitive approaches.

COMPASSIONATE LOVE AND LONELINESS: LATER LIFE MENTAL HEALTH IN THE UNITED STATES

Nirmala Lekhak[1], Tirth Bhatta[2], Eva Kahana[3], and Joel Synder[1], *1. University of Nevada, Las Vegas, Nevada, United States, 2. University of Nevada Las Vegas, Las Vegas, Nevada, United States, 3. Case Western Reserve University, Cleveland, Ohio, United States*

Loneliness is a serious public health problem that affects over 25% of older adults and is associated with an increased risk of depression, cognitive decline, and premature death. Previous research on social support mechanisms that contribute to loneliness has consistently illustrated the role of emotional support in reducing loneliness. However, the importance of compassionate love in reducing loneliness and, as a consequence, improving psychological well-being in later life has received little attention. Neurobiology indicates that the brain regions associated with loneliness and compassion overlap, suggesting that increasing compassion-related emotions may help alleviate loneliness. Using data from a nationwide web-based survey (n=1,861), we examined the influence of compassionate love on loneliness and assessed whether loneliness mediates the relationship between compassionate love and mental health outcomes. Even after controlling for emotional support, estimates from an ordinary least squares regression (OLS) model suggest that older adults who felt loved had significantly lower levels of loneliness (b=-0.84, $p< 0.001$). Feeling of love also contributed to significantly fewer depressive symptoms (b=-2.03, $p< 0.001$) and anxiety (b=-1.07, $p< 0.001$). Loneliness completely mediated the effect of compassionate love on anxiety (b=-0.82, $p< 0.001$) and significantly mediated its influence on depressive symptoms (b=-1.18, $p< 0.001$). Our findings underscore the need to design interventions that increase compassionate love to reduce loneliness and improve psychological wellbeing among older adults.

SOCIAL SUPPORT AND LONELINESS AS DETERMINANTS OF THE ONSET OF DISABILITY AMONG PUERTO RICAN OLDER ADULTS

Amilcar Matos-Moreno[1], Neil Mehta[2], Eduardo Villamor[3], Lu Wang[3], and Carlos Mendes de Leon[4], *1. The Pennsylvania State University, Bayamon, Pennsylvania, Puerto Rico, 2. UTMB, Galveston, Texas, United States, 3. University of Michigan, Ann Arbor, Michigan, United States, 4. University of Michigan, Ann arbor, Michigan, United States*

Background: The effect of loneliness and social support on health is poorly understood among older Puerto Ricans. As family size continues to decrease in Puerto Rico due to out-migration, a higher number of older adults have fewer family members to rely on, which may lead to detrimental health outcomes.Method: Using both waves (2002-03 and 2006-07) of the Puerto Rican Elderly: Health Conditions database, we examined the association between social support, living alone, and incident disability among a sample of older adults over 60 years of age residing in Puerto Rico. Disability was defined as the occurrence of difficulties with Activities of Daily Living (ADLs).

Results: 13.4% of older adults in our sample developed some form of disability. Older adults who developed a disability indicated receiving higher levels of social support (2.04 vs. 1.64) and loneliness (30.7% vs. 22.8%). Using multivariate logistic regression, we found that receiving social support increased the odds of developing a disability by 17% (OR: 1.17; CI: 1.02 – 1.35). Older adults who live alone had 58% higher odds of developing a disability (OR: 1.58; CI: 1.01 – 2.46).

Conclusion: The presence of social support and loneliness was correlated with a population prone to developing disabilities. Our findings concur with the well-established literature on psychosocial determinants in late life. However, this study represents the first attempt to understand psychosocial measures and disability in Puerto Rico. Public health organizations and healthcare systems must develop new societal mechanisms of support for older adults at risk of developing disabilities.

EXAMINING THE CUMULATIVE EFFECTS OF SOCIAL ISOLATION AND LONELINESS IN OLDER ADULTS WITH HIV

Moka Yoo-Jeong, *Northeastern University, Melrose, Massachusetts, United States*

Social isolation exists when one has limited or lacks social contact with others and is distinct from loneliness, an affective state on the perception of isolation. Social isolation and loneliness are recognized as risks to well-being among older adults. Less in known about the cumulative effects of social isolation and loneliness in older persons with HIV (OPWH). Using cross-sectional data on OPWH (age ≥50) recruited from an outpatient HIV clinic in Atlanta, GA (N=146), we aimed to 1) describe the overlap between social isolation and loneliness and 2) examine the combined effects of social isolation and loneliness on quality-of-life (QoL), HIV-related stigma, depressive symptoms, and comorbidity burden. Loneliness and social isolation were assessed using the PROMIS-Social Isolation Scale and Social Network Index, respectively. Participants were grouped into four categories into 'lonely only,' 'isolated only,' 'both lonely and isolated,' or 'neither.' Bivariate and adjusted associations were conducted. Among participants (mean age=56.53), 26.7% (n=39) were considered 'lonely' only, 12.3% (n=18) 'isolated' only, 15.1% (n=22) 'both lonely and isolated,' and 45.9% (n=67) 'neither.' In bivariate analyses, individuals categorized as 'both lonely and isolated' were likely to have past homelessness and higher depressive symptoms, stigma, and comorbidity burden, and lower QoL. In adjusted models, 'both isolated and lonely' significantly predicted QoL, stigma, and depressive symptoms. Findings highlight the critical emphasis on targeting OPWH who are both isolated and lonely.

A NEW NORMAL: EXAMINING THE LINKAGES BETWEEN SOCIAL TECHNOLOGY AND LONELINESS

Yeon Ji Ryou[1], Natasha Peterson[1], Mengya Wang[1], and Joseph Svec[2], *1. Iowa State University, Ames, Iowa, United States, 2. Iowa state university, Ames, Iowa, United States*

As the COVID-19 pandemic continues to shape social landscapes, social isolation and loneliness are major issues with mental and physical ramifications. In recent years, individuals of all ages are turning to social technology (ST) to communicate with loved ones. However, the viability of ST as a substitute to in-person interaction remains hotly debated. Moreover, few studies examined how psychosocial factors interact with ST in mental health outcomes. Using the 2020 survey data (N = 1,969) from Health and Retirement Study (HRS), this research examines whether and to what extent ST ameliorates loneliness among 65+ individuals. We identify which personality dimensions moderate the relationship between ST and loneliness using the conceptual framework of the five-factor and the unified theory of acceptance and use of technology model. Linear regression analyses are conducted to determine direct and interaction effects. Results indicate that greater ST use corresponds negatively with loneliness. We also observe that particular personality traits (e.g. extraversion) are negatively associated with loneliness, while neuroticism corresponds positively with loneliness. In the interaction between neuroticism and ST, neuroticism mitigates the association between social technology and loneliness. These findings indicate that ST can be a positive source of social connectivity but the extent may be conditioned on personality profiles. Plausibly, neurotic individuals may exacerbate behavioral propensities by technology use. As evidenced by the robust independent effects of ST and conditional nature of technology connections with neurotic profiles. These findings imply that future intervention should consider individual differences when developing mental health programs using ST.

SESSION 4560 (SYMPOSIUM)

INTERACTIONS BETWEEN SLEEP AND BIOLOGICAL MARKERS OF AGING

Chair: Christopher Kaufmann Discussant: Katie Stone

There is well documented evidence that sleep architecture and circadian patterns change as people age in part due to accumulation of comorbidities, polypharmacy, and other factors inherent to the aging process. While a number of studies have examined sleep in the context of these factors, recent advances in the assessment of biological aging (including epigenetic age, metabolomics, and measurement of inflammatory biomarkers) have made it possible to identify potential mechanisms by which sleep impacts the aging course. In this symposium, we will highlight research that investigates the link between sleep disturbances and biological factors in order to identify whether sleep could be a modifiable risk factor for accelerated aging. Our first presentation will examine the association between insomnia symptoms and short sleep duration with epigenetic age acceleration using data from the Health and Retirement Study. Second, we will describe whether objectively measured sleep characteristics are associated with a number of metabolomic markers of aging. The third presentation will center around the extent to which social disparities in presence of inflammatory biomarkers may be mediated by sleep quality. Finally, we will examine how daytime sleepiness may be associated with longitudinal BMI trajectories. These presentations will, as a whole, highlight the importance of sleep as a contributor to healthy aging and longevity, and inform the development of interventional approaches targeting biological mechanisms to promote successful aging more broadly.

SHORT SLEEP AND INSOMNIA ARE ASSOCIATED WITH ACCELERATED EPIGENETIC AGE

Cynthia Kusters[1], Eric Klopack[2], Eileen Crimmins[3], Teresa Seeman[4], Steve Cole[4], and Judith Carroll[1], *1. University of California, Los Angeles, Los Angeles, California, United States, 2. University of Southern California, Leonard Davis School of Gerontology, Los Angeles, California, United States, 3. University of Southern California, Los Angeles, California, United States, 4. University of California Los Angeles, Los Angeles, California, United States*

Short sleep (<6 hours) and insomnia are independently associated with greater risk for age-related disease suggesting that insufficient sleep may accelerate biological aging. Epigenetic age acceleration is an estimate of biological aging that predicts morbidity and mortality. We tested whether insomnia symptoms and short sleep duration relates to epigenetic age in 2783 participants in the Health and Retirement Study. Insomnia and short sleep were associated with an 0.70(95%CI:0.23-1.17;P: 0.005) and 1.45(95%CI:0.67-2.24;P:0.001) years acceleration of GrimAge, respectively, as well as a faster pace of aging (DunedinPoAm; 0.015(95%CI: 0.005-0.024; P:0.006); 0.021(95%CI: 0.006-0.037; P:0.009)). Compared to healthy sleepers, Individuals with the combination of short sleep and insomnia had an accelerated GrimAge (1.34;95%CI: 0.49-02.19; P:0.003) and a greater DunedinPoAm (0.025; 95%CI: 0.009-0.041; P:0.004). Our findings indicate short sleep and insomnia are linked to epigenetic age acceleration, suggesting that these individuals have an older biological age that may contribute to risk for comorbidity and mortality.

ASSOCIATIONS BETWEEN SLEEP AND REST: ACTIVITY CHARACTERISTICS AND METABOLOMIC PROFILES IN OLDER MEN

Qian Xiao[1], Joshua Sampson[2], Aladdin Shadyab[3], Andrea LaCroix[3], Kristine Yaffe4, and Katie Stone4, *1. The University of Texas Health Science Center at Houston,*

Houston, Texas, United States, 2. FDA, Silver Spring, Maryland, United States, 3. University of California, San Diego, La Jolla, California, United States, 4 University of California, San Francisco, San Francisco, California, United States

The association of sleep and rest-activity rhythms (RAR) with metabolic health is not fully understood. Previous studies have identified multiple metabolite markers in amino acid and lipid pathways associated with various characteristics of sleep. However, most of the studies used self-reported sleep, and limited studies have examined 24-hour RAR profiles, a more complete picture of activity. We studied 950 older men and measured metabolomics from fasting blood samples. We identified numerous metabolomic markers that were cross-sectionally associated with actigraphy-based measures of sleep (total sleep time, sleep efficiency, sleep timing) and RAR (amplitude, acrophase, mesor and overall rhythmicity). The majority of the associated metabolites were amino acids and lipids from a wide range of pathways, including metabolism pathways of branched chain amino acid metabolism, fatty acids, and gamma-glutamyl amino acids. Our preliminary findings suggest that sleep and RAR are widely involved in human metabolism.

SOCIAL DISPARITIES IN INFLAMMATORY BIOMARKERS MEDIATED BY POOR SLEEP QUALITY

Joseph Obiagwu, Christina Mu, and Soomi Lee, *University of South Florida, Tampa, Florida, United States*

This study investigated whether sleep quality mediates the relationship between race/SES and biomarkers (CRP, IL6, IL10, TNF-α). Participants in the Midlife in the United States Study (n=1,689; Mage=53.02) completed the Pittsburgh Sleep Quality Index and provided information on eight life-course indicators to measure SES. Black individuals and those with lower SES had poorer sleep quality and higher inflammation compared to their counterparts. Poorer sleep quality mediated the relationship between being Black and higher CRP (β=0.02, 95%CI [0.002, 0.04]), IL6 (β=0.008, 95%CI [0.0002, 0.02]), IL10 (β=0.008, 95%CI [0.0004, 0.02]), and TNF-α (β=0.004, 95%CI [0.0002, 0.01]). Poorer sleep quality also mediated the relationship between lower SES and higher CRP (β=-0.01, 95%CI [-0.01, -0.001]), IL6 (β=-0.003, 95%CI [-0.007, -0.00]), IL10 (β=-0.003, 95%CI [-0.01, - 0.0003]), and TNF-α (β=-0.002, 95%CI [-0.004, -0.0002]). Improving sleep quality may help reduce the risk of inflammation in at-risk groups and subsequently reduce health disparities.

DAYTIME SLEEPINESS AND WEIGHT CHANGE AMONG ADULTS: FINDINGS FROM THE WISCONSIN SLEEP COHORT STUDY

Yin Liu[1], Jodi Barnet[2], Erika Hagen[2], Paul Peppard[2], Eric Reither[1], Emmanuel Mignot[3], and David Plante[4], *1. Utah State University, Logan, Utah, United States, 2. University of Wisconsin Madison, Madison, Wisconsin, United States, 3. Stanford University, Palo Alto, California, United States, 4. University of Wisconsin-Madison, Madison, Wisconsin, United States*

BMI trajectories are associated with nighttime sleep, but it is less clear how they relate to daytime sleepiness. We examined the association between levels and changes in daytime sleepiness and BMI among men and women using growth curve models among 1047 participants in the Wisconsin Sleep Cohort Study (mean [sd] age = 51.1 [8.0] years at baseline). The outcome variable was BMI (kg/m2). Key predictors were self-reported sleepiness measured by the Epworth Sleepiness Scale (ESS), and the objective Multiple Sleep Latency Test (MSLT) scores at each data collection wave. Men, but not women, who were sleepier had higher BMI levels. Age moderated the association between changes in ESS and MSLT sleepiness and BMI trajectories. The association was weaker for older men, but stronger for younger men; such effect was the opposite for women. The MSLT models further suggested that women who were sleepier had steeper increases in BMI over time.

SESSION 4570 (SYMPOSIUM)

NEW SPINS ON CLASSIC IDEAS ABOUT CONTEXT IN ADULT EMOTIONAL DEVELOPMENT

Chair: Tabea Springstein Co-Chair: Tammy English

Individuals often experience improvements in emotional well-being into old age. Understanding mechanisms contributing to these emotional outcomes in daily contexts can inform ways to support healthy aging. Development is embedded within various contexts that shape individuals' experiences. Novel perspectives are emerging on how to conceptualize context and the way it can contribute to emotional development during the aging process. This symposium illustrates four innovative ways to consider contextual contributions to emotional well-being across adulthood. The first talk will use experience sampling to illustrate age differences in how daily situations contribute to emotion regulation related processes, showing that older adults can more easily distinguish between emotions when in familiar situations. The second talk will take a fresh perspective on psychosocial contexts by distinguishing between types of social interactions in couples, highlighting the important role of affection for well-being in adulthood. The third talk will introduce the idea that the body itself provides context for emotional processes, showcasing that the way this context affects emotional experience changes as individuals age. The fourth talk will center on how renewing our classical developmental models of context in modern ways can help to overcome shortcomings of previous research and provide insight into how engagement with environmental features contributes to well-being across the lifespan. In sum, this symposium features innovative perspectives on how context can be leveraged to gain a deeper understanding of psychosocial development into old adulthood and illustrates specific ways individuals can navigate their social world to preserve or improve mental health across adulthood.

FAMILIAR CONTEXTS, FAMILIAR EMOTIONS? A NEW PERSPECTIVE ON CONTEXT-SPECIFIC EMOTION PROCESSES IN OLDER ADULTHOOD

Tabea Springstein, and Tammy English, *Washington University in St. Louis, St. Louis, Missouri, United States*

As people age, their emotional well-being tends to be maintained or improves. Theories of adult development suggest that features of the context (e.g., more familiar environments) and successful management of emotions contribute to this effect. This talk focuses on how familiarity may promote emotional differentiation (e.g., knowing whether one feels angry or sad) in daily life, an important predecessor to emotion regulation success. A sample (N=290) of community participants between the ages of 25 and 85 years old completed an experience sampling study (6x/10days). When people were more familiar with their current situation, they differentiated more between emotions. The relationship between familiarity and differentiation was stronger for older adults than younger adults. These results support the perspective that emotional well-being benefits from wisdom accrued over the lifespan, such that older adults are at more of an advantage when their daily contexts afford for them to draw on their prior experiences.

ALL YOU NEED IS LOVE? SPOUSES' AFFECTION ACROSS MARITAL INTERACTION CONTEXTS

Claudia Haase, Jacquelyn Stephens, and Tabea Meier, *Northwestern University, Evanston, Illinois, United States*

Affection is a positive emotion that plays an important role in intimate relationships. In a laboratory-based dyadic study of 52 middle-aged married couples (104 individuals) from highly diverse socioeconomic backgrounds, we examined spouses' subjective experience of affection across different marital interaction contexts, correlates, and specificity. Results showed that (1) wives and husbands experienced lower affection in a conflict conversation compared to a positive conversation. Moreover, (2) for wives, higher affection in the conflict conversation was associated with lower physiological reactivity (i.e., less heart rate acceleration from baseline to conflict discussion). For wives, higher affection was also associated with higher marital satisfaction for themselves and their husbands. These findings were specific to affection and did not robustly emerge for other positive emotions. These findings support views of affection as a positive, context-sensitive emotion that may become particularly important in intimate relationship conflict. Directions for future research are discussed.

AGING BODY AS CONTEXT: THE ROLE OF INTEROCEPTIVE AGING IN MID- AND LATE-LIFE EMOTION

Jennifer MacCormack, *University of Virginia, Charlottesville, Virginia, United States*

Interoceptive sensations (e.g., racing heart, clenched gut) are often closely tied to emotion. Older adults tend to exhibit reduced sensitivity and awareness of their interoceptive sensations relative to younger adults (e.g., Khalsa et al., 2009; Mikkelsen et al., 2019; Murphy et al., 2019), yet the emotional implications of such interoceptive differences remain unclear. Herein, I present two behavioral cross-sectional studies (N=350) documenting age differences in how adults (18-75 yrs) link their interoceptive sensations to emotions (Study 1: cognitive behavioral task; Study 2: experience sampling). Results reveal that from midlife into late life, coherence between interoceptive sensations and emotions increasingly weakens, both behaviorally and in self-reports. Age effects are most prominent for high arousal sensations and states. These findings provide converging evidence with recent neuroimaging results (MacCormack et al., 2020) showing the importance of interoceptive aging and related shifts in physiological arousal as potential pathways by which emotions transform across adulthood.

INFLUENCE OF EARTH, WIND, AND FIRE ON WELL-BEING: THE CLASSIC CONCENTRIC CIRCLES MODEL OF CONTEXT IS ALSO FROM THE 1970S

Michelle Ng[1], Angelina Garron[1], Denis Gerstorf[2], and Nilam Ram[3], *1. Stanford University, Palo Alto, California, United States, 2. Humboldt Universität zu Berlin, Berlin, Berlin, Germany, 3. Stanford University, Stanford, California, United States*

Classic bioecological models of human development (Bronfenbrenner, 1979) highlight the influence that five layers of context have on individuals' function and growth. Modern versions specifically highlight five specific aspects of context (socio-economic, social, physical, care/service, and technology) that influence both how older adults negotiate their daily lives and how they age. Using a collection of empirical findings obtained from our analyses of longitudinal panel data from the German SOEP, experience sampling data from iSAHIB, and screenome data from the Stanford HSP, we illustrate how differences in individuals' engagement with green spaces (earth), ambient air pollution (wind), and smartphones (fire) may contribute to differences in daily emotional well-being and developmental changes in life satisfaction. We then use these examples to elucidate shortcomings of the hierarchical models used to frame investigations of context and development for the past 40 years – and suggest the classic models be renewed rather than continually recycled.

SESSION 4580 (PAPER)

OPIOID USE AND PRESCRIBING PATTERNS

CHARACTERISTICS OF OLDER ADULTS WHO DIED FROM OPIOIDS AS A CAUSE OF DEATH DURING THE COVID-19 PANDEMIC

Armiel Suriaga, and Ruth Tappen, *Florida Atlantic University, Boca Raton, Florida, United States*

There was a 1,886% increase in opioid overdose deaths among people 55 years and above, from 518 in 1999 to 10,292 in 2019 in the U.S. The National Institute on Drug Abuse reported a 30% increase in drug overdose deaths in 2020, where it claimed nearly 100000 American lives. However, few studies focused on the individual opioids that caused more deaths in the aging population and their death circumstances. This retrospective study aims to describe the sociodemographic characteristics of older adults who died from opioids as a cause of death (COD) in Florida during the COVID-19 pandemic in 2020, using descriptive statistics in SPSS 28. De-identified data from the Florida Department of Law Enforcement in 2020 were used in this study. A total of 1656 cases of decedents (ages > 65 years) were analyzed; 348 out of 1656 cases had opioids as a COD. Age ranged from 65 to 103, mean age of 73.31 (SD= 7.690). Majority of decedents were males (67.3%), non-Hispanic whites (86.5%). Nearly 80% died from accidents, suicide at 18.1%; 99.1% of cases happened in urban counties. Fentanyl caused more deaths (n=135), then morphine (n=48), oxycodone (n=42), and hydrocodone (n=29).The study results have direct clinical practice implications to patient safety, particularly the opioid deaths that resulted from accidents. Opioid harm reduction interventions should be tailored to older adults' specific needs, specifically in urban counties. Healthcare providers should pay extra attention to opioids that cause more deaths, i.e., fentanyl, morphine, oxycodone, and hydrocodone to safeguard public safety.

CONTINUED OPIOID USE REDUCES PERCEIVED CHANCE OF LIVING TO AGE 75 AMONG YOUNG-OLD INDIVIDUALS WITH CHRONIC PAIN

Gillian Fennell, *University of Southern California, Los Angeles, California, United States*

Pain limits older adults' predictions of their own life expectancies. Due to their analgesic properties and simultaneous linkages to depression, poor subjective health, and functional disability, it is uncertain if the use of opioids augments or contributes to limitations in subjective life expectancy (SLE). This study uses 2016 and 2018 data from the Health and Retirement study to assess the predictive value of prescription opioid use transitions on perceived chances of living to age 75 (SLE). Our sample includes 50 to 62 year-olds who reported pain in both waves (N=1,977). The OLS model controls for pain intensity and activity interference, socio-demographic factors, six chronic conditions, depression, and the 2016 baseline outcome measure. Relative to non-opioid users, respondents who transitioned off of opioids after 2016 reported significantly higher SLEs in 2018 (b=5.56, p=.05). Respondents who used opioids in both waves reported significantly lower SLEs relative to non-opioid users (b=-4.17, p=.02). Individuals who began using opioids following the 2016 wave were no different on SLE than non-opioid users (p=.11). Higher 2016 SLE predictions and being female were associated with higher SLEs. Being never married and ever having diabetes were negatively associated with SLE. Continued opioid use among individuals with chronic pain reduced anticipated chances of living to 75 whereas transitioning off of such medications had the opposite effect. Despite their analgesic properties, prescribed opioid use has negative effects on future outlook independent of pain, health status, and depression. As a consequence, continued opioid users may poor health and/or financial planning decisions.

DISCHARGE LOCATIONS AFTER HOSPITALIZATIONS INVOLVING OPIOID USE DISORDER AMONG MEDICARE ENROLLEES

Patience Moyo[1], Kimberly Goodyear[1], Eric Jutkowitz[2], Kali Thomas[2], and Andrew Zullo[1], *1. Brown University School of Public Health, Providence, Rhode Island, United States, 2. Brown University, Providence, Rhode Island, United States*

Hospitalizations involving opioid use disorder (OUD) are increasing in the Medicare population. Rising OUD-related acute care use emphasizes the need to understand where post-acute care is provided and opportunities to facilitate OUD treatment in those settings. We conducted a retrospective cohort study using 2016-2018 Medicare Provider Analysis and Review (MedPAR) files linked to enrollment data and the Residential History File (RHF) for 100% of Medicare fee-for-service beneficiaries aged ≥18 years. We used diagnostic codes for opioid dependence or "abuse" to identify OUD from MedPAR data. The RHF identified hospital discharge locations. Our analysis included 459,763 OUD-related hospitalizations. Overall, individuals < 65 years (60.3%), female (53.7%), or Medicare-Medicaid dually enrolled (59.1%) were the majority. The mean (standard deviation) length of stay was 5.5 (6.6) days and 31.3% of OUD-related hospitalizations required intensive care use. Seventy percent of patients with OUD-related hospitalizations were discharged home, 15.8% to skilled nursing facilities (SNFs), 9.6% to non-SNF institutional facilities, 2.5% home with home health services, and 1.8% died in-hospital. Within 30 days of hospital discharge, the range for 30-day all-cause readmissions was 27.7% (home) to 47.5% (non-SNF institutional setting). The 30-day all-cause mortality ranged from 3.1% (home without health) to 6.4% (non-SNF institutional settings). Given that over one-quarter of OUD-related hospitalizations resulted in discharge to locations other than home and that many institutional post-acute care settings cannot obtain OUD medications, modifying Drug Enforcement Administration regulations and expanding access to OUD medications for aging adults in post-acute and long-term care settings must be a near-term policy focus.

MEDICATIONS ASSOCIATED WITH GERIATRIC SYNDROMES AND HOSPITALIZATION RISK IN HOME HEALTHCARE PATIENTS

Jinjiao Wang[1], Jenny Shen[2], Fang Yu[3], Yeates Conwell[2], Yue Li[4], Thomas Caprio[4], Avantika Shah[5], and Sandra Simmons[6], *1. University of Rochester School of Nursing, Rochester, New York, United States, 2. University of Rochester Medical Center, Rochester, New York, United States, 3. Arizona State University, Phoenix, Arizona, United States, 4. University of Rochester, Rochester, New York, United States, 5. Johns Hopkins University, Baltimore, Maryland, United States, 6. Vanderbilt University Medical Center, Nashville, Tennessee, United States*

Polypharmacy is common in the home health care (HHC) setting. This study examined the prevalence, predictors, and impact of medications associated with geriatric syndromes (MAGS) use on subsequent hospitalization in HHC patients. Data from the HHC electronic medical records, the Outcome and Assessment Information Set (OASIS), and Medicare HHC claims of 6,882 adults ≥ 65 years old receiving HHC from a large, non-profit HH agency in New York State in CY 2019 were used. MAGS use was identified from active medications reconciled during HHC visits and defined as total count and in quartiles. Hospitalization during the HHC episode was operationalized as a time-to-event variable. Regression analyses were conducted to identify predictors of MAGS use, and survival analyses were conducted to examine the association between MAGS use and hospitalization. Nearly all (98%) of the HHC patients used at least one MAGS and 41% of all active medications were MAGS. A higher MAGS count was found among HHC patients who were non-white, community-referred, with more comorbidities, depressive symptoms, and functional limitations. A higher MAGS count was also related to increased risk for hospitalization. Moreover, higher quartiles of MAGS use combined with having ≥10 diagnoses predicted a 2.5-fold increase in hospitalization risk, relative to the lowest quartile of MAGS use and having < 10 diagnoses. In conclusion, over 40% of medications taken by HHC patients are MAGS, which, along with multimorbidity, increased hospitalization risk. HHC clinicians should identify MAGS use to inform deprescribing discussion with patients and their prescribers.

SESSION 4590 (SYMPOSIUM)

OPPORTUNITIES AND OUTCOMES OF CENTERING OLDER ADULTS IN PATIENT-ORIENTED AND COMMUNITY-ENGAGED RESEARCH

Chair: Carrie Leach Co-Chair: Carol Geary Discussant: Discussant should be Carol Geary also

Community engagement is critical for achieving context-sensitive and culturally appropriate communication, implementation and research approaches that can lead to better public and patient health outcomes. Though patient and community-engaged approaches are increasingly utilized in social research, the inclusion of older adults remains limited, as are methodologies that will help inform adult-centric programs and interventions. To advance the science of community engagement and implementation, this symposium brings together methodological innovations to help researchers shift from involving older adults as participants in research, toward collaboratively engaging and partnering with older adults in the design and conduct of research. The first presentation centers on place-based health disparities by starting with a statewide survey to identify communities that researchers could engage. The second highlights how the involvement of older adults led to the development of tactics for connecting with the hardly-reached, people over the age of 75, with health enhancing services and support. The third discusses a model for greater involvement of older adults to draw out lessons for implementation science in long-term care. The final presentation demonstrates an innovative approach to pilot new solutions with multidisciplinary and community partners in clinical settings. This CEnR and PPER interest group collaborative symposium concludes by imagining ways to integrate the diverse perspectives to advance the science of engaged research and implementation in community and clinical settings. This symposium represents diverse perspectives on involving community stakeholders meaningfully and equitably with research, to bend the later life health equity arc toward greater inclusion and justice.

COMMUNITY PERSPECTIVES ON COMMUNICATION DISPARITIES IN LATE OLD AGE AND TACTICS TO CONNECT WITH THE HARDLY REACHED

Carrie Leach, and Thomas Jankowski, *Wayne State University, Detroit, Michigan, United States*

Individuals who face the greatest health burdens often have the fewest communication resources to draw from to help them cope. Communication infrastructure theory provides a framework for understanding how communication resources and context constrain and enable connections to health enhancing information. Data collected from 1,609 older adults through in-depth interviews and a random sample survey in one midwestern county in Michigan as part of a multi-year, multi-level community engaged study and a statewide random digit dial telephone survey showed that age influenced integration in a communicative structure. Findings suggest that the dynamics of living into late old age result in communication disparities through diminishing interpersonal resources, activity, and opportunities to congregate. Actionable knowledge and strategies provided to community leaders on how to connect with the hardly reached, individuals age of 75 and older, are presented.

MULTISTAGE SAMPLING FOR TRANSLATIONAL COMMUNITY RESEARCH: ZOOMING OUT TO HONE IN ON PLACE-BASED HEALTH DISPARITIES

Daniel Rong Yao Gan, *Simon Fraser University, Vancouver, British Columbia, Canada*

Whereas researchers strive for generalizability, community-engaged research (CEnR) typically involves only a few specific communities. Drawing on Weberian ideal type, I outline the use of an innovative blended-methods approach to sample the communities in which CEnR practitioners would collect in-depth data. To complement typical practices of entering a community without preconceived ideas, understanding how communities in the sampling frame relate to one another is important for equigenic (place-based health equity) implementations. The selection of neighborhood communities from quadrants in 2x2 matrices allows pertinent concepts to emerge and relevant solutions to be drawn from thriving communities to aid program co-creation and implementation in other communities. For example, this has led to the identification of communities in British Columbia with differing socioeconomic status, social capital, and coping during COVID-19. This methodological innovation is congruent with asset-based community development (ABCD) to minimize arbitrariness in sampling decisions and advance health equity in our cities.

A SUCCESSFUL MODEL FOR AMPLIFYING THE VOICES OF OLDER ADULTS IN LONG-TERM CARE AND SERVICES AND SUPPORT RESEARCH

Rachel Lessem[1], Rebecca Berman[2], and Amy Eisenstein[3], *1. CJE SeniorLife, Chicago, Illinois, United States, 2. Leonard Schanfield Research Institute, Chicago, Illinois, United States, 3. RRF Foundation for Aging, Chicago, Illinois, United States*

The experiential voice of older adults receiving long term services and supports (LTSS) is largely absent from health research hampering the development of effective interventions. While many have the capacity to participate in the design, development, and delivery of research, researchers traditionally do not recognize such capacity, may be unsure how to seek input, or may not appreciate the extent to which such input can improve the research enterprise. But the participation of these older adults can ensure that patient-centered research meaningfully addresses their care preferences and desired health outcomes, and can improve the effectiveness of care and patients' quality of life. Through three PCORI-funded projects, we developed a successful model for addressing barriers to amplify these voices. We outline barriers to the dissemination and implementation of this model, and suggest next steps to test strategies to amplify the voices of older adults in long-term care.

USING COLLABORATIVE ACTION RESEARCH TO PILOT TELEPRESENCE ROBOTS IN LONG-TERM CARE

Lillian Hung, *University of British Columbia, Vancouver, British Columbia, Canada*

The COVID-19 pandemic has exposed the fragile state of patient involvement in research and presented new opportunities. The telepresence robot project aims to tackle social isolation and loneliness in older people with dementia in Long-Term Care (LTC) homes. My team took a Collaborative Action Research (CAR) approach to work with stakeholders, emphasising meaningful involvement of patient partners (people with dementia), family partners, frontline healthcare workers throughout all phases of the research process. In this paper presentation, I will discuss how we apply the core principles of CAR to engage stakeholders to carry out the study during the COVID-19 pandemic – a challenging time. It is precisely at times like this that we need to work with patient partners and frontline workers to uncover lessons learned for meaningful solutions to address the most pressing social problems. I will share stories about challenges and creative strategies used. Finally, practical lessons learned will be discussed.

SESSION 4600 (SYMPOSIUM)

PERCEIVED AND PERFORMANCE FATIGABILITY: NOVEL FINDINGS ON CORRELATES, CONSEQUENCES, AND CANDIDATE GENES

Chair: Nancy W. Glynn Co-Chair: Jennifer Schrack
Discussant: Eleanor Simonsick

Characterizing fatigability enables quantification of an individual's susceptibility to fatigue in the context of standardized physical task(s). This approach eliminates self-pacing, and is a less-biased, more sensitive approach to assess the presence and severity of fatigue, a critical prodromal symptom of chronic and acute health conditions. Collectively, we have established the Pittsburgh Fatigability Scale (PFS) and Borg Rating of Perceived Exertion at the end of a standardized 5-minute treadmill walk (RPE Fatigability) as prognostic indicators of aging-related outcomes. Recently, we extended our methodological work in developing a novel accelerometry-based performance fatigability measure of slowing down during in-lab walking (Pittsburgh Performance Fatigability Index, PPFI). This symposium presents findings from the Study of Muscle, Mobility, and Aging (SOMMA), Long Life Family Study (LLFS), and Baltimore Longitudinal Study of Aging (BLSA). Specifically, using SOMMA, Ms. Qiao will share development and validation of the PPFI using a usual-paced 400m walk, Ms. Moffit will report the association of fitness (i.e., VO2peak) with PFS physical and mental fatigability, and extending the SOMMA findings, Dr. Moored will detail the dual roles of fitness and fatigability on life-space mobility. Using LLFS data, Ms. Gay will report associations of variants (SNPs) in 272 candidate autosomal genes involved in energy metabolism (previously associated with mitochondrial dysfunction disease) with PFS physical fatigability. Lastly, using BLSA data, Dr. Wanigatunga will compare the discriminatory power of RPE Fatigability versus general fatigue symptoms for predicting mortality. Our Discussant, Dr. Simonsick, will provide critical review in the context of new directions for fatigability research.

VALIDATION OF THE PITTSBURGH PERFORMANCE FATIGABILITY INDEX FROM USUAL-PACED 400 M WALK

Yujia (Susanna) Qiao[1], Jaroslaw Harzelak[2], Pamela Toto[3], Kyle Moored[4], Bret Goodpaster[5], Adam Santanasto[6], barbara Nicklas[7], and Nancy W. Glynn[8], *1. University of Pittsburgh, Schoold of Public Health, Pittsburgh, Pennsylvania, United States, 2. Indiana University, School of Public Health in Bloomington, Bloomington, Indiana, United States, 3. University of Pittsburgh, Pittsburgh, Pennsylvania, United States, 4. Johns Hopkins Bloomberg School of Public Health, Baltimore, Maryland, United States, 5. AdventHealth, Orlando, Florida, United States, 6. School of Public Health, University of Pittsburgh, Oakmont, Pennsylvania, United States, 7. Wake Forest School of Medicine, Winston-Salem, North Carolina, United States, 8. School of Public Health, University of Pittsburgh, Pittsburgh, Pennsylvania, United States*

The Pittsburgh Performance Fatigability Index (PPFI, higher=greater fatigability), a novel accelerometer-based performance fatigability measure, was recently developed for adults aged ≥60 years. We validated PPFI during a usual-paced 400m walk in 429 individuals enrolled in the Study of Muscle, Mobility and Aging (age=76.9±5.3years, 57.6% women, gait speed=1.0±0.2 m/s from 4-meter walk). PPFI quantifies percent of performance decrement (i.e., slowing down) during 400m walk by comparing area under the observed cadence trajectories to the hypothetical area that reflects sustaining maximum cadence for the entire walk. PPFI scores (mean=2.1%±2.5%, range: 0-21.7%) demonstrated convergent validity with Short Physical Performance Battery (SPPB, Pearson correlation (r)=-0.32) and mobility (time to walk 400m, r=0.47). PPFI scores discriminated higher versus lower physical function (SPPB: 1.6% (≥10) vs. 2.9% (<10), p<.001), adjusted for age, sex, height, and weight. PPFI is the first validated accelerometer-based objective risk assessment tool for measuring performance fatigability, an established marker of functional decline.

ASSOCIATION BETWEEN AEROBIC CAPACITY AND PERCEIVED FATIGABILITY: THE STUDY OF MUSCLE, MOBILITY, AND AGING (SOMMA)

Reagan Moffit[1], Daniel Forman[1], Paul Coen[2], barbara Nicklas[3], Kyle Moored[4], Yujia (Susanna) Qiao[5], Peggy Cawthon[6], and Nancy W. Glynn[7], *1. University of Pittsburgh, Pittsburgh, Pennsylvania, United States, 2. AdventHealth, Orlando, Florida, United States, 3. Wake Forest School of Medicine, Winston-Salem, North Carolina, United States, 4. Johns Hopkins Bloomberg School of Public Health, Baltimore, Maryland, United States, 5. University of Pittsburgh, Schoold of Public Health, Pittsburgh, Pennsylvania, United States, 6. California Pacific Medical Center Research Institute, San Francisco, California, United States, 7. School of Public Health, University of Pittsburgh, Pittsburgh, Pennsylvania, United States*

Peak aerobic capacity declines with age concomitant with greater fatigability and slower gait speed. We explored these relationships with cross-sectional SOMMA data (N=422, age=76.7±5.1, 57.4% women, gait speed= 0.97±0.18 m/s from a 4m walk). Participants completed a treadmill peak oxygen consumption test (VO2peak) and the self-administered Pittsburgh Fatigability Scale (PFS, range: 0-50; higher=greater fatigability). Mean VO2peak was 19.4±4.2 ml/kg/min, PFS Physical score was 16.9±8.5 points, and PFS Mental score was 8.1±8.2 points. Pearson correlations between VO2peak and PFS Physical and Mental scores were r=-0.36 and r=-0.23, respectively. For every one standard deviation higher VO2peak, PFS Physical and Mental scores were lower by 2.07 points (CI: -3.00, -1.13) and 1.10 points (CI: -2.07, -0.17), respectively, when adjusted for clinic site, age, race, sex, and self-reported physical activity. Future SOMMA analyses will evaluate a likely bidirectional association between VO2peak and fatigability, as well as examine their potential mediating effects on physical function.

DUAL ROLES OF FITNESS AND FATIGABILITY IN THE LIFE-SPACE MOBILITY OF OLDER ADULTS

Kyle Moored[1], Yujia (Susanna) Qiao[2], Andrea Rosso[3], Frederico Toledo[3], Steven R. Cummings[4], Bret Goodpaster[5], Stephen Kritchevsky[6], and Nancy W. Glynn[7], *1. Johns Hopkins Bloomberg School of Public Health, Baltimore, Maryland, United States, 2. University of Pittsburgh, Schoold of Public Health, Pittsburgh, Pennsylvania, United States, 3. University of Pittsburgh, Pittsburgh, Pennsylvania, United States, 4. San Francisco Coordinating Center, San Francisco, California, United States, 5. AdventHealth, Orlando, Florida, United States, 6. Wake Forest School of Medicine, Winston-Salem, North Carolina, United States, 7. School of Public Health, University of Pittsburgh, Pittsburgh, Pennsylvania, United States*

Objective fitness and perceived fatigability may interact to limit mobility within the larger environment (life-space mobility). We assessed this cross-sectionally in SOMMA (N=371, mean age=76.4±5.0). Life Space Assessment scores (range: 0-120, 5-point difference=clinically relevant, e.g., going outside additional 1-3 days/week) incorporated level, frequency, and assistance used for life-space mobility (Mean=82.7±18.8). Fitness was measured as VO2peak (Mean=19.5±4.2 mL/kg/min) from a symptom-limited treadmill test. Higher fatigability was defined as a Borg Rating of Perceived Exertion (RPE, range: 6-20) ≥10 after a five-minute steady-state treadmill test. Each 1-SD higher VO2peak was associated with a 2.2-point higher life-space score (95% CI: 0.25-4.07, p=.027). After adjustment for demographic, lifestyle, and health confounders, the association between fitness and life-space mobility was significant only for those with higher fatigability (RPE≥10: B=5.70, 95% CI: 0.79-10.60, p-interaction=.008). Older adults with both lower fitness (objective capacity) and higher fatigability (perceived capacity) may be at greatest risk of reduced real-world mobility.

ENERGY METABOLISM RELATED CANDIDATE GENE ASSOCIATION STUDY OF PERCEIVED PHYSICAL FATIGABILITY

Emma Gay[1], Adam Santanasto[2], Ryan Cvejkus[3], Mary Wojczynski[4], Mary Feitosa[5], and Nancy W. Glynn[6], *1. University of Pittsburgh School of Public Health, Pittsburgh, Pennsylvania, United States, 2. School of Public Health, University of Pittsburgh, Oakmont, Pennsylvania, United States, 3. University of Pittsburgh, Pittsburgh, Pennsylvania, United States, 4. Washington University, Saint Louis, Missouri, United States, 5. Washington University, St Louis, Missouri, United States, 6. School of Public Health, University of Pittsburgh, Pittsburgh, Pennsylvania, United States*

Mitochondrial energy production decreases while fatigability increases with age. Genes associated with energy metabolism may contribute to fatigability. Using Long Life Family Study (LLFS), we initially assessed variants (SNPs) in 272 candidate autosomal genes involved in energy metabolism (previously associated with mitochondrial dysfunction disease) with perceived physical fatigability. Two generations of LLFS enrollees (N=2342, mean age=73.7, range 60-108 years) completed the Pittsburgh Fatigability Scale (PFS, 0-50, higher=greater fatigability) at Visit 2 (2014-2017). Physical fatigability prevalence was 42.1% (PFS≥15). Generalized linear mixed models assessed the association of each SNP with continuous PFS (GENESIS R package) adjusted for age, sex, field center, and family relatedness. We found no associations with perceived physical fatigability, all p>2.5E-7 (Bonferroni multiple comparison corrected p-value). Next steps will examine variants in the mitochondrial genome and BTBD3, another promising candidate gene recently discovered. Genetic biomarker(s) may identify individuals susceptible to greater fatigability to target for early intervention.

PERCEIVED FATIGABILITY AND MORTALITY IN MID-TO-LATE LIFE IN THE BALTIMORE LONGITUDINAL STUDY OF AGING

Amal Wanigatunga[1], Xiaomeng Chen[2], Francesca Marino[3], Eleanor Simonsick[4], Luigi Ferrucci[4], and Jennifer Schrack[1], *1. Johns Hopkins Bloomberg School of Public Health, Baltimore, Maryland, United States, 2. Johns Hopkins School of Medicine, Baltimore, Maryland, United States, 3. Johns Hopkins Bloomberg School of Public Health, Washington, District of Columbia, United States, 4. National Institute on Aging, Baltimore, Maryland, United States*

This study hypothesized that perceived fatigability, fatigue standardized to walking, would better discriminate mortality risk than general fatigue symptoms. We leveraged perceived fatigability, self-reported tiredness, self-reported low energy and mortality data from 1,112 participants aged ≥50 years. Hazard ratios (HRs) of all-cause mortality (198 [17.8%] events) by either z-scored fatigability, tiredness, and energy level were estimated using Cox proportional hazards models. Model discrimination was compared using Harrell's C-statistics (C). After full covariate adjustment, 1 SD higher perceived fatigability, tiredness and low energy level were associated with higher mortality risk (HR=1.20, 95% confidence interval [CI]:1.05-1.37; HR=1.28, 95% CI:1.11-1.48; HR=1.26, 95% CI:1.10-1.45, respectively). The model for perceived fatigability (C=0.8039) had comparable discrimination to tiredness (C=0.8085,p=0.26) and low energy level (C=0.8067,p=0.41). While perceived fatigability was associated with higher mortality risk, it did not exhibit superior ability to discriminate mortality risk than self-reported fatigue symptoms among persons in mid-to-late life.

SESSION 4610 (SYMPOSIUM)

PRESIDENTIAL SYMPOSIUM: BUILDING AND LEVERAGING COMMUNITY PARTNERSHIPS THAT EMBRACE DIVERSITY, ENRICH DISCOVERY, AND REIMAGINE AGING

Chair: Kalisha Bonds Johnson Co-Chair: Brianna Morgan Discussant: Katherine Abbott

Are you an ESPO member or early careerist who is interested in creating meaningful and engaging partnerships with different stakeholders? Want to learn how to leverage partnerships across diverse research settings and make impactful change? Or are you unsure of all the “hype” surrounding engaging communities and key stakeholders? If you answered “yes” to any of these questions, this symposium is for you. The ESPO Presidential Symposium will highlight three speakers who will share their career stories and a discussant with expertise in building and keeping important collaborations that influence aging research. Speakers include Drs. Christopher G. Engeland, Andrea Gilmore-Bykovskyi, and Martina Roes. Dr. Katherine Abbott will serve as the discussant. Starting at the basic science end of the research spectrum, Dr. Engeland will focus on communicating and collaborating at the intersections between research settings to carry science from the bench to the bedside. Next, moving to research that focuses on aging older adults in clinical research, Dr. Gilmore-Bykovskyi will discuss how she has established, maintained, and evolved her career in Alzheimer’s disease and related dementias across diverse research paradigms. Lastly, Dr. Roes will provide and international perspective and shares how she builds trust with the co-creation of research with persons living with dementia and their significant others.

PROS AND CONS OF PERFORMING RESEARCH AT AN INTERSECTION OF MULTIPLE DISCIPLINES

Christopher Engeland, *Pennsylvania State University, University Park, Pennsylvania, United States*

In the last few decades, team science has become increasingly common and the need for interdisciplinary researchers has likewise increased. There is a stronger need than ever for individuals who can speak across disciplines, serving as a hub (and sometimes a translator) to unite researchers in different fields. Researchers with diverse methods (from those using animal models and bench-side science to biobehavioral observations and clinical approaches) all have a strong need for understanding each other’s work and to express it clearly to others. The ability to function and communicate at multiple intersections is needed to optimize the interpretation and understanding of scientific findings, along with their translation to clinical practice, implementation to intervention, and dissemination to the public. Performing research at these complex intersections of fields and roles is both challenging and rewarding. The pros and cons of a research career situated at these intersections will be discussed.

ENGAGED RESEARCH: HUMILITY, LISTENING, BETTER QUESTIONS, BETTER ANSWERS

Andrea Gilmore-Bykovskyi, *University of Wisconsin-Madison, Madison, Wisconsin, United States*

The expansive field of aging science comprises diverse disciplines, perspectives, and approaches to address questions that extend from strengthening our understanding of biological aging to promoting wellbeing among diverse aging populations. Engaged research practices represent a cross-cutting series of diverse epistemological beliefs and pragmatic practices in the conduct of research with broad relevance to areas of inquiry across the translational aging research continuum. This presentation will describe experiences with the establishment, maintenance, and continual evolution of engaged research practices in an interdisciplinary program of health services research focused on Alzheimer’s disease and related dementias (AD/ADRD). Specifically, this presentation will discuss: a) conceptualizations of engagement and its relationship to equitable research, b) engagement as praxis for the conduct of equitable research, c) personal reflections on experiences with and the practice of humility, listening, and valuing stakeholders’ distinctive expertise, and d) practical recommendations for early career scholars approaching engaged research.

ENGAGING AND INVOLVING PEOPLE LIVING WITH DEMENTIA IN RESEARCH: WHAT TO (NOT) EXPECT

Martina Roes, *German Center for Neurodegenerative Diseases (DZNE), Witten, Nordrhein-Westfalen, Germany*

Collaborating across disciplines, professions, and countries as well as engaging a variety of stakeholders has been a goal for researchers for a long time. Interestingly, when people living with dementia and their significant others are actively involved and become a co-researcher or a member of a patient advisory board, the perspective of what collaboration and/or engagement and involvement means, becomes blurry. The intersection between the individual reality of people living with dementia and researchers can be understood as (a) a door that opens up and leads to new (multiple) perspectives and understandings or (b) a disaster because misconceptions of dementia hinder mutual trust building. This presentation will provide examples on how to build trust and how sustain a relationship over the course of time (and progression of the disease). Since living with dementia is highly stigmatized this presentation will also reflect on the impact of misconceptions of dementia on engagement.

SESSION 4620 (SYMPOSIUM)

PSYCHOSOCIAL AND BEHAVIORAL PREDICTORS OF HEALTH AND AGING

Chair: Eileen Graham Co-Chair: Nicholas Turiano

Crucial to understanding the aging process is to identify modifiable characteristics that can be targeted in hope of optimizing health across adulthood. This symposium brings together a diverse set of talks about the biopsychosocial and behavioral processes that influence aging outcomes. Turiano used a national sample to demonstrate that individuals with higher levels of neuroticism often use food to cope with stressors which ultimately results in a greater central adiposity and elevated glycated hemoglobin. Zavala used an epidemiological sample of long-banked frozen blood samples to successfully extract DNA and methylation biomarkers from 140 adults and found that stress measures are associated with accelerated biological aging. Luo used coordinated analysis to explore how correlations between personality traits and four health outcomes fluctuate over time, and found the associations between personality (level/change) and health increased in strength through middle adulthood and early stage of late adulthood but weakened in very old age. Jackson found that individuals who experienced high and increasing loneliness in older adulthood had worse cognitive function and steeper cognitive decline than expected given their observed post-mortem neuropathology (i.e., worse cognitive resilience). Lastly, Pfund investigated how personality and social support change together and found within and between person associations between personality and social support, and evidence that retirement was associated with an increase in social support. In sum, this symposium presents novel evidence for the associations among personality, stress, social support, and lonliness are associated with physical and cognitive health in old age.

PERSONALITY TRAITS PREDICT DIABETES RISK IN ADULTHOOD: THE MEDIATING EFFECTS OF USING FOOD TO COPE WITH STRESS

Nicholas Turiano[1], Jacob Alderson[1], Meredith Willard[1], Sina King[1], and Páraic Ó Súilleabháin[2], *1. West Virginia University, Morgantown, West Virginia, United States, 2. University of Limerick, Limerick, Limerick, Ireland*

Identifying the individual characteristics that predict which adults will develop obesity and diabetes is crucial. This study included national data from 902 participants (aged 25-75) in the Midlife Development in the U.S. (MIDUS) study. Participants completed the Big-5 personality trait measure in 1995-1996, and behavior/health variables between 2004-2009. We tested whether levels of certain personality traits would predict an elevated risk of diabetes via hemoglobin A1c (HbA1c) levels through eating behaviors. A structural equation modeling framework demonstrated good fit when testing indirect effects (CFI = 0.95; RMSEA = 0.05). Indirect effects revealed that higher levels of neuroticism predicted greater waist circumference and higher HbA1c levels due to an increased use of food to cope with problems (IE =0.10; $p<0.05$). Moreover, indirect effects were found for conscientiousness, albeit in a protective direction. Our findings suggest that personality traits may be an early predictor of behavior and thus long-term adverse health outcomes.

APPLYING NEW METHODS TO EXISTING DATASETS TO TEST STRESS EFFECTS ON BIOLOGICAL AGING

Daisy Zavala[1], Natalie Dzikowski[2], Shyamie Gopalan[3], Kerry Reid[4], Jennifer Graham-Engeland[5], Christopher Engeland[6], Krishna Veeramah[4], and Stacey Scott[2], *1. Stony Brook University, Queens, New York, United States, 2. Stony Brook University, Stony Brook, New York, United States, 3. Duke University, Durham, North Carolina, United States, 4. Stony brook University, Stony Brook, New York, United States, 5. Pennsylvania State University, Pennsylvania State University, Pennsylvania, United States, 6. Pennsylvania State University, University Park, Pennsylvania, United States*

Novel opportunities to examine how life experiences connect to health and mortality through biological aging have increased due to the affordability of genomic analysis. Although epidemiological studies suggest associations between stress and accelerated biological aging, most if not all measures in the past have been global, data cross-sectional, and from primarily white samples. As part of a completed measurement study, a diverse sample (n=140, 25-65 years, Mage=47, 65% Female) provided detailed stress measures, including EMA and lifetime stress assessments, and consented to future analysis of their blood samples. We successfully used decade-old blood samples to estimate methylation-based epigenetic clocks and examined them within the context of various stress measures as a preliminary phase of a future longitudinal study. Additional whole genome sequencing will also allow for future work that incorporate continuous measures of genomic ancestry when examining lifetime discrimination-related stress, rather than simply testing for demographic group differences.

DOES PERSONALITY ALWAYS MATTER? EXAMINING THE MODERATING EFFECT OF AGE ON THE PERSONALITY-HEALTH LINK

Jing Luo[1], Bo Zhang[2], Eileen Graham[1], and Daniel Mroczek[1], *1. Northwestern University, Chicago, Illinois, United States, 2. Texas A&M University, College Station, Texas, United States*

The current research examined how the associations between the level and changes in the Big Five personality traits and different types of health outcomes (self-rated, physical, cognitive, and physiological health outcomes) differ across ages over the lifespan (Sample 1, age range: 15-100) and during the aging process (Sample 2, age range: 50-109) in particular. Using data from the two large longitudinal studies, we observed three important patterns based on the results. First, levels and changes in personality traits demonstrated substantial effects on health across different life phases, with the effects observed even in very old ages. Second, overall, the prospective relations between personality traits/changes in personality traits and health outcomes increased in strength in mid adulthood and/or early stages of late adulthood; however, the strength of their connections diminished in very old ages. Finally, there were some trait-specific and health outcome-specific patterns in the age-differential associations between personality and health.

ASSOCIATIONS BETWEEN LONELINESS AND COGNITIVE RESILIENCE TO NEUROPATHY IN OLDER ADULTS

Kathryn Jackson[1], Emily Wilroth[1], Jing Luo[1], Bryan James[2], Anthony Ong[3], David Bennett[2], Daniel Mroczek[1], and Eileen Graham[1], *1. Northwestern University, Chicago, Illinois, United States, 2. Rush University, Chicago, Illinois, United States, 3. Cornell University, Ithaca, New York, United States*

Loneliness in the aging population is a concern, as increased loneliness is associated with decreased cognitive function and increased neuropathology. Less is understood about the relationship between loneliness and cognitive resilience. Cognitive resilience is defined as the discordance between a person's actual and expected cognition given their neuropathology and can be estimated by extracting residuals from a model regressing cognition on neuropathology. Using data from two longitudinal aging cohorts (MAP/MARS), we estimated cognitive resilience proximate to death and cognitive resilience over time to use as the key outcomes. We then regressed these two cognitive resilience indicators onto loneliness level and slope. Higher baseline loneliness and increasing loneliness over time were both associated with lower cognitive resilience. Our results suggest that loneliness should be included into resilience-based prevention models, and interventions aimed at optimizing cognitive function across older adulthood should include loneliness reduction as a potential area of focus.

CHANGES IN PERSONALITY TRAITS AND SOCIAL SUPPORT BEFORE AND AFTER RETIREMENT

Gabrielle Pfund[1], Patrick Hill[2], Mathias Allemand[3], Marie Kivi[4], Anne Ingeborg Berg[4], Valgeier Thorvaldsson[4], and Isabelle Hansson[4], *1. Northwestern University, Chicago, Illinois, United States, 2. Washington University in St. Louis, St. Louis, Missouri, United States, 3. University of Zurich, Zurich, Zurich, Switzerland, 4. University of Gothenburg, Gothenburg, Vastra Gotaland, Sweden*

Aging is tied to transitions in occupational, social, and personal contexts, which can have implications for changes in who one is and how connected they feel to others. The current study uses data from 5,844 older adults (Ages: 60-66) with six annual reports on the Big Five personality traits and three distinct social support types (family, friends, relationships) to investigate how personality and social support change together, and the role retirement plays in these changes. Random intercept-cross lagged panel models were conducted to evaluate the associated changes in each trait and social support type while accounting for the time-varying covariate of retirement status. Higher social support across all relationship types was associated with higher agreeableness, extraversion, and conscientiousness and lower neuroticism both between- and within-person. Furthermore, entering retirement predicted an increase in social support with friends and relationship partners, but no consistent change in any of the personality traits.

SESSION 4630 (PAPER)

SUICIDE

ASSESSING THE PSYCHOMETRIC PROPERTIES OF THE GERIATRIC SUICIDE IDEATION SCALE (GSIS) IN MIDDLE-AGED AND OLDER MEN

Marnin Heisel[1], and Gordon Flett[2], *1. The University of Western Ontario, London, Ontario, Canada, 2. York University, Toronto, Ontario, Canada*

Middle-aged and older men have high rates of suicide, necessitating focused risk detection. We developed the Geriatric Suicide Ideation Scale (GSIS; Heisel & Flett, 2006) as an age-specific, multidimensional suicide risk assessment tool. The GSIS has shown strong psychometric properties in clinical, community, and residential samples (see Heisel & Flett, 2016), yet research has lagged investigating its utility with middle-aged and older men. The purpose of the present study was thus to assess the psychometric properties of the GSIS administered to 82 men, 55 years and older (M=63.3, SD=4.6 years), who participated in a meaning-centered psychological intervention group for those concerned about or struggling with the transition to retirement (Heisel et al., 2020). Psychometric analyses included investigation of participant response characteristics, internal consistency, and construct validity. Findings demonstrated acceptable internal consistency for GSIS totals (α =.88) and for its Suicide Ideation, Death Ideation, Loss of Personal and Social Worth, and Perceived Meaning in Life subscales (α =.62-.81). Positive associations between the GSIS and negative psychological factors (depression, anxiety, hopelessness, loneliness, perceived lack of mattering to others, and history of suicidal behavior; r =.30 to .51) and negative associations with positive factors (life satisfaction, psychological well-being, perceived support, and meaning in life; r = -.21 to -.51) supported its construct validity. These and other findings will be discussed in the broader context of upstream population level approaches to suicide risk detection and prevention.

IS NARCISSISTIC PERSONALITY ASSOCIATED WITH SUICIDE IDEATION IN MIDDLE-AGED AND OLDER MEN?

Marnin Heisel[1], Gordon Flett[2], and Paul Links[3], *1. The University of Western Ontario, London, Ontario, Canada, 2. York University, Toronto, Ontario, Canada, 3. McMaster University, Hamilton, Ontario, Canada*

Older adults have high rates of suicide, necessitating theory and research on factors that contribute to suicide risk and may be targets for intervention. Clark (1993) theorized that age-related losses and transitions can trigger narcissistic injury in older men, and lead to mood decline, substance misuse, loss of insight, and suicide ideation and behavior. We tested elements of Clark's model in a secondary analysis of a geriatric depression clinic database (n=574), and reported a positive association between clinician-diagnosed Narcissistic Personality (NP) and suicide ideation and behavior, controlling for depression severity (Heisel et al., 2007). We sought to replicate and extend these findings in 82 community-residing men, 55 years and older (M=63.3, SD=4.6), who participated in a trial of Meaning-Centered Men's Group (MCMG; Heisel et al., 2020) for those concerned about or struggling with the transition to retirement. Participants completed the Pathological Narcissism Inventory (Pincus et al., 2009), Geriatric Suicide Ideation Scale (Heisel & Flett, 2006), and Geriatric Depression Scale (Yesavage et al., 1983). Linear regression analyses indicated a significant association between PNI-Contingent Self-Esteem and GSIS totals (t=2.41, p=.019) and GSIS Loss of Personal Worth (t=2.10, p=.040) and Perceived Meaning in Life Subscales (t=2.80, p=.007), controlling for depressive symptom severity (Geriatric Depression Scale; Yesavage et al., 1983), suggesting an association between suicide ideation and self-esteem issues. These and other findings will be discussed in a broader thematic context regarding masculinity, loss, life transitions, and suicide prevention.

RETIREMENT TRANSITIONS AND COMPLETED SUICIDE DURING RECOVERY FROM THE GREAT RECESSION: EVIDENCE FROM THE NVDRS

Briana Mezuk[1], Aparna Ananthasubramaniam[2], Linh Dang[2], and David Jurgens[2], *1. University of Michigan, School* *of Public Health, Ann Arbor, Michigan, United States, 2. University of Michigan, Ann Arbor, Michigan, United States*

One million older Americans retire annually. While these transitions are not generally associated with poor mental health, the broader macro-economic context in which retirement transitions take place may shape how they relate to mental health. The objective of this study was to use state-of-the-art natural language processing (NLP) to develop a model to identify retirement transitions from textual data in the National Violent Death Reporting System (NVDRS), and to use that model to examine how the number of suicides related to retirement transitions changed during the recovery from the Great Recession. Data come from the NVDRS (2003 - 2018, n=62,165), a state-based registry of suicide deaths. We used RoBERTa to train a NLP model to identify retirement transitions (e.g., recent retirement, anticipated retirement, unable to retire despite wanting to) from 1,291 annotated sentences from NVDRS text narratives of suicide decedents aged ≥55 (model performance: F1=0.92). Applying this model, 19.35 of every 1,000 suicides among decedents aged ≥55 years mentioned a retirement transition. Decedent characteristics associated with retirement transitions were younger age (< 75 years), having a college education and experiencing financial problems. The probability that a narrative referenced a retirement transition increased 1.495-fold during the Great Recession (2007 - 2009) and declined during recovery (2009-2016) before beginning to increase again. Findings illustrate the utility of NLP methods to identify workforce transitions from NVDRS narratives, and further understanding the impact of macro contextual events like the Great Recession on population mental health.

SESSION 4640 (PAPER)

TECHNOLOGY APPLICATIONS

FACTORS ASSOCIATED WITH ELECTRONIC WEARABLE DEVICE USE AMONG US OLDER ADULTS

Mengchi Li[1], Qiwei Li[2], Chakra Budhathoki[3], Sarah Szanton[4], and Junxin LI[3], *1. Johns Hopkins, University, Baltimore, Maryland, United States, 2. Johns Hopkins School of Nursing, Baltimore, Maryland, United States, 3. Johns Hopkins University, Baltimore, Maryland, United States, 4. Johns Hopkins University School of Nursing, Baltimore, Maryland, United States*

Electronic wearable devices(EWD) have been increasingly used in the adult population. Although health benefits of using EWDs may be appealing through health self-monitoring(e.g., physical activity, heart rate, and sleep), safety alerts(e.g., fall risk detection), or stress reduction(breathing technique), there is a lack of understanding in EWD use among older adults. This cross-sectional study used self-reported data of 3370 older adults aged 65 to 104 years from the Health Information National Trends Survey 2019 and 2020. We examined the prevalence of EWD use and used Logistic Regression Models to identify social factors (gender, race/ethnicity, education, and income) associated with the use of EWDs in older Americans. We found that EWD users increased from 13.3% in 2019 to 17.4% in 2020 in older Americans. After adjusting for age, insurance, smoking, marital-status, chronic conditions, region, and all other social factors of interest, we found that older men(Odds Ratio[OR]= 0.58, 95%Confidence Interval[CI]:0.45, 0.73), Black/African American older adults(OR=1.50, 95%CI: 0.41, 0.68), older adults who did not attend college(OR=0.62, 95%CI: 0.46, 0.83), and those with household income lower than $35,000(OR=0.32, 95%CI: 0.24, 0.46) were less likely to use EWDs. Interestingly, before adjustment, EWD use in Black/African American older adults(OR: 1.02, 95%CI:0.74, 1.34) did not differ from that in White/Caucasian older adults. Our findings suggest inequality of EWDs use in older Americans: those with lower education and income had less access to EWDs and fewer potential health benefits from EWDs. This study highlights the needs of equal access to EWDs and addressing social inequalities among older Americans.

IS ONLINE ACCESS AND ACTIVITY ASSOCIATED WITH BETTER MOOD IN OLDER ADULTS LIVING ALONE DURING THE COVID-19 PANDEMIC?

Yael Koren[1], and Suzanne Leveille[2], *1. University of Massachusetts Boston, Brookline, Massachusetts, United States, 2. University of Massachusetts Boston, Boston, Massachusetts, United States*

Older adults living alone during the COVID-19 pandemic face risks for social isolation and mental health problems. The goal of this study was to investigate the relationship between access to internet-capable devices or utilizing email/texting, social networking [SN], or health-related internet use [HIU] and psychological outcomes (depressive and anxiety symptoms) among older adults living in the community during the early months of the pandemic, March, 2020-May, 2020. A cross-sectional analysis of the National Health and Aging Trends Study (NHATS, Round 10) was conducted, using multivariable logistic regression. Adults aged ≥85y were more likely to live alone than those aged 65-84y (34.3% and 24.9% respectively, p< 0.001). Additionally, 39.6% of women lived alone compared with 21.2% of men (p< 0.001). Fewer people living alone had access to an internet-enabled device than those living with others (10.4% and 5.4%, respectively). Among older adults living alone, utilizing SN and HIU was associated with lower likelihood of depression or anxiety (Depression: adj.OR 0.36, CI 0.17-0.77; Anxiety: adj.OR 0.31 CI 0.13-0.76). Alternatively, among those living with others, using email/ texting was associated with lower likelihood of depression and anxiety (Depression: adj.OR 0.23, CI 0.13-0.46, Anxiety: 0.33 CI, 0.17-0.67). In summary, internet activity was associated with reduced risk for depression and anxiety among older adults who lived alone or with others early in the pandemic. Further research is needed to better understand the potentially mitigating role of internet activities among older adults at risk for isolation and associated mood disturbances.

PATIENT PERCEPTIONS OF USING VOICE-BASED DIETARY ASSESSMENT TOOLS AMONG OLDER ADULTS

Tiffany Driesse[1], Xiaohui Liang[2], Michael Fowler[3], Jing Yuan[2], Hillary Spangler[3], David Lynch[4], and John Batsis[3], *1. UNC School of Medicine, University of North Carolina at Chapel Hill, Chapel Hill, North Carolina, United States, 2. University of Massachusetts*

Boston, Boston, Massachusetts, United States, 3. University of North Carolina at Chapel Hill, Chapel Hill, North Carolina, United States, 4. UNC, Chapel Hill, North Carolina, United States

Poor diet among older adults is a risk factor for developing multiple chronic diseases. Dietary recall comprises an important component in intervention research and clinical care. Commonly used tools include the web-based automated self-administered 24-hour assessment (ASA-24). Yet voice assistant (VAS) systems (i.e., Amazon Alexa) have not been developed for this purpose. Hence, we evaluated patient perceptions on performing a VAS-based dietary assessment among older adults. Community-dwelling adults (age 65+ years) participated in two virtual sessions who reported their past 24-hour intake, first using ASA-24, and then using a VAS. All completed a Likert questionnaire (binary, % strongly agree/strongly disagree reported) regarding the simplicity of using both systems, completion time, and user satisfaction. Semi-structured interviews allowed us to ask about technology use. Of the 40 participants (100% enrolled), mean age was 69±1.0 years (85% female, 100% white, 5% Latinx). Only 40% owned a VAS; 60% reported having VAS experience prior to the study. After completing both sessions, 80% preferred a VAS over the ASA-24. Participants reported that web-based recalls were unnecessarily complex (60%), time-consuming (50%), and 60% did not wish to use them. Comparatively, VAS recalls were intuitive (75%), easily reportable (85%), and there was willingness to report food while preparing meals (85%). In 16 participants, we evaluated themes of VAS use including easier navigation, less time, and ability to have a natural conversation. A VAS provides a more convenient, conversational, and computerless interaction to report meals over web-based solutions suggesting they hold promise for dietary recall in older adults.

PATIENT PORTAL USE WITHIN OLDER ADULTS' FAMILY CAREGIVING NETWORKS

Julia Burgdorf[1], Chanee Fabius[2], and Jennifer Wolff[2], *1. Center for Home Care Policy & Research, VNS Health, New York, New York, United States, 2. Johns Hopkins Bloomberg School of Public Health, Baltimore, Maryland, United States*

The patient portal (hereafter, "portal") is an online platform allowing patients to view health information, perform health management tasks, and directly message clinicians. Millions of older adults co-manage their health care with family caregivers, yet little is known about the extent to which caregivers use the portal alongside or on behalf of patients. We examined linked data from the 2017 National Health and Aging Trends Study (NHATS), National Study of Caregiving (NSOC), and American Community Survey for 1,675 (weighted n=8,511,568) older adults with disability. We measure older adult and caregivers' respective use of the older adult's portal from NHATS and NSOC. We use weighted, multivariable, ordered logistic regression to model transition from older adult using the portal alone, to co-using the portal with caregivers, to a caregiver using the portal on the older adult's behalf. We find that 9% of older adults use the portal on their own, 2% co-use the portal with a caregiver, and 15% have a caregiver who uses the portal on their behalf (74% have no portal use). In adjusted models, older adults had higher odds of a caregiver using the portal on their behalf (compared to the older adult using the portal alone or in tandem with a caregiver) if they were older (aOR: 1.12; p< 0.001), female (aOR: 2.08; p< 0.01), had probable dementia (aOR: 7.04; p< 0.001), were homebound (aOR: 3.78; p< 0.01), attended doctors' visits with a caregiver (aOR: 3.10; p< 0.01), or lived in a census tract with low broadband accessibility (aOR: 5.76; p< 0.01).

SESSION 4650 (SYMPOSIUM)

THE LANDSCAPE OF ALZHEIMER'S DISEASE AND RELATED DEMENTIAS CAREGIVER COMMUNICATION RESEARCH

Chair: Debra Dobbs Co-Chair: Jessica Yauk Discussant: Harleah Buck

Alzheimer's Disease and Related Dementias (ADRD) affect one in nine adults aged 65 and over. Past research has demonstrated the need for services that improve quality of care for those with ADRD and their caregivers. Those with ADRD are at a greater risk for negative health outcomes. Therefore, it is crucial that those with ADRD receive care consistent with their preferences. However, more research is needed to shed light on effective tools available and patterns of advance care planning (ACP) when it comes to those with ADRD and their caregivers. This symposium highlights the landscape of ACP communication among those with ADRD and their caregivers. The session begins with a study that explored experiences of apathy and preferences for dyadic-communication via mobile health (mHealth) among adults with mild cognitive impairment and their care-partners. The second presentation demonstrates the feasibility and effectiveness of a palliative care education in assisted living program for nurses and administrators on increasing ACP discussions with family caregivers of residents with dementia. The third presentation investigates ACP among African Americans with ADRD and their caregivers and the critical role the community can play in facilitating communication. The final presentation explores how ACP differs by race, ethnicity and ADRD status using data from the 2018 Wave of the Health and Retirement Study. Future directions for implementation of these innovations for improving ACP communication among caregivers and persons with ADRD will be discussed.

EFFECTIVENESS OF A PC EDUCATION PROGRAM IN ASSISTED LIVING IN IMPROVING DISCUSSIONS WITH DEMENTIA FAMILY CAREGIVERS

Debra Dobbs[1], Jessica Yauk[1], Carlyn Vogel[1], Dany Fanfan[2], Harleah Buck[3], William Haley[1], and Hongdao Meng[1], *1. University of South Florida, Tampa, Florida, United States, 2. University of Florida, Gainesville, Florida, United States, 3. Csomay Center for Gerontological Excellence, Iowa City, Iowa, United States*

There is a need for improved communication in assisted living communities (ALCs) for staff and family caregivers of persons with dementia. This study is a cluster randomized trial in 10 ALCs (N=23 nurses and administrators; N= 122 residents with dementia) of a PC education (PCEAL) program for dementia care providers facilitated by hospice nurse educators. Baseline, 3- and 6-month data was collected for documentation of advance care planning (ACP) discussions. The PCEAL program had a moderate effect on ACP discussions at the 3-month follow in the treatment (N=17) compared to the control group (N= 6) (Cohen's d = 0.72, 95% CI [0.25, 1.19]). The findings indicate that the PCEAL program potentially improves ACP discussions with family members of persons with dementia. We will discuss recommendations for tailoring the PCEAL program to include other direct and administrative staff and to elicit the perspective of families about quality of communication.

DIFFERENCES IN ADVANCE CARE PLANNING AMONG RACIAL AND ETHNIC MINORITIES AND PERSONS WITH ADRD

Jessica Yauk, Hongdao Meng, and Debra Dobbs,
University of South Florida, Tampa, Florida, United States

Advance care planning (ACP) is an important process to enable individuals to make their preferences known in the event of dementia onset. Racial and ethnic minorities have an increased risk of developing dementia. Understanding more about ACP differences by race and dementia status will help improve ACP communication among minority populations. For the current study the 2018 wave of the Health and Retirement Study (N=8,663) to test the relationship between dementia status and ACP and if there were differences by race. Findings indicated that both African Americans and Hispanics are less likely to have completed ACP than non-Hispanic Whites. In unadjusted models, having a dementia diagnosis indicated a lower likelihood of completing ACP; dementia was not significant in the final model when controlling for predisposing and enabling factors. More research on the predisposing and enabling factors that influence ACP among minority and dementia populations is needed.

EXPERIENCES WITH APATHY AND MHEALTH PREFERENCES AMONG ADULTS WITH MILD COGNITIVE IMPAIRMENT

Pilar Ingle[1], Evan Plys[2], Danielle Kline[2], Emma Stark[2], and Jennifer Dickman Portz[3], *1. University of Denver, Lakewood, Colorado, United States, 2. University of Colorado School of Medicine, Aurora, Colorado, United States, 3. University of Colorado Anschutz, Aurora, Colorado, United States*

Apathy is common early in dementia, often increases in severity as illness progresses, and is one of the most pervasive neuropsychiatric symptoms associated with Alzheimer's Disease and related dementias (ADRDs). This study explored experiences of apathy and preferences for dyadic-communication via mobile health (mHealth) among adults with mild cognitive impairment (MCI) and their care-partners. Semi-structured interviews were conducted with 10 ADRD-related health providers (5 behavioral neurologists, 2 nurse practitioners, 2 geriatricians, 1 nurse, 1 social worker), 9 patients with MCI (5 male, mean age = 73), and 6 of their care-partners. Participants expressed interest in the development of mHealth dyadic communication tools targeting apathy symptom monitoring, dyadic understanding of apathy, spiritual and religious coping, sharing ADRD health information, and resources for addressing burdensome behavioral symptoms of MCI. This research provides preliminary insight to the development of apathy specific mHealth communication strategies that may improve patient and care-partner quality of life.

EMBRACING COMMUNITY: ADVANCE CARE PLANNING FOR AFRICAN AMERICAN OLDER ADULTS LIVING WITH DEMENTIA

Karen Moss[1], Kathy Wright[2], Emika Miller[3], Kimberly Lawson[4], Karen Rose[1], Todd Monroe[5], and Celia Wills[5], *1. The Ohio State University, Columbus, Ohio, United States, 2. The Ohio State University College of Nursing, Columbus, Ohio, United States, 3. Ohio State University, Columbus, Ohio, United States, 4. African American Alzheimer's and Wellness Association, Westerville, Ohio, United States, 5. Ohio State University College of Nursing, Columbus, Ohio, United States*

Lower socioeconomic status African American older adults living with dementia and their family caregivers face unique advance care planning challenges, including achieving appropriate preference-consistent healthcare near the end of life. The purpose of this project within a larger multi-stakeholder study is to assess community stakeholder perspectives on the needs of African American older adults living with dementia and their family caregivers. Diverse community-based organization leaders (n=9) were interviewed and identified the following thematic needs: Reframing of Advance Care Planning, Clarification of Misinformation, and Expansion of Available Resources. Community leaders expressed strong desires to assist families with advance care planning. The use of creative, culturally-tailored, non-traditional approaches to this process offers innovative ways to promote advance care planning through community engagement. This will change the narrative on advance care planning from a cultural perspective while embracing diversity, enriching discovery, and reimaging aging in the community

SESSION 4660 (SYMPOSIUM)

THE LEGACY OF HELEN KIVNICK: THE IMPACT OF VITAL INVOLVEMENT AND CREATIVITIES ON WELL-BEING IN LATE LIFE

Chair: Carolyn Adams-Price

Helen Kivnick was an extraordinary woman whose body of work strongly influenced and continues to influence the field of gerontology. Her classic work on vital involvement in late life, some of which was conducted with Erik and Joan Erikson, could be considered the foundation of current perspectives on positive gerontology, and creativity and aging. The current symposium will include both personal and theoretical takes on the legacy of Kivnick's work, especially her interests in vital involvement and creativity. Kivnick emphasized the possibility for older adults to adapt to new situations, even in very late life, and while experiencing physical and cognitive decline. Two of the speakers will speak on their personal experiences with Kivnick, while two others will emphasize research and theory derived from Kivnick's work. Dr. Adams-Price will introduce the symposium by addressing the significance of vital involvement as a concept in aging, as well as the ways creativity can improve well-being in late life. Dr. Wyatt-Brown will describe her long friendship with Dr. Kivnick, including Kivnick's comments in their book with Ruth Karpen and Margaret Gullette. The Big Move, which describe Wyatt-Brown's life with her husband in continuing care. Dr. Chee will discuss her research on patients with dementia who participated in a story-telling intervention, which increased their meaningful engagement in their environment. Finally, Ms. Linda Davis will recall her long partnership with Kivnick and the results of the national study they conducted on the benefits of creativity interventions for at risk- older adults in HUD housing.

VITAL INVOLVEMENT IN LATE LIFE: HELEN KIVNICK'S VITAL CONCEPT FOR GERONTOLOGY+

Carolyn Adams-Price, *Mississippi State University, Mississippi State, Mississippi, United States*

Carolyn Adams-Price will lead off the symposium with a discussion of Kivnick's impact on gerontology and the arts. Her various arts interests will be discussed, including her interests in choral and African music. Much of the talk will focus on the concept of vital involvement, why it was revolutionary, and how it connects to current research on positive gerontology, creativity, and adaptation in late life. Adams-Price will address in detail the benefits that participation in creative activities can impart to older adults, based on her own research on creative benefits, and will provide a framework for studying those benefits in the future.

MY LONG CLOSE FRIENDSHIP WITH HELEN KIVNICK

Anne Wyatt-Brown, *University of Florida, Gainesville, Florida, United States*

Anne Wyatt-Brown will discuss meeting Dr. Kivnick at a conference at Case Western Reserve in the 1980s, organized by David Van Tassel, who was introducing academics to the field of Gerontology. Kivnick was invited to discuss her work with Erik Erikson. Wyatt-Brown will discuss her long friendship with Kivnick, which continued until Kivnick's death at age 70. Wyatt-Brown will also discuss Kivnick's chapter in their book The Big Move with Ruth Karpen and Margaret Gullette, where Kivnick comments with compassion and insight about the steps Wyatt-Brown took to become vitally involved in the eldercare community, where she lived with her seriously ill husband.

THE ART, WELLNESS, AND VITAL INVOLVEMENT IN AGING PROGRAM: MY WORK WITH HELEN KIVNICK

Linda Davis, *Aging, Wellness and the Arts, INDIANAPOLIS, Indiana, United States*

Linda Davis will discuss her partnership with Helen Kivnick on The Art, Wellness and Vital Involvement in Aging (AWVIA) Program. AWVIA began in 2009 as an innovative approach to health programming in HUD Affordable Senior Housing, employing engaging creative activities to attempt to address the despair and loneliness often found in older adults who have low social engagement, due to health, mobility, or economic circumstances. In 2013, Davis teamed up with Helen Kivnick to develop the Vital Involvement Model, which employs creative activities to increase meaningful engagement with the world. Over 6 years, AWVIA was employed by 84 HUD Senior Housing communities across the U.S. Kivnick and Davis received funding from NEA for a quasi-experimental study on the participants. Information from more than 2,000 qualitative narratives suggests the program decreased isolation, increased self-reliance, generativity, and a sense of mastery in participants. Examples of the narratives will be shared.

IT COULD BE ANYTHING YOU WANT!: VITAL INVOLVEMENT OF PERSONS WITH DEMENTIA IN CREATIVE GROUP STORYTELLING

Kyong Hee Chee, Seoyoun Kim, and Olga Gerhart, *Texas State University, San Marcos, Texas, United States*

The benefit of vital involvement (VI) in dementia care is largely unknown. The purpose of this study is to demonstrate VI elements in a creative group storytelling program for persons living with dementia (TimeSlips). After offering 6 weekly storytelling sessions for 4 small groups in a memory care community, we interviewed participants (n = 21), family members (n = 2), and care associates (n = 6) to obtain feedback on the program. Themes from narratives in the audiorecorded and transcribed interviews suggest that participants enjoyed the program, enacting their personal values, strengths, and interests, and incorporating their past and current experiences, as supported by their sociospatial environment (e.g., facilitator, co-participants, researchers, shared table). When paired with the VI practice, creative group storytelling has potential to magnify favorable outcomes for participants with dementia, who may express more fully their meaningful engagement with their inner (psychological) and external (social and physical) world.

SESSION 4670 (SYMPOSIUM)

USING ANOCRITICISM AS AN ANALYTICAL FRAMEWORK: PERSPECTIVES FROM THE HUMANITIES

Chair: Kate de Medeiros Co-Chair: Roberta Maierhofer

To date, Gender Studies and Age Studies (predominantly humanities-based approaches to studying old age) have mostly remained two separate areas of research despite the ontological and epistemological similarities of both fields. As Maierhofer points out, "[a]ge/[a]geing studies would not have been established as a field without the theoretical and methodological approaches established through feminist theory." Age studies research has largely focused on cultural representations (e.g., novels, films) and social manifestations of either age or gender but not both. Considering this limitation in research, this interdisciplinary panel discusses cultural and social intersections of age and gender from a theoretical as well as an empirical perspective. Taking Maierhofer's analytical approach of 'anocriticism' as a starting point, the contributions of this panel explore intersections of age and gender in society, culture, and cultural representations. The first paper traces the historical development of anocriticism, from its feminist origins to its current application in Age Studies scholarship. The second paper presents research from two studies which used anocriticsm as an analytical framework. The third reports findings from an analysis of two novels. Here, an anocritical lens was used to deconstruct heteronormative assumptions about gender and age. The final paper presents an anocritical, qualitative analysis of narratives from five older men with regarding their performance of masculinities and power. As the papers demonstrated, anocriticism as theoretical framework, allows for a multi-dimensional yet nuanced analysis of cultural and social intersections of age and gender.

ANOCRITICISM: THEORIZING AND DISCOVERING INTERSECTIONS OF AGE AND GENDER

Roberta Maierhofer, *University of Graz / Center for Inter-American Studies , Graz, Steiermark, Austria*

This paper presents historical research on the theoretical foundations and application of 'anocriticism' as a method to trace portrayals of female aging in American literary texts to understand what it means to be "aged by culture" (Gullette 2004). Originally developed in the 1990s in context of American Studies as an analytical framework for the analysis of cultural representations of intersections of age and gender in literature, anocriticism brings together the feminist tradition of Elaine Showalter's (1985) "gynocriticism" – a study of women writers and of the history, styles, themes, genres and structures of writing by women – through analysis of narratives and Germaine Greer's (1992) use of "anophobia" (from Latin "anus" for "old woman") to describe the fear of old women. The paper presents examples of anocriticism in practice in age studies and gerontology and highlights its potential for future multidisciplinary and interdisciplinary application.

ANOCRITICAL READINGS OF THE INTERSECTIONS OF AGE AND GENDER IN AMERICAN LITERATURE: A FEMINIST CRITIQUE

Nicole Haring, *University of Graz, Graz, Steiermark, Austria*

Intergenerational relationships have been present features in texts from the American literary canon that often problematizes the intersections of age and gender. This paper investigates how representations of intergenerationality provide the opportunity to explore the concepts of relationality and intersectionality through a feminist lens. Maierhofer's concept of anocriticism was used in in the analysis of Julia Alvarez' In the Time of the Butterflies (1994) and Yaa Gyasi's novel Homegoing (2016) to validate individual experiences of gendered ageing. This paper presents ways in which this particular intersection can be viewed as a potential site of resistance towards what it means to grow old as a woman. Placing literature in a cultural, social, and political context, traditional paradigms can be reconstructed and heteronormative assumptions of age and gender can be deconstructed by focusing on the individual narratives and their potential for resistance.

ANOCRITICISM AND THE PERFORMANCE OF MASCULINITY IN OLDER MEN

Kate de Medeiros, *Miami University, Oxford, Ohio, United States*

While anocriticism is a feminist framework often applied in the context of literary gerontology, this paper uses an anocriticism approach to consider how hegemonic masculinities and old age reveal a separation between cultural stereotypes of age and chronological age. Narratives from 5 men aged 65 and over, who participated in a qualitative study on everyday attributions of depression, were analyzed using an anocriticism framework. Results revealed that participants both claimed and contested their chronological age as an identity marker. Of particular note were claims related to the stereotype of loss of vigor in later life, with each man making a clear point to affirm his virility and sexual prowess independent of other interview questions. Overall, findings point to an important way to read interview data through an anocritical lens, paying particular attention to ways that power are questions and performed in relation to age.

SESSION 4680 (SYMPOSIUM)

USING PHOTOVOICE TO EXPLORE THE STRUCTURED ENVIRONMENT AND ADVANCE POLICY IN MULTIPLE CONTEXTS

Chair: Melissa Hladek Discussant: Hae-Ra Han

Contextual factors, including social determinants of health, have gained recognition for greatly influencing aging trajectories and chronic disease progression. Although traditional qualitative research gives a rich understanding of the internal psychological experience, it is unable to assess socio-cultural and built environment aspects of life apart from the verbal descriptions from participants. This symposium examines the use of Photovoice as a tool to assess the socio-cultural and structural context surrounding the participant. This symposium will present a narrative review on the use of current Photovoice methodologies in dementia care; results from three studies using photovoice, one with participants with mild cognitive impairment and their caregivers to explore their perceptions of aging in their home, the second exploring the lived experience and structural barriers among older adults with pre-frailty or frailty awaiting kidney transplant, and the third exploring the older adult peer mentors' experience providing community-delivered hearing care. The talks will also address practical aspects of using photovoice such as institutional review board tips, logistical challenges, interview preparation and coding approaches. The fifth talk will describe Photovoice result dissemination strategies, including photo exhibits and stakeholder meetings, used to engage the community and advance policy to improve disparities. Photovoice as a research tool originally aimed to reinforce empowerment for those marginalized in society to describe their lived environment. This important aim is augmented in this symposium by improving researchers' understanding of context to design more impactful research.

NARRATIVE LITERATURE REVIEW OF PHOTOVOICE STUDIES TO EXPLORE METHODOLOGY, ANALYSIS, AND THE DEMENTIA EXPERIENCE

Emerald Jenkins[1], Phatt Thaitrong[2], Janiece Taylor[1], jenni Seale Reiff[1], Grace Huynh[1], Melissa Hladek[1], and Sarah Szanton[3], *1. Johns Hopkins University, Baltimore, Maryland, United States, 2. University of Alabama, Tuscaloosa, Alabama, United States, 3. Johns Hopkins University School of Nursing, Baltimore, Maryland, United States*

Dementia is a serious public health concern requiring effective interventions to address older adults' unmet needs. Photovoice, an underutilized and effective communication method for persons with waning abilities, provides insight into lived experiences and diverse needs. The purpose of this study is to understand current methodologies, analysis, and participant insights from photovoice literature in persons with dementia. A narrative review was conducted through PubMed, CINAHL Plus, and PsycINFO. From eleven eligible studies, insights were categorized via the 5-level Hierarchy Model of Needs in Dementia incorporating the 3-level Blackfoot Native American belief. Synthesized findings suggest providing dyadic opportunities to: (1) spend time in the natural world, (2) link activities for healthy aging with a need for hard work, and (3) recognize the importance of social determinants of health/disease when focusing on brain health. This review fills the knowledge gap regarding the lived experience of persons with dementia using relevant photovoice methodology.

USING PHOTOVOICE TO UNDERSTAND THE LIVED EXPERIENCE AND ENVIRONMENT OF OLDER ADULTS AWAITING KIDNEY TRANSPLANT

Melissa Hladek[1], Deborah Wilson[2], Meera Shanbhag[1], Katie Krasnansky[1], Jeremy Walston[1], Qian-Li Xue[1], Mara McAdams-DeMarco[3], and Sarah Szanton[2], *1. Johns Hopkins University, Baltimore, Maryland, United States, 2. Johns Hopkins University School of Nursing, Baltimore, Maryland, United States, 3. NYU Grossman School of Medicine and NYU Langone Health, Baltimore, Maryland, United States*

End-stage renal disease (ESRD) causes age-accelerating disease and disproportionally affects older and minority patients; the preferred treatment is kidney transplantation (KT). Rates of KT have risen 5-fold for older adults since 1990 but there is great heterogeneity in KT outcomes by frailty and waitlist status. The person-environment fit theory posits that improving a person's lived environment will facilitate optimal individual functioning. We recruited a balanced sample of 20 participants (mean age 60, range 35-82) with respect to their frail/ pre-frail and inactive/ active waitlist status to explore personal experience and the lived environment through the use of photovoice, gaining insight into the person-environment fit of those older adults awaiting KT. We will discuss IRB issues, recruitment and logistical tips with using Photovoice. This work will help to inform what vulnerable and marginalized older adults awaiting KT must be prepared for psychologically and physically, including modifications needed to their lived environments.

PHOTOVOICE STUDY TO EXPLORE THE PHYSICAL DISABILITY EXPERIENCE IN OLDER ADULTS WITH MCI/EARLY DEMENTIA

Emerald Jenkins[1], Janiece Taylor[1], Allyson Evelyn-Gustave[1], Erika Hornstein[1], Jennifer Wolff[2], George Rebok[2], and Sarah Szanton[3], *1. Johns Hopkins University, Baltimore, Maryland, United States, 2. Johns Hopkins Bloomberg School of Public Health, Baltimore, Maryland, United States, 3. Johns Hopkins University School of Nursing, Baltimore, Maryland, United States*

Adults aging with mild cognitive impairment (MCI)/early dementia often experience physical disability, yet most research is focused on cognitive or physical disability rather than both. Understanding the experiences of this population and their care partners will help identify unmet needs and potential solutions. The purpose of this study is to explore perceptions of daily experiences relevant to aging in place in this population. We used human-centered design, critical ethnography, photos, written narratives, and semi-structured interviews with community-dwelling care partners (mean age: 63 years (SD= 7.48)) and older adults with MCI/early dementia and physical disability (mean age: 84.5 years (SD =2.60)) (total n= 9). Example participant insights included: preferred nonpharmacological remedies for pain, environmental constraints resulting in further isolation, systems of reminders relevant to the older adults' preferences, and the importance of shared dyadic activities. This study demonstrates participants' lived experiences and challenges faced and informs tailoring of an evidenced-based intervention.

CAPTURING OLDER ADULT PEER MENTORS' EXPERIENCE WITH COMMUNITY-DELIVERED HEARING CARE THROUGH PHOTOVOICE

Carrie Nieman[1], Audrey Mossman[2], Julie Yi[3], Jonathan Suen[3], Frank Lin[4], Sarah Szanton[5], and Hae-Ra Han[3], *1. Johns Hopkins University School of Medicine, Baltimore, Maryland, United States, 2. University of Washington School of Medicine, Seattle, Washington, United States, 3. Johns Hopkins University, Baltimore, Maryland, United States, 4. Johns Hopkins Cochlear Center for Hearing and Public Health, Baltimore, Maryland, United States, 5. Johns Hopkins University School of Nursing, Baltimore, Maryland, United States*

While age-related hearing loss is common, disparities in care exist by race, ethnicity, and socioeconomic position. HEARS is a hearing care intervention that incorporates over-the-counter hearing technology, partnering older adults with peer mentors via a community health worker (CHW) model to address disparities. Through a randomized controlled trial, 8 older adult peer mentors delivered the HEARS intervention. We aimed to understand the CHWs' perspectives on their role through photovoice. Participants took photos illustrating the intervention, their role, and hearing health. Semi-structured interviews (n=4) and a focus group were conducted. CHWs responded positively to the intervention and were satisfied with their role. A notable theme was the value of serving as a peer mentor. Participants valued the opportunity for generativity, learning as older adults, and associated social benefits. Our findings demonstrate an opportunity to engage older adults in the evaluation process, expanding access to hearing care, and in peer mentorship.

"WE WILL SURVIVE ... BUT I JUST WANT MORE FOR US": DISSEMINATING PHOTOVOICE FINDINGS TO ADVANCE FOOD POLICY AND EQUITY

Anika Hines[1], Rebecca Brody[2], Zehui Zhou[3], Kennedy McDaniel[4], Chiazam Omenyi[3], Edgar Miller, III[5], Lisa Cooper[5], and Deidra Crews[6], *1. Virginia Commonwealth University School of Medicine, Richmond, Virginia, United States, 2. Williams College, Williamstown, Massachusetts, United States, 3. Johns Hopkins Center for Health Equity, Baltimore, Maryland, United States, 4. Johns Hopkins School of Nursing, Baltimore, Maryland, United States, 5. Johns Hopkins School of Medicine, Baltimore, Maryland, United States, 6. Johns Hopkins University, Baltimore, Maryland, United States*

Poor food environments and disproportionate food insecurity among African Americans (AAs) represent determinants of chronic disease disparities by race/ethnicity. We used PhotoVoice to explore the food environment in Baltimore, MD, through the perspectives of Black residents with hypertension. Findings illuminated structural racism and classism as root causes of "food desert" conditions. Respondents provided critical analysis of existing food access barriers, including problematic policies, and offered asset-based solutions. Using an exhibition of participants' photographs to set the tone of the discussion, we will convene a stakeholder meeting including study participants, community advisory board members, local and state government agencies, civic organizations, community farmers, agricultural organizations, non-profit food providers, churches, local restauranteurs, convenience store owners, insurance payers, and transportation providers. Discussion will center on three areas of action informed by findings: systems level issues; individual activation, agency, and advocacy; and community-based solutions. Meeting proceedings will be disseminated through academic and lay publications.

SESSION 4690 (SYMPOSIUM)

AGING IN CROSS-NATIONAL CONTEXTS

Chair: Jennifer Ailshire Discussant: Eunyoung Choi

Cross-national comparative research is a useful tool for identifying common aspects of, and risk factors for, healthy and unhealthy aging across populations and sociocultural contexts. The papers in this symposium use harmonized data from the Gateway to Global Aging to examine a range of topics in aging and provide new insights into long-standing and emerging questions in aging research. Using data on 31 countries, Ehrlich estimates the population attributable fraction of dementia due to vision impairment, a treatable and thus potentially viable target for interventions to slow progression to dementia. Seligman et al., use a frailty index validated in multiple countries to provide new evidence for which aspects of socioeconomic status (SES) – education, income, rural residence – are most strongly linked to frailty in Brazil, China, and India, three highly populated and rapidly aging countries. Using recent harmonized data on stress, Chen et al. examine the association between cumulative social stressors and cognitive function trajectories in the US and UK, finding interesting patterns in the relationship with status and change over time. Finally, several harmonized aging studies collected data throughout the COVID-19 pandemic, and Mair et al., take advantage of this to gain insights into how family structure impacted experiences of loneliness among older adults during the pandemic in the U.S. and across Europe. The papers in this symposium demonstrate the tremendous potential for using cross-national comparisons to deepen our understanding of health and well-being among older adults.

VISION IMPAIRMENT IN A GLOBAL LIFE COURSE MODEL OF POTENTIALLY MODIFIABLE DEMENTIA RISK FACTORS

Joshua Ehrlich[1], Jenna Goldstein[1], Bonnielin Swenor[2], Heather Whitson[3], Kenneth Langa[1], and Phillip Veliz[1], *1. University of Michigan, Ann Arbor, Michigan, United States, 2. Johns Hopkins University, Baltimore, Maryland, United States, 3. Duke University, Durham, North Carolina, United States*

Vision impairment (VI) is a risk factor for accelerated cognitive decline and incident dementia. An estimated 90% of VI is preventable. Nonetheless, VI has not been included in the dominant life-course models of dementia risk factors. We sought to strengthen existing models of potentially modifiable dementia risk factors through the inclusion of VI using cross-sectional survey data from the Gateway to Global Aging project (G2Aging) from 31 countries. Prevalence rates and communalities from the G2Aging will be used to estimate the population attributable fraction (PAF) of dementia due to VI. It is expected that the PAF for VI will range from 1.0%-2.0%, suggesting that >10,000,000 prevalent dementia cases globally may potentially have been prevented through healthy vision. Since a large majority of VI can be treated with cost-effective but underutilized interventions, this may represent a viable target for future interventional research that aims to slow cognitive decline and prevent dementia.

FRAILTY AND SOCIOECONOMIC STATUS IN BRAZIL, CHINA, AND INDIA

Benjamin Seligman[1], Arunika Agarwal[2], and David Bloom[2], *1. David Geffen School of Medicine at UCLA, Los Angeles, California, United States, 2. Department of Global Health and Population, Harvard T.H. Chan School of Public Health, Boston, Massachusetts, United States*

Frailty, the vulnerability to poor health outcomes following physiologic stress, acts as a measure of physiological age that can be used to compare the health of older populations. Using a frailty index validated in multiple countries, we looked at the relationship between four measures of socio-economic status (SES) and frailty in Brazil, China, and India. For SES measures, we considered within-country income and wealth deciles, education level, and rural residence. Analysis used beta regression, first within each country, then with combined data with country fixed effects and country-by-SES interactions. We found evidence of strong, statistically significant negative associations between education level and frailty in all three countries. Associations between frailty and income or wealth decile or rural residence were small and inconsistently statistically significant. This demonstrates the key role of education for healthy aging and the value of harmonized frailty measures for comparative studies of older populations.

ASSOCIATIONS BETWEEN CUMULATIVE STRESS AND COGNITIVE FUNCTION IN HRS AND ELSA

Ruijia Chen[1], Harold Lee[2], Sakurako Okuzono[3], and Laura Kubzansky[3], *1. University of California, San Francisco, San Francisco, California, United States, 2. University Of North Carolina At Chapel Hill, Chapel Hill, North Carolina, United States, 3. Department of Social and Behavioral Sciences, Harvard T.H. Chan School of Public Health, Boston, Massachusetts, United States*

Despite growing research linking stressors with poorer cognition, less research explicitly considers stress from several sources, which often co-occurs and accumulate to influence health. We used the Global Gateway Harmonized data (HRS: n=8,888; mean age: 74 years; ELSA: n=6,715; mean age: 65 years) to examine whether higher cumulative stress is associated with lower levels of and faster decline in cognitive function. We fit linear mixed effect models to assess the stress-cognition associations. After adjusting for all covariates, baseline cumulative stress was associated with lower baseline cognitive function in both HRS (β=-0.02, 95%CI -0.04, -0.01) and ELSA (β=-0.03, 95%CI -0.05, -0.01). Unexpectedly, higher baseline cumulative stress was associated with slower cognitive decline in HRS (βtime*stress=0.001, 95%CI 0.002,0.01) but not in ELSA. The stress-cognition associations may differ among adults in the US and the UK. Future research should investigate how cumulative stress may operate differently to influence cognitive function across different populations.

UNPARTNERED AND CHILDLESS OLDER ADULTS' RISK OF LONELINESS DURING COVID-19 BY COUNTRY CONTEXT

Christine Mair[1], Bruno Arpino[2], Nekehia Quashie[3], and Radoslaw Antczak[4], *1. University of Maryland, Baltimore County (UMBC), Baltimore, Maryland, United States, 2. Department of Statistics, Computer Science, Applications, Firenze, Toscana, Italy, 3. University of Rhode Island, Kingston, Rhode Island, United States, 4. Institute of Statistics and Demography, Warszawa, Warminsko-Mazurskie, Poland*

Older adults with non-traditional family structures (unpartnered and childless) may be at higher risk for loneliness. Yet, experiences of loneliness during COVID-19 can vary depending on a country's context (e.g., culture, demography, COVID-19 mitigation policies, severity of the pandemic). We explore associations between older Europeans' family structure and loneliness to assess risks for those with non-traditional family structures (e.g., unpartnered vs partnered, childless vs parents) during the pandemic across a variety of country contexts. We analyze data from the Survey of Health, Ageing and Retirement in Europe (SHARE) collected before (2019/2020) and twice during (2020, 2021) the pandemic to examine if unpartnered and childless older adults are at higher risk of loneliness, and compare results by multiple indicators of country context (fertility and partnership rates, stringency of COVID mitigation policies, population age composition, and COVID fatality rates). Results of this study can potentially inform current and future pandemic mitigation strategies.

SESSION 4691 (SYMPOSIUM)

PUBLIC HEALTH POLICY: EXPERIENCE OF 2022 GSA SUMMER POLICY INTERNS

CHRONIC PAIN'S PAINFUL IMPACT ON COGNITIVE FUNCTIONING

Lilian Azer,[1] Hanamori Skoblow,[2] Eileen Flores,[3] Danielle Llaneza,[4] Weiwei Zhang,[1] and Patricia D'Antonio[5], *1. University of California, Riverside, Riverside, California, United States, 2. University of Missouri, Columbia, Missouri, United States, 3. Penn State, State College, Pennsylvania, United States, 4. Rutgers University, Piscataway, New Jersey, United States, 5. The Gerontological Society of America, Washington, District of Columbia, United States*

One in five Americans adults report experiencing chronic pain and stated it has negatively impacted their lives by limiting their engagement in activities. The magnitude of pain experienced is more severe in older adults, which may be due to age-related differences in pain perception pathways leaving older adults more vulnerable to the negative impact of pain. The most common type of chronic pain experienced by older adults involves musculoskeletal disorders, which is consistent with age-related declines muscle strength and mass. Declines in handgrip strength is associated with chronic pain perception and poor cognitive functioning. Older adults who experience severe chronic pain have worse working memory and attention. The experience of chronic pain is attentionally demanding on cognitive processes making it difficult for older adults to draw their attention away from pain perception during cognitively demanding tasks. Chronic pain is also associated with accelerated decline in cognition, dementia, and Alzheimer's Disease pathogenesis. As a GSA policy intern, I represented GSA in the Protecting Access to Pain Relief Coalition to explore policy initiatives and recommendations in relation to chronic pain experienced by older adults. Research on chronic pains' impact on cognitive and physical function is often conducted in isolation. However, they seldom occur in isolation during real-world tasks. Therefore, research on tasks that involve simultaneous physical and cognitive functioning in relation to chronic pain is imperative. In addition, handgrip strength should be considered as a useful cost-effective screening tool as a measure for cognitive decline in older adults with chronic pain.

THE INTERSECTIONS OF AGING BELIEFS AND POLICY

Hanamori Skoblow,[1] Lilian Azer,[2] Danielle Llaneza,[3] Eileen Flores,[4] and Patricia D'Antonio[5], *1. University of Missouri, Columbia, Missouri, United States, 2. University of California, Riverside, Riverside, California, United States, 3. Rutgers University, Piscataway, New Jersey, United States, 4. Penn State, State College, Pennsylvania, United States, 5. The Gerontological Society of America, Washington, District of Columbia, United States*

Ample evidence and stereotype embodiment theory indicate that older adults' internalized beliefs about aging are related to their health and well-being over time. Aging beliefs are constructed and reinforced socioculturally, interpersonally, and structurally, the latter of which includes federal, state, and local policies. For instance, policies affect resource allocation for Older Americans Act programs, job security and safeguarding from workplace age discrimination, access to medical services or treatments, and financial well-being via tax and retirement law. Heterogeneity in community and organization-level public health policies during the first year of the COVID-19 pandemic also shaped and were shaped by beliefs about aging. Further, policies that acknowledge and address ageism not only promote positive health, social, and financial outcomes for older adults, but also allow all of the public to benefit from older adults' participation in society. As a GSA policy intern, I tracked and analyzed legislation that is relevant for optimal aging outcomes, identified implicit age bias in policy, and framed policy recommendations that promote positive aging beliefs. Effective policies and collective action that reduce ageism, facilitate intergenerational contact, and ensure access to necessary services have the potential to benefit all of us as we age, not only directly, but also indirectly through beliefs about aging.

PUBLIC HEALTH POLICY IN AN AGING POPULATION

Eileen Flores,[1] Danielle Llaneza,[2] Hanamori Skoblow,[3] Lilian Azer,[4] and Patricia D'Antonio[5], *1. Penn State, State College, Pennsylvania, United States, 2. Rutgers University, Piscataway, New Jersey, United States, 3. University of Missouri, Columbia, Missouri, United States, 4. University of California, Riverside, Riverside, California, United States, 5. The Gerontological Society of America, Washington, District of Columbia, United States*

In the U.S., cancer and its related issues have an impact on public health, such as increased death rates and economic burdens due to lost productivity and associated treatment costs. Along the cancer control continuum, there are ample opportunities to enact policies that can improve cancer prevention, detection, and survivorship. As the US population ages, health policies that address barriers to cancer prevention and optimal survivorship care for older adults will be key. The intersection of policy and public health has gained momentum in the last decade. Changes resulting from the Affordable Care Act and President Biden's recently set goals (i.e. reduce age-adjusted death rates from cancer by at least 50% and improving the experience of people and their families living with and surviving cancer) for the Cancer Moonshot program have ignited the role of public health policy and its implications among the US population. As a policy intern, I had the opportunity to advocate on behalf of GSA, the nation's largest aging organization, for research initiatives (e.g. ARPA-H) that amplify opportunities to address policies in public health. Advocating for initiatives that accelerate the government's biomedical and health research to embrace a geroscience approach will continue to spearhead much needed opportunities to directly impact policies surrounding aging and cancer.

POLICY IMPLICATIONS ON CLINICAL PRACTICE: AN EXPLORATION

Danielle Llaneza,[1] Eileen Flores,[2] Lilian Azer,[3] Hanamori Skoblow,[4] and Patricia D'Antonio[5], *1. Rutgers University, Piscataway, New Jersey, United States, 2. Penn State, State College, Pennsylvania, United States, 3. University of California, Riverside, Riverside, California, United States, 4. University of Missouri, Columbia, Missouri, United States, 5. The Gerontological Society of America, Washington, District of Columbia, United States*

Clinical practice is direct and indirect work with and for patients to improve their wellbeing. Typically, clinical practice is specific to the discipline and institutional body in which providers work. Additionally, caring for older adults requires a review of the biological, psychological, and social aspects of their health to address their needs and diseases. Therefore, policy has significant albeit gradual effects on clinical practice. Health policies and legislation change clinical guidelines, options, and barriers. Federal and state-level policies influence clinical practice factors such as billing, provider knowledge, student training, treatment access, and availability of interventions. Understanding the needs of both patients and providers is imperative to creating clinical practices in line with policy. The collaboration between researchers, providers, and policymakers promotes inclusive and equitable recommendations for health care practices. Yet, often health policy at the federal level is a formidable dynamic that requires expertise and cooperation for all stakeholders that is often not readily accessible. A critical component of this work is reaching providers and patients where they are most often located with information dissemination and outreach efforts. As a GSA policy intern, I explored policy initiatives that directly and indirectly influenced clinical practice across disciplines from the Department of Health of Human Services, National Institute of Aging at NIH, Centers for Medicare & Medicaid Services, and other agencies and reviewed methods that promoted health equity in health care. We need better policy to improve our clinical practice to increase treatment options, expand access, and tailor delivery for our patients.

SESSION 4700 (PAPER)

COGNITION AND DEMENTIA

BEHAVIORAL AND PSYCHOLOGICAL SYMPTOMS OF DEMENTIA (BPSD) IN HOSPITALIZED OLDER ADULTS WITH AD/ADRD

Allison Marziliano, Alex Makhnevich, Edith Burns, Michael Diefenbach, and Liron Sinvani, *Northwell Health, Manhasset, New York, United States*

The epidemiology of Behavioral and Psychological Symptoms of Dementia (BPSD) in hospitalized older adults with Alzheimer's Disease (AD) and AD-related dementias (ADRD) has not been well-characterized. The purpose of this abstract is to examine the prevalence, patient-level factors and hospital outcomes associated with BPSD in hospitalized older adults with AD/ADRD. Data was extracted from the electronic health record (EHR) of older adults (aged 65+ years) with AD/ADRD, admitted to one of 7 hospitals in the greater New York metropolitan area during 2019. Three independent coders reviewed the EHR and recorded the presence or absence of the 11 domains of the Neuropsychiatric Inventory (NPI), a validated measure of BPSD. Of N = 1,865 hospitalized older adults with AD/ADRD, 1,564 had BPSD (prevalence = 83.9%). The most commonly reported BPSD were agitation (72.3%) and anxiety (17.7%). Older age (M = 84.6, SD = 7.6 versus M = 82.4, SD = 7.8, p = .000) and antipsychotic medication use prior to hospital admission (91% of the older adults who used home antipsychotics had BPSD, p = 000) was associated with BPSD. With regard to hospital outcomes, BPSD was associated with: increased mortality (of those who died, 90.6% had BPSD, p = .006), and increased likelihood of readmission to the hospital within 30 days of discharge (of those readmitted, 89.3% had BPSD, p = .007). Given its high prevalence and associated poor outcomes, recognizing and managing BPSD in hospitalized patients with AD/ADRD is critical to improving quality of care for this vulnerable population.

COGNITIVE FUNCTION AND HELP-SEEKING AMONG US CHINESE OLDER ADULTS WITH ELDER MISTREATMENT

Ying-Yu Chao[1], An-Yun Yeh[2], Peijia Zha[1], and XinQi Dong[3], *1. Rutgers, the State University of New Jersey, Newark, New Jersey, United States, 2. College of Staten Island CUNY, New York, New York, United States, 3. Rutgers, New Brunswick, New Jersey, United States*

Purpose: Elder mistreatment (EM) in immigrants with cognitive decline is an understudied public health problem. Cognitive function plays an important role in individuals' ability to seek help. This study aimed to examine the associations between cognitive function and help-seeking among U.S. Chinese older adults reported EM.

Methods: Data were from the Population Study of Chinese Elderly in Chicago (PINE). Five instruments were used to measure cognitive function, including the Mini-Mental State Examination, East Boston Memory Test Immediate Recall and Delayed Recall, Digit Span Backwards, and Symbol Digit Modalities Test. Informal/formal help-seeking intentions and behaviors were measured. Descriptive statistics, linear regression, and logistic regression were performed.

Results: A total of 450 participants reported EM. Most victims sought help from informal sources (53.48%), followed by any sources (11.42%) and formal sources (3.34%). About one-third of participants did not seek any help. Higher episodic memory was associated with an increase in help-seeking intentions among Chinese older adults with financial mistreatment (p < .05) and poly-victimization (p < .01). Lower working memory was associated with an increase in help-seeking intentions among those with caregiver neglect (p < .001). Compared to not seeking help, higher executive function was associated with a higher likelihood to seek help from any sources among Chinese older adults with psychological mistreatment (p < .05). Conclusion/implication: This study highlights the associations between cognitive function and help-seeking among this underserved population. Culturally tailored interventions are suggested to promote help-seeking for different types of cognitive impairment among Chinese older adults with EM.

EXPLORING THE USE OF MACHINE LEARNING TO IMPROVE DEMENTIA DETECTION: AUTOMATING CODING OF THE CLOCK-DRAWING TEST

Mengyao Hu[1], Yi Lu Murphey[2], Song Wang[2], Tian Qin[2], Zixuan Zhao[2], Richard Gonzalez[1], Vicki Freedman[1], and Laura Zahodne[1], *1. University of Michigan, Ann Arbor, Michigan, United States, 2. University of Michigan-Dearborn, Dearborn, Michigan, United States*

Alzheimer's disease and related dementias, a leading cause of disability among older adults, has become a critical public health concern. The clock-drawing test (CDT), which asks subjects to draw a clock, typically with hands showing 11:10, has been widely used as a screening tool to detect dementia in clinical research and surveys. The clock-drawings are often coded into binary (e.g., normal vs. abnormal) or ordinal scores. A limitation in large-scale studies is that the manual-coding of CDT could result in biases if coders interpret and implement coding rules differently. Several small-scale studies have explored the use of machine learning methods to automate CDT coding. Such studies either have had limited success with ordinal coding or have used methods that are not designed specifically for complex images. This study aims to create and evaluate an intelligent CDT-scoring system that automatically codes ordinal CDT scores using deep learning neural networks (DLNN) methods including resnet101, EfficientNet-B3, and Visual Transformer. We used a large repository of CDT images from the 2011-2019 National Health and Aging Trends Study, a panel study of Medicare beneficiaries ages 65 and older. Results show that 1) DLNN has achieved a high scoring accuracy; 2) DLNN generates more consistent and accurate scores than trained lay coders, compared to expert coders with a neuropsychology background; 3) DLNN-coded CDT scores are highly correlated with self-reported dementia diagnosis and performance-based assessments of memory. This study offers a model for automating coding of other drawing tests used to evaluate a variety of cognitive functions.

INFLUENCE OF POSTTRAUMATIC STRESS AND ABNORMAL SPIROMETRY ON COGNITIVE PERFORMANCE IN 9/11 WTC RESPONDERS

Andrea Zammit[1], Charles Hall[2], Sean Clousten[3], and Benjamin Luft[3], *1. Rush Alzheimer's Disease Center, Chicago, Illinois, United States, 2. Albert Einstein College of Medicine, Bronx, New York, United States, 3. Stony Brook University, Stony Brook, New York, United States*

Post-traumatic stress disorder (PTSD) and abnormal spirometry are highly prevalent mental and health conditions in World Trade Center (WTC) responders. We tested the hypothesis that PTSD symptomatology and abnormal spirometry are conjointly and synergistically associated with poorer cognitive performance. A total of 1,326 responders (mean age = 53.1, SD = 8.1, 92% males) from the WTC Health Program took part in the study. PTSD symptomatology was assessed using the PCL-IV, and we calculated the FEV1/FVC ratio to measure pulmonary function. Cogstate assessments measured cognitive performance. Linear regressions were employed to evaluate PTSD and pulmonary function on cognitive performance while adjusting for age, sex, education, smoking status, and comorbidity. Higher PTSD symptomatology and lower pulmonary function were independently and conjointly negatively associated with cognitive performance. Further, a significant synergistic effect was present in that higher severity of PTSD symptomatology in the presence of lower pulmonary function was associated with poorer cognitive performance (estimate = -0.096, SE = 0.03, p <0.001). Results suggested that chronic stress and lung damage might share underlying biological mechanisms, including inflammatory and oxidative stress pathways, which may also be affecting the brain. Early intervention efforts to mitigate preventable cognitive decline in high-risk populations should be studied.

PSYCHOMETRIC PROPERTIES OF THE NEUROPSYCHIATRIC INVENTORY QUESTIONNAIRE FOR THAI OLDER ADULTS WITH DEMENTIA

Kaipeng Wang[1], Ladson Hinton[2], Sue Levkoff[3], Siranee Sihapark[4], Komatra Chuengsatiansup[5], and Hongtu Chen[6], *1. University of Denver, Denver, Colorado, United States, 2. University of California Davis, Sacramento, California, United States, 3. University of South Carolina, Columbia, South Carolina, United States, 4. Boromarajonani College of Nursing, Khon Kaen, Khon Kaen, Thailand, 5. Society and Health Foundation & Sirindhorn Anthropology Center, Nonthaburi, Nonthaburi, Thailand, 6. Harvard University, Boston, Massachusetts, United States*

Psychiatric and behavioral symptoms are highly prevalent among persons living with dementia. Clinical evaluation of those symptoms is critical for assessment of dementia progression and development of effective treatment. The Neuropsychiatric Inventory Questionnaire (NPI-Q) is a brief informant-based instrument to assess the severity of 12 types of neuropsychiatric symptoms among persons with dementia and associated caregiver distress. Although Thailand is experiencing a rapid increase in the prevalence with dementia, there is no validated instrument to assess neuropsychiatric symptoms in Thailand. This study aims to examine the psychometric properties of the NPI-Q instrument among older adults with dementia in Thailand. Data were collected from 353 participants aged 60 and over with probable dementia, at least one neuropsychiatric symptom, and an adult family caregiver willing to participate in the study. We examined the internal consistency, factorial validity, and criterion validity of the NPI-Q instrument. NPI-Q has acceptable internal consistency (Cronbach's α=0.77). Principal component analysis yielded a five-factor solution, which accounted for 63% of the variance. The five factors included (1) agitation, anxiety, and irritability, (2) delusions, hallucinations, apathy, and disinhibition, (3) euphoria, motor disturbance, and night disturbance, (4) depression, and (5) abnormal appetite. We found that higher NPI-Q severity score was significantly associated with higher geriatric depression, associated caregiver distress, caregiver burden, and caregiver depression and lower quality of life among older adults and their caregivers, which confirmed the criterion validity of the instrument. Findings provide support for use of the NPI-Q among older adults with dementia in Thailand.

TOXIC STRESS, RESILIENCY RESOURCES, AND TIME TO DEMENTIA DIAGNOSIS AMONG AMERICANS AGED ≥50 YEARS IN THE HRS 2006–2016

Allan Nkwata[1], Ming Zhang[2], Xiao Song[2], Bruno Giordani[1], and Amara Ezeamama[3], *1. University of Michigan, Ann Arbor, Michigan, United States, 2. University of Georgia, Athens, Georgia, United States, 3. Michigan State University, East Lansing, Mississippi, United States*

Toxic stress (TS), resiliency-promoting factors (RPFs) and their interactions were investigated in relationship to incident dementia in a sample (n = 6516) of US adults ≥50 years old enrolled in the HRS between 2006-2016. TS included experiences of everyday discrimination and RPF included personal mastery. Race/ethnicity was self-reported as African American (AA), Caucasian, or Other. Multivariable Cox proportional hazards regression models estimated TS-, RPF- and race-associated hazard ratios (HR) for dementia diagnosis and 95% confidence intervals (CIs) with adjustment for comorbidity and socio-demographic factors. Discrimination-associated risk of dementia diagnosis on average increased with education level [discrimination x education, p = 0.032; HR = 1.75 (95% CI: 1.01–3.03) if < high school, HR = 5.67 (95% CI: 2.94–10.94) if high school completed and HR = 2.48 (95% CI: 1.53–4.00) if ≥some college education]. Likewise, AA vs. Caucasian race disparity in new-onset dementia was evident (HR = 2.12, 95% CI: 1.42–3.17) among adults with high-mastery while absent (HR = 1.35, 95% CI: 0.75–2.41) among adults with low mastery (Mastery x Race, p = 0.01). TS is a contextual driver of incident dementia that seemingly operates in a race and RPF-dependent manner. Heterogeneity pattern suggests that TS may overwhelm the cognitive reserve benefit of RPF particularly in status-inconsistent contexts including persons subjected to discrimination despite high education and in AA individuals despite high mastery. Policies that reduce discrimination and promote equitable treatment by race/ethnicity may support cognitive resiliency and reduce the risk of dementia diagnosis in adult Americans.

SESSION 4710 (SYMPOSIUM)

COMMUNITY ENGAGEMENT: INDIGENOUS AND NONINDIGENOUS RESEARCHERS

Chair: Jordan Lewis Co-Chair: Steffi Kim

In response to populations that have been chronically underserved and underrepresented within the social sciences, scholars have outlined the need for community-based engagement strategies and research methodologies that are able to represent the voices of those communities to promote culturally informed, appropriate, and driven health initiatives. This symposium introduces and discusses Indigenous research methodologies that are empowering and emphasize the knowledge and wisdom of Indigenous Elders, shares urban Elder engagement strategies, explores engagement strategies for Indigenous and non-Indigenous researchers, and describes the impacts of exclusion of Indigenous voices from research. The first presentation by Maria Crouch and her colleagues will introduce an Elder-centered research methodology as exemplified by two research studies. The second presentation by Steffi Kim focuses on outreach and research engagement strategies to reach Alaska Native Elders in the urban environment. The third presenter, Jordan Lewis, shares and discusses community-based research as an insider and outsider in your own community, outlining research practices, positionality, and accuracy in research. Finally, Lyn Holley will discuss themes emerging from her review of the literature that explored the impacts of the application of "top-down" Eurocentric approaches to inquiry on American Native people and the implications of these findings.

ELDER-CENTERED RESEARCH METHODOLOGY: RESEARCH THAT DECOLONIZES AND INDIGENIZES

Maria Crouch[1], Steffi Kim[2], Zayla Asquith-Heinz[3], Elyse Decker[4], Nyche Andrew[5], Rosellen Rosich[6], and Jordan Lewis[7], *1. Yale School of Medicine, New Haven, Connecticut, United States, 2. University of Minnesota, Minneapolis, Minnesota, United States, 3. University of Minnesota Medical School, Minneapolis, Minnesota, United States, 4. Swarthmore College, Swarthmore, Pennsylvania, United States, 5. Yale University, New Haven, Connecticut, United States, 6. University of Alaska Anchorage, Anchorage, Alaska, United States, 7. University of Minnesota Medical School, Duluth, Minnesota, United States*

Alaska Native (AN) Elders have historically been underrepresented in research. Innovative AN research posits that practice-based evidence is fundamental to culturally grounded, multifaceted methods. Semi-structured interviews were conducted with 34 AN Elders and 12 AN and non-Native caregivers in two studies exploring cultural understandings of memory and successful aging. The design and implementation of these studies employed Elders at every level of the research, ensuring cultural relevancy, outcomes, and dissemination activities. Findings reflect the benefits of engaging AN Elders in research and reveal methods for best practices: 1) creating Advisory councils; 2) identifying stakeholders 3) weaving together Elder and Western knowledge systems; and 4) the reciprocal nature of Elder engagement and wellbeing. This complimentary research builds on Elder-centric principles and lays the foundation for an Elder-centered research methodology that can be adapted and applied in other studies to encourage engagement of older adults in meaningful, restorative, and enculturated ways.

URBAN ENGAGEMENT STRATEGIES FOR ALASKA NATIVE ELDER PARTICIPATION IN RESEARCH

Steffi Kim, *University of Minnesota, Minneapolis, Minnesota, United States*

Given the current threats to health for older Indigenous people, it is important to understand the health needs and perceptions of older Indigenous people who play a pivotal role in the health and wellbeing of their communities. The underrepresentation of Indigenous voices has led to research, health promotion efforts, and community engagement that has largely been unsuccessful in facilitating culturally grounded and effective health promotion. Engaging Indigenous Elders in research has often been a challenge for researchers – Indigenous and non-Indigenous. Reaching Indigenous Elders within the urban environment can even be more challenging at times based on dispersed communities due to challenging historical contexts, experiences of racism, and mistrust. This presentation is based on the employed engagement strategies of urban-based Alaska Native Elders. Developing policies and programs to promote healthy aging in Indigenous communities requires the voices of those living within their communities.

CONDUCTING COMMUNITY-BASED RESEARCH AS AN INSIDER AND OUTSIDER IN YOUR OWN COMMUNITY

Jordan Lewis, *University of Minnesota Medical School, Duluth, Minnesota, United States*

As an Alaska Native from the Bristol Bay region, this presentation will discuss being an insider and outsider in your own community and how it impacts research studies. Using case studies from my dissertation research, this presentation will discuss positionality and how to collect objective data, the lack of objectivity in getting, analyzing, and reporting data, and how research methods influenced my study. I will also discuss challenges and benefits of being an insider, including enhancing the validity of the research process, data collection, and analysis, understanding the group's culture. The results include trusting relationships with communities, the Elders' voices guiding the findings, an appreciation for the challenge of conducting research as an insider and outsider. This presentation will conclude with a discussion on how to obtain objective data and ensure the accuracy of findings through community-engagement principles and the benefits of working in your own community.

EXAMINING EXCLUSION FOR GUIDANCE TO INCLUSION: A GOOD IDEA?

Lyn Holley, *University of Nebraska at Omaha, Omaha, Nebraska, United States*

This paper is based on a literature review that informed writing of a chapter for a new edited book, Moving beyond the rhetoric - research with older service users – why ethics and integrity matter. (Emerald, in review). This literature review was undertaken to ground guidance for the chapter in the book that addresses ethics in research with American Indians of all tribes on lands currently part of the USA. A theme that emerged uninvited was the many ways in which inquiry that was unintentionally or deliberately unethical also operated to reduce inclusion of American Indians in research – often the very research needed to discern or demonstrate value of various clinical, social, or other types of interventions needed to improve policies or practices. This paper explores that theme and its implications for research with American Indians.

SESSION 4720 (SYMPOSIUM)

CONTINUOUS WORK-BASED LEARNING IN THE NURSING HOME SETTING

Chair: Judith Meijers

Nursing homes face challenges caused by increasing numbers of older adults with frailty and multimorbidity, and complexity of care in combination with decades of under resourcing and severe workforce challenges. In most countries the vast majority of direct care in LTC homes is provided by a large unregulated workforce that is largely unregulated, female, racialized and poorly remunerated. The results are severe difficulties in recruiting and retaining staff at all levels and a tendency to substitute less qualified workers for more highly qualified and more highly remunerated. Less well reported are the significant pressures that critical LTC home managers face. However, they are equally under duress especially in the wake of a global pandemic. Developing a culture of continuous learning and integrating this into daily nursing practice is one promising way to attenuate these challenges, ensure a high quality of care and a better equipped nursing staff. However, insight into strategies and interventions that contribute to such a continuous work-based learning culture in nursing homes is still relatively limited. In this symposium we will focus on different approaches to increasing workplace learning in long term care.

ELEMENTS OF AN INTERPROFESSIONAL LEARNING CULTURE IN NURSING HOMES

Judith Meijers[1], Merel (E.A.) Van Lierop[1], Frank Verbeek[2], Miranda Laurant[2], Erik van Rossum[3], Sandra Zwakhalen[1], and Anneke Van Vught[2], *1. Maastricht University, Maastricht, Limburg, Netherlands, 2. HAN University, Nijmegen, Gelderland, Netherlands, 3. Zuyd University of Applied Sciences, Maastricht, Limburg, Netherlands*

Healthcare professionals in nursing homes need to be able to keep up with changes at work, deal with a growing complexity in healthcare demands and have to keep developing themselves within a team to be able to plan and deliver high quality of care. To keep up with these changes and demands, an interprofessional learning culture must be stimulated. Insight about developing such a culture in nursing homes is lacking. A scoping review was performed. Articles were examined on actions that positively influence the development of an interprofessional learning culture. 51 Actions were identified. The influencing factors were divided in eight main themes i.e. (1) communication, (2) shared goals, (3) tasks and responsibilities, (4) learning and knowledge, (5) work approaches, (6) attitude, (7) leadership, and (8) safety, respect and transparency. These actions form a basis for an interprofessional learning culture but should be operationalized and tailored to practice use.

LINC TOOL: USING QUALITY DATA, COACHING, AND AN IMPROVEMENT CYCLE FOR LEARNING AND IMPROVEMENT IN LONG-TERM CARE

Merel (E.A.) Van Lierop[1], Judith Meijers[1], Erik van Rossum[2], and Sandra Zwakhalen[1], *1. Maastricht University, Maastricht, Limburg, Netherlands, 2. Zuyd University of Applied Sciences, Maastricht, Limburg, Netherlands*

Providing high quality of care can be challenging for nursing staff because of the continuous changes in healthcare. Nursing staff needs to learn continuously to remain employable and deal with these challenges. Therefore, availability of a continuous learning and improvement tool (LINC tool) using nursing quality data and an improvement cycle to maintain high quality of care in long-term care is important. The development of this tool took place in co-creation with researchers, experts, educational staff and nursing staff working in long-term care. Taskforces with researchers and experts on quality data and education were established to develop the main steps of the tool. Nursing staff was involved in the development and testing of the tool. The LINC tool consists of 1) Assessment of the current learning climate and preferred quality data for nursing staff to work with, 2) Discussing findings from step 1 with the nursing staff team and formulate learning topics, 3) Start improvement cycle (PDCA cycle) using one learning climate topic and one quality data topic as a case to improve quality of care and improve the learning climate. During this cycle, nurse coaches are available to help nursing staff use the LINC tool materials. The LINC tool can be used to improve long-term care and has proven to be feasible. However, the LINC tool is currently tested in more nursing staff teams to increase its usability and effectiveness. Further development of the LINC tool is therefore a constant cycle of developing, implementing, testing, and evaluating, all in cooperation with stakeholders.

SUPPORTING NURSING HOME MANAGERS TO ACT ON PERFORMANCE FEEDBACK DATA: A PROVINCEWIDE IMPLEMENTATION

Carole Estabrooks[1], Seyedehtanaz Saeidzadeh[1], Stirling Bryan[2], Peter Norton[3], Liane Ginsburg[4], Matthias Hoben[1], and Don McLeod[5], *1. University of Alberta, Edmonton, Alberta, Canada, 2. Michael Smith Health Research, Vancouver, British Columbia, Canada, 3. University of Calgary, Calgary, Alberta, Canada, 4. York University, Toronto, Ontario, Canada, 5. Translating Research in Elder Care, Edmonton, Alberta, Canada*

INFORM (Improving Nursing home care through Feedback on perfoRMance data) is a tested research intervention targeting care managers that demonstrated positive two year follow up results and has subsequently been shaped into an operationally acceptable “implementation package”. This package or innovation is being scaled up in one Canadian province’s total Long-Term-Care (LTC) home population with in depth process evaluation during the first cohort of LTC homes. This evaluation will, among other things, assess sector needs for adaptation (vs fidelity). At its core INFORM is designed to address managers’ learning needs with respect to using data to make positive change in a continuous learning loop. We will discuss the transformation of a research intervention to a sector innovation and report on interim process evaluation results.

SESSION 4730 (PAPER)

DISCRIMINATION

CORRELATES OF RACIAL DISCRIMINATION TRAJECTORIES AMONG BLACK MIDDLE-AGED AND OLDER ADULTS

Kellee White[1], Shuo Huang[2], and Bethany Bell[3], *1. University of Maryland College Park School of Public Health, College Park, Maryland, United States, 2. University of Maryland, College Park, Maryland, United States, 3. University of Virginia, Charlottesville, Virginia, United States*

Single cross-sectional measures of racial discrimination may mask the dynamic nature and cumulative impact of repeated exposures to discrimination. Characterizing racial discrimination trajectories, patterns of repeated exposure, may provide insight on age-related patterns of health risk and resilience. However, there is a dearth of research exploring racial discrimination trajectories. This study characterizes racial discrimination trajectories and identifies trajectory correlates among a nationally representative sample of middle-aged and older black adults who participated in the Health and Retirement Study (2006-2018). Repeated measures latent profile analysis was employed to identify racial discrimination trajectories. Logistic regression models, estimating odds ratios (ORs) and 95% confidence intervals (CIs), were conducted to investigate sociodemographic and neighborhood-level predictors of racial discrimination trajectories. Two racial discrimination trajectories were identified: low to moderate (82%) and persistently high (18%). Individuals 65+ (OR: 0.45; 95% CI: 0.32, 0.64) and female sex (OR: 0.59; 95% CI: 0.45, 0.76) were associated with a lower odds of belonging to the persistently high racial discrimination trajectory class. Individuals reporting higher levels of major lifetime experiences of discrimination (OR: 1.47; 95% CI: 1.33, 1.63) and greater neighborhood social cohesion (OR: 1.30; 95% CI: 1.1, 1.50) predicted membership in the persistently high racial discrimination trajectory class. These findings suggest heterogeneity in the cumulative patterning of discrimination among black middle-aged and older adults. Discrimination trajectories may enable greater precision in estimating the health consequences of cumulative exposure to discrimination. Future studies are warranted to determine whether membership in specific trajectory classes confers differential risk to age-related conditions.

PERCEIVED DISCRIMINATION, DEPRESSIVE SYMPTOMS, AND COGNITIVE CONTROL AMONG MEXICAN-ORIGIN WOMEN

Elizabeth Muñoz[1], Hin Wing (Florence) Tse[2], Jinjin Yan[3], and Su Yeong Kim[1], *1. The University of Texas at Austin, Austin, Texas, United States, 2. Department of Human Development and Family Sciences, The University of Texas at Austin, Austin, Texas, United States, 3. University of Texas at Austin, Austin, Texas, United States*

Mexican-origin adults comprise over 60% of the Latino population in the U.S., and are at greater risk for cognitive impairment compared to non-Latino Whites. Older Mexican-origin women are also disproportionally affected by cognitive impairment compared to their non-Latino White counterparts. Identifying early-life precursors for reduced cognitive function can inform prevention efforts. Perceived discrimination is a ubiquitous stressor with emergent evidence linking it to cognitive function and no studies testing mechanisms of this association among Mexican-origin women. Using data from a three-wave longitudinal study of Mexican-origin women spanning 8 years (n = 595, mean baseline age = 38.89 (5.74)) living in central Texas, we tested the longitudinal associations between baseline daily and ethnic discrimination on a task of cognitive control at Wave 3 and the mediating effects of Wave 2 depressive symptoms. We also tested the moderating effects of age, education, and financial difficulties on these links. Structural equation model results indicated that baseline daily discrimination was associated with slower reaction times at Wave 3 and that depressive symptoms at Wave 2 mediated this association; models controlled for age, education, and baseline depressive symptoms. Ethnic discrimination was positively associated with Wave 2 depressive symptoms, but not with cognitive control. Greater daily discrimination was associated with faster reaction times among those with lower financial difficulties. Findings show that greater daily discrimination is subsequently associated with lower cognitive control through increased depressive symptoms and highlight the need for future research to consider the socioeconomic context under which these links operate among Mexican-origin women.

RISK AND RESILIENCE: HIGHLIGHTING MINORITY STRESS IN A LIFESPAN SAMPLE OF SEXUAL MINORITIES

Michael Vale[1], and Toni Bisconti[2], *1. Sacred Heart University, Fairfield, Connecticut, United States, 2. University of Akron, Akron, Ohio, United States*

Older sexual minorities (OSM), or those older adults sexually attracted to the same sex, are at risk for poorer well-being, which is rooted in the stresses of being marginalized. There is limited knowledge on how older age contextualizes the minority stress process. OSM have witnessed more stigmatized sociopolitical climates, yet report less minority stress compared with younger adults, which may be due to having accrued lifetime practice with stigma. The current study explores age differences in the daily experiences of minority stress in a sample of sexual minorities stratified across the lifespan. Data from a baseline sample of 355 sexual minorities (ages 18-90) confirmed previous research that OSM experienced lower minority stress compared with their younger counterparts (p<.05). Additionally, an age-stratified subset of this sample (N=112; ages 19-79) answered daily surveys for 3 weeks (N=1,923). Using multilevel modeling, we found that older age moderated the daily stress-distress relationships between outness disclosure and positive affect (B=-.005, p<.05); internalized homonegativity and positive affect (B=.004, p <.05) and negative affect (B=-.005, p<.05), and experienced microaggressions and negative affect (B=.007, p<.05). OSM had weaker relationships among four different daily minority stressors and worse daily well-being. There also was support that the associations between age and minority stress were partially mediated by lifelong exposure with marginalization. This project highlights the intersection of sexuality and aging and emphasizes the unique resilience of OSM. The results of this study inform both theory and practice and contribute to a better understanding of how to address OSM' health disparities.

SEXUAL AND MARITAL SATISFACTION IN OLDER ADULTHOOD: EFFECTS OF CHILDHOOD AND ADULTHOOD VIOLENCE EXPOSURE

Jooyoung Kong[1], Scott Easton[2], and Yan Zhang[1], *1. University of Wisconsin-Madison, Madison, Wisconsin, United States, 2. Boston College, Boston, Massachusetts, United States*

Objectives: Guided by Finkelhor and Browne's traumagenic dynamics model, the current study examines: 1) the long-term effects of childhood sexual abuse (CSA) and other adverse childhood experiences (ACEs) on older adults' sexual and marital satisfaction, 2) the mediating role of intimate partner violence (IPV) victimization in the association between childhood adversities and sexual and marital satisfaction, and 3) whether gender moderates the mediational association. Research Design and

Methods: Using the Wisconsin Longitudinal Study, we analyzed data from 4,239 older adults between the 2004/2005 (Wave 1, Mean age = 65 years) and 2011 (Wave 2, Mean age = 72 years) data collections. The structural modeling approach was employed where the independent variables were CSA and ACEs, the dependent variables were sexual and marital satisfaction in Wave 2, and the mediators were IPV victimization and sexual and marital satisfaction in Wave 1.

Results: Both CSA and ACEs were associated with lower levels of sexual satisfaction and marital satisfaction in late adulthood. IPV victimization mediated the association between ACEs and marital satisfaction. The hypothesized moderated mediation by gender was not supported. Discussion and Implications: Using a population-based sample, this is one of the first studies demonstrating that distal life events such as CSA and ACEs can undermine older adults' sexual and marital health, and revictimization in adulthood may serve as a mechanism for the association. Timely intervention is needed to prevent persistent negative effects of childhood violence.

THE ROLE OF COPING IN THE ASSOCIATION BETWEEN DISCRIMINATION AND HEALTH OVER TIME IN SEXUAL MINORITY OLDER ADULTS

Christi Nelson, *University of Washington, Edmonds, Washington, United States*

While research on lesbian, gay, and bisexual (i.e., sexual minority) middle-aged and older adults has increased over the past decade, there is still a critical need for more research on the health and resilience in this marginalized group, especially longitudinal research. This study examined the differences in the associations between perceived daily discrimination and the physical and mental health of sexual minority and heterosexual adults over time and assessed the moderating effects of problem-focused and emotion-focused coping on these associations. The sample for this study consisted of sexual minority (n=162) and propensity matched heterosexual (n=324) middle-aged and older adults (mean age at baseline=43 years, SD=12.5) with data from three waves of the Midlife in the United States (MIDUS) study, spanning approximately 20 years. Results found that, for sexual minority participants, reporting higher perceived discrimination was associated with a greater number of chronic conditions at baseline, but was also associated with a significant decrease in the number of chronic conditions over time. For the heterosexual participants, both high and low perceived daily discrimination was associated with an increase in the number of chronic conditions over time. The results of this study also found significant moderating effects of coping on the number of chronic conditions and self-rated mental health over time. Problem-focused coping may protect against the negative effects of discrimination on health. These results are suggestive of a "steeling" effect or a resistance to stress achieved through exposures to adversity for the sexual minority middle-aged and older adults in this study.

SESSION 4750 (PAPER)

EXPERIENTIAL SERVICE LEARNING IN GERONTOLOGY

In this session, gerontology educators describe how different experiential strategies can be used to enhance students' aging education across a range of classrooms.

AN INNOVATIVE MULTIDISCIPLINARY PAID APPRENTICESHIP PROGRAM TO DEVELOP A NEW WORKFORCE IN GERONTOLOGY

Anita Sharma, *University of Louisiana Monroe, Monroe, Louisiana, United States*

There is an acute need to develop new workforce talent in the Gerontology industry due to (a) a rapidly increasing older population; (b) new and evolving needs of older adults due to increased life spans and the long-term impact of COVID-19, and (c) high attrition rates of the current workforce due to death and retirement. One practical strategy to increase new talent is to develop paid apprenticeship opportunities for undergraduate students from different disciplines. The author developed multiple hybrid apprenticeship opportunities to create an "earn and learn" program through funds received from the Louisiana Board of Regents. The program was open to students from all majors because Gerontology is a multi-disciplinary field and there is a need to provide gerontological training to professionals from different disciplines to prepare them to serve older adults in different types of settings. As a pilot project, ten students were selected after an application process. Students in this project were required to complete two three-credit hour fully online courses in Gerontology with a grade of "B" or better. They were also required to complete an eight-hour orientation to help them develop soft skills to work with older adults during their apprenticeship period. They were then required to complete a 150-hour paid summer-apprenticeship in an organization that serves older adults and/or people with disabilities. The program was successful with a 100% completion rate. The students enrolled in this program completed the final step by presenting their apprenticeship experiences at a conference organized by the author.

DEATH AND GRIEF IN INTERGENERATIONAL SERVICE LEARNING: EXPLORATIONS FROM THE FIELD

Sara Bartlett[1], and Phyllis Solomon[2], *1. Cal Poly, San Luis Obispo, San Luis Obispo, California, United States, 2. University of Pennsylvania, Philadelphia, Pennsylvania, United States*

Intergenerational service-learning has been established as an effective pedagogical strategy for undergraduate gerontology education but can challenge students and instructors alike if an older adult participant dies during such a program. Currently, there is a lack of literature to provide guidance to instructors about how to address such an event. Examination of a case study of such an occurrence during the Lives Well Lived intergenerational service-learning program seeks to advance the field by describing an example of such an event and how an instructor might seek to address it. Grief literature, including theories such as Kübler-Ross' stage model, Worden's TEAR model, and Wortman and Silver's approach, as well as Doka's concept of disenfranchised grief are examined and applied to this challenging situation. Applying these theories as a framework, recommendations are given for addressing death and grief in service-learning including: (1) assessment of the course, instructor, student, and situation; (2) creating opportunities for grief processing and (3) resources for on and off campus grief and instructor support. Providing education on death, grief and grieving as integral course content and allowing student choice in how to proceed with the project should a death occur are key recommendations to consider. Implications call for more research related to this topic.

QUALITATIVE COMPARISON OF TWO INTERGENERATIONAL SERVICE-LEARNING PROGRAMS

Sara Bartlett[1], Sky Bergman[1], Phyllis Solomon[2], and Zvi Gellis[2], *1. Cal Poly, San Luis Obispo, San Luis Obispo, California, United States, 2. University of Pennsylvania, Philadelphia, Pennsylvania, United States*

Intergenerational service-learning programs are an effective and frequently used training modality in undergraduate education and are often examined using qualitative methods. It is less common to qualitatively examine two such programs to compare their outcomes. This study reports qualitative findings from a mixed-methods study comparing two intergenerational service-learning programs in an undergraduate Psychology of Aging class. The longer, more relational intervention, the Lives Well Lived program, matched students and older adults exemplifying "successful aging" in a mutual interviewing, life review project utilizing documentary film, photography, and memoir creation. The comparison intervention, the Meals That Connect/Lunch Bunch program, also exposed students to older adults exemplifying successful aging, but in a shorter, less relational way. A convenience sample of 128 students (65 in the intervention group and 63 in the comparison group) answered post-intervention open-ended questions about what they liked/disliked about the program in which they participated, as well as any viewpoints about aging they felt changed or were reinforced by the project. Thematic analysis revealed students in both groups experienced decreased ageism and improved attitudes about aging. However, those participating in the Lives Well Lived program had closer relationships with the older adults participating in the project, expressed more positivity about their own aging process, and indicated more willingness to engage in future intergenerational relationships. Use of a comparison project in qualitative examination of intergenerational service-learning adds greater insight into such programs' outcomes, enhancing quantitative effectiveness examinations.

TEACHING GERONTOLOGY TO SOCIAL WORK STUDENTS: APPLYING THE EXPERIENTIAL LEARNING USING ETHNOGRAPHIC INTERVIEW

Lun Li[1], and Yeonjung Lee[2], *1. MacEwan University, Edmonton, Alberta, Canada, 2. Chung-Ang University, Seoul, Seoul-t'ukpyolsi, Republic of Korea*

There is an increasing need for well-trained social workers to support the growing aging population in Canada. Still, concerns arise regarding social work students' insufficient knowledge and understanding of aging and aging-related issues. This study aims to examine social work students' experience when experiential learning through ethnographic interview with older adults is applied as a pedagogical approach. This study was conducted based on two cohorts of social work undergraduate students who enrolled in a gerontology course in a Canadian university between 2020 and 2021. Students conducted an ethnographic interview with older adults aged 70 years and older and wrote a reflection paper as an assignment. We did a thematic analysis of eight reflection papers in which consent was obtained from students. We find that students connect aging-related theories/models to various topics discussed during their ethnographic interview, reflect on their personal experiences with aging family members, and show a positive perception of aging and attitude towards working with aging. The findings also suggest the benefit of adopting an approach of experiential learning through the ethnographic interview with older adults to teach gerontology to social work students. We offer recommendations for educators to create opportunities for students, especially from social work or other helping professions who traditionally have shown a lack of interest in working with older adults, to meet and interact with older adults, and to further enhance students' competencies and interests in the fields of senior care.

TRANSFORMING AN INTERGENERATIONAL SERVICE-LEARNING PROJECT DURING THE COVID-19 PANDEMIC

Renee' Zucchero, and Annaliet Delgado-Rodriguez, *Xavier University, Cincinnati, Ohio, United States*

The COVID-19 pandemic has required transformation in the delivery of higher education and pedagogy that is used. The Co-Mentoring Project links undergraduate Psychology of Aging students with older adult volunteers for an intergenerational service-learning experience. Prior to the pandemic, the Project was delivered via an in-person format. During the pandemic, the Project transitioned to a virtual format. Self-reported postproject evaluations from undergraduate students (n= 30) and older adults (n= 27) during the two academic years prior to the pandemic were compared to evaluations from students (n= 26) and older adults (n= 28) during two years of the pandemic. Mann-Whitney U Tests revealed no significant differences in older adult and student postproject evaluation outcomes between in-person and virtual formats. For example, there were no differences in older adult level of enjoyment between the in-person (Md= 5, n= 27) and virtual formats (Md= 5, n= 28), U = 405.00, z = .84, p = .40. Likewise, there no differences in student level of comfort interacting with older adults between in-person (Md= 5, n= 30) and virtual formats (Md= 5, n= 26), U = 389.00, z = -.02, p = .99. Qualitative information from the postproject evaluations indicated participants were glad to have had the opportunity to meet virtually during the pandemic, however they preferred an in-person format. These results support the conclusion that intergenerational service-learning can be successfully implemented virtually. This paper will describe the transformation of the Project from an in-person to virtual format, and advantages and disadvantages of both formats.

SESSION 4760 (SYMPOSIUM)

FUNCTION FOCUSED CARE FOR ACUTE CARE: OVERCOMING RECRUITMENT, MEASUREMENT, AND IMPLEMENTATION POST-COVID-19

Chair: Barbara Resnick

To help patients spend more time engaged in physical activities and avoid the complications that occur Function Focused Care for Acute Care was developed (FFC-AC-EIT). FFC-AC-EIT includes the implementation of four steps: (1) Environment and policy assessments; (2) Education of staff; (3) Establishing patient goals; and (4) Mentoring and motivating of staff, patients, and families. A total of 600 patients from 12 hospitals will be included. Eligibility of patients is based on being 55 years of age and older, admitted for a medical reasons excluding COVID-19, and demonstrating evidence of dementia. Outcome measures are obtained at baseline, discharge, 1, 6 and 12 months post discharge and include physical function, physical activity, pain and pain management, psychological and behavioral symptoms associated with dementia, delirium and adverse events (falls, rehospitalizations, nursing home admissions). Due to COVID-19 innovative approaches were implemented to be able to initiate and continue with the study. These included: identifying potential participants that were COVID-19 free off site; transitioning some intervention activities with staff to online; completing verbal consent with proxies versus face to face; adjusting follow up MotionWatch 8 deliveries and placements to be done without face to face interaction; and adjusting recruitment time periods and intervention activities to fit with intermittently high periods of COVID-19. This symposium will describe intervention challenges, solutions and lessons learned, describe an effective process and measurement model for identification of participants with dementia; and provide optimal ways to measure pain and physical activity among older adults with dementia.

OVERCOMING RECRUITMENT APPROACHES TO IDENTIFY PARTICIPANTS WITH DEMENTIA

Elizabeth Galik, *University of Maryland, Baltimore, Baltimore, Maryland, United States*

Clinically the work up for dementia often includes a history and physical, neuropsychiatric screening measures and neuroimaging. These assessments are neither practical nor realistic when identifying participants for research studies. To confirm a diagnosis of dementia for study participants in the FFC-AC-EIT study we developed a measurement model. The model included four measures: the AD8, the Functional Activities Questionnaire, the Clinical Dementia Rating Scale, and the Saint Louis University Mental Status Examination. In the first 346 patients consented, 176 were enrolled and 158 were ineligible. The mean age of the participants was 80.70 (SD=9.60) and the majority were female (64%) and white (66%). There was evidence of reliability based on internal consistency and construct validity based on model fit using Rasch analysis and Structural Equation Modeling. All four measures are recommended as a pragmatic way in which to comprehensively determine evidence of dementia for research studies.

OVERCOMING CHALLENGES TO PAIN ASSESSMENT AND FACTORS THAT INFLUENCE PAIN IN PATIENTS WITH DEMENTIA

Ashley Kuzmik, *Penn State University, University Park, Pennsylvania, United States*

The purpose of this study was to describe the optimal way to measure pain among older hospitalized patients with dementia and evaluate the factors that influence pain. The PAINAD is described as a reliable and valid observation measure of pain in this population based on Rasch analysis and was invariant to gender or racial biases. Using this measure and a protocol for observation of pain, pain and associated factors were obtained on the first 112 participants from 6 hospitals in the FFC-AC-EIT study. For descriptive purposes and to guide interventions, factors that were associated with pain were tested. The following factors explained 61% of the variance: functional focused care activities performed, delirium, and quality of care interactions. Those that performed more functional activities, had less delirium, and had higher (more positive) quality of care interactions were less likely to have pain. The findings also supported the use of the PAINAD.

MEASUREMENT CHALLENGES AND SOLUTIONS WHEN EVALUATING PHYSICAL ACTIVITY AMONG HOSPITALIZED PATIENTS WITH DEMENTIA

Brittany Drazich, *University of Maryland, Baltimore, Maryland, United States*

Obtaining subjective reports of physical activity from individuals is known to be biased. With increased creation, dissemination, and use of technology, approaches for objective measurement have improved. Although actigraphy is increasingly used, challenges include a lack of clearly established cut off levels for vigorous, moderate, and low level activity in older individuals, decreased arm movement with walking, and the impact of comorbidities (e.g., Parkinson's Disease) on actigraphy readings. The advantages of the MotionWatch 8 over other devices will be discussed and our protocol for use shared. The findings from the first 200 participants will be described and challenges to interpretation addressed. The majority of the study participants were willing to wear the MotionWatch 8 during hospitalization. Using innovative approaches to avoid direct patient contact due to concerns related to COVID-19, follow up activity was obtained at 1 month post discharge. Lastly, recommendations for interpretation of findings will be provided.

IMPLEMENTING FUNCTION-FOCUSED CARE IN THE HOSPITAL: LESSONS LEARNED

Marie Boltz, *Penn State, Pennsylvania State University, Pennsylvania, United States*

The mentorship provided by the nurse interventionist is an important implementation strategy to support Function-focused care adoption in hospitalized older adults with dementia. The nurse interventionist works with unit champions and interdisciplinary stakeholder teams over a 12 month period. The first interaction includes using a brainstorming approach to develop unit-specific goals to support the integration of function-focused care into routine care delivery. Implementation strategies at the unit level include flexible staff training, involving staff in evaluations of care interactions, targeting pragmatic measures, and a feedback loop. Based on content analysis of field notes we will describe stakeholder goals established, action plans, and barriers and facilitators to meet goals in four hospital units. Key findings include the influence of leadership support, communication strategies, engagement of direct care staff, interdisciplinary collaboration, access to human and material resources, and contextual factors within the hospital setting (including pandemic-related challenges).

SESSION 4770 (PAPER)

HEALTH AND SOCIAL SERVICES: FROM COMMUNITY AND POST-ACUTE CARE INTERVENTIONS TO TRAUMA-INFORMED CARE SURVEY RESEARCH

A CITATION REVIEW OF DISSEMINATION AND IMPLEMENTATION MODELS UTILIZED IN AGING RESEARCH WITHIN THE UNITED STATES

Jennifer Sullivan[1], Anna Rae Montano[2], Heather Davila[3], Marlena Shin[4], Chelsea Hawley[5], Jaime Hughes[6], Kelly O'Malley[4], and Camilla Pimentel[5], *1. VA LTSS COIN / Brown University, Providence, Rhode Island, United States, 2. VA Providence Healthcare System, Providence, Rhode Island, United States, 3. VA Iowa, Iowa City, Iowa, United States, 4. VA Boston Healthcare System, Boston, Massachusetts, United States, 5. VA Bedford Healthcare System, Bedford, Massachusetts, United States, 6. Wake Forest, Wake Forest, North Carolina, United States*

The application of implementation science in aging research has been growing. To our knowledge, there has been no study detailing the Dissemination and Implementation (D&I) Models utilized in aging research. The goal of this citation review is to further understand D&I models frequency and nature of their use in aging research. We identified 111 Dissemination and Implementation (D&I) Models compiled on the dissemination-implementation.org website. We then conducted a citation analysis on them, searching Web of Science and PubMed databases. We extracted key data from identified articles up to January 28, 2022. Search terms were broad and included aging, older, elderly and geriatric. To be included, articles had to be in peer-reviewed journals, in English, and occur in the United States. We identified 297 articles meeting our eligibility criteria. The nature of the way D&I models used to advance evidence-based practice in aging research and practice varied as did the number of citations over time. Of the D&I models included in this review, only one (4E Framework) was developed within the aging research field. The top five models included: CFIR, RE-AIM 1.0, Behavior Change Wheel, Greenhalgh Diffusion of innovation in Service Organization and CBPR. Citations were distributed across many frameworks and yet only totaled less than 1% of all D&I Model citations suggesting there are many ways the field can grow in the future.

COMPLEXITY IN PSYCHOSOCIAL INTERVENTIONS: CASE STUDIES FROM A STROKE TRANSITIONS TRIAL

Emmanuel Chima[1], Amanda Woodward[2], Anne Hughes[1], Michele Fritz[1], Paul Freddolino[1], Sarah Swierenga[1], Constantinos Coursaris[3], and Mathew Reeves[1], *1. Michigan State University, East Lansing, Michigan, United States, 2. Michigan State University, Ann Arbor, Michigan, United States, 3. HEC Montreal, Montreal, Quebec, Canada*

The Michigan Stroke Transitions Trial (MISTT) tested whether in-home social work case management (SWCM) or SWCM combined with access to a website providing stoke-related information improved outcomes relative to usual care for patients discharged home post-stroke and their caregivers. The aims of this secondary analysis are 1) to describe the actual support social work case managers (SWCM) provided to MISTT participants and 2) use select case studies to illustrate the relationship between SWCM and quantitative patient and caregiver outcomes. Data for the study were derived from SWCM case notes on 157 patients and their caregivers who received the MISTT intervention. Case notes were coded in two steps with a subset of cases coded by two researchers and reviewed for interrater reliability in each step. The first round of coding was guided by primary SWCM intervention goals. The second round of coding identified SWCM sub-themes within each primary goal. Key themes indicate SWCMs aided with understanding the post-hospitalization period, helped patients navigate a range of systems and services, identified needs and supported patient goals, provided psychosocial support, and centered support on stroke recovery and prevention. Case studies illustrate ways in which SWCM were key supports during the transition period, but that support does not cleanly align with quantitative findings from patient-reported outcomes. This study aligns with a growing body of work documenting the complexity of transitions of care and has implications for how we support patients and caregivers as they move from inpatient to outpatient care and measure outcomes.

HOME-DELIVERED MEAL DELIVERIES AND FEELINGS OF SAFETY FOR OLDER AMERICANS ACT PARTICIPANTS

Claire Pendergrast[1], and Heather Menne[2], *1. Syracuse University, Syracuse, New York, United States, 2. RTI International, Washington, District of Columbia, United States*

Home-delivered meals supported by the Older Americans Act (OAA) serve a dual purpose of improving nutritional intake and providing regular social contact for older adults. This regular contact can increase feelings of safety experienced by meal recipients. The benefits of home-delivered meal services may vary between meal recipients based on sociodemographic characteristics. Variation in home-delivered meal clients' reports of feeling safer at home because of regular meal delivery visits was examined to support ongoing efforts to increase social engagement and equity through the delivery of OAA services. Using data from the 2019 National Survey of Older Americans Act Participants (NSOAAP) home-delivered meal module, descriptive statistics and logistic regression were conducted to identify the characteristics associated with feeling safer at home because of meal delivery visits. The majority (85%) of meal recipients report feeling safer because of meal delivery visits, and rates were especially high for rural recipients (92%), those with a high school education or less (89%),racial/ethnic minorities (94%), and those with three or more ADL limitations (90%). Logistic regression found that rural residence (OR=3.3), lower educational attainment (OR=2.0), racial/ethnic minority status (OR=4.7), living alone (OR=1.6), and having 3+ ADLs (OR=1.9) were significantly associated with higher odds of feeling safer at home because of meal delivery visits; however, age, gender, and suburban residence were not significant. Findings suggest that benefits of home-delivered meal programs are supporting the needs of traditionally disadvantaged groups and broadly increasing meal recipients' sense of safety in their homes.

LINKING DISADVANTAGED HEALTHCARE PATIENTS TO HOME- AND COMMUNITY-BASED SERVICES: CAN NEEDS BE MET?

Farida Ejaz, Miriam Rose, and Courtney Reynolds, *Benjamin Rose Institute on Aging, Cleveland, Ohio, United States*

As part of a larger study examining the social determinants of health, the current analysis focuses on 254 older and disabled, Medicare Advantage patients from 19 primary care clinics in Texas. The patients faced challenges such as depression, limitations in activities of daily living (ADL) and dementia. They received a home-based, social work intervention to examine their needs, an individualized care plan was created, they were offered home and community-based services, and followed over a four-month period. The median age of the sample was 69 years, 71% were Hispanic/Latino, 80% had a high school education or less, and 76% had a monthly income of less than $1,361. A total of 823 needs were identified in these patients, and 1,126 service recommendations were made. Some needs required more than one service recommendation or vice versa. The most frequently identified needs involved food assistance (136 patients received 220 nutritional service recommendations), home modifications/housing (118 patients offered 159 services), and ADLs (115 patients, 147 services). During the four-month period, social workers reported that services related to food assistance met patient needs 61% of the time; 52% for home modifications/housing; and 75% for ADLs. Reasons for unmet needs included service applications still in process/waiting lists; services being unavailable (e.g., lack of mental health providers); and refusals by patients, and family/friends. Practice and policy implications include the possibility that four months is not enough time to fully address needs, and some patients may need more intensive assistance and motivation to apply for and access services

SESSION 4780 (SYMPOSIUM)

HOME HEALTHCARE ACCESS AND UTILIZATION AMONG VULNERABLE POPULATIONS IN THE US AND PUERTO RICO

Chair: Maricruz Rivera-Hernandez

Home health (HH) care utilization among Medicare beneficiaries has exploded, serving over 3.3 million users (The Medicare Payment Advisory Commission, 2021). With the aging of the population and the preference for Home- and Community-Based Services and/or person-centered care delivered in the home, HH care use is expected to continue increasing. Prior research has highlighted inequitable access and use of HH rooted in structural and social determinants of health (Fashaw-Walters et al., 2022). However, more research is needed about disparities in timely access to quality of care and outcomes among racial and ethnic and rural populations. Furthermore, the literature regarding post-acute care has often excluded Puerto Rico HH beneficiaries (Rivera-Hernandez et al., 2020). Given the need to ensure equity of care post-pandemic, there is a pressing need to understand disparities in care and outcomes, specifically using representative data. This symposium will feature four presentations that provide novel insight regarding HH care utilization and outcomes among vulnerable populations. Individual presentations will describe 1) Home health care services utilization among Medicare beneficiaries in Puerto Rico; 2) Public reporting role in exacerbating disparities in access; 3) Differences in home healthcare latency following hospitalization for ADRD patients by race/ethnicity and rural and urban locations; 4) Racial disparity in the start of home healthcare in high-risk ADRD patients by the quality of home health and impact on rehospitalization. In addition, studies in this panel will discuss policy and clinical implications, as well as directions for future research regarding equitable access and health outcomes among HH users.

THE IMPACT OF PUBLIC REPORTING ON INEQUITIES IN HIGH-QUALITY HOME HEALTH UTILIZATION

Shekinah Fashaw-Walters[1], Momotazur Rahman[2], Gilbert Gee[3], Vincent Mor[2], and Kali Thomas[2], *1. University of Minnesota School of Public Health, Minneapolis, Minnesota, United States, 2. Brown University, Providence, Rhode Island, United States, 3. UCLA, Los Angeles, California, United States*

Literature suggests that public reporting of quality may exacerbate disparities in access to high-quality post-acute and long-term care for older adults. The objective of this study was to evaluate the impact of the home health (HH) 5-star ratings on changes in high-quality HH agency (HHA) use, by race, ethnicity, income level, and place-based factors. Using a difference-in-differences framework, we found that after introduction of 5-star ratings adjusted rates of high-quality HHA use increased for all HH users, except for Latinx, Asian American/Pacific Islander, and low-income HH users, and disparities in access to high-quality HHAs were exacerbated for each of these groups. Last, we found that users within predominantly Latinx and lower income neighborhoods had a significantly greater decrease in their use of high-quality HHAs. Policymakers should be aware of the potential unintended consequences of public reporting and should consider adding measures of equity to the publicly reported information.

RACE AND RURAL-URBAN DIFFERENCES IN HOME HEALTHCARE LATENCY IN PATIENTS WITH DEMENTIA

Amit Kumar, *Northern Arizona University, Flagstaff, Arizona, United States*

Given the need to ensure equity of timely access to post-acute care among minority groups in rural areas, there is a pressing need to understand disparities in the start of home healthcare among minorities with Alzheimer's disease and Related Dementia (ADRD). This study investigates differences in the timing of initiation of home healthcare services following acute hospitalization for ADRD patients by race/ethnicity and rural and urban locations. A secondary analysis was conducted among older adults with ADRD using Medicare data, discharged to home following an episode of acute hospitalization in 2016-2017. The study outcome was a delay in the start of home healthcare after two days of hospital discharge, defined as a home health latency. Compared to non-Hispanic Whites residing in urban areas, Blacks living in urban areas and Hispanics living in rural areas have a significantly higher odd of home health latency 1.15 (95%CI;1.11-1.18) and 1.06 (95%CI;1.02-1.10), respectively.

RACIAL DISPARITY IN THE START OF HOME HEALTHCARE IN HIGH-RISK ADRD PATIENTS BY THE QUALITY OF HOME HEALTH

Indrakshi Roy, *Northern Arizona University, FLAGSTAFF, Arizona, United States*

Improving the quality and timely access of home health care is a new quality measure and particularly crucial in high-risk ADRD adults following hospitalization. However, a significant portion of older patients waits longer than 2 days to receive home healthcare. In this study, we examine how the quality of home health agency and race are associated with the delay in care among ADRD patients receiving home healthcare and how this delay mitigates the risk of rehospitalization. We find that Black patients in low rated home health agencies have 28% higher odds of delay in care compared to White patients in high rated home health agencies (Odds ratio (95% CI) =1.28 (1.21 - 1.36)). Timely initiation of home health care also reduces the risk of rehospitalization in minority older adults with ADRD.

SESSION 4790 (SYMPOSIUM)

INNOVATIONS IN REMOTE SUPPORT FOR DEMENTIA FAMILY CAREGIVERS

Chair: Kylie Meyer Co-Chair: Lyndsey Miller Discussant: Jeffrey Kaye

Remote delivery of dementia caregiver interventions can decrease delivery costs, and make it more feasible to provide evidence-based interventions to caregivers across the country. As the science behind remote delivery develops, new technologies and their applications can ensure preservation of important intervention components and principles, as well as novel forms of data collection. In this symposium, investigators will present on studies that demonstrate how technology can be used to improve delivery and assessment of remote caregiver interventions. Walter Dawson, D.Phil, will share findings from the Support via Technology: Living and Learning with Advancing Alzheimer's disease and related dementia (STELLA) intervention. Using secondary data collected via weekly survey, he examined the association between costs of care and behavioral symptoms of dementia. Next, Allison Gibson, PhD, MSW, will present results from focus groups about caregivers' experiences of the Harmony at HOME (H@H), a telehealth intervention to improve person-environment fit and limit behavioral symptoms of dementia. Kylie Meyer, PhD, will present results from the Learning Skills Together intervention, which uses teleconferencing to teach family caregivers how to provide complex care tasks while adhering to self-efficacy theory. Lastly, Shirin Hiatt, MPH, MS, RN, will present findings from the REmote Assessment and Dynamic Response (READyR) study, which tests the application of remote monitoring technology to assess adherence to value-based care (e.g., autonomy) among spousal family care partners. Each study was supported by the Emory University Roybal Center for Dementia Caregiving Mastery or Oregon Roybal Center for Care Support Translational Research Advantaged by Integrating Technology.

STICK TO THE THEORY: FINDINGS FROM A COMPLEX CARE INTERVENTION FOLLOWING TRANSITION TO DIGITAL DELIVERY

Kylie Meyer[1], and Carole White[2], *1. Case Western Reserve University, Cleveland, Ohio, United States, 2. UT Health San Antonio, San Antonio, Texas, United States*

Two thirds of family caregivers to persons living with dementia provide complex care tasks, including medical/nursing tasks, and nearly half worry about making a mistake. Learning Skills Together (LST) was designed to prepare caregivers to provide complex care through hands-on instruction (e.g., practice using a gait belt). Consistent with self-efficacy theory, the in-person intervention integrated behavioral modeling, strengths-based feedback, and knowledge-building. COVID-19 prompted a transition to digital delivery of LST over Zoom. Intervention content was modified to accommodate a digital approach while continuing to adhere to self-efficacy theory. Results from a pre- and post-test pilot study (N=35) indicate improvement in self-efficacy on (mean difference (MD)=1.0, SD= 1.6, p-value=0.004). Caregiver comments during qualitative interviews affirm intervention objectives were met. For example, caregivers described the importance of peer learning (modeling) during discussion. Results indicate that complex care intervention can be digitally delivered to family caregivers to improve self-efficacy surrounding complex care.

THE READYR PROGRAM'S INTERIM FEASIBILITY, ACCEPTABILITY, AND EFFECTS ON VALUES-BASED CARE AND RELATIONSHIP QUALITY

Shirin Hiatt[1], Joel Steele[2], Chao-Yi Wu[1], and Lyndsey Miller[1], *1. Oregon Health & Science University, Portland, Oregon, United States, 2. Portland State University, Portland, Oregon, United States*

This study evaluated preliminary feasibility, acceptability and efficacy of the READyR program, a remote intervention for early stage dementia dyads designed to assess and address values-based care and relationship quality. Measures of program acceptability, preparation for future care, and relationship quality were examined pre- and post-intervention. Feasibility was high among the first 10 enrolled dyads who completed phase 1: 39 out of 40 sessions were completed with 100% retention. Acceptability was also high with nearly 95% reporting that participation was easy and that they would recommend it to others. Insufficient time was the only critique reported by 17%. Medium/large effects were found in improvements to positive interactions (d=-0.71 95%CI [-1.34-.00]), relationship strain (d=0.53 95%CI [.-.15-1.18]), and awareness (d=-0.91 95%CI [-1.64- -0.15]) and avoidance (d=-0.53 95%CI [-1.18-.15]) of preparation for future care needs. The READyR program shows preliminary feasibility, acceptability, and efficacy in improving values-based care and relationship quality remotely.

INCREASING DEMENTIA CARE MASTERY FOR RURAL CAREGIVERS: LESSONS FROM ADAPTING THE HARMONY @ HOME INTERVENTION

Allison Gibson[1], Laura Henley[2], Vickie Fairchild[3], David Goss[3], Carolyn Baum[4], Gregory Jicha[1], and Elizabeth Rhodus[1], *1. University of Kentucky, Lexington, Kentucky, United States, 2. HealthPRO Heritage, Louisville, Kentucky, United States, 3. Northeast AHEC, St. Clair Healthcare, Morehead, Kentucky, United States, 4. Washington University School of Medicine in St. Louis, St. Louis, Missouri, United States*

Providing care support to rural Alzheimer's disease and related dementia (ADRD) caregivers has always been challenging, but particularly with the COVID-19 pandemic, new barriers have emerged for families in accessing care support. Delivered via telehealth, Harmony at HOME (H@H) provides dementia care mastery for caregivers of persons with ADRD in the skills of assessing and modifying the home environment to promote "person-environment fit," whereby increasing functional activity engagement and minimizing maladaptive behaviors. To enhance care supports specific to the needs of rural communities, this study reports the findings of two focus groups with rural caregivers who participated in the H@H intervention. Focus groups were aimed to identify the needs of caregivers in rural communities to guide adaptation approaches for future implementation of the H@H intervention in these underserved areas. Additional studies to assess real-world efficacy of the adaptations to H@H are needed as a next step toward implementing this intervention in clinical, home care settings.

WHAT DO 'BEHAVIORS" COST? UNDERSTANDING COSTS IN DEMENTIA CARE PARTNER-BASED RESEARCH

Walter Dawson[1], Sarah Gothard[1], Nora Mattek[2], Jeffrey Kaye[1], and Allison Lindauer[1], *1. Oregon Health & Science University, Portland, Oregon, United States, 2. Oregon Health and Science University, Portland, Oregon, United States*

The out-of-pocket costs to care for individuals living with dementia are high, and is exacerbated by the expense of managing behavioral and psychological symptoms of dementia (BPSD) (e.g., depression, irritability). STELLA (Support via TEchnology: Living and Learning with Advancing AD) is a telehealth-based intervention that provides a personalized approach to teach care partners (CPs) strategies to manage BPSD. To understand the relationship between BPSDs and costs, weekly surveys were administered to CPs (n=12). Surveys asked about out-of-pocket costs incurred from: hospitalizations and emergency department (ED) utilization, primary care visits, use of paid in-home care, prescription drugs, and over-the-counter medications. The most frequent cost reported by CPs was prescription drug related (11 CPs), while costs associated with hospitalizations and ED were the least frequently reported (4 CPs). A longitudinal weekly survey-based approach to quantify CP costs is a novel approach examine an intervention outcome (cost) that matters to families and policymakers.

SESSION 4800 (SYMPOSIUM)

NOVEL BEHAVIORAL INTERVENTIONS TARGETING COGNITIVE-MOTOR NEUROPLASTICITY IN OLDER ADULTS

Chair: Tanvi Bhatt Co-Chair: Susan Hughes Discussant: Susan Hughes

Comparatively little is known about the ability of physical activity to improve or maintain cognitive function in older adults. Our Midwest Roybal Center uses social/behavioral theory to promote engagement in physical activity in order to improve this outcome. In 2019, we received funding to establish a Multimodal Connectomics Core that enabled investigators to examine concurrent changes in cognitive function and brain connectivity by providing access to fMRI imaging. The Connectomics Core enabled investigators for the first time to examine cognitive function and changes in brain connectivity simultaneously by providing access to fMRI imaging as well as MRI data storage and data analysis. It enabled measuring of standardized participant outcomes selected from the NIH toolbox. This Symposium describes findings from the first three completed pilots and discusses their implications for the field. The first pilot by Bronas examined effect of a 6-month home-based walking program in people chronic kidney disease on cognitive function and intervention induced neuroplasticity compared to usual care. The second pilot by Marquez adapted the Fit & Strong! program to test the combined impact of physical activity and interactive health education for managing mood on cognitive function among older adults with depression. The third pilot by Bhatt examined the effectiveness of 4 weeks of exergaming combined explicit cognitive training on behavioral measures of fall-risk (physical and cognitive) and their associations with brain integrity measures. The discussant will initiate discussion based on outcomes of these pilots and future directions for developing them into larger studies or clinical translation.

DUAL-TASK TRAINING FOR IMPROVING COGNITIVE-MOTOR INTERFERENCE

Tanvi bhatt[1], and Lakshmi Kannan[2], *1. University of Illinois at Chicago, Chicago,, Illinois, United States,*
2. University of Illinois at Chicago, Chicago, Illinois, United States

Dr. Bhatt will discuss the differences in types of cognitive motor interference patterns experienced for different tasks (gaitand volitional versus reactive balance) in cognitively intact versus people with mild cognitive impairment. She will discuss the effectiveness of dual-task training and exergaming on gait, volitional and reactive balance control in older adults with mild cognitive impairment. After 4 weeks of such training, the results showed beneficial effects on improving volitional based performance when performed with a cognitive task (i.e., spatial memory and executive function) and had significant improvement in NIH toolbox (cognitive- increased working memory, episodic memory and executive function, and motor-increased gait speed). However, its positive effects on dual task reactive balance control were limited. Additionally, the speaker will go on to discuss the associations of balance control deficits in mild cognitive impairment with neural correlates (structural and functional brain integrity) to understand the attributing factors to increased fall risk in people with mild cognitive impairment.

ENHANCING WELL-BEING THROUGH EXERCISE DURING OLDER AGE

David Marquez, *University of Illinois Chicago, Chicago, Illinois, United States*

Dr. Marquez's Roybal pilot Enhancing Well-Being Through Exercise During Older Age piloted an adaptation of a group exercise evidence-based program for people with arthritis symptoms, Fit & Strong!, that included education on emotional wellbeing and mental health. The pilot used a waitlist design to test the 8-week program among Black residents reporting depressive symptoms living in a senior housing facility. A battery of physical, emotional, and cognitive outcomes were collected pre and post intervention and a subset of participants (n=11) received MRIs pre and post. The sample included 28 participants (n=13 intervention, n=15 waitlist) who had a mean age of 69.8, were 89% female, reported a mean of 3.6 chronic conditions, and an average WOMAC pain score of 5.7 (moderate pain). Though under-powered, analyses show greater improvements in key physical activity and cognitive domains among the intervention group compared to the waitlist group.

EFFECT OF A 6-MONTH HOME-BASED WALKING PROGRAM ON COGNITIVE FITNESS IN OLDER ADULTS WITH CHRONIC KIDNEY DISEASE

Ulf Bronas, *University of Illinois Chicago, Chicago, Illinois, United States*

We have previously demonstrated that cognitive status and white matter integrity are highly associated with physical fitness in older adult patients with chronic kidney disease (CKD). We present data from a two group RCT determining effect of a 6-month home-based walking intervention on physical and cognitive fitness compared to usual care. The intervention included use of a wearable activity monitor, weekly didactic phone meetings, interactive tools and monthly coach-delivered feedback. The intervention group had a 78% compliance rate to the 6-month exercise program (159.9 (149.2) minutes/week). Executive function composite score and global cognitive for intervention group > than control group. Additionally, global white matter integrity and functional connectivity improved in the intervention group and declined in the usual care group. We conclude that a home-based physical activity intervention can have significant improvement on cognitive health and neuroplasticity in older adults with CKD and lowering their risk of developing AD/ADRD

SESSION 4810 (SYMPOSIUM)

NOVEL GENOMIC AND EXCEPTIONAL LONGEVITY FINDINGS FROM THE LONG LIFE FAMILY STUDY

Chair: Mary Wojczynski Co-Chair: Nancy W. Glynn
Discussant: Evan Hadley

The Long Life Family Study (LLFS), funded by the National Institute on Aging, is an international collaborative study of the genetics and familial components of exceptional longevity and healthy aging. We phenotyped 4,953 individuals from 539 two-generational families (1,727 proband; 3,226 offspring) at baseline (2006-2009). A second visit (2014-2017) was conducted for 2,904 (478 proband; 2,426 offspring) participants. The longitudinal, comprehensive in-person visits measured domains of healthy aging, including physical performance, cognition, and blood markers. Extensive genetic analyses were performed using the baseline blood draw, including genotyping with the Illumina 2.5M Human Omni array, linkage analyses with the families, whole genome sequencing using the TopMED protocol, and metabolomic assays. Collectively, this symposium will present novel findings that examined differences in end of life events and cause of death between non-exceptional and exceptional long-lived women, elucidate potential rare variants associated with exceptional longevity, and examine new potential metabolomics pathways involved in gait speed and cardiovascular disease. Specifically, Dr. Galvin will share results from three Danish nationwide studies (including LLFS) on different end of life events in long-lived female siblings. Then, Dr. Gurinovich will share findings on new uncommon variants associated with extreme longevity. Next, Dr. Kuipers will discuss associations between lipid metabolomics and vascular health. Lastly, Dr. Santanasto will discuss lipid metabolomics associated with lower odds of slow gait speed. Dr. Evan Hadley, NIA, will be the discussant and will share insights and propose future directions for LLFS.

END-OF-LIFE EVENTS AND CAUSES OF DEATH IN DANISH LONG-LIVED FEMALE SIBLINGS

Angeline Galvin[1], Svetlana Ukraintseva[2], Konstantin Arbeev[2], Mary Feitosa[3], Anne Newman[4], and Kaare Christensen[5], *1. University of Southern Denmark, Odense, Syddanmark, Denmark, 2. Duke University, Durham, North Carolina, United States, 3. Washington University, St Louis, Missouri, United States, 4. University of Pittsburgh, Pittsburgh, Pennsylvania, United States, 5. Southern Denmark University, Odense, Syddanmark, Denmark*

Long-lived siblings have better health and survival compared to "sporadic" long-lived individuals, but it is unknown whether they also differ in end-of-life events and causes of death. Deceased Danish long-lived female siblings (n=833, mean age at death=95.6) were identified through national health registers compared to controls matched on sex, year-of-birth, and year-of-death. End-of-life events (hospitalizations, emergency room visits, medication within the five years before death) and causes of death were analyzed using linear models with fixed effects and multinomial logistic models, respectively. End-of-life events and causes of death were not statistically significantly different between long-lived female siblings and "sporadic" long-lived individuals. However, long-lived female siblings presented non-significant higher risk of ischemic heart disease and cancer – and lower risk of mental diseases and accidents. The analyses will be extended to include men, a longer follow-up, and focus on dementia in the last years of life.

GENOME-WIDE ASSOCIATION STUDY OF EXTREME LONGEVITY USING WHOLE-GENOME SEQUENCING DATA

Anastasia Gurinovich[1], Harold Bae[2], Zeyuan Song[3], Anastasia Leshchyk[3], Mengze Li[3], Stacy Andersen[4], Thomas Perls[3], and Paola Sebastiani[1], *1. Tufts Medical Center, Boston, Massachusetts, United States, 2. Oregon State University, Corvallis, Oregon, United States, 3. Boston University, Boston, Massachusetts, United States, 4. Boston University School of Medicine, Boston, Massachusetts, United States*

Extreme longevity (EL) runs in families which supports the hypothesis that this is a genetically regulated trait. However, with the exception of APOE, genome-wide association studies (GWAS) of EL have not identified many genetic variants that replicate in independent studies. The majority of GWAS of EL have used imputed genotype data. Recently, the Long Life Family Study has generated the largest whole-genome sequencing data of centenarians and matched controls. We perform single-variant and gene-based tests of EL in these data using the nf-gwas-pipeline with the saddle point approximation adjustment of the p-values. These analyses suggest that, in addition to the APOE/TOMM40 region, some uncommon variants of GRM7 (chr3), AUTS2 (chr7), KIF13B (chr8), SLC2A14 (chr12), and ADCY9 (chr16) genes, and other intergenic SNPs in chromosomes 5, 10, and 20 may be implicated with EL.

ASSOCIATION OF PLASMA LIPID METABOLITES WITH ANKLE-BRACHIAL INDEX IN THE LONG LIFE FAMILY STUDY

Allison Kuipers[1], Ryan Cvejkus[1], Bharat Thyagarajan[2], Gary Patti[3], Mary Feitosa[4], Jonas Mengel-From[5], Emma Barinas-Mitchell[1], and Joseph Zmuda[1], *1. University of Pittsburgh, Pittsburgh, Pennsylvania, United States, 2. University of Minnesota Twin Cities, MINNEAPOLIS, Minnesota, United States, 3. Washington University, Department of Chemistry, Genetics, and Medicine, St. Louis, Missouri, United States,* *4. Washington University, St Louis, Missouri, United States, 5. University of Southern Denmark, Odense, Syddanmark, Denmark*

We tested the association of lipid metabolites with ankle-brachial index (ABI) in the LLFS. Minimum ABI from doppler was used. Participants underwent phlebotomy after >8 hours fasting. Plasma metabolites were isolated via solid phase extraction. Lipid metabolites (N=193) were measured using RPLC-MS and corrected for batch effects in 948 participants. We used linear mixed models adjusted for age, sex, site, fasting, and relatedness. Twenty metabolites were associated with ABI (FDR P<0.05), of which 17/20 were triacyclglycerol (TAG) species, plus cholesterol ester (22:6), phosphatidylcholine (35:7), and phosphatidylethanolamine (38:7). After additional adjustment for traditional ABI risk factors, only two TAGs (50:1, 42:0) were significantly associated after multiple testing correction. While not significant in the base model, the metabolite lysophosphatidylcholine (18:3) demonstrated a marginally significant protective association after full adjustment (P=0.014). While triglycerides are known correlates of atherosclerotic deposition, these findings may identify novel metabolic correlates of peripheral vascular health in long-lived individuals.

LIPIDOMIC ANALYSIS OF GAIT SPEED IN THE LONG LIFE FAMILY STUDY

Adam Santanasto[1], Mary Fiestosa[2], Michael Lustgarten[3], Kaare Christensen[4], Gary Patti[5], Joseph Zmuda[1], Ryan Cvejkus[1], and Mary Wojczynski[5], *1. School of Public Health, University of Pittsburgh, Oakmont, Pennsylvania, United States, 2. Washington University School of Medicine in St. Louis, St. Louis, Missouri, United States, 3. Tufts University, Boston, Massachusetts, United States, 4. Southern Denmark University, Odense, Syddanmark, Denmark, 5. Washington University in St. Louis, St. Louis, Missouri, United States*

Gait speed is a predictor of overall health and mortality in older adults. Metabolomics may provide insights into biological mechanisms underlying gait speed. Herein, we examined the association between 193 lipid metabolites with gait speed in 1,717 adults (52.1% women) aged 82.0 ± 14.5. Lipidomic analysis was performed using liquid chromatography-mass spectrometry. Gait speed was measured over 4-meters and slowness was defined as <0.8m/s. Logistic regression, adjusted for age, sex, field center, height, fasting-duration and familial-relatedness, were used to examine the association between log-transformed metabolites with slowness. A false discovery rate (FDR) of p<0.05 was employed to account for multiple comparisons. Gait speed was 0.83 ± 0.32 and 53.4% had slowness. Three lipid metabolites were significantly associated with lower odds of slowness: an acylcarnitine, sphingomyelin and a ceramide non-hydroxy fatty acid-sphingosine. Our results potentially link lipids involved with mitochondrial beta-oxidation and nerve signal transduction to gait speed in older adults.

SESSION 4820 (PAPER)

NURSING HOME RESOURCES, PATTERNS OF CARE DURING THE PANDEMIC, AND QUALITY

DOES FIVE-STAR QUALITY RATING MATTER FOR NURSING HOME QUALITY DURING THE COVID-19 PANDEMIC?

Lei Yu, Xiao Qiu, and Na Sun, *Miami University, Oxford, Ohio, United States*

Objectives Nursing homes (NH) confronted tremendous difficulties considering confirmed residents Covid-19 cases and deaths in the U.S. The Centers for Medicare & Medicaid Services (CMS) applies the Five-Star Quality Rating (FSQR) to indicate the quality of care in nursing homes based on health inspection surveys, staffing as well as care process and resident outcomes during the COVID-19 pandemic. This study aims to examine whether FSQR was related to the total number of NH resident Covid-19 cases and deaths.Design This study analyzed 6,978 nursing homes across the country with data from CMS Nursing Home Compare, CMS COVID-19 Nursing Home Public File, Long-term Care Focus, Payroll Based Journal, Rural-Urban Commuting Area. Negative binomial regressions were used to investigate associations between FSQR and NH COIVD-19 outcomes controlling for state fixed effects and clustering of nursing homes within counties. The characteristics of facility, residents, payer-mix, nursing staff, and geographic location were also controlled. ResultsComparing to NH with 1-star in Health Inspection, Staffing, or Overall ratings, NH with better performance have lower risk of having increased number of COVID cases and deaths among residents. Further, nursing home Quality Measures rating is not significantly associated with residents' COVID-19 deaths. ConclusionOverall, the FSQR is a useful measure of quality in part when investigating NH's performance during the COVID-19 pandemic. Future policymakers should pay special attention to providers performing poorly in FSQR when improving the quality of nursing homes, particularly regarding infection control.

HOSPICE UTILIZATION AMONG LONG-STAY NURSING HOME RESIDENTS DURING THE COVID-19 PANDEMIC

Xiao (Joyce) Wang[1], Emma Belanger[1], Kali Thomas[1], Debra Dobbs[2], and David Dosa[1], *1. Brown University, Providence, Rhode Island, United States, 2. University of South Florida, Tampa, Florida, United States*

Background: The COVID-19 pandemic has had significant impacts on nursing home residents. This study aims to examine how hospice utilization changed among long-stay nursing home residents between January and September in 2020, as compared with the same period in 2019, nationally. Design: A retrospective cohort study of residents present in US nursing homes as long-stay as of January 1st, 2019 and 2020, respectively. A subgroup of residents who died from January to September in each year was also examined. We utilized the Minimum Data and multiple administrative claims data. We compared hospice utilization rate between 2019 and 2020 nationally and by state. Outcomes: This study examined: 1) any hospice utilization among long-stay residents from January to September in 2019 and 2020 respectively, and 2) hospice utilization in the last 30 days of life among the decedent subgroup, which we also tracked as a factor of percent change in mortality rate at the state level.

Results: The hospice utilization rate among long-stay residents was 19.4% in 2019 and 19.7% in 2020. The rate was 27.5% in 2019 and 24.2% in 2020 among the decedent subgroup ($\chi 2=553.1$, $p< 0.001$), although the absolute number of decedents using hospice in the last 30 days of life was higher in 2020 than 2019. Substantial state variation in hospice utilization was observed, mostly following patterns in community-level infections.

Conclusions: Hospice managed to continue service delivery despite many challenges. The pandemic highlights the importance of integrating hospice and palliative care into emergency preparedness planning.

NORTH CAROLINA NURSING HOME AND PUBLIC HEALTH RESILIENCE DURING 2021 OF THE COVID-19 PANDEMIC

Sandi Lane, Trent Spaulding, Adam Hege, Maggie Sugg, and Lakshmi Iyer, *Appalachian State University, Boone, North Carolina, United States*

Since the onset of the COVID-19 pandemic many healthcare organizations have operated in a climate of uncertainty. Building resilience is one method used to survive and thrive during periods of uncertainty. Measuring an organization's resilience (ability to prepare for, respond and adapt during time of change) allows the organization to identify its vulnerabilities and set priorities to avert negative outcomes during an untoward event. Through collaboration with four long-term care professional associations, the Benchmark Resilience Tool (BRT-13) resilience survey was disseminated to North Carolina long-term care leaders in April 2021. The BRT-13 survey was also sent to North Carolina public health officials via email during the same timeframe. The BRT-13 contains 13 resilience (RES) items divided into two factors of adaptive capacity (AC) and planning (PL) on a five-point Likert scale of strongly disagree (1) to strongly agree (5). Organizational factors surveyed included type of facility, rural-urban classification area designation, ownership type, level of debt, level of profitability, and employee satisfaction. A total of 142 completed surveys were received, 101 (71%) from long-term care leaders and 41 (28.9%) from Public Health officials. Overall average resilience scores ranged from 3.96 for public health respondents to 4.46 for continuing care retirement communities (CCRC) respondents. Analysis of Variance (ANOVA) was employed to compare the three factors (AC, PL, and RES) to the organizational factors. Resilience was significantly associated with one factor, employee satisfaction. Our findings indicate that organizations can build resilience through processes that contribute to staff satisfaction.

REFRAME, REFORM, AND TRANSFORM: POLICY APPROACHES TO IMPROVE NURSING HOME QUALITY IN THE UNITED STATES

Angela Perone, *University of California - Berkeley, Berkeley, California, United States*

Nursing homes (NHs) are one of the most heavily regulated industries in the United States. However, concerns about quality of care remain, especially for more vulnerable residents, including those with dementia. Concerns only increased during recent natural disasters and the COVID-19 pandemic. Community and industry advocates have suggested diverse reforms that prompted new federal policies. This study poses the following research questions: (1) How do federal policies compare with proposals by community (staff and patient advocates) and industry (NH) advocates to improve quality of care in NHs before and during the pandemic; and (2) How do federal policies address micro, mezzo, and macro level issues? To address these questions, this study employs a multi-level comparison case study design. Primary data includes systematically collected and analyzed federal bills, CMS regulations, and community and industry reports, press releases, and website data from 2018 through 2022. Findings revealed that policy proposals fell into three categories: reframe, reform, and transform. Reframe approaches included minimal transformation at the micro-level. Reform approaches involved more mezzo and macro-level changes. Transform approaches proposed significant structural changes at the macro-level. Community advocates presented far more transformative changes than industry advocates and federal policymakers. Federal policies focused on reframe and reform solutions at the micro level and rarely proposed transforming macro-level structures (e.g., workforce structural inequities). This study has important implications for research, policy, and practice by exposing limitations and strengths of proposed solutions for addressing resident care and concludes with suggestions for better aligning with community advocates.

THE IMPACT OF SOCIAL DEPRIVATION ON COVID-19 INFECTIONS IN NURSING HOMES

Robert Weech-Maldonado[1], Justin Lord[2], Ganisher Davlyatov[3], Akbar Ghiasi[4], and Gregory Orewa[1], *1. University of Alabama at Birmingham, Birmingham, Alabama, United States, 2. Louisiana State University at Shreveport, Bossier City, Louisiana, United States, 3. University of Oklahoma, Oklahoma City, Oklahoma, United States, 4. University of the Incarnate Word, San Antonio, Texas, United States*

Health inequities vary along social and economic gradients. The COVID-19 pandemic and nursing home infections have highlighted this fact. Using the Centers for Medicare and Medicaid Services' Nursing Home COVID-19 Public File, Brown University's LTCFocus, Robert Graham Center's Social Deprivation Index, and CMS Nursing Home Payroll Based Journal Staffing Data. We examined the relationship between community resource scarcity, as conceptualized by the Social Deprivation Index (SD) and COVID-19 incidence rates in nursing homes. After controlling for interstate differences, organizational enabling factors, as well as, facility-level resident and community-level characteristics, nursing homes located in communities with medium levels of social deprivation had 4.4% more COVID-19 infection rates (Incidence Rate Ratio [IRR] = 1.04; $p < 0.05$) and communities with high levels of social deprivation had 7.5% higher COVID-19 infection rates (Incidence Rate Ratio [IRR] = 1.07; $p < 0.01$) as compared to nursing facilities located in areas of low social deprivation. From a policy perspective, nursing homes, that are located in socially deprived communities, may need additional resources, such as, funding for staffing and personal protective equipment in the face of the pandemic. The COVID-19 pandemic has sharpened the focus on healthcare disparities and societal inequalities in the delivery of long-term care.

SESSION 4830 (SYMPOSIUM)

NURSING HOME SOCIAL SERVICES DIRECTORS' ROLE AND RESPONSIBILITIES

Chair: Mercedes Bern-Klug Discussant: Colleen Galambos

While most of the nursing home literature focuses on residents and nurses, there is a growing literature on social services staff and family members of nursing home residents. Social services staff include social workers as well as non-social workers with responsibility for assessing and care planning for resident psychosocial issues, as well as a host of other responsibilities including working with families. This symposium presents findings from the National Nursing Home Social Services Directors Survey (NNHSSDS), a cross-sectional (2019) nationally representative study (n=924) that collected data on social services staff characteristics, departmental role responsibilities, and training needs. In this session three papers developed from these data are presented to document the extent to which social services staff are involved with family members, their interest in receiving training on how they can support other staff in understanding resident abuse and exploitation (at the hands of family, fellow residents, or staff), and neglect. As demanding as the social services role is, many holding the position of social services director report they are thriving (not just surviving) in the role. A final paper describes which variables help to distinguish those who report they are thriving versus those who do not. Implications to be discussed include what administrators could do to make the social services director's job more attractive. The RRF Foundation for Aging provided data collection support for the NNHSSDS.

THRIVING OR SURVIVING? FACTORS ASSOCIATED WITH NURSING HOME SOCIAL SERVICE DIRECTORS REPORTING THRIVING AT WORK

Nancy Kusmaul[1], Mercedes Bern-Klug[2], Kevin Smith[3], and Dana Cheek[3], *1. University of Maryland Baltimore County, Baltimore, Maryland, United States, 2. University of Iowa, IOWA CITY, Iowa, United States, 3. University of Iowa, Iowa City, Iowa, United States*

Nursing homes (NHs) provide care to medically complex residents. Social services (SS) are primarily responsible for addressing residents' psychosocial needs. High staff turnover in nursing homes is a significant problem. When SS staff leave, training and experience goes with them. Much research has explored nursing staff turnover, far less about SS staff turnover. Social service workers who are thriving are more focused, innovative, and engaged. This study explored characteristics contributing to NH SS directors reporting thriving at work. We surveyed 924 NH SS directors from randomly selected nursing homes. Guided by Spreitzer's model, a hierarchical logistic regression was conducted utilizing unit contextual factors and individual agentic behaviors to examine likelihood of thriving. Unit contextual factors, i.e. being valued, feeling influence, and the NH providing quality care had the greatest influence on SS directors reporting thriving at work. These results suggest great potential for NHs to foster thriving in SS directors.

ELDER ABUSE TRAINING NEEDS AMONG NURSING HOME SOCIAL SERVICES DIRECTORS

Amy Roberts[1], Georgia Anetzberger[2], Kevin Smith[3], and Mercedes Bern-Klug[4], *1. Miami University, Oxford, Ohio, United States, 2. Case Western Reserve University, Cleveland, Ohio, United States, 3. University of Iowa, Iowa City, Iowa, United States, 4. University of Iowa, IOWA CITY, Iowa, United States*

This study aims to identify elder abuse training needs among social services directors. Using nationally representative data from the 2019 National Nursing Home Social Services Directors Survey, we found that approximately three-quarters of directors reported either a moderate or strong interest in receiving training in the following areas: (1) the types of abuse, neglect, and/or exploitation by staff, residents, family and/or other visitors…; (2) establishing trust with a resident and/or family member who feels mistreated by the nursing home or a staff member…; and (3) interacting with visitors whose behaviors are perceived as threatening to residents or staff. Hierarchical logistic regressions found significant associations between strong interest in each training topic and facility, department, and director characteristics. Additional training may enhance directors' skills in explaining basic information about elder abuse and supporting other staff with strategies to address elder abuse and difficult interpersonal dynamics among staff, residents, families, and visitors.

A DEGREE IN SOCIAL WORK INCREASES FAMILY ENGAGEMENT WITH THE SOCIAL SERVICES DEPARTMENT

Amy Roberts[1], Nancy Kusmaul[2], Amber Alaniz[3], and Mercedes Bern-Klug[4], *1. Miami University, Oxford, Ohio, United States, 2. University of Maryland Baltimore County, Baltimore, Maryland, United States, 3. University of Iowa, Iowa City, Iowa, United States, 4. University of Iowa, IOWA CITY, Iowa, United States*

This mixed-methods presentation will examine the role of social services directors in supporting the family members of nursing home residents. A logistic, hierarchical regression (n= 924) found a positive association between the social services director having a degree in social work and strong agreement with "family members regularly engage the expertise of the social services department." A qualitative analysis of written-in comments to the question, “What do you like about your job?” identified 234 comments that described directors’ view of the importance of working with and supporting families. A content analysis revealed that two types of support are provided to families, instrumental and emotional. Instrumental support includes connection to resources for adjustment, financial needs, and discharge planning. Emotional support includes activities such as helping people through transitions, and coping with grief and loss. Appropriately trained social services directors can offer different types of support and be valued resources for families.

SESSION 4840 (SYMPOSIUM)

POINT-OF-CARE TESTING FOR THE FRAILTY PHENOTYPE PREDICTS POSTSURGICAL OUTCOMES

Chair: Mamoun Mardini Co-Chair: Christopher Kaufmann

Frailty is a cornerstone in geriatric medicine and is known to be strongly associated with poor postsurgical outcomes. Fried and colleagues defined frailty as a syndrome with five interlinked components, including weakness, low energy, slow walking speed, decreased physical activity, and unintentional weight loss. Consequently, frailty could serve as a useful measure for the purposes of pre-probability risk assessment for clinical outcomes after a surgery. Electronic health records (EHR) are a rich source of information, and when harnessed appropriately, could provide a valid presurgical frailty screening metric and be used towards anticipating adverse postsurgical outcomes. The growing adoption of EHR in clinical settings can help in identifying patients in need of enhanced intervention to promote recovery following a surgery. However, to date, few studies have fully characterized how individual frailty components, as assessed in the clinic, could be a predictor of postsurgical outcomes. This symposium will examine how presence of frailty and its individual components predict three postsurgical clinical outcomes: length of stay, 30-day mortality, and discharge disposition. We will present data from a unique dataset of approximately 14,000 patients who underwent frailty assessment at the University of Florida-Health (UFHealth) presurgical clinic as part of their standard clinical evaluation. Our presentations will examine each frailty syndromic components and overall frailty as predictors of the outcomes of interest. Findings will demonstrate the utility of electronic health records data for the allocation of at-risk patients for poor postsurgical outcomes. Funding: UF Claude D. Pepper Older Americans Independence Center P30AG028740 and R01 AG055337.

IDENTIFYING THE FRAILTY COMPONENTS THAT ARE MOST IMPORTANT IN PREDICTING POSTSURGICAL OUTCOMES

Mamoun Mardini, Emily Smail, Patrick Tighe, Catherine Price, Christopher Kaufmann, and Todd Manini, *University of Florida, Gainesville, Florida, United States*

Presurgical frailty among patients is strongly associated with poor postsurgical outcomes. In the prior presentations of this symposium, we assessed the associations between each individual frailty syndromic component and three postsurgical outcomes. However, it remains unclear whether individual relationships remain after accounting for presence of the other components. In regression models that included all frailty components, demographic information, and medical history, results showed that weight loss and slow walking speed were significantly associated with length of stay and 30-day mortality, respectively. Of note, the odds of mortality in patients with slow walking speed was over three times higher than patients with normal walking speed. Lastly, weaker grip strength was strongly associated with discharge to more intensive care (vs. to home). These findings suggest that frailty screening should be universally applied before surgical procedures for better risk stratification.

IMPACT OF UNINTENTIONAL WEIGHT LOSS AND EXHAUSTION ON CLINICAL OUTCOMES FOLLOWING SURGERY

Christopher Kaufmann, Mamoun Mardini, Emily Smail, Patrick Tighe, Catherine Price, and Todd Manini, *University of Florida, Gainesville, Florida, United States*

For patients undergoing surgery, unintentional weight loss and exhaustion, two hallmarks of frailty, may be salient markers for identifying patients at risk for adverse postsurgical outcomes. This study examined how these frailty components impact postsurgical outcomes including length of stay, 30-day mortality, and discharge disposition. Patients with weight loss and exhaustion pre-surgery experienced greater length of stay, and higher odds of 30-day mortality as well as lower likelihood of being discharged home. After adjustment for confounders including age, sex, race, and disease history, the above results for the most part remained significant, although statistical significance was lost for 30-day mortality and some discharge dispositions. Results highlight importance of assessing frailty components to enhance surgical care in older adults.

LOW PHYSICAL ACTIVITY AND SLOW GAIT AS PREDICTORS OF POSTSURGICAL CLINICAL OUTCOMES

Emily Smail, Mamoun Mardini, Patrick Tighe, Catherine Price, Christopher Kaufmann, and Todd Manini, *University of Florida, Gainesville, Florida, United States*

Low physical activity and slow gait are independently associated with adverse health outcomes of aging (e.g., hospital readmission and mortality). The objective of this study was to build on current knowledge using presurgical indicators of frailty to predict postsurgical outcomes (i.e., length of stay, 30-day mortality, and discharge disposition). In a sample of over 8,900 patients, low physical activity and slow gait were both associated with a greater length of stay, higher odds of mortality, and lower odds of being discharged to home (vs. more intensive care). Associations remained significant for 30-day mortality and discharge disposition in fully adjusted models (adjusting for age, sex, race, and disease history). These results suggest that measuring movement-based presurgical markers of physical activity and slow gait may be useful for identifying patients at risk for poor postsurgical outcomes.

PRESURGICAL GRIP STRENGTH PREDICTS POSTSURGICAL OUTCOMES IN OLDER ADULTS

Todd Manini, Mamoun Mardini, Emily Smail, Patrick Tighe, Catherine Price, and Christopher Kaufmann, *University of Florida, Gainesville, Florida, United States*

Muscle weakness is a strong predictor of a myriad of health outcomes among older adults. However, measures of muscle strength are not incorporated in healthcare settings which is partly due to a lack of established clinical applicability. Maximal grip strength was measured in 11,668 older patients (73.2+/-6.0 yrs, 50.3% female) during a standard presurgical consultation. Each kilogram of maximal grip strength was associated with approximately 1-hour shorter length of stay. Patients categorized as having weak muscle strength according to sex-based norms had a higher 30-day post-surgery mortality than their non-weak counterparts (Odds Ratio: 2.5, p=0.002 after statistical adjustment of age, sex, race and disease history). Additionally, patients with weak muscle strength were less likely to be discharged home than patients without weakness (68.8% vs. 83.9% returning home, p<0.01). Grip strength is a consistent predictor of post-surgical outcomes that might be used to improve care management.

SESSION 4850 (SYMPOSIUM)

POSITIVE AFFECT IN DEMENTIA CARE DYADS

Chair: Joan Monin Discussant: Claudia Haase

Positive affect is important for physical health, well-being, and relationships. Yet, most studies of dementia care dyads have focused on negative outcomes, such as depression and caregiver burden. We present findings from studies that address this important research gap. The first two speakers present findings from actor partner interdependence models using secondary data from a randomized controlled trial of persons with early-stage dementia (PWD) and their spouses. Specifically, Dr. Monin will show that actor quality of life is significantly related to positive affect cross-sectionally, controlling for functional status of each partner and PWD behavioral symptoms. Ms. Piechota will present longitudinal findings demonstrating that when spouses were high in difficulty regulating emotions, the PWD's positive affect decreased over three months, controlling for intervention arm and covariates. The second two speakers will present findings from two different studies of persons living with behavioral-variant frontotemporal dementia (bvFTD), Alzheimer's disease (AD), and controls that engaged in laboratory conflict discussions. Dr. Brown will show that caregivers of individuals with bvFTD reported greater decreases in positive emotion across the discussion relative to caregivers of individuals with AD and language variants. She will also discuss how caregivers who reported greater decreases in positive emotion had higher levels of depressive symptoms, controlling for their partner's diagnosis and level of cognitive impairment. Finally, Dr. Chen will provide evidence that bvFTD caregivers had lower emotional well-being according to the SF-36 than AD caregivers and controls, and this effect was fully mediated by bvFTD caregivers' lower positive emotional connections.

ASSOCIATIONS BETWEEN HEALTH AND POSITIVE AFFECT IN SPOUSAL DEMENTIA CARE DYADS

Joan Monin[1], and Kalisha Bonds Johnson[2], *1. Yale School of Public Health, New Haven, Connecticut, United States, 2. Emory University, Atlanta, Georgia, United States*

Little is known about the conditions that foster greater positive affect in the daily lives of spousal dementia care dyads in the early stages of dementia. This study aimed to examine the extent to which multiple indicators of health, including activities of daily living needs, quality of life, and the person with dementia's behavioral symptoms were associated with each partner's positive affect in daily life. Using secondary baseline data from a randomized controlled trial testing a stress reduction intervention in 63 couples (N=126), we examined whether individuals' multiple health indicators were associated with their own positive affect (actor effects) and their partner's positive affect (partner effects). Actor partner interdependence model results showed that for both persons with dementia and spouses, actor quality of life was the greatest predictor of positive affect, controlling for all other actor and partner health indicators (β=.04, SE=.01, t(67.1)=3.36, p=.001).

EMOTION REGULATION AND POSITIVE AFFECT IN SPOUSAL DEMENTIA CARE DYADS

Amanda Piechota[1], Joshua Novak[2], Thi Vu[3], and Joan Monin[1], *1. Yale School of Public Health, New Haven, Connecticut, United States, 2. Auburn University, Auburn, Alabama, United States, 3. Yale University, New Haven, Connecticut, United States*

The early stages of dementia can be a time of stress and uncertainty for spouses, yet little attention is paid to positive experiences. It is important to understand whether there are individual differences in emotion regulation that impact the positive affect of the individual and the partner. Drawing from interdependence theory, we hypothesized that one spouse's greater difficulty regulating emotions would be associated with their spouses lower positive emotions over time. We used self-report data from an intervention study with three assessment points (baseline, two weeks, and three months) of 45 older adult married couples (N=90) where one spouse has early-stage dementia. Both partners completed the Difficulties in Emotion Regulation Scale and the Positive and Negative Affect Scale. Results from the longitudinal actor partner interdependence model showed that when care partners were high in difficulty regulating emotions, their partner's positive affect decreased (β = -0.343, p <.01), controlling for intervention arm and covariates.

INFORMAL DEMENTIA CAREGIVERS' EMOTIONAL EXPERIENCES DURING CONFLICT AND DEPRESSIVE SYMPTOMS

Casey Brown[1], Yuxuan Chen[2], and Robert Levenson[3], *1. Georgetown University, Washington, District of Columbia, United States, 2. UC Berkeley, Berkeley, California, United States, 3. University of California, Berkeley, Berkeley, California, United States*

Emotional interactions may change as a result of dementia and negatively impact caregivers' mental health. We examined 62 dementia caregivers' emotional experiences during conflict with their partners, including 22 individuals with behavioral variant frontotemporal dementia (bvFTD), 20 with Alzheimer's disease (AD), and 20 with a language variant of frontotemporal dementia (language variant). Dyads engaged in a 10-minute conversation involving conflict. Caregivers watched recordings of their conversation while rating their emotional valence using a rating dial. Caregivers of individuals with bvFTD reported greater decreases in positive emotion across the conversation relative to caregivers of individuals with AD and language variants. Caregivers who reported greater decreases in positive emotion across the conversation had higher levels of depressive symptoms, even after accounting for their partner's diagnosis and level of cognitive impairment. Findings suggest bvFTD caregivers experience the greatest declines in positive emotion during conflict, with potential implications for depression.

POSITIVE EMOTIONAL CONNECTION AND CAREGIVER WELL-BEING IN BEHAVIORAL-VARIANT FRONTOTEMPORAL DEMENTIA

Kuan-Hua Chen[1], Claire Yee[1], Casey Brown[2], Anna Sapozhnikova[3], Peter Pressman[4], Jennifer Merrilees[5], Barbara Fredrickson[6], and Robert Levenson[1], *1. University of California, Berkeley, Berkeley, California, United States, 2. Georgetown University, Washington, District of Columbia, United States, 3. Pacific Anxiety Group, San Francisco, California, United States, 4. University of Colorado School of Medicine, Aurora, Colorado, United States, 5. University of California, San Francisco, San Francisco, California, United States, 6. University of North Carolina at Chapel Hill, Chapel Hill, North Carolina, United States*

Behavioral-variant frontotemporal dementia (bvFTD) is characterized by impairment in socioemotional functioning. Spouses caring for individuals with bvFTD often experience profound health/well-being declines, compared to Alzheimer's disease (AD) caregivers and non-caregiving older adults. We hypothesized that disrupted positive emotional connections between spousal caregivers and individuals with bvFTD contribute to caregivers' lower emotional well-being. 23 bvFTD-caregiver, 23 AD-caregiver, and 17 control dyads had a 10-minute conflict conversation in the laboratory. Positive emotional connections were measured as the covariation of partners' positive emotional behaviors during the conversation. Caregiver emotional well-being was assessed via questionnaire (SF-36). We found that bvFTD caregivers had lower emotional well-being than AD caregivers and controls (who did not differ from each other, t=.80, p=.43), c=-.70, p<.01. Importantly, this effect was fully mediated by bvFTD caregivers' lower positive emotional connections, c'=-.38, n.s. We speculate that lower positive emotional connections can cause social isolation and contribute to bvFTD caregivers' health/well-being declines.

SESSION 4860 (SYMPOSIUM)

PRECLINICAL DEMENTIA CARE AND PREVENTION IN CONTEXT: FROM INSIGHTS TO ACTION

Chair: Daniel Rong Yao Gan Co-Chair: Patricia Heyn
Discussant: Emily Greenfield

Dementia affects people with lower socioeconomic statuses disproportionately. People with undiagnosed Alzheimer's disease may or may not express dementia symptoms depending on their brain reserve, cognitive reserve, and their ability to compensate for brain pathology. Much of these depend on their childhood education, but late-life social engagement may also play a role. As lifespan increases globally, preclinical dementia care and prevention in community settings will be increasingly important. The characteristics of everyday environments that are kind to various changes amid declining cognition may enhance the quality of life of older adults with and without dementia. Such environments may be available or unavailable in diverse communities of varying socioeconomic statuses. This collaborative symposium between the ADRD and CEnR interest groups brings together multidisciplinary scholars to imagine psychosocial interventions that could mitigate place-based disparities in cognitive health. The first presentation frames the importance of relational perspectives in a biopsychosocial-ecological model of care amid cognitive decline. The second presentation shows the cognitive impact of networks among kinless older adults across Europe. The third presentation explores community perspectives on preventive brain health programs in various neighborhoods. The fourth presentation centers the voice and action of people with dementia to improve their neighborhood social environments. The final presentation identifies policy implications for community-based care and prevention from network perspectives. Discussions will distil the significance of community for persons living with and without dementia diagnosis to generate place-based interventions that may better support care and prevention in diverse settings, and identify structural barriers to these efforts.

A BIOPSYCHOSOCIAL-ECOLOGICAL, FAMILY-FRAMED APPROACH TO DEMENTIA CARE

Carol Podgorski, *University of Rochester, Rochester, New York, United States*

An individual's experience of cognitive impairment is shaped by biopsychosocial factors, including their own perceptions of illness as well as interactions with family members, healthcare providers, and the communities in which they live. With advancing illness an individual's dementia care requires the involvement and commitment of others, usually family. Hence, the quality of a person's illness experience is shaped largely by relationships with family members and others throughout their respective communities. Current models of dementia care recognize family members as an important part of the care team, but fail to consider a patient's family system and relationships as social determinants that affect care outcomes. This presentation will introduce a biopsychosocial-ecological, family-framed approach to dementia care that addresses factors that influence care considerations at both the individual and relational levels of the social ecological networks that the patient and their family members occupy.

KINLESSNESS AND COGNITIVE FUNCTION AMONG EUROPEAN OLDER ADULTS

Christine Mair[1], and Katherine Ornstein[2], *1. University of Maryland, Baltimore County (UMBC), Baltimore, Maryland, United States, 2. Johns Hopkins, University, Baltimore, Maryland, United States*

So-called "kinless" older adults (unpartnered and childless) are a growing population across the globe who may be at higher risk for social isolation and cognitive decline. Yet, this group of older adults is understudied in dementia-related research and their risk of cognitive decline likely varies by country context. We analyze data from the Survey of Health, Ageing & Retirement in Europe (SHARE) to explore cognitive decline by family structure and country. We assess cognitive decline along a gradient of "kinlessness" by comparing older adults with a) partner and child, b) partner and no child, c) no partner and child, and d) no partner and no child across 20 European countries. Results of this study will outline the dementia risks faced by the growing population of older adults with non-traditional family structures and highlight characteristics of country context that might enhance or reduce risk of cognitive decline for "kinless" older adults.

"PEOPLE DON'T LIVE IN A VACUUM": CO-DEVELOPING A BRAIN HEALTH PILOT PROGRAM IN THE COMMUNITY THROUGH CITIZEN SCIENCE

Claire Wang[1], Daniel Rong Yao Gan[2], Eireann O'Dea[3], and Brain Health in the Community (BHIC) Steering Committee[2], *1. Johns Hopkins University , Baltimore City, Maryland, United States, 2. Simon Fraser University, Vancouver, British Columbia, Canada, 3. Simon Fraser University, North Vancouver, British Columbia, Canada*

The Psychosocial Model of Everyday Cognitive Resilience identifies social identity as an important determinant of older adults' wellbeing as they experience cognitive decline in community settings. We engaged community-dwelling older adults to assess the model and co-develop programs that address existing gaps through twelve focus groups. N=55 older adults were recruited from various community organizations. Two 1-hour sessions discussed (1) variables that were important to older adults, namely neighbourhood friendship and social experiences, and (2) how these mediated the effects of self-expression, time outdoors, and communal provisions on mental wellbeing. Many participants highlighted the importance of strong friendship for deeper needs such as grief support, whereas others pointed out the relevance of meaningful activities or volunteering opportunities for a sense of purpose. Overall, a speed-friending program with an emphasis on listening was desirable for connecting and contributing socioemotionally to develop "happy medium" friendships, while piloting evidence-based interventions for brain health.

FLIPPING STIGMA ON ITS EAR: A TOOLKIT FROM PARTICIPATORY ACTION RESEARCH

Mariko Sakamoto[1], Jim Mann[1], Deborah O'Connor[2], and Alison Phinney[1], *1. University of British Columbia, Vancouver, British Columbia, Canada, 2. School of Social Work - University of British Columbia, Vancouver, British Columbia, Canada*

People living with dementia face persistent stigma, discrimination and social exclusion, with significant emotional, physical and social consequences. Addressing this requires changing attitudes and fostering actions for communities to include people with dementia as citizens with agency and self-determination. This presentation highlights the work of an Action Group (AG) of people living with dementia. As part of a four-year Participatory Action Research study aimed at addressing the stigma, discrimination and social exclusion that is so common to the dementia experience, members of the AG in partnership with the research team developed the Flipping Stigma on its Ear Toolkit. Focus will be on the action-oriented nature of this research project, an overview of the toolkit, and exploration of the communal space that was created by AG members in the process of working together, learning from one another, and making a collective contribution towards addressing stigma, discrimination and social exclusion.

SOCIAL NETWORKS AND COGNITIVE FUNCTION: POLICY IMPLICATIONS FROM RECENT RESEARCH

William McConnell[1], Katherine Haggar[1], Mohit Manchella[2], Adam Roth[3], and Brea Perry[3], *1. Florida Atlantic University, Boca Raton, Florida, United States, 2. University of Southern Indiana, Carmel, Indiana, United States, 3. Indiana University, Bloomington, Indiana, United States*

This presentation will describe a series of research projects using Social Network Analysis (SNA) to measure the personal social networks of community-dwelling older adults at-risk for or currently experiencing dementia. The first part of the presentation will provide a brief overview of SNA methods, including advantages of SNA compared to more traditional social activity scales. The second part of the presentation will present evidence from multiple studies to identify distinct pathways linking upstream social network characteristics to downstream pathophysiological processes in the aging brain. In particular, we will distinguish between cognitive stimulation experienced in expansive social networks and neuroendocrine benefits derived from cohesive social networks. The third part of the presentation will present implications for psychosocial interventions to reduce health disparities in dementia care and prevention. We recommend leveraging the multidimensional functionality of social networks across the lifecourse to influence multiple cognitive health pathways simultaneously.

SESSION 4870 (SYMPOSIUM)

REIMAGINING ALZHEIMER'S RESEARCH: ON THE ROAD TO NEW DISCOVERIES

Chair: Stacy Andersen Co-Chair: Lenora Smith Discussant: Allison Gibson

Organized by the Alzheimer's disease and related dementias (ADRD) Interest Group, this symposium aims to highlight unique approaches to address 1) ADRD risk reductions through social and biological factors, and 2) quality of life of those with dementia. The first two presentations introduce remote communication technologies used for behavioral interventions, one for preventing social isolation and the resultant cognitive decline using videochats by recruiting socially isolated older adults with mild cognitive impairment (MCI). The results of the recently completed randomized controlled trial provide evidence of a positive effect on cognition suggesting enhanced cognitive reserve. Another is for delivering a behavioral symptom intervention for community-dwelling persons with ADRD using telehealth. Researchers will highlight the feasibility, opportunities, and challenges of remote behavioral interventions. The third presentation focuses on micro-level communication between persons living with dementia and their family caregivers. By examining video-recorded home care observations, findings suggest caregiver education on positive interactions could facilitate more meaningful interaction with persons with ADRD. The fourth presentation explores pain among those with ADRD, a multifaceted phenomenon with health and functional consequences. Using the NHATS dataset, researchers show a continued need to detect and address pain in clinical settings particularly among persons with ADRD. The symposium concludes with a presentation using the CHARLS study to investigate correlations between inflammation or kidney-related metabolic biomarkers and cognition. Results provide longitudinal evidence of an association of kidney function and inflammation with cognitive test scores supporting the need to broaden dementia etiology research beyond the amyloid-cascade theory.

I-CONECT RESULTS: ENHANCING SOCIAL INTERACTIONS IMPROVES COGNITIVE FUNCTION IN SOCIALLY ISOLATED PARTICIPANTS

Hiroko Dodge[1], Chao-Yi Wu[1], Kexin Yu[2], Peter Lichtenberg[3], Laura Struble[4], Kathleen Potempa[4], and Lisa Silbert[1], *1. Oregon Health & Science University, Portland, Oregon, United States, 2. Oregon Health & Science University, Palo Alto, California, United States, 3. Wayne State University, Detroit, Michigan, United States, 4. University of Michigan, Ann Arbor, Michigan, United States*

Epidemiological studies suggest that social isolation is a risk factor of dementia although the underlying mechanisms are not well known. A core component of social isolation is a lack of conversational interactions. We recently completed a NIH-funded multi-center randomized controlled trial called Internet-Based Conversational Engagement Clinical Trial (I-CONECT, ClinicalTrials.gov: NCT02871921), which aimed to examine whether social engagement, specifically conversational interactions through webcam and internet, could improve cognitive function in socially isolated older adults with mild cognitive impairment (MCI) or normal cognition. The data was un-blinded in August, 2021. We found strong evidence of efficacy in the primary (global cognitive function, Cohen's d = 0.73, p=0.03) and secondary (memory function, Cohen's d=0.67, p=0.03) outcomes at Month 6 (high-dose post-trial endpoint) and Month 12 (maintenance-dose post-trial-endpoint), respectively, using the mixed model for repeated measures. We will present the background, COVID-19 pandemic related protocol modifications and the primary results of this intervention project.

USE OF TECHNOLOGY TO DELIVER AND MONITOR NONPHARMACOLOGICAL INTERVENTION FOR ADRD WITH BEHAVIORAL SYMPTOMS

Elizabeth Rhodus, Rosmy George, Richard Kryscio, Justin Barber, Allison Gibson, Donna Wilcock, and Gregory Jicha, *University of Kentucky, Lexington, Kentucky, United States*

Onset of the COVID-19 pandemic created numerous barriers to providing care supports and clinical research for persons living with Alzheimer's disease and related dementias (ADRD). Technology offered one avenue for continued care support and clinical data collection. This study reports on the use of technology to deliver a 6-week, non-pharmacological care intervention directed toward caregivers of persons with ADRD and remote data collection including cognitive assessment, biometric data, and survey data for community-residing persons with ADRD and behavioral symptoms (N=28). Benefits and challenges of such technology use for intervention delivery and data collection will be discussed. Benefits include increased geographical outreach, no travel time, and greater scheduling flexibility. Challenges include access to technology (equipment and/or internet), internet connection quality, ease of use, and equipment return at study completion. These findings offer specific aspects to consider while designing and implementing remote care programming and clinical research for community-residing persons with ADRD.

MICROLEVEL COMMUNICATION BETWEEN FAMILY CAREGIVERS AND PERSONS LIVING WITH DEMENTIA

Sohyun Kim[1], and Wen Liu[2], *1. University of Massachusetts, Amherst, Massachusetts, United States, 2. University of Iowa, Iowa City, Iowa, United States*

Little is known about the relationship between family caregivers and persons living with dementia communication at micro-level (smallest verbal and nonverbal behavior unit). Micro-level communication was assessed second-by-second using 75 in-home video recordings from 19 caregiver-care recipient dyads. Each care recipient (N = 38) and caregiver (N = 42) behavior unit was paired and compared using Spearman's partial correlation. Two-hundred twenty care recipient-caregiver behavior unit pairs were correlated (n = 148 verbal, n = 72 nonverbal pairs, rs range = .456 - .990, all p < .05). Ninety-one caregiver facilitative-care recipient engaging behavior unit pairs (e.g., comfort/empathetic touch, using humor) were positively correlated (rs range = .460 - .990, all p < .05). Eighteen caregiver disabling-care recipient challenging behavior unit pairs (e.g., withdrawing) were positively correlated (rs range = .456 - .697, all p < .05). Individualized caregiver education for matching and adjusting communication is needed to facilitate meaningful interaction.

IMPLICATION OF PAIN ON MOBILITY, FALLS, AND PSYCHOLOGICAL OUTCOMES FOR PEOPLE LIVING WITH DEMENTIA

Annalisa Na[1], Leslie McClure[1],
Rose Ann DiMaria-Ghalili[2], and Laura Gitlin[1], *1. Drexel University, Philadelphia, Pennsylvania, United States, 2. Drexel University, College of Nursing and Health Professions, Philadelphia, Pennsylvania, United States*

Dementia and pain can challenge mobility, increase fall risk, and result in psychological consequences; however, the extent of these relationships among community-dwelling people living with dementia (PLWD) is unclear. Using the National Health and Aging Trends Study, we examined 9,974 community-dwelling older adults (female=57%, age>85yrs=18%) for pain prevalence, mobility (i.e., Short Physical Performance Battery [SPPB]), falls, and psychological outcomes (i.e., depression and anxiety) using four groups with and without dementia (+PLWD/-PLWD) and pain (+Pain/-Pain). Groups were compared at baseline with ANOVA and chi-square and over time with repeated-measures ANOVA models. Pain (+PLWD= 56.8%; -PLWD=49.8%) most commonly affected the low-back and knee. Group differences were significant for baseline mobility, falls, and psychosocial outcomes, $p<0.01$, but not SPPB over time. Therefore, pain is common, especially at low back and knee, and associated with health and function among PLWD, indicating a need for early and effective interventions that can preserve quality of life.

THE ASSOCIATION BETWEEN COGNITION AND METABOLIC BIOMARKERS AMONG PARTICIPANTS FROM THE CHARLS LONGITUDINAL COHORT

Diefei Chen, *Johns Hopkins Bloomberg School of Medicine, Baltimore, Maryland, United States*

Inflammatory or kidney-related metabolic biomarkers have been correlated with cognition and risk for developing dementia among older adults. Using the China Health And Retirement Longitudinal Study, we investigated the cross-sectional correlations between metabolic biomarkers and cognitive outcomes that were ascertained in the same wave, as well as measures lagged by data collection waves. After excluding participants with diagnoses of dementia, we analyzed the association of each biomarker (e.g., White Blood Cell count, Creatinine, Blood Urea Nitrogen, Uric Acid, Cystatin C, C-Reactive protein) with scores from cognitive tests. We then identified biomarkers that showed consistent associations across waves. Having elevated CRP (1-3 mg/L) was positively associated with cognitive test scores; whereas abnormal levels of Creatinine (Low: <0.74 for male and <0.59 for female; High:>1.35 for male and >1.04 for female) were associated with poorer outcomes. These results provide biomarker evidence of the importance of kidney function and inflammation in dementia research.

SESSION 4880 (SYMPOSIUM)

THE BLUES AND OLDER MINORITY MUSICIANS: MORE THAN JUST MUSIC XXIX

Chair: John Migliaccio Co-Chair: Michael Marcus

The “ ’Bo Diddley’ Track”; GSA, 2022 Indianapolis, INLIndianapolis has been described as “The Crossroads of America,” with a long history of fostering the music and entrepreneurial spirit of Black Americans. Starting in 1915 with Mrs. C.J. Walker, America’s first female millionaire and her cosmetic enterprise, and the Starr Piano Company and its Gennett Records Studio – identified as “The Cradle of Recorded Jazz” in the 1920s and 30s – both were instrumental in national distribution of the works of the earliest blues, jazz, country, and gospel artists including Louis Armstrong, King Oliver, Alberta Hunter, and Charlie Patton among others.Indianapolis continues to host a thriving Blues music community, and will host the 29th consecutive year of GSA’s “Bo Diddley Track” with local older minority musicians, one of GSA’s most popular and fun events. This year will feature a lecture, interview, and mini-performance with leading local blues musicians exploring their life, influences, music and resilience, followed by a typically raucous live blues performance that evening at a local blues hot-spot, with prizes for the first 50 GSA attendees. This has been going on for 29 years for a reason, folks---don’t miss it!

THE BLUES AND OLDER MINORITY MUSICIANS: MORE THAN JUST MUSIC XXIX

John Migliaccio, *Maturity Mark Services Co., LLC, White Plains, New York, United States*

The Blues and Older Minority Musicians: More Than Just Music XXIXThe “ ’Bo Diddley’ Track”; GSA, 2022 Indianapolis, INLecture/Interview/ Performance: TBAIndianapolis has been described as “The Crossroads of America,” with a long history of fostering the music and entrepreneurial spirit of Black Americans. Starting in 1915 with Mrs. C.J. SESSION 4890 (SYMPOSIUM)

THE ELDER MISTREATMENT EMERGENCY DEPARTMENT TOOLKIT: ADDRESSING ELDER MISTREATMENT DURING COVID-19 AND BEYOND

Chair: Rebecca Stoeckle Co-Chair: Kristin Lees Haggerty
Discussant: Terry Fulmer

Elder Mistreatment (EM) is a prevalent problem that too often goes undetected. Hospital emergency departments (ED) offer a unique opportunity to screen for elder mistreatment and connect patients at risk with needed services but most do not have training and protocols in place to help staff screen for and respond to EM. In 2020, the National Collaboratory to Address Elder Mistreatment partnered with five hospitals to test the feasibility of implementing a streamlined set of tools and training known as the Elder Mistreatment Emergency Department Toolkit, and conducted two qualitative studies to better understand related barriers and facilitators to addressing EM. The presentations in this symposium share results from case studies at two feasibility test sites: Heywood Hospital, a small community hospital in central Massachusetts, and Lyndon B. Johnson Hospital, the busiest Level III Trauma Center in Texas, each presented by the respective site's local clinical champion. Following presentations by the clinical champions, National Collaboratory expert core faculty will report results from two related qualitative studies. The first explores barriers and facilitators to communication between EDs and Adult Protective Services (APS) and the second explores older adult survivors' own perspectives on the screening and response tools used in the feasibility study. The results of these studies highlight the need for streamlined and easy-to-use tools for identifying and responding to EM in busy EDs, the need for a personalized and trauma-informed approach to screening, and the importance of a personalized approach to connecting the ED and APS.

IMPLEMENTATION OF THE ELDER MISTREATMENT EMERGENCY DEPARTMENT TOOLKIT AT LYNDON B. JOHNSON HOSPITAL

Sherry Plummer[1], Jason Burnett[2], Ruthann Froberg[3], Randi Campetti[4], and Kim Dash[4], *1. Lyndon B. Johnson General Hospital, Houston, Texas, United States, 2. The University of Texas McGovern Medical School at Houston, Houston, Texas, United States, 3. Education Development Center, Inc., Waltham, Massachusetts, United States, 4. Education Development Center, Waltham, Massachusetts, United States*

Lyndon B. Johnson Hospital (LBJ) has the busiest Level III trauma and emergency department (ED) in Texas. Located in the busiest Houston zip code for Adult Protective Services reports, LBJ staff routinely assess older adults for mistreatment with no formal screening and response protocol. An ED-wide staff assessment revealed formal training needs for elder mistreatment (EM) detection, management, and reporting. Between October and December 2019, 55% of ED bedside nurses were trained along with 75% of charge nurses, and 12 clinical and nurse case managers, resulting in improved knowledge regarding EM screening and response best practices. In January 2021, LBJ staff implemented the Elder Mistreatment Screening and Response Tool (EM-SART). This resulted in 1,218 complete screens, 23 cases of suspected EM (2%), and 4 confirmed EM cases. Despite the pandemic and other challenges, LBJ staff demonstrated resilience and dedication, and reported EM training, screening, and response protocol efficacy.

IMPLEMENTATION OF THE ELDER MISTREATMENT EMERGENCY DEPARTMENT TOOLKIT AT HEYWOOD HOSPITAL

Carol-Lynne Papa[1], Randi Campetti[2], Ruthann Froberg[3], Kristin Lees Haggerty[3], and Kim Dash[2], *1. Heywood Hospital, Gardner, Massachusetts, United States, 2. Education Development Center, Waltham, Massachusetts, United States, 3. Education Development Center, Inc., Waltham, Massachusetts, United States*

Beginning in 2016, Heywood Hospital, a 134-bed community hospital located in Central Massachusetts, partnered with the National Collaboratory to Address Elder Mistreatment to design and test a care model for identifying and responding to elder mistreatment (EM) in hospital emergency departments (ED). In February 2020, Heywood Hospital began implementing the care model known as the Elder Mistreatment Emergency Department (EMED) Toolkit as part of a five-site feasibility study. This presentation shares local results from the feasibility study and strategies for implementing the EMED Toolkit. 95% of Heywood staff participated in an online training program and, over 9 months, 4,588 (84%) of all older ED patients were screened for EM. Of these, 19 screened positive and 11 were reported to Adult Protective Services, a more than 7-fold (annualized) increase over the prior year. Most of the remaining positive cases were connected with community-based resources through Heywood's Social Services Program.

EMERGENCY DEPARTMENT: ADULT PROTECTIVE SERVICES RELATIONSHIP IN RESPONSE TO ELDER MISTREATMENT

Theresa Sivers-Teixeira[1], Erin Thayer[2], Carmen Van Den Heever[1], and Bonnie Olsen[1], *1. University of Southern California, Alhambra, California, United States, 2. University of Southern California - Keck School of Medicine, Alhambra, California, United States*

Universal screening of older adults in emergency departments (ED) effectively improves identification of elder mistreatment (EM). To realize improved response, collaboration between ED providers and staff and local Adult Protective Services (APS) is essential. Qualitative data was derived from transcribed and coded key informant interviews with 10 APS workers and 5 ED clinical providers from 6 states. Results indicate each entity approaches EM from a different global perspective which informs key strategies to build effective response. ED providers focus on acute medical needs while APS focuses on long-term psychosocial needs. Assignment of specific individuals in both entities to be liaisons between ED and APS would support improved communication and collaboration. Education should focus on 1) capabilities and limitations in EM response and 2) clarity regarding bilateral sharing of information. Both entities report participation in multidisciplinary teams is valuable to foster collaboration on effective interventions in EM cases.

PERSPECTIVES OF THE EM-SART: INTERVIEWS WITH ADULT PROTECTIVE SERVICES CLIENTS

Jason Burnett[1], Kristin Lees Haggerty[2], Randi Campetti[3], and Rebecca Stoeckle[2], *1. The University of Texas McGovern Medical School at Houston, Houston, Texas, United States, 2. Education Development Center, Inc., Waltham, Massachusetts, United States, 3. Education Development Center, Waltham, Massachusetts, United States*

Older adults who experience mistreatment are more likely to visit emergency departments (ED), yet screening and response protocols in these health care settings are sorely lacking. Protocols designed with the mistreated older adult's perspective in mind are needed to maximize efficacy and effectiveness. In this study, 18 mistreated older adults completed semi-structured perspective interviews regarding the ED Elder Mistreatment Screening and Response Tool (EM-SART). The findings highlight the importance of training healthcare staff to ask elder mistreatment (EM) questions in a preset context and to ask EM questions with empathy, concern, privacy, and clarity. Participants also stressed the desire to be reported to Adult Protective Services, but to also be included in the safety planning. These findings have direct implications for training health care workers to screen and respond to EM in the ED.

SESSION 4900 (PAPER)

STATE- AND SYSTEMS-LEVEL RESEARCH INTO ELDER ABUSE AND NEGLECT

A POLICY ANALYSIS OF ELDER ABUSE PREVENTION LEGISLATION: TRANSLATION OF NATIONAL INITIATIVES TO THE STATE LEVEL

Autumn Decker[1], Kathryn Bruzios[1], Raven Weaver[1], and Cory Bolkan[2], *1. Washington State University, Pullman, Washington, United States, 2. Washington State University Vancouver, Vancouver, Washington, United States*

Elder abuse (EA) is an under-recognized global public health threat in need of enhanced research and policy attention, with 1 in 6 older adults experiencing at least one form of abuse/neglect. Public policy changes, such as the federal 2017 Elder Abuse Prevention and Prosecution Act (EAPPA), aim to address EA, but little is known regarding translation and implementation of the initiatives to state-levels. Applying a thematic analytic approach, we identified four major themes from the EAPPA: criminal investigation support; abuse reporting; financial exploitation; and training/technical assistance. Then, we conducted a comparative policy analysis to evaluate each state's EA statutes enacted since 2017 to determine whether statutes were updated to reflect the EAPPA's goals. Preliminary findings from 10 states (i.e., states with the greatest proportion of older adults in each Health & Human Services region) showed that eight states had updated statutes relevant to an identified theme(s). Eight states updated statutes related to financial exploitation, highlighting the growing concern over this specific type of abuse. Four states updated statutes related to reporting, reflecting problems with identifying and detecting elder abuse. Two states updated statutes regarding investigation, demonstrating minimal emphasis on elder abuse investigation. No states updated statutes relevant to training/technical assistance. These findings indicate significant state-level variability in translation and implementation of recent legislation. More recognition, research, and policy attention to EA, in the U.S. and globally, is needed. We conclude with recommendations for innovation and prevention policy efforts coupled with multidisciplinary collaborations to strengthen implementation against EA at the state-level.

ADULT MALTREATMENT OUTCOMES OF A TARGETED CASE MANAGEMENT INTERVENTION FOR SELF-NEGLECT

Courtney Reynolds, Farida Ejaz, and Miriam Rose, *Benjamin Rose Institute on Aging, Cleveland, Ohio, United States*

A longitudinal study to prevent self-neglect among at-risk, older (age 60+) or disabled (age 18+) healthcare patients was conducted collaboratively by a gerontological research institute, a health care system, and Texas Adult Protective Services (APS). Selected patients ($n = 285$) from 19 primary care clinics received targeted case management services for four months by a trained social worker. Their median age was 70, 72% were Hispanic/Latino, 79% had a high school education or less, and 73% had monthly income less than $1,361. A screening tool was used to identify adult maltreatment during baseline and posttest interviews. Consistent with national prevalence rates, 86% of participants at baseline, and 90% at posttest, reported they had not recently experienced abuse. In this sample, we found a significant decrease in mean scores on the screening tool from baseline ($M = 0.24$, $SD = 0.63$) to posttest ($M = 0.14$, $SD = 0.48$); $t(241)$, $p < 0.05$. Six of the seven participants reported by project social workers to APS had at least one allegation of self-neglect. APS administrative data were also examined and included another 10 study participants reported to APS during the study. In total, 21 reports were made, with 26 allegations of maltreatment, of which 35% were validated, all for self-neglect; 70% of self-neglect allegations reported by project social workers were validated. Results suggest that targeted case management services could reduce the incidence of self-neglect. Similar targeted interventions may help to identify, report, and address other forms of adult maltreatment.

APS PERSPECTIVES ON CHALLENGES AND STRATEGIES SERVING CLIENTS DURING THE COVID-19 PANDEMIC SURGE

Alyssa Elman[1], Elaine Gottesman[2], Lena Makaroun[3], E-Shien Chang[4], Sunday Clark[1], and Tony Rosen[5], *1. Weill Cornell Medical College / NewYork-Presbyterian Hospital, New York, New York, United States, 2. New York-Presbyterian Hospital/Weill Cornell Medical Center, New York, New York, United States, 3. VA Pittsburgh Healthcare System, Pittsburgh, Pennsylvania, United States, 4. Weill Cornell Medical College, New York, New York, United States, 5. Weill Cornell Medical College / NewYork-Presbyterian Hospital, PELHAM, New York, United States*

The initial surge of the COVID-19 pandemic and public health measures in response dramatically impacted Adult Protective Services' (APS) ability to conduct investigations and provide services, requiring agencies to quickly adapt. Our goal was to describe challenges for APS and strategies they developed to respond. We conducted 6 focus groups and 7 interviews during March-April 2021 used a semi-structured topic guide, with 31 participants from APS leadership, supervisors, and case workers in New York City, a community hard hit by the initial COVID surge. Focus groups and interviews were recorded and transcribed, with data analyzed to identify themes. Participants identified 9 major challenges, including: clients using concern about COVID-19 to refuse APS workers' access to their home, necessity to perform home visits/wellness checks on behalf of other agencies who had suspended home visits, and dependence on in-office activities including receiving paper mail. Participants reported 30 formal and informal strategies adopted to address challenges. These included 13 focusing on maximizing client engagement while maintaining client and APS worker safety, such as: adding a pre-investigation before a home visit to assess COVID-19 risk/exposure, offering clients masks and hand sanitizer to build trust, and close collaboration with other agencies/programs including joint visits. Also, 17 strategies were reported to allow for remote work and support staff, including: modifying processes to replace paper mail with electronic communication/processing, offering counseling services, formally recognizing excellent performance, and leadership reaching out personally to check on staff members. These findings may inform APS planning for future large-scale societal disruptions.

RISK FACTORS AND IMPACT OF FINANCIAL FRAUD ON OLDER ADULTS AND DISADVANTAGED COMMUNITIES

Marguerite DeLiema[1], and Paul Witt[2], *1. University of Minnesota, Twin Cities, Minneapolis, Minnesota, United States, 2. Federal Trade Commission, Washington, District of Columbia, United States*

In 2021, Americans age 80 and older reported median fraud losses of $1,300 per incident, substantially higher than younger age groups (Federal Trade Commission, 2022). Using data from the Federal Trade Commission's Sentinel Fraud Complaint Database and the Area Deprivation Index, this study assesses the demographic and contextual correlates of consumer fraud victimization in the United States. Models show a positive association between living in a disadvantaged community and reporting victimization (versus reporting no losses after being targeted). Black and Hispanic consumers are significantly more likely report victimization, although non-Hispanic White victims report higher average fraud losses. Results also show that older adults are significantly less likely to report fraud victimization relative to people age 30 and younger, but older victims lose hundreds of dollars more, on average. Applying a sentiment analysis to the consumer complaint narratives, we find that compared to emotionally neutral complaints, emotionally positive and emotionally negative complaints are positively associated with reporting victimization versus reporting no losses. Gift cards are the most common method of payment demanded by fraud criminals overall, but victims who pay using cash, wire transfer, or cryptocurrency lose significantly more money, on average. To limit the impact of fraud on the aging population, consumer protection agencies need to focus their efforts on educating older adults and members of socially and economically disadvantaged communities about scams, as well as enforce greater controls on cryptocurrency exchanges and retail gift card sales.

SELF-NEGLECT OF OLDER ADULTS: HOW CAN ADULT PROTECTIVE SERVICES HELP?

Pi-Ju Liu[1], Zach Hass[1], Sara Stratton[2], Karen Conrad[3], and Ken Conrad[3], *1. Purdue University, West Lafayette, Indiana, United States, 2. San Francisco Adult Protective Services, San Francisco, California, United States, 3. University of Illinois Chicago, Chicago, Illinois, United States*

Adult Protective Services (APS) is the only government agency dedicated to investigating elder mistreatment. This frontline agency also provides and coordinates needed services to its clients, but their service effectiveness has not been extensively investigated. Over half of all APS cases investigated are self-neglect. Although no universal definition of self-neglect exists in the literature, self-neglecting older adults fail to perform self-care tasks, such as getting adequate nutrition, maintaining personal hygiene, obtaining medical care, protecting oneself from danger, managing one's finances– all of which may threaten their health or safety. In partnership with San Francisco and Napa APS, levels of self-neglect were measured using the Elder Self-Neglect Assessment Short-Form during case investigation (before APS interventions) and at case closure (after APS interventions). Services accepted and received by clients at case closure were also documented. A total of 634 older adults' (on average 77 years old; 50% females) were found to be self-neglecting during the six-month pilot demonstration. Overall, levels of self-neglect decreased after APS interventions (t=-16.97, p<.001). Most common services included care/case management (7%) and mental health services (12%). Services associated with decreased levels of self-neglect included in-home assistance services (b=-1.14, p<.05) and care/case management (b=-0.79, p<.10). Using standardized measures before and after implementing the services needed by older adults allows identification of services that decrease mistreatment. In this study, standardized assessment by APS impacted both practice and research to help advance the understanding of this elder mistreatment type.

SESSION 5000 (PAPER)

ATTITUDES ABOUT AGING

AGE GROUP DIFFERENCES IN VIEWS ON ONE'S OWN OLDER ADULTHOOD

Shelbie Turner[1], Shannon Jarrott[2], and Karen Hooker[3], *1. Weill Cornell Medical College, Pitman, New Jersey, United States, 2. The Ohio State University, Columbus, Ohio, United States, 3. Oregon State University, Corvallis, Oregon, United States*

Most of the current scholarship on views on one's aging focuses on middle and older adulthood, prompting lifespan theorists to call for studies about views on one's aging throughout the entire lifespan (Kornadt et al., 2020). In this study, we established a factor structure to Kornadt et al.'s (2020) Domain Specific Future Selves Scale, which prompted respondents to rate their thoughts on their self in old age across 9 different items. We then utilized measurement invariance testing to analyze how the factor structure differed between 433 young (18-39), 485 middle-aged (40-64), and 286 older adults (65 and older). Via Exploratory and Confirmatory Factor Analyses, three latent factors emerged, constituting future older selves in the domain of social lives (a=0.78), work and finances (a=0.62), and physical health (a=0.76). The model maintained configural (RMSEA = 0.06, CFI = .96; TLI = .95), metric (RMSEA = 0.06, CFI = .97; TLI = .96), and scalar (RMSEA = 0.06; CFI = .96; TLI = .95) invariance across all three age groups. Latent mean testing revealed that older adults thought more positively about their future social lives (p=0.005), work and finances (p=0.05), and health (p=0.02) than did younger adults, and more positively about their social lives (p=0.001) and health (p=0.05) than middle-aged adults. Results from this study offer additional psychometric validation of a measure of future selves that researchers can use across the lifespan, and deeper theoretical understanding of how domain-specific views on one's own older adulthood might differ between age groups.

ASSOCIATIONS BETWEEN MEDIA CONSUMPTION AND AGEIST ATTITUDES: A CROSS-NATIONAL ANALYSIS

Erfei Zhao[1], Eileen Crimmins[2], Elizabeth Zelinski[2], and Eunyoung Choi[3], *1. University of Southern California, Leonard Davis School of Gerontology, Los Angeles, California, United States, 2. University of Southern California, Los Angeles, California, United States, 3. School of Global Public Health, New York University, Los Angeles, California, United States*

The mass media has been thought to be associated with public opinion, often creating and sustaining stereotypes. However, little is known about the role of media exposure in people's ageist attitudes, particularly at a cross-national level. This study examines whether the daily use of different media types is associated with personal attitudes towards older people. We analyzed data from 59,103 adults across 54 countries, using the World Value Survey wave 6 (2010-2014). Personal ageist attitudes were assessed by whether participants agree that older people are a burden on society. We used logistic regression, controlling for individual- and country-level factors. Our findings suggest that people's exposure to media is significantly associated with their attitudes towards older adults, but differently by the platform and respondents' age. Those who used newspaper (OR:1.66, CI:1.38-1.98), magazines (OR:1.67, CI:1.27-2.20), and radio (OR:1.42, CI:1.23-1.65) were more likely to have negative attitudes toward older people, whereas those who used TV (OR:0.62, CI:0.53-0.72) and internet (OR:0.76, CI:0.65-0.89) were less likely to. Further, the effects of newspaper and radio consumption on people's attitudes were moderated by respondents' age. Younger adults' ageist attitudes had a stronger negative relationship with these media types compared to those that are older. For the older age group, in contrast, more consumption of newspapers and radio are associated with less ageist attitudes. Future studies may focus on the content of each platform and assess their effect on people's ageist attitudes by age groups in order to understand how to foster a more age-friendly media environment.

DEMENTIA-RELATED STIGMA IS ALIVE AND NOT WELL AMONG UNREGULATED HOME CARE WORKERS

Marie Savundranayagam, Shalane Basque, and Audrey Gruneberg, *Western University, London, Ontario, Canada*

Dementia-related stigma is pervasive despite the growing rates of dementia globally. The social cognitive model of stigma contends that stigma is created and maintained through negative stereotypes, prejudice, and discrimination towards people who belong to a group. Research on dementia-related stigma highlights the prevalence of stigmatizing views among formal care providers. However, little is known about how stigma is created and maintained by the ways in which frontline care providers talk about persons living with dementia. Accordingly, this study aimed to identify ways in which stigmatizing language is used by home care workers when describing routine care interactions with clients living with dementia. Semi-structured interviews were conducted with 30 unregulated home care workers, who shared their experiences caring for clients with dementia. We used conventional content analysis to identify themes related to dementia-related stereotypes, prejudice, and discrimination. Under stereotypes, persons with dementia were portrayed as objects, infants, not engaging, and cognitively and behaviorally unstable. Under prejudice, persons with dementia invoked pity, fear, disdain, and emotional fatigue. Under discrimination, participants shared experiences of excluding/ignoring, controlling, and using patronizing communication with persons living with dementia. Uncovering common examples of stigmatizing language offers opportunities to train home care workers to use person-centered communication. It is noteworthy that stigmatizing language emerged, when not asked about directly. Our findings underscore the persistence of dementia-related stigma and the need for training to eliminate stigma.

DO BELIEFS THAT OLDER ADULTS ARE INFLEXIBLE SERVE AS A BARRIER TO RACIAL EQUITY?

Kimberly Chaney[1], and Alison Chasteen[2], *1. University of Connecticut, Storrs, Connecticut, United States, 2. University of Toronto, Toronto, Ontario, Canada*

Past research has demonstrated that older adults are stereotyped as less malleable than younger adults, such that older adults are perceived to be less capable of changing their beliefs and learning new things. Moreover, beliefs that people are less malleable are associated with lower confrontations of prejudice, as perpetrators are seen as less capable of changing their (prejudiced) behavior. The aim of the present research was to integrate these lines of research to demonstrate that endorsement of ageist beliefs that older adults are less malleable will lead to lower confrontation of anti-Black prejudice espoused by older adults. Across four experimental studies (N = 1,310), people were less likely to confront anti-Black prejudice espoused by an 82 year-old compared to a 62, 42, or 20 year-old, due, in part, to beliefs that older adults are less malleable. Further exploration demonstrated that malleability beliefs about older adults were held across young, middle-aged, and older adult samples, though older participants were the least likely to confront prejudice, regardless of perpetrator age. Alternative mechanisms are explored, including respect, perceived social influence, and perceived awareness of egalitarian norms. These findings demonstrate how stereotypes about older adults can impede racial equality and highlight that interventions geared towards reducing ageism could, in turn, lead to greater racial equality.

NEIGHBORHOOD ADVERSITY AND COGNITIVE HEALTH: THE MODIFYING ROLE OF SELF-PERCEPTIONS OF AGING

Eunyoung Choi[1], Elizabeth Zelinski[2], Jennifer Ailshire[2], and Yuri Jang[2], *1. School of Global Public Health, New York University, Los Angeles, California, United States, 2. University of Southern California, Los Angeles, California, United States*

Research has documented the increased risk of cognitive impairment among older adults living in socioeconomically disadvantaged neighborhoods. Much less is known about the factors that moderate this risk. We conceptualized self-perception of aging (SPA) as a potential moderator because it reflects core beliefs about the self at older ages but is also closely linked to late-life health. Guided by the diathesis-stress model that postulates the interactive roles of cognitive styles and stressors in shaping health outcomes, we hypothesized that more positive SPA would buffer the effects of neighborhood adversity on cognitive function. Using data from the Health and Retirement Study (2008–2016), the analytic sample consisted of adults aged 54 and older (N=5,902). Cognitive function was assessed by the Telephone Interview for Cognitive Status. The neighborhood indicators included 1) poverty rates at the census tract level, 2) perceived neighborhood social cohesion, and 3) perceived neighborhood disorder. Three-level growth curve models were separately estimated for each neighborhood indicator's effect as well as its interaction with SPA on the 8-year cognitive function trajectories. Findings showed that higher poverty rates, more disorder, and less cohesion were associated with lower initial levels of cognitive function but slower rates of cognitive decline. SPA partially moderated the linkage between neighborhood adversity and the level of cognitive function. More positive SPA was associated with reduced negative effects of living in neighborhoods with higher poverty rates and more physical disorder. These findings highlight the intersection of an individual-level psychological factor and a contextual-level factor in shaping late-life cognition.

SESSION 5001 (BIOLOGICAL SCIENCES INVITED SYMPOSIUM)

BS GSA AND AMERICAN AGING ASSOCIATION JOINT SYMPOSIUM

Chair: Blanka Rogina

AGING-RELATED VEGF IMPAIRS MUSCLE REGENERATION

Yori Endo[1], Charles Hwang[2], Yuteng Zhang[2], Ronald Neppl[2], Shailesh Argawal[2], and Indranil Sinah[2], *1. Harvard Medical School, Boston, Massachusetts, United States, 2. Brigham and Women's Hospital, Boston, Massachusetts, United States*

Purpose: Aging is associated with frailty, a parameter that correlates with mortality and loss of muscle mass. The molecular mechanisms behind aging-associated impairment of muscle regeneration remain incompletely understood. We hypothesized VEGF-A with known role in angiogenesis and muscle progenitor differentiation to regulate regeneration in aged skeletal muscle.

Methods: Young C57BL/6 (10 weeks old) and old C57BL/6 mice (24 months old) were subjected to muscle cryoinjury to induce regeneration. Quantifications of cross-sectional area (CSA) of regenerating myofibers were performed. Tibialis anterior muscle lysates was used for quantifying VEGF-A. To evaluate the role of VEGF in muscle regeneration, a similar experiment was performed on VEGFlo mice with a 75% decrease in VEGF-A activity and littermate controls. ML228, a hypoxia signaling activator that increases VEGF-A levels, was injected into young and old mice as well as VEGFlo and littermate controls.

Results: Old mice exhibited marked reduction in the VEGF-A protein levels and regenerating myofiber CSA on DPI 10 (1250 vs. 833μm2, p<.001). Similarly, VEGFlo mice exhibited significantly smaller regenerating fiber CSA as compared to littermate controls on DPI 10 (541 vs. 238μm2, p=.0011). Pharmacological augmentation of VEGFA using ML228 increased muscle VEGF levels by 2 folds and skeletal muscle regeneration in both old mice (25% increase in regenerating fiber CSA, p<.01) and VEGFlo (20% increase in regenerating fiber CSA, p<.01) mice, but not young or littermate controls.

Conclusions: Muscle regeneration declines with aging in correlation with loss of VEGFA levels within skeletal muscle. Supplementation of VEGFA represents a therapeutic target for sarcopenia.

BODY WEIGHT INFLUENCES MUSCULOSKELETAL ADAPTATION TO LONG-TERM VOLUNTARY WHEEL RUNNING DURING AGING

Yukiko Kitase[1], Vallejo Julian[2], Yixia Xie[3], Mark Dallas[3], Sarah Dallas[3], Mark Johnson[3], Michael Wacker[4], and Lynda Bonewald[1], *1. Indiana University School of Medicine, Indianapolis, Indiana, United States, 2. University of Missouri-Kansas City, School of Dentistry and Medicine, Kansas City, Missouri, United States, 3. University of Missouri-Kansas City, School of Dentistry, Kansas City, Missouri, United States, 4. University of Missouri-Kansas City, School of Medicine, Kansas City, Missouri, United States*

Frailty is a key hallmark of aging and exercise has been shown to delay aging effects. This study was initiated based on the hypothesis that voluntary wheel running (VWR) starting at 12 mo until 18 or 22 mo of age would benefit the female murine musculoskeletal system. Based on the final body weight, the mice were separated into high (HBW) and low body weight (LBW) subgroups. Beneficial effects of VWR were observed on soleus muscle mass and contractile force at both ages, although HBW led to greater increases at 22 mo. VWR increased fiber cross-sectional area by 20%, leading to more type I and fewer IIA fibers in soleus. HBW mice were resistant to age-related decline in Extensor digitorum longus (EDL) mass and contractile force. EDL in 18 mo HBW also showed 15% higher contractile force following VWR while muscle from 18 & 22 mo LBW responded to VWR with greater osteocyte protective factor secretion. Skeletal adaptation to VWR was also dependent on body weight, with HBW showing higher femoral cortical thickness and area under sedentary conditions. VWR maintained osteocyte dendrite number in HBW. VWR increased periosteal and endosteal circumferences in HBW, suggesting compensation for loss of material strength. Consistent with this, VWR maintained higher bone mechanical properties in 18mo LBW. In summary, VWR alters musculoskeletal parameters depending on body weight with HBW contributing to more muscle mass and strength to prevent sarcopenia while bone retains better mechanical properties in LBW but HBW contributes structural modification to prevent osteopenia.

LIPID REGULATION BY DGA1, CUT6, AND SRE1 CONTRIBUTE TO THE GENOTOXIC STRESS RESPONSE IN FISSION YEAST

Wilber Escorcia, Mauricio Dominguez, Maryam Khzyr, Sam Burek, Jack Pluth, Meghan Graber, Hayley Barta, and Alex Rausenberger, *Xavier University, Cincinnati, Ohio, United States*

Lipids are essential for cell growth and maintenance, intracellular signaling, and cellular energetics. When exposed to environmental insults, cells activate lipid metabolism programs that facilitate the response, recovery, and exit from stressful conditions. Failure to regulate lipid storage and utilization is associated with accelerated aging, which compounds genomic instability. In this study, we test the physiological consequences of disruptions to three lipid regulator genes frequently found to be mutated in human cancers. Since the products of these genes show functional homology in fission yeast, we examine how lipid deregulation by two enzymes (Dga1DGAT2 and Cut6ACC) and one transcription factor (Sre1SREBF1) influence the response to genotoxic stress in this organism. Using microscopy quantification of lipid staining, we observe abnormal homeostatic control of lipid levels in cells lacking Dga1, Cut6, and Sre1. These phenotypes are enhanced in sub-lethal doses of DNA damage (UV-C light) and are associated with altered cell fitness and proliferation. Furthermore, in response to genotoxicity, these lipid regulator mutants exhibit disrupted nuclear segregation, abnormal cell dimensions, and altered lifespan. These data suggest functional mechanisms that may contribute to the deregulated metabolic and physiological environments of prematurely aged cells and of tumors in human cancers.

THE ROLE OF PPARδ-DRIVEN β-OXIDATION IN BONE HEALTH DURING AGING

Matt Prideaux[1], Tom O'Connell[1], and Yukiko Kitase[2], *1. Indiana University, Indianapolis, Indiana, United States, 2. Indiana University School of Medicine, Indianapolis, Indiana, United States*

Musculoskeletal disorders are a significant complication of aging, leading to increased morbidity and mortality. However, current understanding of the mechanisms by which aging affects skeletal health is limited. Osteocytes are the most numerous and long-lived bone cells and play key roles in maintaining bone mass by responding to anabolic signals such as mechanical loading. Energy metabolism is dysregulated in many cells with aging, however regulation of energy metabolism in osteocytes and how this is affected during aging and by mechanical loading remains undefined. To investigate this, we first used IDG-SW3 osteocyte cells to determine the effects of mechanical loading on osteocytes in vitro by applying fluid flow shear stress (FFSS). FFSS increased Pparδ and Cpt1 expression, key promoters of fatty acid β-oxidation (FAO). Pharmacological antagonism of PPARδ or CPT1 resulted in dysregulated expression of key bone remodeling genes and impaired ATP release in response to FFSS. In vivo, mechanical loading significantly increased FAO in tibia cortical bone. However, FAO was impaired in the bones from aged mice. To further elucidate the role of osteocyte FAO, we deleted PPARδ specifically in osteocytes (PPARδ cKO), which resulted in decreased FAO and bone volume in female PPARδ cKO mice. Lastly, treatment of aging mice with the PPARδ activator GW0742 resulted in significantly increased bone mineral content, density and trabecular bone volume. These findings suggest important functions of osteocyte energy metabolism during aging and with mechanical loading on bone and identify PPARδ-driven FAO as a novel therapeutic target for improving skeletal health with aging.

CLARIFYING THE ROLE OF RESILIENCE IN NONHUMAN PRIMATE AGING USING A BABOON CELL MODEL

Daniel Adekunbi[1], Cun Li[1], Peter Nathanielsz[1], and Adam Salmon[2], *1. University of Wyoming, Laramie, Wyoming, United States, 2. The University of Texas Health Science Center at San Antonio, San Antonio, Texas, United States*

Aging is associated with defects in homeostatic maintenance. Delineating the dynamics of the homeostatic network is challenging in vivo and often limited by endpoint measurements. However, we have developed carefully controlled translatable cellular models to bridge some of these challenges using primary cells obtained from male and female baboons across the life course (4 to 21 years). We recently published findings showing that donor age corresponds to loss of cellular resilience to oxidative stress in males but not in females. Responses to thapsigargin-induced endoplasmic reticulum (ER) stress were also age and sex dependent, though with different pattern than that of oxidative challenge. Young females alone were vulnerable to ER stress, while young males and old females were not affected. These data highlight that primary cells retain donor characteristics regarding molecular mechanisms associated with aging including those dependent on sex. To further investigate these mechanisms, we investigated whether the proteostatic machinery contributes to cellular resilience outcome following ER stress. In female donors, we find significant decrease in 20 S proteasome activity and expression of its catalytic subunit (PSMB 8) in female-derived fibroblasts under basal or ER stress conditions when compared to males. ER oxidoreductin 1 (ERO1) as well as autophagy marker, LC3-II/I ratio, were significantly higher in young females compared to young males during ER stress. These data highlight the propagation of sexual dimorphisms in cellular resilience at the molecular level and suggest that sex differences in maintenance of proteostasis contributes to the vulnerability of young females to ER stress.

SESSION 5010 (PAPER)

CARE MODELS AND DEMENTIA

AN INNOVATIVE MODEL OF CARE FOR SUBJECTS WITH DEMENTIA IN ITALY—IL PAESE RITROVATO—THROUGH THE SARS-COV-2 PANDEMIC

Paolo Mazzola[1], Gaia Ferraguzzi[2], Mariella Zanetti[3], and Giuseppe Bellelli[4], *1. Università degli Studi di Milano-Bicocca, Monza, Lombardia, Italy, 2. Università degli Studi di Milano, Milano, Lombardia, Italy, 3. Cooperativa La Meridiana, Monza, Lombardia, Italy, 4. University of Milano-Bicocca, Monza, Lombardia, Italy*

"Il Paese Ritrovato" is an innovative long-term facility dedicated to subjects with mild-to-moderate Alzheimer's disease or other dementias, located in Monza (Lombardia, Italy).By living in a village that resembles a community neighborhood, it aims at people's wellbeing and represents a shift in the paradigm of traditional nursing home care, allowing the guests to visit the hair stylist, the supermarket, and various activities according to their personal habits, always supported by trained professionals.We performed a retrospective cohort study on 60 subjects, comparing their characteristics before and during the SARS-CoV-2 pandemic, from June 2018 to December 2020. We collected demographic information, cognition, comorbidity, functional status, engagement in the activities through Popularity Index (PI) and Engagement Social Index (ISE), and use of psychoactive medications.The follow-up is performed every 6 months from admission: T0, T6, T12, and T18 are the time-points. The assessment performed during the pandemic is called Tcovid.Compared to a relative stability in cognition before the pandemic, the assessment at Tcovid showed an accelerated worsening of MMSE and CDR scales. We observed an increase in the prescription of antipsychotics (+5%), antidepressants (+11.7%), and benzodiazepines (+1.7%). As expected, engagement in activities dropped (lower PI and ISE). Functional status gradually worsened during the follow-up, according to the natural progression of dementias, but Tcovid slightly accelerated this process and overall worsened the balance performances.Although we are currently unable to quantify the negative effect of this reorganization, future studies need to address the real impact of pandemic on the guests' performances.

CHANGING TALK (CHAT) ONLINE COMMUNICATION EDUCATION FOR ADULT DAY CARE STAFF: EVALUATION AND FUTURE DIRECTIONS

Kristine Williams[1], Carissa Coleman[2], Maria Hein[3], Clarissa Shaw[4], Yelena Perkhounkova[4], and Tim Beachy[5], *1. University of Kansas Medical Center, Lawrence, Kansas, United States, 2. University of Kansas, Kansas City, Kansas, United States, 3. University of Iowa College of Nursing, Iowa City, Iowa, United States, 4. University of Iowa, Iowa City, Iowa, United States, 5. University of Iowa, Iowa City, Kansas, United States*

Communication education has been effective in reducing elderspeak use for nursing home staff and subsequently reduces resistiveness to care and inappropriate antipsychotic medication use in residents living with dementia. Communication is fundamental for dementia care and educating staff in other long-term service and support settings such as Adult Day Care (ADC) is needed. Tailoring education to the specific setting is indicated to optimize acceptability and effectiveness. ADC staff (N=22) from 3 ADC centers participated in the Changing Talk: Online Training (CHATO). Results for the 19 staff who completed the education program were analyzed. A focus group was conducted with a subset of participants to evaluate feasibility, applicability, and directions for tailoring for ADC settings. Knowledge gain was demonstrated by score increases 15.0 percentage points (p<.001) from pre- to post-education on the Changing Talk Scale (CHATS). Confidence in Dementia Care (CODE) scores significantly increased after CHATO (p=.05), indicating an increase in confidence in caring for clients with dementia. The mean Modified Diffusion of Innovation scale score was 2.2 (1=intend to use skills in practice to 5=don't intend to use), indicating intent to use with clients. Program evaluation ratings were positive indicating satisfaction. Focus group participants reported that the CHATO was valuable and recommended ADC specific scenarios. The results support the value of CHATO for ADC staff as well as specific directions to better tailor the education to increase applicability in this LTSS setting.

IDENTIFYING ASSISTED LIVING SAFETY PRIORITIES: A DELPHI PANEL WITH RESIDENT, FAMILY, AND PROFESSIONAL STAKEHOLDERS

Cassandra Dictus[1], Youngmin Cho[1], Victoria Bartoldus[1], Matthias Hoben[2], Stephanie Chamberlain[2], and Anna Beeber[3], *1. University of North Carolina - Chapel Hill, Chapel Hill, North Carolina, United States, 2. University of Alberta, Edmonton, Alberta, Canada, 3. Johns Hopkins University, Baltimore, Maryland, United States*

While assisted living (AL) communities emphasize resident safety, one barrier to resident safety is a lack of information about AL stakeholders' safety priorities. As part of a larger research project to create a toolkit to foster resident and family engagement in safety in AL, we created a stakeholder panel that includes 13 AL residents, family members, and professionals (i.e., direct care workers, administrators, researchers, and policymakers). This paper describes a web-based Delphi process to create a ranked safety priority list with stakeholders. After three rounds involving online surveys and Zoom group discussions, the stakeholder group came to a consensus on a final list of 14 ranked safety priorities. Using verbatim transcripts of the Zoom discussions and chat, we conducted content analysis to highlight the rationales for the 14 ranked safety priorities on the final list. Reasons to prioritize safety concerns included the seriousness of the impact on AL residents and system-level root causes. These findings will be used to guide the development of a toolkit to improve resident and family engagement in the safety of AL. This list can also help AL communities and researchers at large to better understand what safety priorities are most important to a broad range of AL stakeholders and why.

THE SHORT- AND LONG-TERM IMPACTS OF DEMENTIA ON PREVENTIVE CARE UTILIZATION AND HEALTH BEHAVIORS

Zhuoer Lin, and Xi Chen, *Yale University, New Haven, Connecticut, United States*

Identifying early and consistent signals of dementia risk may offer people more time to prepare for the future, helping to delay the onset or slow the progression of dementia. Using the 1995-2018 waves of Health and Retirement Study, we offered novel evidence on the impacts of dementia and its precursors on a rich set of preventive care utilization and health behaviors in a longitudinal sample of Americans aged 50 and older. Leveraging both within- and between-individual variations in an event study, we characterized short- and long-term dynamic changes in preventive care and health behaviors relative to the incidence of dementia, suggesting early behavioral indicators of the disorder. 3,488 persons with incidence of dementia were identified and 22,619 consecutive person-waves around the incidence of dementia were included to estimate short-term effect. Individuals who never developed dementia were further included as the comparison group for long-term estimation. Results from statistical models showed that incidental dementia was associated with significant reductions in preventive care utilization, including cholesterol test, flu shot, mammogram, prostate test, and dental visit. Significant declines were also found in physical activities and body weights. Moreover, growing declines were observed in preventive care utilization, physical activities, and body weight 4-6 years prior to the incidence of dementia, with escalating impact over time. These findings highlight vulnerability and costs dementia risk may accrue to disrupt preventive care utilization and health behaviors. Targeted interventions are needed to detect signals associated with dementia risk to shield individuals from adverse behavioral and health consequences.

EVALUATION OF COGNITION IN PRIMARY CARE (CPC): A PILOT STUDY TO INCREASE EARLY DETECTION AND MANAGEMENT OF DEMENTIA

Annette Fitzpatrick[1], Barak Gaster[1], Jaqueline Raetz[1], Basia Belza[1], Monica Zigman Suchsland[1], Karen Tracy[2], Benjamin Olivari[3], and Lisa McGuire[3], *1. University of Washington, Seattle, Washington, United States, 2. GSA, Washington, District of Columbia, United States, 3. CDC, Atlanta, Georgia, United States*

Despite evidence that early detection of mild cognitive impairment and dementia leads to improved patient care, these conditions remain under-diagnosed in primary care. To address this gap at University of Washington Medicine, we have developed and pilot-tested a program to increase cognitive evaluations and improve dementia care by primary care providers (PCPs). The Cognition in Primary Care (CPC) program was designed utilizing stakeholder-selected components of the GSA KAER (Kickstart-Assess-Evaluate and Refer) Model and Toolkit (2020 Edition), developed by the Gerontological Society of America (GSA). In this presentation we will describe evaluation of the CPC Program including (a) education training; (b) use of assessment tools integrated within the electronic health record (e.g. potentially harmful medications, depressive symptoms, alcohol use, sleep apnea, etc.); (c) practice recommendations such as dedicated evaluation appointments, diagnoses and referrals, and (d) PCP use of community resources for post-diagnosis support. A total of 66 PCPs participated in the series of 3 CME educational seminars. Over 93% of participants reported the content to be highly relevant and expected to incorporate it into their practice; commitments to use specific tools were made. Analysis is underway to determine impact of the program by comparing the above metrics before and after the training as well as between trained and untrained PCPs. Results from this evaluation will inform modifications to increase utilization of the CPC Model within UW Medicine, will be used to package the program to share with other primary care systems, and will guide future enhancements to the GSA KAER Toolkit.

SESSION 5020 (SYMPOSIUM)

CARING FOR OLDER ADULTS ACROSS THE CARE CONTINUUM: EXPERIENCES OF OLDER ADULTS AND FORMAL CAREGIVERS

Chair: Rose Ann DiMaria-Ghalili Discussant:
Rose Ann DiMaria-Ghalili

As individuals age, they are at risk of experiencing health challenges that can contribute to poorer health outcomes and increase health care costs. During acute care crises and through the continuum of dealing with chronic diseases, older adults rely on formal caregivers to provide care and support. Formal caregivers' delivery of care can be challenged during difficult patient cases (e.g., providing wound care to a person exhibiting behavioral and psychological symptoms of dementia) and during high stress times, such as working through a pandemic. However, during difficult times, resilience among formal caregivers can have a positive affect on care delivery. This symposium identifies some of the health challenges experienced by aging adults, challenging experiences of nurses, levels of resilience among formal caregivers, and discusses the implications for nursing care and future research. Ms. Coates examines trends in adverse drug admissions among older adults in the United States using the 2018 Healthcare Cost and Utilization Project's National Inpatient Sample. Dr. Hwang explores the relationship between nutrition, inflammation, and physical and mental health in aging adults with chronic leg wounds. Dr. Sefcik discusses nurses' experiences caring for community-dwelling persons living with dementia and chronic wounds. Mr. Hathaway examines factors that contribute to resilience in staff of a continuing care retirement community during the late stage of the COVID-19 pandemic. Dr. DiMaria-Ghalili, discussant, will synthesize these findings and offer insights on designing interventions to address health challenges and recommendations for supporting formal caregivers.

TRENDS IN ADVERSE DRUG EVENT ADMISSIONS AMONG OLDER ADULTS IN THE UNITED STATES

Martha Coates[1], Patricia Shewokis[1], and Rose Ann DiMaria-Ghalili[2], *1. Drexel University, Philadelphia, Pennsylvania, United States, 2. Drexel University, College of Nursing and Health Professions, Philadelphia, Pennsylvania, United States*

Older adults experience adverse drug events (ADEs) putting them at risk for increased morbidity and mortality. Utilizing the 2018 Healthcare Cost and Utilization Project's National Inpatient Sample, we identified the prevalence of ADE admissions among adults 65 and older and examined the differences in characteristics and discharge outcomes in those with and without a primary diagnosis of an ADE (n=2,647,673). ADEs accounted for 7.4% of discharges and had higher odds of needing post-discharge care including transfer to a skilled nursing facility (OR=1.08, 95% CI [1.07, 1.09]) and home-health care (OR=1.1, 95% CI [1.09,1.1]). In the ADE group, hospital charges were higher ($39,609 vs. $38,649, p< .01) and length of stay (6+ days) longer (OR=1.53, 95% CI [1.52,1.55]). Opiates, diabetic agents, benzodiazepines and narcotics were frequently associated with ADEs. Older adults discharged after an

ADE have increased healthcare utilization. Education on medication self-management is needed to prevent ADEs in older adults.

NUTRITION, INFLAMMATION, AND PHYSICAL AND MENTAL HEALTH IN AGING ADULTS WITH CHRONIC WOUNDS

Yeji Hwang[1], Zachary Hathaway[1], Isabella Stoll[1], Shelby Hufnal[1], Peter Lewin[1], and Rose Ann DiMaria-Ghalili[2], *1. Drexel University, Philadelphia, Pennsylvania, United States, 2. Drexel University, College of Nursing and Health Professions, Philadelphia, Pennsylvania, United States*

Nutritional status can impact the healing of chronic leg wounds (CLW). This secondary data analysis examined characteristics associated with nutritional status among aging adults (N=62, M= 57.5, SD 12.1 years of age) living with a CLW who were enrolled in a randomized control trial to test a novel ultrasound intervention on wound healing. Nutritional status (Mini-Nutrition Assessment, [MNA]), physical and mental health (36-Item Short-Form Health Status Survey), and inflammation (high-sensitivity C-Reactive Protein [CRP]) were measured at baseline. Majority of the participants were male (54.8%), non-Hispanic Black (67.7%) and either malnourished or at risk of malnutrition (64.5%). Compared to individuals with normal nutrition, individuals with malnutrition or risk for malnutrition had on average poorer physical health (38.7 vs 33.4, $p <0.01$), mental health (52.4 vs 45.8, $p=0.03$) and greater inflammation (CRP=13.4 vs 24.0, $p=0.05$). Tailored interventions targeting nutritional status, inflammation, physical and mental health are needed in aging adults with CLW.

NURSES' EXPERIENCES CARING FOR PERSONS LIVING WITH DEMENTIA AND CHRONIC LEG WOUNDS IN THE COMMUNITY

Justine Sefcik[1], Olivia Hernandez[1], Isabella Stoll[1], Zachary Hathaway[1], Ellen Bass[1], and Rose Ann DiMaria-Ghalili[2], *1. Drexel University, Philadelphia, Pennsylvania, United States, 2. Drexel University, College of Nursing and Health Professions, Philadelphia, Pennsylvania, United States*

A gap exists with understanding the care required for community-dwelling persons living with dementia (PLWD) who have chronic wounds. As one step to address this gap we explored the experiences of nurses who care for community-dwelling PLWD that have chronic diabetic foot and venous leg ulcers. A qualitative descriptive approach with a conventional content analysis was undertaken. We conducted 5 focus groups with Home Health Nurses (n = 13) and nurses holding specialty certifications (e.g., wound care) (n = 3); 87.5% female, 69% White, non-Hispanic, mean age = 52 (range 32-67), mean years of experience as a nurse = 23.8. The main themes identified were 1) the challenges with dementia (e.g., confusion, taking dressings off), 2) concerns about the person (e.g., medical issues, financial considerations), and 3) adjusting interventions (for wounds and behavioral symptoms). Study findings can inform the develop of future novel interventions for PLWD and chronic wounds.

COVID-19 PANDEMIC AND RESILIENCE IN STAFF OF A CONTINUING CARE RETIREMENT COMMUNITY

Zachary Hathaway[1], Kathleen Fisher[1], Martha Coates[1], Shelby Hufnal[1], Isabella Stoll[1], Justine Sefcik[1], and Rose Ann DiMaria-Ghalili[2], *1. Drexel University, Philadelphia, Pennsylvania, United States, 2. Drexel University, College of Nursing and Health Professions, Philadelphia, Pennsylvania, United States*

Residents and staff of continuing care retirement communities (CCRC) experienced many challenges during the COVID-19 pandemic including loss, social isolation, and staff turnover. This study examined factors that contribute to resilience in staff during the late stage of the pandemic using the Connor-Davidson Resilience Scale. Resilience scores ranged from 0 (low) to 100 (high). A total of 96 staff (76% female) were enrolled, and average age was 48.41 years (SD = 16.16). Average resilience in staff was 75.16 (SD = 11.81). Those under 35 years of age reported lower resilience scores (M = 67.38) compared to those 35-49 years of age (M = 76.65), 50-64 (M = 75.83), and 65 years and older (M = 82.71), $p <.05$. Staff who were married scored higher than those who were not (M = 76.63 vs 69.05), $p < .05$. Findings can inform professional development programs aimed at increasing coping skills in staff.

SESSION 5030 (SYMPOSIUM)

DEMENTIA CARE THROUGHOUT THE TRAJECTORY AND ACROSS SETTINGS: RESULTS FROM THE DEVELOP AD RESEARCH STUDY

Chair: Lauren Hunt Co-Chair: Katherine Ornstein
Discussant: Lauren Massimo

About 1 in 8 older adults in the United States has dementia, making it one of the biggest public health issues facing society today. The impact of dementia ranges across health and social systems, yet consideration of these contexts--which are of great relevance to patients and families--has been underexplored in prior research. In this symposium, we will present findings from the Deploying High-Value Longitudinal Population-Based data in Dementia Research (DEVELOP AD Research) study. This multicenter collaboration leverages existing population-based data sources to examine the health and social impacts of dementia throughout the trajectory of decline and across acute, long-term, and community-based settings. Session one will describe how acute care utilization increases in the years before the onset of incident dementia. Session two will examine the association between dementia and increased mortality risk after disruptive medical events, including hip fracture and pneumonia. Session three will report on the prevalence and patterns of medication overuse and misuse in community-dwelling people with dementia. Session 4 will estimate how many community-dwelling individuals, including those with dementia, could benefit from home-based medical care. Session 5 will focus on hospice use patterns and hospice care quality rating in people admitted to hospice for dementia versus other conditions. Together, these presentations provide a wide lens on the health and social experiences and needs of people with dementia at the national level, leading to a better understanding of how society can better address the challenges of caring for this growing population.

EMERGENCY DEPARTMENT AND INPATIENT HOSPITAL HEALTHCARE UTILIZATION IN THE YEARS PRECEDING INCIDENT DEMENTIA

Raj Kumar[1], Katherine Ornstein[2], Evan Bollens-Lund[1], Jing Li[3], Ken Covinsky[4], and Amy Kelley[1], *1. Icahn School of Medicine at Mount Sinai, New York, New York, United States, 2. Johns Hopkins, University, Baltimore, Maryland, United States, 3. Cornell University, Ithaca, New York, United States, 4. University of California, San Francisco, San Francisco, California, United States*

There is evidence health utilization increases after incident dementia, particularly toward the end of life. However, less is known about utilization in the years before dementia. Our study objectives were to compare outpatient emergency department (ED) and inpatient hospital utilization in the six years preceding incident dementia compared to a reference group without dementia. We obtained data on n=5,547 Beneficiaries from the Health and Retirement Study-Medicare linked sample, and defined dementia using a validated algorithm. Those with (n=1,241) and without (n=4,306) dementia were balanced on confounders using inverse probability weighting applied to longitudinal Generalized Estimating Equation models. We found persons with dementia had greater odds of ED (OR=1.46, 95% CI: 1.21, 1.77) and inpatient hospital (OR=1.35, 95% CI: 1.12, 1.63) usage in the years preceding dementia compared to those without dementia across a comparable timespan. This study provides evidence to suggest greater healthcare burden may exist before manifestation of dementia.

THE EFFECT OF DISRUPTIVE MEDICAL EVENTS ON MORTALITY IN PEOPLE WITH AND WITHOUT DEMENTIA

Lauren Hunt[1], Sean Morrison[2], Siqi Gan[1], Edie Espejo[1], W. John Boscardin[1], Rebecca Rodin[2], Katherine Ornstein[3], and Alexander Smith[1], *1. University of California, San Francisco, San Francisco, California, United States, 2. Icahn School of Medicine at Mount Sinai, New York, New York, United States, 3. Johns Hopkins University, Baltimore, Maryland, United States*

Disruptive medical events such as pneumonia and hip fracture occur more frequently among older adults with dementia than those without dementia. It is not well-understood whether these events increase the risk of mortality to a greater extent for people with dementia (PWD) compared to people without dementia (PWoD). Using data from the Health and Retirement Study linked to Medicare claims, we estimated the impact of hip fracture and pneumonia on risk of mortality among 700 PWD and 12,438 PWoD using a Cox proportional hazards model. PWD had a higher risk of mortality both in the case of hip fracture (HR 1.64, 95% CI 1.31, 1.96) and pneumonia (HR 1.21 95% CI 1.09, 1.34) compared to PWoD who experienced those events. This study provides evidence that dementia may increase mortality after a disruptive medical event and suggests that the clinical course of dementia may not always be slow and gradual.

UNNECESSARY AND HARMFUL MEDICATION USE IN COMMUNITY DWELLING PERSONS WITH DEMENTIA

W. James Deardorff[1], Bocheng Jing[1], Matthew Growdon[1], Kristine Yaffe[1], Kenneth Boockvar[2], and Michael Steinman[1], *1. University of California, San Francisco, San Francisco, California, United States, 2. Icahn School of Medicine at Mount Sinai, New York, New York, United States*

Persons with dementia (PWD) often have multiple comorbidities which results in extensive medication use despite potentially limited benefit and increased risk of adverse events. Compared to the nursing home, little is known about medication overuse and misuse among the ~70% of PWD in the community. Therefore, we examined medication use from Medicare Part D prescriptions among 1,289 community-dwelling PWD aged ≥66 from the Health and Retirement Study. We classified medication overuse as over-aggressive treatment of chronic conditions (e.g., insulin/sulfonylurea use with hemoglobin A1c<7.5%) and medications inappropriate near the end of life. We classified medication misuse as medications that negatively affect cognition (strongly anticholinergics/sedative-hypnotics) and problematic medications (using Beers and STOPP criteria). We describe the prevalence and patterns of different types of medication overuse/misuse. Frequently problematic medications included antipsychotics (9%), benzodiazepines (12%), and gabapentinoids (13%). Our findings highlight the burden of unnecessary/harmful medications among PWD and inform future deprescribing interventions.

WHO CAN BENEFIT FROM HOME-BASED MEDICAL CARE?

Katherine Ornstein[1], Bruce Leff[1], Jennifer Reckrey[2], Evan Bollens-Lund[2], Margaret Salinger[3], Yihan Wang[2], and Christine Ritchie[4], *1. Johns Hopkins University School of Medicine, Baltimore, Maryland, United States, 2. Icahn School of Medicine at Mount Sinai, New York, New York, United States, 3. Harvard Medical School/Massachusetts General Hospital, Boston, Massachusetts, United States, 4. Massachusetts General Hospital, Boston, Massachusetts, United States*

Leaving the home to access medical care may result in undue burden for patients with dementia and other serious illnesses and their caregivers. While home-based medical care (HBMC) may be beneficial for many older adults, it is not clear how to best identify individuals who could benefit from such services. Using the 2015 NHATS linked to Medicare claims we estimated prevalence across multiple overlapping subtypes: Individuals who have moderate/severe dementia; are homebound; have serious illness; are frail; rely on assistive devices; have high caregiving needs; those with minimal primary care and high ED use; and those who met previously established criteria for Independence at home. Using these criteria, more than half of community-dwelling older adults could benefit from HBMC and more than 25% meet multiple criteria. Medicare and other payers can benefit from targeted identification of patients who could benefit from HBMC.

SPECTRUM OF DEMENTIA IN OLDER HOSPICE RECIPIENTS

Lauren Hunt[1], Irena Cenzer[1], Alexander Smith[1], Amy Kelley[2], Melissa Aldridge[2], Kenneth Covinsky[1], and Krista Harrison[1], *1. University of California, San Francisco, San Francisco, California, United States, 2. Icahn School of Medicine at Mount Sinai, New York, New York, United States*

We know little about differences between hospice enrollees with dementia co-existing with another terminal illness (like cancer), those dying from dementia (as principal hospice diagnosis), and those dying with no dementia. We used the National Health Aging and Trends Study linked to Medicare claims to compare characteristics, hospice use patterns, and care quality ratings. Among 1,105 decedent hospice-enrollees age 70+, we found 39% were dying with coexisting dementia, 17% from dementia, and 44% without dementia. In adjusted analyses, those dying with dementia had similarly high rates of functional impairment, higher rates of clinical needs, and worse measures of care quality compared to elders dying from dementia. Hospice use patterns were different for elders dying with dementia compared to elders without dementia. In summary, 56% of older hospice enrollees have dementia, mostly in addition to another terminal illness. Their differing hospice experience implies changes are needed to hospice care and policy.

SESSION 5050 (SYMPOSIUM)

ENRICHING THE LIVES OF OLDER VETERANS: THE GEROFIT WAY

Chair: Katherine Hall Co-Chair: Adam Gepner

Gerofit is a clinical exercise program for Veterans ages 65 years and older with multi-morbidities and functional limitations that place them at elevated risk for institutionalization. It was declared a VHA "Best Practice" in 2017 and was selected for widespread dissemination and implementation, with over 30 Gerofit programs spanning the country. The original Gerofit program consists of supervised, facility-based exercise, offered 3 days per week in a group setting. Each exercise prescription incorporates aerobic training, progressive resistance training, and specialized exercises for balance and physical function. Everything changed in March 2020 when facilities began receiving orders to shut down face to face encounters and social distancing measures were put in place. Within six weeks, all of our sites had transitioned to group-based virtual classes, aptly called Gerofit to Home (GTH). This symposium includes 2 presentations that explore the effect of GTH on physical functioning and health-related quality of life outcomes in veteran participants during the pandemic: one focusing on resilience among GTH adopters vs. non-adopters in patients formerly participating in facility-based Gerofit; and the second focusing on patients enrolled directly in to GTH (no facility-based experience). The third presentation describes differences in physical function and health gains among Gerofit participants with and without peripheral artery disease (PAD). The fourth and fifth presentations describe augmented models of care to enrich the Gerofit experience for a) participants with supplemental nutrition programming and b) advanced physical therapy trainees through a Gerofit resident training model.

GEROFIT TO HOME (GTH) AS A NEW MODEL OF CARE

Rebekah Harris[1], Miriam Morey[2], Elisa Ogawa[1], Alan Wesley[3], Jonathan Bean[1], and Katherine Hall[2], *1. VA Boston, Boston, Massachusetts, United States, 2. Durham VA Health Care System, Durham, North Carolina, United States, 3. Puget Sound VA, Seattle, Washington, United States*

Gerofit, a facility-based program transitioned to GTH, a completely virtual structured exercise program, at the onset of the pandemic and previously demonstrated that Veterans already engaged sustained performance with this transition (In-Person vs GTH, n=46; arm curls 19.7 vs 19.0 reps; 30-second chair stand 14.3 vs 15.9 reps). This study investigated whether gains in performance are achieved and sustained in Veterans who participated in GTH only, as it is unknown if virtual programs are as robust as facility-based programs. Measures of performance (3-month mean change, n=45, Arm Curls +3.4 reps; 30-second chair stand +1.5 reps) and self-reported function (SF-36 + 1.8 points) will be assessed from baseline to 3,6, and 12 months. Pooled results from 14 sites have been accumulated and change scores, age and gender-based percentile changes and clinically meaningful thresholds will be presented. This knowledge can have implications to support programs for older adults aging in place.

CAN VIRTUAL EXERCISE PROMOTE PHYSICAL RESILIENCE DURING THE COVID-19 PANDEMIC AMONG ACTIVE OLDER ADULTS?

Kenneth Manning[1], Stephen Jennings[1], Megan Pearson[1], Richard Sloane[2], Katherine Hall[3], Kyle Bourassa[1], and Miriam Morey[3], *1. Durham VA Healthcare System, Durham, North Carolina, United States, 2. Duke University Medical Center, Durham, North Carolina, United States, 3. Durham VA Health Care System, Durham, North Carolina, United States*

Background: Gerofit is a facility-based exercise and health promotion program for older Veterans that transitioned to virtual delivery in March 2020. Little is known about how virtual exercise would promote resilience in the physical function of individuals previously participating in-person.

Methods: Preliminary data from 1 of 14 sites was gathered 72 Veterans returning to facility-based exercise after COVID mandated shutdowns. 39 individuals chose not to participate virtually, and 33 actively participated virtually for over 1 year. Re-entry data were then compared to the patients' most recent test. Assessment means were compared within groups.

Results: Change scores from T1 to T2 were: -1.19 versus +2.4 repetitions for 30-second arm curls; +1.57 repetitions for 30-second chair stands; and -113.87 versus -77.3 yards for six-minute walk distance for non-virtual versus virtual groups. Implications: Participation in virtual exercise interventions may promote resilience and resistance to functional decline in previously active individuals during enforced isolation.

VIRTUAL NUTRITION EDUCATION AND PRODUCE DELIVERY INCREASES DIETARY QUALITY AMONG OLDER VETERANS

Elizabeth Parker[1], Sarah Cassatt[2], Jamie Giffuni[3], Leslie Katzel[4], Heidi Ortmeyer[5], and Odessa Addison[6], *1. University of Maryland School of Medicine, Baltimore, Maryland, United States, 2. University of Maryland,* *Baltimore and Baltimore County, Baltimore, Maryland, United States, 3. Geriatric Research Education & Clinical Center, Baltimore, Maryland, United States, 4. VAMHCS/UMB, Baltimore, Maryland, United States, 5. Baltimore VA Medical Center, Baltimore, Maryland, United States, 6. Department of Physical Therapy and Rehabilitation Science, Baltimore, Maryland, United States*

This project assessed the impact of a 14-week virtual group nutrition education plus produce delivery on diet quality of Baltimore GEROFIT participants. RD led classes focused on healthy aging content. Participants could receive an optional bag of local produce. Dietary intake assessed via a 24-hour recall was used to calculate healthy eating index (HEI-2015; higher scores=higher diet quality). Twelve participants enrolled in the program. Two participants discontinued produce delivery due to physical/environmental limitations prohibiting preparation; seven completed recalls at pre/post and received produce (86% male; 71% Caucasian; age=73 years; BMI=33 kg/m2). There were no changes in overall diet. However, among participants who received >80% of produce (n=4), HEI scores increased (+5.4 points). Daily F&V increased by 1.9 servings. Daily protein intake decreased (-25g). This study highlights areas for program improvement including a stronger emphasis on protein intake and incorporating physical/environmental adaptations that may increase participation among older Veterans with disabilities.

UTILIZING PHYSICAL THERAPY RESIDENTS' AS HEALTH PROMOTION EXPERTS TO IMPROVE QOL FOR OLDER VETERANS

Susan Patel, *Cincinnati VA Medical Center, Cincinnati, Ohio, United States*

Gerofit, an evidence-based supervised exercise and health promotion program for older Veterans, has demonstrated success with its best practice model through the improved health, physical function, and well-being of participants. In 2017, Cincinnati VA Medical Center (CVAMC) launched an innovative approach to address the staffing needs of this wellness program by utilizing a Physical Therapy (PT) resident model for Gerofit group supervision/functional testing. As licensed PTs, residents engage in year-long advanced training in geriatrics across a variety of settings. They encounter adults who have unhealthy behaviors (lack of physical activity, smoking, poor nutrition, inadequate sleep, and stress), and demonstrate the knowledge/skills to reduce risk factors, prevent/treat chronic disease, prescribe physical activity/exercise, perform interventions consistent with the biopsychosocial paradigm, design/deliver individualized exercise prescriptions, and lead telehealth group exercises classes for Veterans. This presentation will explore how PT residents are in an ideal position to promote health/wellness in the Gerofit Program.

FUNCTIONAL IMPROVEMENTS AMONG OLDER VETERANS WITH PAD FOLLOWING 12 MONTHS OF EXERCISE TRAINING

J Antonio Gutierrez[1], Megan Pearson[2], Lin Gu[1], Katherine Hall[3], Sunil Rao[4], and Miriam Morey[3], *1. Durham VA Medical Center, Durham, North Carolina, United States, 2. Durham VA Healthcare System, Durham, North Carolina, United States, 3. Durham VA Health Care System, Durham, North Carolina, United States, 4. DURHAM VA MEDICAL CENTER, DURHAM, North Carolina, United States*

The prevalence of peripheral artery disease (PAD) increases exponentially with age and is associated with heightened risk of functional impairment. We assessed baseline function and compared changes in mobility among older Veterans with PAD participating in Gerofit, a clinical exercise program. A total of 545 Veterans (mean age: 79 years) completed baseline, 3-, 6-, and 12-month mobility assessments and were divided into the following cohorts: PAD (n=99) and no PAD (n=446). Assessments included 10-m walk speed, 6-min walk distance, 30-s chair stands, and 8-ft up-and-go time. Veterans with PAD performed worse on all measures than non-PAD Veterans at baseline. Veterans with PAD demonstrated significant improvements ($p < 0.05$) in all measures from baseline at 3, 6 and 12 months. There were no significant differences in change scores between PAD and non PAD across all time points, controlling for age, except for 8-ft up-and go. PAD Veterans benefit from function-based exercise.

SESSION 5060 (PAPER)

INFLAMMATION

AFFECTIVE REACTIVITY TO DAILY STRESSORS AND IMMUNE GENE EXPRESSION IN THE MIDUS STUDY

Abner Apsley[1], Sun Ah Lee[2], Aarti Bhat[3], David Almeida[2], and Idan Shalev[2], *1. Pennsylvania State University, University Park, Pennsylvania, United States, 2. The Pennsylvania State University, University Park, Pennsylvania, United States, 3. The Pennsylvania State University, State College, Pennsylvania, United States*

Past research indicates that an individual's affective reactivity to daily stressors is associated with elevated levels of inflammatory biomarkers such as interleukin-6 and C-reactive protein. Here, we assessed individuals' positive and negative affective reactivity to daily stressors, and their association with expression levels of genes in the conserved transcriptional response to adversity (CTRA; proinflammatory and type-1 interferon antiviral genes). We hypothesize that gene expression levels of CTRA genes are a possible explanatory mechanistic link between higher levels of affective reactivity and inflammatory markers. Our study included 199 individuals from the Midlife in the United States Refresher study (ages 26-71, 52.8% female, and 17.9% non-white) who participated in the Gene Expression and Daily Diary Projects. Individuals provided whole blood for gene expression analysis and completed an 8-day telephone interview to assess daily experiences. Positive and negative affective reactivity scores were used to indicate magnitude of an individual's changes in daily affect on stressor-days versus non-stressor-days, and were computed using multilevel modeling. Three CTRA gene expression scores were created for each individual, representing the average expression of proinflammatory, type-1 interferon, and a combination of both. Preliminary findings suggest a negative association between the CTRA composite score and negative affective reactivity to daily stressors (β = -0.963, p = 0.034), controlling for covariates. Further analyses will use affective reactivity to predict individual CTRA genes, correcting for multiple testing. This study will be the first to examine the relationship between daily assessments of emotions and gene expression levels in a representative U.S. cohort.

RACIAL AND ETHNIC DIFFERENCES IN THE LIFE COURSE INFLUENCES OF SOCIOECONOMIC STATUS ON ADULT SYSTEMIC INFLAMMATION

AMBER KELLY[1], Patricia Morton[2], Fatima Eid[3], and Kenneth Ferraro[4], *1. Wayne State University, Ferndale, Michigan, United States, 2. Wayne State University, Detroit, Michigan, United States, 3. Wayne State University, Dearborn, Michigan, United States, 4. Purdue University, West Lafayette, Indiana, United States*

Two fundamental causes of health disparities in the U.S. are race and socioeconomic status (SES). Although these disparities emerge early in the life course, there is limited research on how race/ethnicity intersects with SES over the life course to influence later-life systemic inflammation—a key pathogenic process of health for older adults. Moreover, life course studies on systemic inflammation often focus on Black/White differences. Analyzing a sample of Black, White, and Hispanic Americans, this study examined the intersecting influences of childhood SES, race/ethnicity, and adult education on three time points of later-life inflammation levels (measured using C-reactive protein [CRP]). Longitudinal mixed-effects models were estimated using a sample of U.S. men (n=4,137) and women (n=6,187) over age 50 from the Health and Retirement Study during a decade of observation (2006-2016). Black men who experienced low childhood SES had higher levels of CRP than White men with low childhood SES; education did not moderate these associations. Education had a stronger protective effect against systemic inflammation for Hispanic men who experienced childhood socioeconomic disadvantage compared to their White counterparts. For women, the protective effect of education on systemic inflammation was stronger for White women compared to Black and Hispanic women. There were no significant childhood SES interactions for women. Findings indicate that the effects of SES on later-life systemic inflammation are contingent upon race/ethnicity, suggesting that intersectionality operates over the life course to produce health disparities in later-life. However, adult education acts as a leveler of life course inequality for Hispanic men.

SOCIAL DIFFERENCES IN ALLOSTATIC LOAD TRAJECTORIES ACROSS ADULTHOOD

Christine Walsh[1], Yang Yang[2], Daniel Belsky[3], Sarah Mills[2], Marissa Hall[2], and Shelley Golden[4], *1. Carolina Population Center, University of North Carolina, Chapel Hill, North Carolina, United States, 2. University of North Carolina at Chapel Hill, Chapel Hill, North Carolina, United States, 3. Mailman School of Public Health, Columbia University, New York City, New York, United States, 4. University of North Carolina at Chapel Hill, Chapel HIll, North Carolina, United States*

Chronic psychosocial stress has been indicated as a potentially important driver of U.S. health disparities. Allostatic load (AL) is an indicator of cumulative biological risk or "wear and tear" on the body resulting from repeated adaptations to life stressors. A population-level examination of AL may be particularly useful in understanding the intermediate physiological dysregulation that underlies social inequalities in health. No study has yet documented changes in allostatic load over a wide range of ages and intersecting sociodemographic groups. To address this gap, we pooled biomarker data from three U.S. longitudinal cohort studies (National Longitudinal Study of Adolescent to Adult Health, Midlife Development in the U.S., and the Health and Retirement Survey) to create an integrated dataset covering individuals ages 24 to over 95 from several birth cohorts. We conducted growth curve models to examine associations of AL trajectories with cohort and multiple dimensions of social identity. We found more recently born cohorts were associated with higher mean levels in AL as compared to earlier-born cohorts. Net of cohort, education, and other covariates, Black men and women and Hispanic men had significantly higher AL than their White counterparts. These differences were present in early adulthood and persisted at all ages. Hispanic women experienced the largest increases in AL with age, surpassing nearly all other groups at older ages. These findings contribute new knowledge about the temporal dynamics and social patterning of AL as individuals age, particularly intersecting stress exposures as an underlying and enduring source of health inequity.

VIGILANCE, STRESS COPING, AND DISPARITIES IN METABOLIC HEALTH OVER THE LIFE COURSE

Viktoriya Kalesnikava[1], Michele Evans[2], Alan Zonderman[3], and Briana Mezuk[1], *1. University of Michigan, School of Public Health, Ann Arbor, Michigan, United States, 2. National Institute on Aging, Bethesda, Maryland, United States, 3. National Institute on Aging, National Institute of Health, Baltimore, Maryland, United States*

Recent investigations of the mechanisms through which stress may impact cardiometabolic health point to the potential importance of cognitive tendencies (e.g., vigilance, coping strategies) in this relationship. This study examined the associations between vigilance and stress coping with metabolic risk, and whether these associations varied by race and life course socioeconomic status (SES). Data come from the Healthy Aging in Neighborhoods of Diversity across the Life Span (HANDLS) study, a cohort of urban adults (n=3720, baseline age 30-64 years; balanced by race, sex, age and household income). Vigilance was measured by the MacArthur Reactive Responding subscale; stress coping was measured by the Brief Cope scale. Metabolic risk was operationalized by metabolic syndrome z-scores (MetS-Z). Linear mixed models were used to examine longitudinal associations between cognitive tendencies and MetS-Z; interaction terms were used to examine effect modification by race and life course SES. Black participants reported higher adaptive coping; participants experiencing persistent poverty or downward mobility reported higher vigilance and avoidant coping and lower adaptive coping. Overall, vigilance was not associated with metabolic risk. Avoidant and adaptive coping were inversely associated with baseline MetS-Z and further varied by sociodemographic factors. Higher adaptive coping was associated with lower MetS-Z among White adults, while higher avoidant coping was associated with lower MetS-Z among Black adults. Lower stress coping were associated with higher MetS-Z among White participants with low lifecourse SES or downward socioeconomic mobility. In sum, stress coping may modulate the stress-health relationship, but these associations must be interpreted within the intersection of contextual factors.

DEPRESSION, INFLAMMATION, AND THE MODERATING ROLE OF METFORMIN: RESULTS FROM THE MIDUS STUDY

Sumaiyah Syed[1], Iris Yang[1], and Stephanie Wilson[2], *1. Southern Methodist University, Dallas, Texas, United States, 2. Southern Methodist University, DALLAS, Texas, United States*

There is a well-established link between depression and aging-related inflammation, where depression can spur inflammation and affect physical health. Previous animal trials have shown compelling evidence that the use of metformin, the first line of treatment for diabetes, can offset inflammation. These findings have not yet been extended to human samples. This study examined the association between depression and inflammation, specifically the moderating role of metformin usage in middle-aged and older adults. We predicted that metformin would attenuate the link between depression and inflammation. Participants in Project 4 of the Midlife in the United States (MIDUS) Study (n=1255, Mage = 57) provided data on medication use, depressive symptoms, and inflammatory cytokines interleukin (IL)-6, tumor necrosis factor (TNF)-α, and C-reactive protein (CRP). Controlling for age, sex, body mass index (BMI), and comorbidity burden, metformin use moderated the association of depressive symptoms with IL-6 and CRP, but not TNF-α. Higher levels of depressive symptoms were significantly associated with higher interleukin 6 (IL-6) ($p < .001$) and C-reactive protein (CRP) ($p = .033$) among those not using metformin. However, this effect was not significant among those using metformin, suggesting that metformin usage may attenuate the relationship between depression and inflammation. These findings support the potential of metformin in mitigating the link between depression, a well-known behavioral risk factor, and inflammation, a key source of biological aging. Metformin, an accessible and commonly prescribed drug, may have a hidden anti-aging role that may protect against the inflammatory effects of depression.

SESSION 5070 (SYMPOSIUM)

LATE-LIFE CARE FOR OLDER ADULTS: FINDINGS FROM NHATS AND NSOC

Chair: Mengyao Hu Co-Chair: Sarah Patterson

With the aging of the U.S. population, caregiving has become an emerging public health issue that affects the health and quality of life for millions of care recipients and their caregivers. An increasing number of older adults rely on their family caregiver networks and home-based clinical services for physical, social and emotional support. Caregiving plays an important role in health and wellbeing of older adults both in daily life and in the context of health care, e.g., in post-acute caregiving after hospital discharge. There is a growing interest in identifying caregivers in greatest need of support and developing programs and interventions to help these caregivers. This symposium describes caregiver network and examines the roles of the caregiver network and family caregiving support on care recipients' and caregivers' quality-of-life outcomes using the National Health and Aging Trends Study (NHATS) and linked National Study on Caregiving (NSOC). This symposium will 1) evaluate typologies of the structures and compositions of caregiver network and examine their effects on care recipients' well-being; 2) describe findings on associations between caregiving network and caregiver supports with unmet needs among older adults; 3) describe the role of unpaid caregivers after hospital discharge; 4) evaluate effects of family caregiving support in facilitating the use of home-based clinical services by older adults; 5) examine the effects of family disagreement on caregivers' emotional difficulty and overload in dementia caregiving. Together, these presentations suggest important public health implications for research, policy and practice for improving late-life caregiving.

TYPOLOGIES OF CAREGIVING NETWORKS AND OLDER ADULTS' QUALITY OF LIFE

Mengyao Hu, Vicki Freedman, and Sarah Patterson, *University of Michigan, Ann Arbor, Michigan, United States*

This study identifies typologies of caregiving networks of older adults and their effects on older adults' well-being and unmet needs in late life using the National Health and Aging Trends Study (NHATS). NHATS identifies the entire care network of older adults, cataloguing all activities each respondent assists with and the amount of time they spend helping, providing a unique opportunity to evaluate caregiving networks. Using network analysis and cluster analysis, we find that older adults have different types of caregiving networks including large and small networks with a primary caregiver and networks where caregivers share caregiving responsibilities more evenly. Size and structure of the networks are significantly associated with older adults' well-being and unmet needs. These findings highlight the importance of considering the full care network in developing policies and programs to support family caregivers.

THE ROLE OF FAMILY CAREGIVING CONFIGURATIONS AND SUPPORTS IN OLDER ADULT OUTCOMES

Natalie Chong, *Brandeis University, Waltham, Massachusetts, United States*

This study uses data from the 2017-2018 National Health and Aging Trends Study and the 2017 National Study of Caregiving to examine whether caregiving network configuration factors (e.g., if and how multiple caregivers of the same care recipient distribute tasks, responsibility and disagreement among caregivers, involvement of paid caregivers) and caregiver supports (e.g., emotional support, skills training, respite services) are associated with consequences of unmet needs among older adults. Findings from this study will provide greater understanding of how caregiving contexts shape the quality of care and health of older adults who rely on help from family caregivers.

A PROFILE OF POST-ACUTE CAREGIVING

Claire Ankuda, Amy Kelley, and Subashini Rajagopalan, *Icahn School of Medicine at Mount Sinai, New York, New York, United States*

Post-acute care is increasingly shifting from institutional settings into the home, but the impact on family caregivers is unknown. Using NHATS, we identified a cohort of 2,124 older adults enrolled in fee-for-service Medicare with a survey interview conducted within 90 days of discharge from discharge. We first examined the hospitalization characteristics associated with both receipt of family and friend assistance in the 90 days post-discharge and average hours of assistance per week. We then used linked NSOC data to a subgroup of 365 individuals to compare the caregiver reports for caregivers of older adults in the post-acute period vs. not. We found that both the receipt of post-acute family/friend assistance and hours of assistance varied by hospitalization length of stay and discharge services. We also found that post-acute caregivers differed from non-post-acute caregivers in their caregiving tasks and difficulties related to providing care.

THE ROLE OF FAMILIES IN FACILITATING USE OF HOME-BASED SERVICES

Jennifer Reckrey[1], Duzhi Zhao[1], Christine Ritche[2], and Katherine Ornstein[3], *1. Icahn School of Medicine, The Mount Sinai Hospital, New York, New York, United States, 2. Massachusetts General Hospital, Boston, Massachusetts, United States, 3. Johns Hopkins University, Baltimore, Maryland, United States*

Homebound older adults rely on home-based clinical services (e.g., home based medical care) and long-term services and supports (e.g., caregiving support, environmental modifications) to remain living at home, however patterns of service use are unknown. Using data from the 2015 National Health and Aging Trends Study linked to Medicare Claims Data, we identified a population of homebound older adults enrolled in fee-for-service Medicare (n=1066). Latent class analysis identified 3 distinct patterns of home-based service use: low (36%), medium (51%), and high (13%) service use. High family caregiving support was particularly prevalent in the medium service group (35% with over 40 hours of family care per week), but receipt of home-based medical care was minimal in this group. Additional support to connect family caregivers with other home-based services may improve care and outcomes for older adults living at home.

WHEN FAMILIES DISAGREE: CORRELATES AND STRESS PROCESS OUTCOMES OF FAMILY CAREGIVER DISAGREEMENT

Amanda Leggett[1], Hyun Jung Koo[2], Hannah Lee[2], and Elaina Baker[2], *1. Wayne State University, Ypsilanti, Michigan, United States, 2. University of Michigan, Ann Arbor, Michigan, United States*

Dementia caregiving is a family affair, yet prior research suggests that families often disagree about care provision. We explore correlates of such disagreements and how disagreements relate to stress process outcomes of care. The current study examines 552 family caregivers for Medicare-eligible older adults with dementia from the 2017 National Study of Caregiving. We consider demographic and care characteristics as predictors of family disagreement in a multinomial logistic model, and family disagreement as the key predictor of caregiving overload, emotional difficulty, and gains in linear regressions. Females had greater odds of disagreement, while those with friends and family to talk to and providing assistance with household care activities had lower odds of disagreement. Family disagreement was significantly associated with overload (B=0.95, p<.001) and emotional difficulty (B=0.45, p<.05), but not gains. Interventions to help families manage care disagreements and coordinate care may have great impact on caregiver well-being.

SESSION 5080 (SYMPOSIUM)

OLDER ADULT ENGAGEMENT IN COMMUNITY GERONTOLOGY

Chair: Natalie Pope

Community gerontology integrates scholarship on aging and communities through the lens of mesolevel environments, the diverse continua of settings linking micro and macro contexts of aging. This interdisciplinary symposium brings together research exploring the interconnections of older adults' engagement across and within the socio-ecological levels of their lived experiences, place-based communities, and policy contexts. Yeh et al.'s paper elucidates the promises of visual methods in critical qualitative research with older adults to subvert power dynamics and advance social justice in gerontology. Latham-Mintus' paper explores how "weak ties" created by the interaction of social infrastructure within geospatial places and spaces can facilitate longer, healthier lives. Reyes' paper uses an intersectional life course perspective to explore placemaking as civic participation among Latinx immigrants and African American older adults across time and social environments. Plasencia's paper focuses on aging in community among diverse older adults using a photovoice to assess their perceptions and needs within the lived urban environment. Pope and colleagues explore how a multi-state sample of older adults perceive their roles in age-friendly initiatives at individual, organizational, and community levels. Taken together, the papers discuss and contextualize the multidirectional ways older adults engage their place-based communities within larger macro sociopolitical structures – an analysis that highlights the embeddedness of mesolevel community environments both within and between micro and macro spheres. This session further speaks to the importance of centering older adults' experiences in community gerontology by illuminating the ways older adults not only age in community but through layers of community.

OLDER ADULT ENGAGEMENT IN AGE-FRIENDLY COMMUNITY WORK

Natalie Pope[1], Katy (Qiuchang) Cao[2], and Emily Greenfield[1], *1. Rutgers, The State University of New Jersey, New Brunswick, New Jersey, United States, 2. The Pepper Institute on Aging and Public Policy and The Claude Pepper Center, Florida State University, Tallahassee, Florida, United States*

Drawing on 22 interviews with older adults across four states, this qualitative study explores how older adults perceive their age-friendly community work and the personal meaning they derive from participation. Based on iterative coding, findings indicate ways in which geographic differences in the structure and framing of local age-friendly community initiatives set the boundaries, scope, and potential customization of older adult engagement. Across geographies, motivations for starting and sustaining engagement included: perceived personal growth; social connectivity; outlets for advancing skills and passions; and satisfaction from making a difference in the lives of older adults and their broader community. These findings highlight the importance of conceptualizing older adult engagement in age-friendly community work as a dynamic process embedded within intrapersonal, interpersonal, organizational, and community contexts. Demonstrating multiple ways older adults contribute to placemaking, the findings have implications for older adult engagement at various levels and stages of age-friendly community initiatives.

EMANCIPATORY VISIONS: USING VISUAL METHODS TO CO-CONSTRUCT KNOWLEDGE WITH OLDER ADULTS

Jarmin Yeh[1], Laurent Reyes[2], and H. Shellae Versey[3], *1. University of California, San Francisco, San Francisco, California, United States, 2. UC Berkeley, Berkeley, California, United States, 3. Fordham University, Bronx, New York, United States*

Research is a political activity. Researchers are responsible for theories and methods used to explore, explain, or ignore injustices. A need exists for developing new tools and pathways of knowledge based on experiences, language, and intellect of older adults from Black, Indigenous, and People of Color communities. This presentation argues for the utility of visual methods in critical qualitative research as a medium that allows researchers and participants to co-construct knowledge. Lessons learned about implementing projects using visual methods from the intersectional standpoint of the authors – three younger women of color – will be discussed. Promises and complexities of navigating interpersonal dynamics, decolonizing knowledge-production, and scaling visual methods on multiple levels will be elucidated. Collectively, we argue that visual methods are rigorous for subverting power dynamics rooted in extractive research practices, and provide a vehicle for community-engaged participatory action research that has potential to advance social justice in gerontology.

UNDERSTANDING THE ROLE OF SOCIAL INFRASTRUCTURE FOR OLDER ADULT ENGAGEMENT ACROSS GEOGRAPHIC CONTEXTS

Kenzie Latham-Mintus, Lucas Montgomery, and Jeffrey Wilson, *IUPUI, Indianapolis, Indiana, United States*

Using semi-structured interviews of older adults, living alone or with a partner in the community, this research explores themes related to aging in place, social infrastructure, and community engagement across geographic contexts in Indiana. In particular, we are interested in understanding how older adults experience and use the existing social infrastructure in their communities and how these experiences vary across the rural-suburban-urban continuum. Additionally, we examine how social interactions supported by social infrastructure influence the maintenance of social relationships including weak social ties. Because COVID-19 has significantly changed patterns of community engagement among older adults, respondents were asked to discuss their behavior pre- and post-COVID-19. Applying a thematic analysis approach to the data, we explore the interconnections among social infrastructure, community engagement, social relationships, and geographic settings with an emphasis on older adults' experiences and perceptions.

PLACEMAKING AS CIVIC PARTICIPATION: A STORY OF AGENCY AND RESISTANCE AMONG BLACK AND LATINX IMMIGRANT OLDER ADULTS

Laurent Reyes, *UC Berkeley, Berkeley, California, United States*

Placemaking is a collective process that happens every day. However, little has been written about the ways older African Americans and Latinx immigrants create place in their everyday lives. Less has been said about the ways these efforts are examples of civic participation in the context of systemic inequality and oppression. Results from this phenomenological study that applies an intersectional life course perspective shows how older Black and Latinx immigrant adults maintain, preserve, and build their place in a society that continuously threatens their erasure. These results shine light on the ways Black and Latinx communities work to maintain the physical space (i.e., community safety and sanitation), preserve their culture and history, and build structures to ensure access to resources that will empower their communities. Their efforts across the micro, meso, and macro social environments and across time, demonstrates a concerted effort towards creating a dignified and just place in our society to nourish and sustain future generations.

SESSION 5081 (SYMPOSIUM)

DUALS AND ASSISTED LIVING: EXAMINING ACCESS AND OUTCOMES

Chair: Kali Thomas Discussant: Hyunjee Kim

Assisted living, a popular long-term care option for older adults needing personal care assistance, is increasingly serving a vulnerable population of low-income older adults dually-enrolled in Medicare and Medicaid (duals). However, we know very little about the needs of this population, their access to assisted living, the quality of care duals are receiving, and how this varies across states and assisted living providers. This symposium will include five presentations using national data and focused on access to assisted living for duals and the quality of care that duals in assisted living settings receive. The first two presentations take different approaches to investigate access to assisted living and how it relates to Medicaid policy: one examines Medicaid policies and their relationship to geographic access, and the other presents results from an analysis examining the association between Medicaid financing and segregation of duals. The next three presentations highlight important findings related to the quality of care for duals in assisted living: one focuses on concentration of duals in assisted living and its relationship with hospitalization and nursing home placement, one examines injury-related emergency department visits among duals, and the final presentation discusses the ability of duals in assisted living to age in place toward the end of life. The discussant, an expert in Medicaid policy, will conclude with a discussion of states' different approaches for covering services in assisted living through their Medicaid programs, highlighting the opportunities for increasing equitable access and ensuring high quality care is delivered to this vulnerable population.

MEDICAID POLICY AND ASSISTED LIVING ACCESS

Lindsey Smith, *Brown University, Providence, Rhode Island, United States*

Funding for home and community-based services (HCBS), including assisted living (AL), using Medicaid is limited to either Medicaid program waivers or state plan amendments. The Affordable Care Act (ACA) created a new option for the state plan, the Community First Choice 1915(K), that mandates all care is self-directed and inclusive of families in decision making while disallowing waiting lists. This presentation will provide an overview of the various combinations of Medicaid waivers and amendments used by states to cover services in AL. We will then share the results of a study that used coincidence analysis, a configurational comparative method, to compare states' approaches to HCBS Medicaid coverage and a measure of AL geographic access. We found that both Medicaid waivers and 1915(K) amendments are associated with increased geographic access to AL.

MEDICAID FINANCING AND SEGREGATION OF DUALS IN ASSISTED LIVING

Kali Thomas[1], Portia Cornell[2], Cassandra Hua[3], and Momotazur Rahman[1], *1. Brown University, Providence, Rhode Island, United States, 2. Providence VA Medical Center / Brown University, Providence, Rhode Island, United States, 3. Brown University School of Public Health, Providence, Rhode Island, United States*

We used 2018 Medicare enrollment data, a national directory of licensed ALs, and Medicaid state policies. We identified a cohort of 474,661 AL residents and a comparison cohort of 58,911,266 community-residing individuals. We compared the distribution of duals across ALs to the distribution of community-dwelling duals across ZIP codes by taking the ratio of AL Gini index for each state over the community Gini index for each state (the "Gini ratio" or GR). On average, states with both waivers and state plans covering services in AL had the lowest Gini ratio (less segregated than community; GR=0.87;) States with no Medicaid financing for AL had the highest Gini ratio (more segregated than community, GR=1.16). Medicaid coverage for home and community-based services in AL is associated with increased access to AL for duals.

STRUCTURAL INEQUITIES IN OUTCOMES FOR DUAL-ELIGIBLE RESIDENTS IN ASSISTED LIVING

Portia Cornell[1], Cassandra Hua[2], Momotazur Rahman[3], Gauri Gadkari[2], and Kali Thomas[3], *1. Providence VA Medical Center / Brown University, Providence, Rhode Island, United States, 2. Brown University School of Public Health, Providence, Rhode Island, United States, 3. Brown University, Providence, Rhode Island, United States*

We examined the association of AL residents' dual-eligibility and the concentration of dually eligible residents in AL communities with residents' risk of hospitalization and long-term nursing home admission. The exposure was dual status interacted with AL concentration: no-duals, minority-duals [<=50%] (reference group), and majority-duals [>50%]. We found that duals in AL have higher risk of hospitalization and nursing home admission than non-duals. For both duals and non-duals, moving to an AL with a high concentration of duals conferred excess risk of hospitalization. Among duals, however, lower concentration of duals in ALs increases risk of long-term nursing home admission for duals, whereas it is protective for non-duals. The association of higher hospitalization with concentration of duals suggests that quality may be a concern in communities that specialize in care for duals. However, majority-duals ALs may be better equipped to provide more comprehensive care as an alternative to nursing homes.

DUAL ELIGIBILITY AND INJURY-RELATED EMERGENCY DEPARTMENT VISITS AMONG ASSISTED LIVING RESIDENTS

Cassandra Hua[1], Portia Cornell[2], Elizabeth White[3], Katherine Kennedy[4], Ian Nelson[5], and Kali Thomas[3], *1. Brown University School of Public Health, Providence, Rhode Island, United States, 2. Providence VA Medical Center / Brown University, Providence, Rhode Island, United States, 3. Brown University, Providence, Rhode Island, United States, 4. Providence VA Medical Center, Providence, Rhode Island, United States, 5. Miami University, Oxford, Ohio, United States*

Using 2018 Medicare data, we examined the relationship between dual eligibility and injury-related emergency department use among a cohort of assisted living residents (n=116,754). We fit multilevel models with random intercepts at the assisted living community and license type levels. The baseline rate of injury-related emergency department emergency department use was 0.17. After controlling for resident characteristics (i.e., age, sex, race, and chronic conditions), license type characteristics (i.e., dementia care licensure, staffing regulations), and assisted living community characteristics (i.e., size and percentage of residents with dementia), being dually eligible for Medicare and Medicaid was associated with a 12% increase in the probability of having an injury-related emergency department visit (b=.02; p<.001). Assisted living communities that serve duals may have fewer resources and staff to provide personal care, potentially leading to increased rates of injuries.

RETENTION OF DUALLY ELIGIBLE BENEFICIARIES IN ASSISTED LIVING AT THE END OF LIFE

Susan Hayes[1], Nicole Rosendaal[2], Xiao (Joyce) Wang[2], Kali Thomas[2], and Emma Belanger[2], *1. Brown University School of Public Health, Providence, Rhode Island, United States, 2. Brown University, Providence, Rhode Island, United States*

To examine to what extent dually eligible beneficiaries (duals) residing in assisted living remain there toward the end of life, we conducted a prospective cohort study of 98,944 Medicare beneficiaries present at validated AL ZIP codes in January 2017, and who died during a two-year follow-up. The outcome was AL residence in the last 30 days of life. We compared decedents who were not duals (80,156 decedents), with those newly dually eligible in 2017-2018 (3,722 decedents), and those already dually eligible in 2016 (15,066 decedents). Only 36.7% of new dual decedents resided in

AL in the last 30 days of life, compared to 66.2% among those dually eligible in 2016, and 84.5% of those without Medicaid. While 29 states retained over half of all decedents in AL until death, only 8 states retained a majority of dually eligible decedents.

SESSION 5090 (SYMPOSIUM)

RESEARCH AT THE INTERSECTION OF TECHNOLOGY AND AGING

Chair: Jodi McDaniel

New and emerging technologies offer opportunities for the delivery of wide-ranging, adaptable interventions to improve quality of life of older adults. Novel technologies can also improve the quality of measurement methods used in aging research. In this symposium five presentations will describe advanced technologies to promote health and function in older adults. The first will discuss the Urban Aging Residents Coalition (UARC), an organization founded in partnership with an African American older adult community leader to address engaging urban older adults with technology. A primary goal of UARC is to prevent social isolation and promote mental wellness through education and computer literacy. The second presentation will describe a project testing socially assistive robots (SARs) to complement personnel resources in older adults with cognitive impairment in long term care facilities. Study participants were successfully engaged in a participatory design involving repeated sessions with SARs that resulted in prototype refinement. The third presentation will describe current applications of patient communication technologies in acute-critical care settings with a focus on the user experience among older adult patients. The fourth will report on the implementation of an ongoing, in-home Smarthealth technology intervention for two older adult family caregivers of persons with dementia. Study findings showed the intervention improved self-awareness of emotional care and reactions to care recipients. The final presentation will explain an advanced wound measurement system using artificial intelligence to track healing progress in clinical research. The presentations will highlight technologies to support healthy aging and discuss implication for practice, policy, and research.

INTERRATER RELIABILITY OF AN ADVANCED NONCONTACT WOUND MEASUREMENT SYSTEM USING ARTIFICIAL INTELLIGENCE

Jodi McDaniel[1], Alai Tan[2], and Narasimham Parinandi[3], *1. Ohio State University College of Nursing, Columbus, Ohio, United States, 2. The Ohio State University College of Nursing, Columbus, Ohio, United States, 3. The Ohio State University College of Medicine, Columbus, Ohio, United States*

Venous leg ulcers (VLU) are recurring, disabling wounds that develop primarily in older adults with comorbidities. In an ongoing clinical trial testing a nutritional intervention researchers use advanced technology (Swift Skin and Wound) to measure VLU healing over time. This noncontact wound measurement system uses artificial intelligence to automatically calculate wound measurements and track healing progress. However, a subjective component of the Swift system involves delineating wound perimeters on photographs captured with a tablet or smartphone. To evaluate interrater reliability of the system in the current study, measurements of 11 wounds by two independent raters were assessed using an intraclass correlation coefficient (ICC). ICC estimates and their 95% confidence intervals were calculated using SPSS statistical package version 27 based on a mean-rating (k = 2), consistency, 2-way mixed-effects model. For area measures, ICC = 0.99 with 95% confidence interval = 0.998-1.0, indicating the Swift measurement system has excellent interrater reliability.

EXPERIENCES USING A SMARTHEALTH SYSTEM: TWO CASES OF DEMENTIA FAMILY CAREGIVERS

Karen Rose[1], Eunjung Ko[1], Sooyoung Kim[2], Kristina Gordon[3], Hongning Wang[4], and John Stankovic[4], *1. The Ohio State University, Columbus, Ohio, United States, 2. Ohio State University, Columbus, Ohio, United States, 3. The University of Tennessee Department Of Psychology, Knoxville, Tennessee, United States, 4. University of Virginia, Charlottesville, Virginia, United States*

Family caregivers for persons with dementia often times experience stress and burden while caregiving. The COVID-19 pandemic has worsened this situation with increased physical and social isolation, further resulting in health risks in this population. Technology-based interventions have become more commonplace in today's world to address ongoing caregiver needs although gaps in technological literacy and usage still exist among many users. This case study aims to report on the implementation of an ongoing Smarthealth technology intervention for two older adult family caregivers of persons with dementia and to explore their experiences with this system. Data were collected through acoustic monitoring, survey administration, and semi-structured interviews. Intervention effects on changes in emotional states will be discussed. Study findings showed the intervention improved self-awareness of emotional care and reactions to care recipients. Findings in this study highlight the importance and challenges of real-time technology-based intervention implementation in older adult caregiving populations.

URBAN AGING RESIDENTS COALITION (UARC): A HYBRID MODEL TO BRIDGE THE TECHNOLOGY GAP

Kathy Wright[1], Karen Moss[2], Judith Tate[3], Karen Rose[2], and Pamela Shields[4], *1. The Ohio State University College of Nursing, Columbus, Ohio, United States, 2. The Ohio State University, Columbus, Ohio, United States, 3. Ohio State University, College of Nursing, Columbus, Ohio, United States, 4. Urban Aging Residents Coalition, Columbus, Ohio, United States*

The COVID-19 pandemic spotlighted technology barriers for urban Black/African American older adults that lead to chronic stress, social isolation, and inability to fully engage with the world. In partnership with an African American older adult community leader, the Urban Aging Residents Coalition was founded in May 2020 to address engaging older adults with technology. A primary goal of UARC is to prevent social isolation and promote mental wellness through education. Using a hybrid model of videoconferencing and socially-distanced meetings, volunteer health professionals and community members (e.g., Information Technology Technician, Psychologist, and Nurse) delivered education to older adults. Participants also met for computer training to build confidence by sharing technology accomplishments with others (e.g., online bill paying). UARC has 75 active members and conducted over 12 videoconferences and in-person programming. The UARC project serves as a model for community/academic partnerships to support mental wellness and technology use in urban older adults.

PARTICIPATORY DESIGN: AN ESSENTIAL PROCESS FOR SOCIALLY ASSISTIVE ROBOTIC ACTIVITIES IN LONG-TERM CARE SETTINGS

Mion Lorraine[1], Emily Latshaw[1], Yi Chun Lin[1], Miroslava Migovich[2], Ritam Ghosh[2], Nibraas Khan[2], Nilanjan Sarkar[2], and Judith Tate[3], *1. The Ohio State University, Columbus, Ohio, United States, 2. Vanderbilt University, Nashville, Tennessee, United States, 3. Ohio State University, College of Nursing, Columbus, Ohio, United States*

We conducted participatory design research for long term care (LTC) socially assistive robotic activities comprised of social, cognitive and physical components and enhanced human-robot (HRI) and human-human interactions (HHI). Repeated sessions were conducted with 10 geriatric experts (physicians, activity directors, nurses, occupational therapist) and 12 LTC residents (ages 70–92). Two robots, animal and humanoid, were used in combination with virtual reality. Four collaborative activities for paired older adults were designed and evaluated: playing drums to music, completing paintings, a fishing game, and training a dog with simple commands. Within each activity, three levels of difficulty were designed. Stakeholder feedback was obtained through observations and interviews. Numerous modifications were made following each session that addressed hardware, software and activity issues. Modifications were necessary both for the HRI and HHI aspects of the activity. Our experience demonstrates the necessity for participatory design in the deployment of technology for LTC settings.

CURRENT APPLICATIONS OF PATIENT COMMUNICATION TECHNOLOGIES IN GERIATRIC CRITICAL CARE

Mary Beth Happ[1], Emika Miller[2], Judith Tate[3], and JiWon Shin[4], *1. The Ohio State University, Columbus, Ohio, United States, 2. Ohio State University, Columbus, Ohio, United States, 3. Ohio State University, College of Nursing, Columbus, Ohio, United States, 4. University of California, Davis, Sacramento, California, United States*

The availability and utility of patient-centered communication technologies in acute-critical care settings have evolved slowly over the past 30 years with wide variability, little standardization, and few randomized controlled clinical trials (RCT). The COVID-19 pandemic forced rapid expansion and use of communication technologies, particularly between patients and remote family caregivers. To capture changes responsive to the pandemic, this paper reviews current literature (< 5 years) on communication technologies in acute-critical care settings focusing on the user experience among older adult patients. We supplement these findings with case-based evidence from a pilot RCT of an electronic tablet communication application provisioned to mechanically ventilated ICU patients, and efforts toward hospital-wide implementation. Recent literature on patient communication technology consists primarily of qualitative, descriptive accounts of video communication (i.e., ICU visits) or provision of augmentative and alternative communication. Recommendations for required skills, standardization, and research regarding patient communication technology are provided.

SESSION 5091 (BIOLOGICAL SCIENCES INVITED SYMPOSIUM)

PROTEOSTASIS: NOVEL INSIGHTS AND TECHNOLOGIES

Chair: Andrew Pickering

GENETIC AND PHARMACOLOGIC PROTEASOME AUGMENTATION AMELIORATES ALZHEIMER'S-LIKE PATHOLOGY IN MICE AND FLIES

Andrew Pickering, *University of Alabama at Birmingham, Birmingham, Alabama, United States*

The proteasome has key roles in neuronal proteostasis, including removal of misfolded and oxidized proteins, presynaptic protein turnover, as well as synaptic efficacy and plasticity. Proteasome dysfunction is a prominent feature of Alzheimer's disease (AD) (1–3). Artificial impairment of proteasome function can mimic many neurodegenerative phenotypes (4, 5). We report impaired proteasome function to represent an early-stage marker of AD preceding many other markers of the disease. Significantly, we show that prevention of proteasome dysfunction by genetic manipulation in fly and cell culture models of AD delays mortality, cell death, and cognitive deficits. We developed a transgenic mouse with neuronal-specific proteasome overexpression which, when crossed with a mouse model of AD showed reduced mortality and cognitive deficits. To establish translational relevance, we developed a set of novel TAT-based proteasome-activating peptidomimetics. These agonists stably penetrate the blood-brain-barrier and enhance 20S as well as 26S proteasome activity. We show that treatment with these agonists protects against cell death in a cell culture model of AD as well as both cognitive decline and mortality in fly and mouse models of AD. The protective effects observed from proteasome overexpression in our models appear to be driven at least in part by increased turnover of the amyloid precursor protein (APP) by the proteasome. We conclude that the proteasome plays an important role in AD progression. Furthermore, augmentation of proteasome function is protective against AD-like pathogenesis in diverse models of the disease, representing a new therapeutic target for treatment of AD.

PROTEOSTASIS: NOVEL INSIGHTS AND TECHNOLOGIES

Constanza Cortes, *University of Alabama at Birmingham, Birmingham, Alabama, United States*

Skeletal muscle has recently arisen as a novel regulators of Central Nervous System (CNS) function and aging, secreting bioactive molecules known as myokines with proteostasis and metabolism-modifying functions in targeted tissues, including the CNS. Myokine secretion is heavily modified by exercise, suggesting that myokine signaling in the periphery may underlie the well document geroprotective benefits of exercise on the brain. The following studies address muscle proteostasis, a pathway highly activated during exercise, as a potential new regulator of the neurocognitive benefits of exercise. We have recently generated a novel transgenic mouse with enhanced muscle proteostasis via moderate overexpression of Transcription Factor E-B (TFEB), a powerful master regulator of cellular clearance and proteostasis. We have discovered that the resulting enhanced skeletal muscle proteostasis function can significantly ameliorate proteotoxicity and reduce neuroinflammation in the aging CNS. We derived cTFEB;HSA-Cre transgenic mice in the P301S MAPT background and we detected a significant reduction in hyperphosphorylated tau[AT8 phospho-tau antibody] in whole hippocampal lysates and in the dentate gyrus of cTFEB;HSACre;P301S mice compared to their single transgenic P301S littermate controls. Nanostring nCounter®AD panel analysis reveals displayed reductions in microglia activation modules in P301S MAPT/cTFEB:HSACre hippocampi, suggesting reduced neuroinflammation. We also determined that these CNS benefit sin P301S MAPT/cTFEB:HSACre mice were accompanied by activation of exercise-associated neurotrophic signaling and reduced markers of advancing tau-associated pathologies in the hippocampus. These provocative results suggest that enhanced skeletal muscle proteostasis modifies the accumulation of pathogenic tau isoforms and reduces neuroinflammation in the CNS of P301S MAPT mice via activation of exercise-associated signaling in the CNS.

INTERPLAY BETWEEN LOSS OF PROTEOSTASIS AND CELLULAR SENESCENCE: A SPOTLIGHT ON MISFOLDED PROTEIN QUALITY CONTROL

Rahul Samant, *Babraham Institute, Cambridge, England, United Kingdom*

Loss of protein homeostasis ('proteostasis') and onset of cellular senescence are two conserved hallmarks of ageing. Healthy proteostasis relies on tightly-regulated intracellular quality control circuits that co-ordinate clearance of potentially toxic misfolded proteins arising from various internal or external stresses throughout an organism's lifespan. Proteostasis imbalances are mechanistically linked to a broad range of ageing-associated diseases, and are also characteristic of cellular senescence—a permanent cell cycle arrest that prevents uncontrolled proliferation during development, injury repair, and tumorigenesis, but drives ageing-associated frailty, degeneration, and therapy resistance. Across a range of replicative and stress-induced senescence models in primary human cells, we have discovered differences in how misfolded proteins are triaged when compared with proliferating, quiescent, or immortalised cells—especially at the level of ubiquitin-mediated protein clearance systems. Given recent findings that proteostasis modulators act as senolytics with geroprotective properties, our work highlights the need for an improved fundamental understanding of how different ageing hallmarks are inter-connected in order to drive advances in human healthspan.

PARALLEL MEASUREMENTS OF PROTEIN AND CELL TURNOVER REVEAL HOW TISSUE CONTEXT AND AGING SHAPE PROTEIN LIFETIMES

Abigail Buchwalter[1], Kevin Welle[2], Jennifer Hryhorenko[3], Sina Ghaemmaghami[4], and John Hasper[5], *1. University of California, San Francisco, San Francisco, California, United States, 2. Mass Spectrometry Resource Lab, University of Rochester, Rochester, New York, United States, 3. Mass Spectrometry Resource Laboratory, University of Rochester, Rochester, California, United States, 4. Department of Biology, University of Rochester, Rochester, New York, United States, 5. Cardiovascular Research Institute, University of California, San Francisco, San Francisco, California, United States*

The lifespans of proteins can range from moments to years within mammalian tissues. Protein lifespan is relevant to organismal aging, as long-lived proteins can accrue damage over time. It is unclear how protein lifetime is shaped by tissue context, where both cell division and proteolytic degradation contribute to protein turnover. We have developed turnover and replication analysis by 15N isotope labeling (TRAIL) for parallel quantification of protein and cell lifetimes. We have deployed TRAIL over 32 days in 4 mouse tissues to date to quantify cell proliferation with high precision and no toxicity and determine that protein lifespan varies independently of cell lifespan. Variation in protein lifetime is non-random: multiprotein complexes such as the ribosome have consistent lifetimes across tissues, while mitochondria, peroxisomes, and lipid droplets have variable lifetimes across tissues. To model the effects of aging on tissue homeostasis, we apply TRAIL to a mouse model of Hutchinson-Gilford progeria syndrome and uncover fat-specific alterations in cell lifetime and proteome composition, as well as a broad decrease in protein turnover flux. These data indicate that environmental factors influence protein turnover in vivo and provide a framework to understand proteome aging in tissue context.

PHOSPHORYLATION OF ULK1 AT S555 IS REQUIRED FOR METABOLIC ADAPTATIONS TO CALORIC RESTRICTION

Joshua Drake, Anna Nichenko, Orion Wiloughby, Matt Brisendine, Garrett Hays, Grace DiGirolamo, Zach Weingrad, and Ryan McMillan, *Virginia Polytechnic Institute and State University, Blacksburg, Virginia, United States*

Unc-51 Like Autophagy Activating Kinase 1 (Ulk1) is responsible for initiating selective degradation of damaged/dysfunctional mitochondria (mitophagy) once phosphorylated at S555 in response to energetic stress. Mitophagy is integral for mitochondrial health and Ulk1 has been implicated to be important for metabolic adaptation to exercise. Caloric restriction (CR), which extends lifespan and healthspan, has profound metabolic benefits, including improved mitochondrial health. However, the contribution of Ulk1 in adaptation to CR is unknown. To decipher a functional role of Ulk1(S555) in adaptations to CR we used CRISPR-Cas9 generated, loss-of-function Ulk1(S555A) mice, in which Ulk1 cannot be phosphorylated at S555. 6-month-old, male and female homozygous Ulk1(S555A) mice and C57BL6/J (wild type, WT) mice were placed on a 40% CR diet for 8 weeks. Body mass in both male and female Ulk1(S555A) and WT mice was reduced with CR (p < 0.001), however female Ulk1(S555A) were heavier than their WT counterparts (p=0.02). Via nuclear magnetic resonance (NMR), male and female Ulk1(S555A) mice did not lose fat mass during CR. In addition, periovarian (female) and epididymal (male) fat mass was greater in Ulk1(S555A) compared to WT mice post-CR (p < 0.001). Furthermore, fasting blood glucose increased in male and female Ulk1(S555A) post-CR (p < 0.0001), suggesting altered substrate metabolism. In support of this notion, glucose oxidation in both quadriceps muscle and liver of male mice increased in WT following CR but not in Ulk1(S555A) mice (interaction effect p< 0.002). In sum, these data suggest that phosphorylation of Ulk1 at S555 is required for metabolic adaptations to CR.

SESSION 5100 (PAPER)

ADULT PROTECTION AND ELDER ABUSE

A DIGITAL ELDER ABUSE INTERVENTION FOR THE EMERGENCY DEPARTMENT

Fuad Abujarad[1], Esther Choo[2], James Dziura[3], Chelsea Edwards[3], Michael Pantalon[3], Karen Jubanyik[3], Gail D'Onofrio[3], and Thomas Gill[4], *1. Yale University, Orange, Connecticut, United States, 2. Oregon Health & Science University, Portland, Oregon, United States, 3. Yale University, New Haven, Connecticut, United States, 4. Yale School of Medicine, New Haven, Connecticut, United States*

Elder abuse continues to grow as a national issue with significant gaps in standards for identifying victims. The emergency department provides an opportune setting for affected older adults to report abuse privately, but traditional screening methods may miss certain types of elder abuse when there are no visible signs of abuse. Community resources and reporting methods may not be known or can be stigmatized, therefore creating a challenging scenario for victims of abuse to navigate without fear. The VOICES Elder Abuse Intervention (EAI) is a unique self-administrated tablet-based tool with an automated digital coach that combines major components of screening, educational content, and brief psychoeducational interviewing to empower the older adults and encourage self-identification and self-reporting of abuse. The digital format of the tool allows this EAI to be integrated within an existing elder abuse workflow protocol in the emergency department, rather than replacing it entirely. We will discuss our completed study that included (N=1,002) participants over the age of 60, which suggests that patients find the EAI user-friendly and easy to use. For example, 93% of participants agreed that VOICES was appropriate for learning about abuse, and 94% agreed that using VOICES was very easy to use. Informed by these findings, we plan to adapt and evaluate VOICES EAI for use in other older adult populations and healthcare settings.

BARRIERS TO REDUCING AND PREVENTING INVOLUNTARY TREATMENT: THE PERSPECTIVE OF PROFESSIONAL CAREGIVERS

Michel Bleijlevens, Jules Willems, Valeria Lima Passos, and Jan Hamers, *Maastricht University, Maastricht, Limburg, Netherlands*

Measures to which a person resits and/or does not provide consent for are defined as involuntary treatment. The use of involuntary treatment violates the autonomy of (older) persons and causes more harm than benefit. Moreover, it contradicts the values of person-centred care. Nevertheless, its use among Persons Living with Dementia (PLWD) is still common practice and remains difficult to prevent and/or reduce. The aim of this study was to gain insights into the barriers towards the prevention and/or reduction of involuntary treatment in long-term geriatric care. We conducted a cross-sectional, mixed-methods study, including an online survey for professional caregivers, and a semi-structured focus group interview with professional caregivers. A total of 218 participants completed the questionnaire. The percentage of participants that experienced barriers in one of the twenty-two survey items ranged from 15% to 42%. Lack of time; the experienced need to use involuntary treatment; uncertainty about responsibilities of stakeholders; and a lack of knowledge on methods to prevent and/or reduce its use were most seen as barriers. Nursing staff experienced a lack of time more often than other professional caregivers. Working in home care and having no former experience with involuntary treatment usage increased perceived barriers. Participants of the focus group interview confirmed these findings. One out of four professional caregivers experience barriers hindering prevention and/or reduction of involuntary treatment. More research is needed to gain better understanding on how professional caregivers can be supported aiming to, remove barriers and consequently prevent and/or reduce the use of involuntary treatment.

ELDER MISTREATMENT, MORTALITY, AND HOSPITAL READMISSION AMONG MEDICARE BENEFICIARIES, 2015–2018

Monique Pappadis[1], Leila Wood[2], Allen Haas[2], Yong-Fang Kuo[2], and Charles Mouton[2], *1. University of Texas Medical Branch, Galveston, Texas, United States, 2. University of Texas Medical Branch at Galveston, Galveston, Texas, United States*

Elder mistreatment (EM) is a growing public health and safety crisis, with long-term consequences for individuals, families, and communities. We explored whether older adults hospitalized with a primary diagnosis of EM was associated with an increased risk of mortality and unplanned hospital readmission compared to those with a secondary EM diagnosis. We further examined whether EM type and hospital setting was associated with risk of mortality and unplanned hospital readmission. Using 100% of 2015-2018 Medicare files of hospitalized Medicare Fee-for-Service beneficiaries aged 66 and over, we used Kaplan-Meier and Cox proportional hazard models to estimate mortality and unplanned readmission rates by primary versus secondary EM diagnosis, EM type, and facility type. 11,023 patients were hospitalized with an EM diagnosis. The majority were female (64.1%) and Non-Hispanic/Latinx White (74.3%). Neglect was the most common EM type. The three-year mortality rate was 56.7% and one-year readmission rate was 53.8%. Compared to other EM types, patients diagnosed with neglect had a 2.20 (95% Confidence Interval [CI]=1.88-2.56) and 3.21 (95% CI=2.32-4.43) times greater risk for mortality within and after 50-days from discharge, respectively. Patients discharged from a skilled nursing facility (SNF) were at an increased risk of mortality and unplanned readmission compared to those discharged from an acute hospital. Hospitalized patients with a primary EM diagnosis were associated with an increased risk of mortality and readmission compared to those with a secondary diagnosis. Future work should explore care patterns before and after EM diagnosis to identify potential time points for medical and social intervention.

MENTAL HEALTH RESILIENCE IN SWISS OLDER ADULT SURVIVORS OF CHILD WELFARE–RELATED MALTREATMENT

Myriam Thoma[1], Florence Bernays[2], Andreas Maercker[1], and Shauna L. Rohner[1], *1. University of Zurich, Zurich, Zurich, Switzerland, 2. University of Zurich, Zürich, Zurich, Switzerland*

Minors affected by child welfare practices in Switzerland during the last century had a high risk for exposure to childhood trauma and maltreatment. Several studies with this cohort demonstrated substantially higher levels of clinically-relevant psychopathology in older adult survivors in comparison to non-affected control individuals. However, these studies also revealed that not all affected individuals developed mental health disorders over their lifespan. To date, this mental health resilience in survivors of an advanced age is still insufficiently understood. Therefore, this study aimed to assess and compare the resilience profiles of older adults who were formerly affected by child welfare-related trauma and maltreatment (risk group, RG; n = 132; Mage = 71 years) and non-affected, age-matched controls (control group, CG; n = 125). Within the RG, approximately one-third of the individuals had no current or lifetime DSM-5 mental health disorders. In comparison to the survivors with a history of mental ill-health, these individuals were older, had a higher income, and expressed a higher subjective satisfaction with their socio-economic status. Furthermore, they reported less early-life physical abuse, and had lower levels of neuroticism, as well as empathy-related characteristics. In addition, they showed higher levels of self-esteem and trait resilience. Group differences between the RG and CG highlight the importance of considering past adversity in the understanding of mental health resilience in later life.

SELF-ADMINISTRATED ELDER ABUSE INTERVENTION FOR OLDER ADULTS WITH COGNITIVE IMPAIRMENT

Fuad Abujarad[1], Chelsea Edwards[2], Brent Vander Wyk[2], Laura Mosqueda[3], Ula Hwang[2], Judith Neugroschl[4], and Richard Marottoli[2], *1. Yale University, Orange, Connecticut, United States, 2. Yale University, New Haven, Connecticut, United States, 3. University of Southern California, Alhambra, California, United States, 4. Mount Sinai, New York, New York, United States*

Many elder abuse interventions and tools designed to screen for abuse exclude older adults with cognitive impairments (CI) due to the challenges associated with screening and whether the older adult with CI can reliably report elder abuse. However, it has been shown that older adults with CI are among the most vulnerable to experiencing elder abuse. VOICES is an innovative, automated tablet-based elder abuse screening and prevention intervention that is self-administered by the older adult in the provider's waiting room or office. The VOICES Elder Abuse Intervention (EAI) provides screening, educational modules, and brief psychoeducational intervention to enhance and improve identification of elder abuse when there are no visible signs of abuse. The VOICES EAI was already proven successful in terms of feasibility and acceptability in cognitively intact older adults in a busy emergency department setting with (N=1,002). In this study we tested the VOICES EAI with (N=30) participants 60 and above with cognitive impairment at a geriatric center using the Montreal Cognitive Assessment (MoCA) to determine cognitive capacity. Experts in the field of geriatrics and cognitive impairment assisted in grouping participants within three cognitive categories: Mild cognitive impairment (MoCA 23-25), mild dementia (MoCA 16-22) or moderate dementia (MoCA 8-15). Of the (N=30) participants, 29 were able to successfully use the VOICES EAI independently, and most participants were satisfied with the tool. We will discuss the findings of this preliminary study and the implications for future research with older adults with CI.

SESSION 5110 (SYMPOSIUM)

ADULTS' VIEWS OF AGING AS AN UNDERESTIMATED RISK FACTOR FOR HEALTH, WELL-BEING, AND LONGEVITY

Chair: Manfred Diehl Co-Chair: Susanne Wurm Discussant: Becca Levy

Worldwide population aging has greatly increased the diversity of the “aging enterprise.” Research has established a solid portfolio of evidence showing that positive and negative views of aging represent independent resilience or risk factors for health, well-being, and longevity. Indeed, the effects of views of aging remain significant beyond the effects of other risk factors for health and mortality. This raises the following questions: What do we currently know about the effect of self-perceptions of aging (SPA) and subjective age (SA) on health, well-being, and longevity? What are recent advancements and perspectives? Which research questions should be addressed to stimulate further, sustainable developments in research and practice? This symposium addresses these questions with a diverse set of presentations and from different perspectives. Wahl and colleagues will discuss the role of SPA in the clinical context, namely in a sample of older adults with terminal cancer comparing them to older adults without a terminal illness. Based on a population-based sample, Wurm and Schaefer will report findings on the impact of different gain- and loss-related SPA and SA on mortality over a 23-year period. Building on an earlier meta-analysis, Westerberg and colleagues evaluated data from over 100 studies and will present the findings of a systematic review on the role of SPA and SA for health and longevity. Finally, Nehrkorn-Bailey et al. will present findings from a clinical trial that addressed views of aging as a mechanism to promote physical activity. Dr. Becca Levy will serve as the discussant.

LIFETIME CLOSE TO THE END: EFFECTS ON PERCEIVED TIME AND AGING IN OLDER ADULTS WITH ADVANCED CANCER

Hans-Werner Wahl[1], Katsiaryna Laryionava[2], Anton Schönstein[2], Pia Heussner[3], Wolfgang Hiddemann[4], and Eva Winkler[2], *1. Universität Heidelberg, Heidelberg,* *Baden-Wurttemberg, Germany, 2. Heidelberg University, Heidelberg, Baden-Wurttemberg, Germany, 3. Klinikum Garmisch-Partenkirchen GmbH, Garmisch-Partenkirchen, Bayern, Germany, 4. Ludwig-Maximilians University, Munich, Baden-Wurttemberg, Germany*

This study addressed two questions: (1) Does advanced cancer in later life affect a person's awareness of time and their subjective age? (2) Are awareness of time and subjective age associated with distress, perceived quality of life, and depression? We assessed patients with terminal cancer (OAC, n = 91) and older adults with no life-threatening disease (OA, n = 89). All participants were age 50 or older. OAC perceived time as being a more finite resource and felt significantly older than OA controls. Feeling younger was significantly related with better quality of life and lower levels of distress. In the OA group, feeling younger was also associated with reduced depression. Perceiving time as a finite resource was related to higher quality of life in the OA group. Indicators of an older person's awareness of time and subjective aging differ between those with advanced cancer versus controls without a terminal disease.

GAIN- BUT NOT LOSS-RELATED VIEWS ON AGING PREDICT MORTALITY OVER A PERIOD OF 23 YEARS

Susanne Wurm[1], and Sarah Schaefer[2], *1. University Medicine Greifswald, Greifswald, Mecklenburg-Vorpommern, Germany, 2. Leibniz Institute for Resilience Research, Mainz, Rheinland-Pfalz, Germany*

Some 2 decades ago, Levy et al. (2002) published their seminal study on the impact of SPA on mortality over a period of 23 years. Our study aimed at replicating and extending these findings. Based on a large German population-based sample of individuals aged 40+ (N = 2,400), for whom mortality was also documented over 23 years (1996–2019), we investigated the impact of gain- and loss-related SPA and SA on mortality. Data were analyzed with hierarchical Cox proportional hazard regressions. For individuals who perceived aging as ongoing development risk of death was half that of individuals with less gain-related SPA. Viewing aging as associated with physical or social losses could not predict mortality after controlling for covariates (age, gender, education, health-related variables, and psychological variables). Neither could SA predict mortality. The results suggest that mainly gain-related SPA explain differences in mortality and should thus be addressed in intervention studies.

THE EFFECT OF SELF-PERCEPTIONS OF AGING ON PHYSICAL ACTIVITY: RESULTS FROM THE AGINGPLUS STUDY

Abigail Nehrkorn-Bailey[1], Han-Yun (Heidi) Tseng[2], Diana Rodriguez[2], Kaigang Li[2], George Rebok[3], David Roth[4], Shang-En Chung[4], and Manfred Diehl[2], *1. University of Wisconsin-Green Bay, Green Bay, Wisconsin, United States, 2. Colorado State University, Fort Collins, Colorado, United States, 3. Johns Hopkins Bloomberg School of Public Health, Baltimore, Maryland, United States, 4. Johns Hopkins University, Baltimore, Maryland, United States*

The AgingPLUS program targets negative self-perceptions of aging (SPA) as one mechanism to increase physical activity (PA) in adults. This study utilized a mediation model to examine the effect of AgingPLUS on subsequent PA with SPA included as a mediator. Data came from 184 participants (Mage = 59.91 years; SDage = 8.14 years) from the ongoing trial. Although the direct effect from condition to Week 8 PA was not significant, the pathway from condition to Week 4 SPA was significant. Additionally, the pathway from Week 4 SPA to Week 8 PA was marginally significant (β = .11, p = .07). However, the indirect effect was not significant. Given that (1) the AgingPLUS program resulted in significantly more positive SPA and (2) more positive SPA marginally predicted more minutes of subsequent PA, these results provide preliminary support for the efficacy of the ongoing program.

THE EFFECT OF SUBJECTIVE AGING ON HEALTH AND SURVIVAL: A SYSTEMATIC REVIEW OF LONGITUDINAL DATA

Gerben Westerhof[1], Abigail Nehrkorn-Bailey[2], Allyson Brothers[3], Jelena Siebert[4], Han-Yun (Heidi) Tseng[3], Manfred Diehl[3], Hans-Werner Wahl[5], and Susanne Wurm[6], *1. University of Twente, Enschede, Overijssel, Netherlands, 2. University of Wisconsin-Green Bay, Green Bay, Wisconsin, United States, 3. Colorado State University, Fort Collins, Colorado, United States, 4. Heidelberg University, Heidelberg, Baden-Wurttemberg, Germany, 5. Universität Heidelberg, Heidelberg, Baden-Wurttemberg, Germany, 6. University Medicine Greifswald, Greifswald, Mecklenburg-Vorpommern, Germany*

Longitudinal effects of subjective age on adult health and survival are well-documented (Westerhof et al., 2014). This systematic review provides an updated and expanded evaluation of the state of the field. A systematic search in PsycInfo, Web of Science, Scopus, and PubMed resulted in 103 articles: 19 articles from the 2014 meta-analysis and 84 newer articles. Sixty-five articles focused on physical health (e.g., subjective health, objective health, and health behaviors), 41 studied mental health outcomes (e.g., mental health disorders, well-being, and quality of life), and 18 articles used mortality as the outcome. Important developments during the past years include new instruments, particularly multidimensional assessment of subjective aging, and a more fine-grained representation of health outcomes, including bio indicators. A major outcome is that most studies confirmed the longitudinal effects of subjective aging on health as reported previously, but on a much broader study portfolio.

SESSION 5120 (SYMPOSIUM)

AGING RESEARCH IN CRIMINAL LEGAL SYSTEMS: IMPLICATIONS FOR POLICY AND PRACTICE

Chair: Jennifer James Discussant: Brie Williams

ADD

INSIDE-OUTSIDE COMMUNITY ADVISORY BOARDS: ONE MODEL FOR ENGAGING OLDER BIPOC AND WOMEN IN CLINICAL RESEARCH

Jennifer James, *University of California, San Francisco, San Francisco, California, United States*

Historical legacies of unethical research performed on people in prison, coupled with stringent policies intended to protect those who are incarcerated from exploitation, has meant that much clinical research about the health of people who are incarcerated is conducted at a distance, without directly engaging those who are incarcerated in the formulation of studies. As a result, research conducted about correctional healthcare and the healthcare needs of incarcerated persons may not reflect specific stakeholder values or priorities. In this session, we will describe barriers in engaging incarnated older women and BIPOC patients, their healthcare providers, and their loved ones in the research process and new models for the development of research questions that center stakeholder perspectives. We will describe identified priority areas for future research, insight on the ethics of research consent and participation with this population, and methodological considerations for clinical, social, and behavioral research with this vulnerable population.

THE ROLE OF PEER HEALTH WORKS IN ENGAGING INCARCERATED PATIENTS IN RESEARCH

Fernando Murillo, *University of California, San Francisco, San Francisco, California, United States*

Incarcerated peers play a critical role in the provision of care for incarcerated older adults. Peer counsel is part of the culture in carceral settings and official and unofficial caregiving is a necessity for visually, mobility, and cognitively impaired residents of these institutions. Due to their experiences of exploitation by the prison system and research institutions, most older incarcerated people are reluctant to trust community partners or correctional staff members who conduct research in correctional settings. Many older residents who are offered participation in research do not believe any real systemic changes will occur with the publication of findings. This presentation will draw on autoethnographic experiences of a peer health worker in the palliative care setting. We will describe the role that peer health workers play in guiding patients in decision-making around research and interrogate a model of partnering with peer health workers to engage incarcerated older adults in research.

ASSESSING PHYSICAL FUNCTION AND MENTAL HEALTH AMONG OLDER PERSONS IN PRISON

Lisa Barry, *University of Connecticut Center on Aging, Farmington, Connecticut, United States*

As the number of older incarcerated persons grows, evaluating changes in their physical and mental health over time may be important for appropriate planning and needs assessment. Based on findings from the Aging Inmates' Suicidal Ideation and Depression Study (Aging INSIDE), we will provide recommendations for assessing both objective and subjective physical function in older incarcerated persons. We will also discuss our experiences with assessing depression and suicidal ideation in this population and describe how the processes for collecting data needed to be modified during the COVID-19 pandemic. Those attending this session will learn about the pros and cons of using face-to-face assessments and mailed surveys to assess physical function and mental health among older persons in the prison setting and will learn how these outcomes may differ between those who have a life sentence versus those expecting to be released from incarceration in late life.

STRATEGIES FOR PARTNERING WITH CARCERAL SETTING STAFF AND LEADERSHIP

Stephanie Grace Prost, *University of Louisville, Louisville, Kentucky, United States*

The mission of carceral agencies--the pursuit of public safety andsecurity--often conflicts with the primary aim of social justice-oriented scholarship, most notably research objectives related to health promotion in jails and prisons. However, such research is essential to awareness building, policy reformation, and revisions today-to-day practices that increase the health and well-being of historically marginalized populations. As a result, the conduct of aging research within carceral settings requires specialized knowledge and skills including frequent, targeted communication,transparency, humility, and flexibility. This presentation includes discussion of strategies for building and maintaining successful partnerships with local and state-level agencies with examples drawn from four distinct aging research projects, specifically. These partnerships resulted in primary data collection with over 800 carceral constituents including prison hospice program representatives, persons who are incarcerated, and experts in correctional health and art therapies. Lessons learned and opportunities for future partnerships are also described.

SESSION 5130 (PAPER)

ASSESSMENT OF PERSONS WITH ADRD IN COMMUNITY AND ACUTE CARE SETTINGS

ASSESSING DEMENTIA CLASSIFICATION IN THE NATIONAL CORE INDICATORS AGING AND DISABILITY SURVEY

John Mulcahy[1], Taylor Bucy[2], Tetyana Shippee[1], and Eric Jutkowitz[3], *1. University of Minnesota, Minneapolis, Minnesota, United States, 2. University of Minnesota School of Public Health, Minneapolis, Minnesota, United States, 3. Brown University, Providence, Rhode Island, United States*

Improving the quality of long-term care services for older adults is a national priority. The National Core Indicators Aging and Disability (NCI-AD) collects data from multiple states to evaluate long-term care recipients' service satisfaction and needs. Many analysts are interested in exploring the service environments of people living with dementia. However, dementia measurement and reporting varies in NCI-AD between states. Dementia status may be obtained from administrative records or self-reported during the survey. We explored the measurement of dementia in NCI-AD and the implications of relying on administrative or self-reported dementia status. We analyzed NCI-AD data from 2015-2018 representing 24,569 respondents age 65+, of which 5,502 (22.4%) were identified as having dementia. 42.9% of respondents had dementia status determined administratively and 57.1% had it determined during the survey. To assess dementia accuracy by data source, we fit separate LASSO models for both the administrative and survey subpopulations predicting dementia status using demographic and functional predictors. We then used each model to predict dementia status in the subpopulation with discordant dementia data source. Using the administrative model to predict survey reported status resulted in a higher sensitivity than using the survey model to predict administrative status (44.6% vs 32.2%). The diminished predictive accuracy of the survey model suggests administrative records may capture cases of dementia diagnosis that would be missed by self-report. These findings highlight analytical caveats for researchers interested study long-term care quality for people with dementia using NCI-AD, and emphasize the importance of moving towards more standardized dementia reporting.

DEVELOPMENT OF A FRAILTY INDEX FOR PEOPLE WITH DEMENTIA IN THE HEALTH AND RETIREMENT STUDY

Rachel Wilkie, and Jennifer Ailshire, *University of Southern California, Los Angeles, California, United States*

Frailty indices (FI) have been found to predict adverse outcomes, such as, mortality, hospitalization, and institutionalization in older adults. However, traditional FIs often exclude people with dementia (PWD), who may not be able to consent to or complete all of the standard frailty items. While frailty is a known risk factor for onset of dementia and PWD have higher rates of frailty, little is known regarding how frailty predicts outcomes among PWD. Our study aims to develop an FI for PWD and to examine how this index relates to mortality, hospitalization, and nursing home stays. We used data from the Health and Retirement Study to create a 52-item FI for community-dwelling adults aged 50 years and over classified as having dementia (n = 1,107) in 2014. The index includes deficits in four domains: chronic health conditions, functional status, sensory problems, and overall health and wellbeing. A standardized FI score between 0 and 1 was calculated for each respondent. We used logistic regression to examine associations with FI and 2-year mortality, hospitalization, and nursing home stay, adjusting for age and gender. We found that a 0.1 unit increase in FI was significantly associated with higher odds of 2-year mortality (OR 1.39, $p< 0.001$), hospitalization (OR 1.45, $p< 0.001$), and nursing home stay (OR 1.38, $p< 0.001$) for people with dementia. This study developed an FI which is predictive for adverse outcomes among PWD. Future work should explore how socioeconomic and neighborhood factors contribute to the relationship between frailty and adverse outcomes among PWD.

EVALUATING THE FEASIBILITY AND ACCEPTABILITY OF THE WITS WELLNESS COGNITIVE HEALTH PROGRAM

Julie Bobitt[1], Laura Payne[2], Neha Gothe[3], Chelsey Byers[4], and Molly Hofer[5], *1. University of Illinois at Chicago, Chicago, Illinois, United States, 2. University of Illinois Urbana-Champaign, Champaign, Illinois, United States, 3. University of Illinois at Urbana Champaign, Urbana, Illinois, United States, 4. University of Illinois Extension, Champaign, Illinois, United States, 5. University of Illinois Extension, Chicago, Illinois, United States*

About 11% of U.S. older adults are at risk for or have subjective cognitive decline. Although some factors that affect brain health cannot be changed, research indicates lifestyle changes (i.e., physical activity, social engagement, heart-healthy diet) can delay or reduce cognitive decline. Drawing from existing research, UI Extension developed Wits Wellness, a 12-week program designed to enhance brain health among people ages 50 and older. Wits Wellness addresses multiple factors that affect cognitive health (e.g., physical activity, stress, sleep, social isolation, diet). Using a two-arm randomized control trial, 285 participants (mean age = 66.6 years, 24 males) were randomly assigned to the Wits Wellness intervention (in person or virtual) or a waitlist control group. Summative program evaluation surveys indicated adherence to the intervention was high, with 68% of participants attending 9 or more of the 12 sessions. Program acceptability was high, with 82.7% evaluating the program as great to excellent, and 90.8% reporting great to excellent interaction with program leaders. Approximately 63.6% of participant write-in comments included positive statements about the program challenging their brains, and 59.1% indicated the program positively affected participants' socialization. For program feasibility, 90.4% rated the 60-minute weekly sessions 'just right' for program length, while 66.3% rated the 12-week program duration 'just right' and 27.7% rated it 'too long'. Thus, preliminary results suggest that Wits Wellness delivered both in-person and virtually was well attended and highly acceptable in the community setting. Future studies will examine the program's efficacy in improving physical and mental health related outcomes.

FINDING THE MINDS OF OUR ELDERS: TESTING THE MINORITY STRESS AND COGNITION MODEL WITH INDIGENOUS OLDER ADULTS

Cliff Whetung, *NYU Silver School of Social Work, New York, New York, United States*

This study used data from the Health and Retirement Study (HRS) data to investigate how an understudied group of Indigenous Older Adults (IOAs) in the United States fared over a 14-year period (2006-2020) in the domain of global cognitive function. The number of IOAs, defined here as Native American and Alaska Natives, will more than double in the next 30 years. Concurrently, the number of IOAs living with cognitive impairments will also increase. Guided by the Minority Stress and Cognition Model, we tested the hypothesis that discriminatory stress increases the risk of cognitive impairment in later life. Using a robust set of psychosocial (e.g. educational quality, perceived everyday discrimination experiences), behavioral (e.g. substance use, exercise), and physiological (e.g. diabetes, hypertension, obesity) risk factors, we modeled the cognition trajectories 186 IOAs using mixed growth curves. We found that one third of these IOAs reported experiencing everyday discrimination at least once per month, the highest of any ethnic group. They also reported high rates of other risk factors for cognitive impairment like low education, SES, and physical activity, and high rates of depression and chronic health conditions. Our analysis found that everyday discrimination was negatively associated with total cognition among IOAs but that this relationship was mediated by allostatic loads. On average, the total cognition scores of IOAs declined significantly faster than those of Whites. This study has important implications for the integration of stress as a mechanism for cognitive decline and the health equity of Indigenous older adults.

RACIAL/ETHNIC DISPARITIES IN THE EFFECTS OF RECEIVING A DIAGNOSIS OF DEMENTIA ON SOCIAL RELATIONSHIPS

Takashi Amano[1], Addam Reynolds[2], Clara Scher[3], and Yuane Jia[2], *1. Rutgers University-Newark, Newark, New Jersey, United States, 2. Rutgers University, New Brunswick, New Jersey, United States, 3. Rutgers, The State University of New Jersey, New Brunswick, New Jersey, United States*

Although early diagnosis has been recognized as a key strategy to improve outcomes for those with dementia, receiving a diagnosis may negatively influence social relationships. Absent from the literature are considerations of how race/ethnicity may alter these associations. This study examines racial/ethnic variation in the effects of receiving a diagnosis of dementia on social relationships of older adults. Data from the three waves of the Health and Retirement Study were utilized as part of this study. This study examined whether receiving a new diagnosis of dementia changed subsequent social relationships (social networks, social engagement, social support). Regression analyses with inverse probability weighting were performed to estimate the impact of receiving a dementia diagnosis on changes in social relationships. Receiving a new diagnosis of dementia reduced both informal (b = -0.476, p = 0.011, 95% CI = [-0.842, -0.110]) and formal (IRR = 0.688, p = 0.034, 95% CI = [0.487, 0.971]) social engagements. The negative impact of receiving a diagnosis on formal social engagement was stronger among non-Hispanic Blacks (IRR = 0.047, p = 0.007, 95% CI = [0.005, 0.432]). We found no statistically significant impacts of receiving a diagnosis of dementia on social networks and social support. Results suggest that receiving a new diagnosis of dementia may have unintended negative consequences on social engagement and may be more salient for racial/ethnic minorities, such as non-Hispanic Blacks. Practitioners and policymakers should be aware of these consequences and should identify strategies to alleviate the negative implications of receiving a diagnosis.

SESSION 5140 (PAPER)

DEPRESSION

COVID-19 ERA EFFECTS ON OLDER ADULTS' COGNITIVE COMPLAINTS, DEPRESSIVE SYMPTOMS, AND STRESSFUL EVENTS

Suzanne Segerstrom[1], Paris Crosby[1], Dakota Witzel[2], Maria Kurth[3], Soyoung Choun[3], and Carolyn Aldwin[3], *1. University of Kentucky, Lexington, Kentucky, United States, 2. Penn State University, State College, Pennsylvania, United States, 3. Oregon State University, Corvallis, Oregon, United States*

Older adults have adjusted better to the COVID-19 pandemic in terms of their psychological well-being than younger adults. We investigated individual differences in vulnerability within older adulthood as pandemic severity changed, providing a more refined prediction of older adults' adjustment to COVID-19. Participants from this longitudinal study were included if they had at least one semiannual assessment before and one during the COVID-19 era (N = 111, 65% women, age range = 62-96 at onset of COVID-19 era in the US). There were 1,098 pre-COVID-19 assessments (M=9.9, 1/5/2018-1/22/2020) and 265 post-COVID-19 (M=2.4, 1/23/2020-10/31/2021). At each assessment, participants reported on six cognitive complaints (MOS), five depressive symptoms (Geriatric Depression Scale), and six domains of undesirability-weighted stressful life events (Louisville Older Persons Event Scale). Daily national, state, and regional COVID-19 case and death rates were obtained from the Centers for Disease Control and summed for the week preceding each assessment. In multilevel ZIP models, the COVID-19 era significantly increased depressive symptoms (0.68 to 1.18, p < .0001) and stressful events (30.9 to 48.5, p < .0001), but did not significantly affect severity of cognitive complaints. Older age was associated with greater impact of COVID-19 on depressive symptoms and stressful events; women reported more stressful events when pandemic severity was high, but men reported more stressful events when pandemic severity was low. Although older adults in general have adjusted better to the pandemic than younger adults, the old-old had greater vulnerability to this unavoidable event than the young-old.

EFFECTS OF DEPRESSIVE SYMPTOMS ON COGNITIVE BEHAVIORAL INTERVENTIONS WITH CUSTODIAL GRANDMOTHERS

Carol Musil[1], Alexandra Jeanblanc[1], Christopher Burant[2], and Jaclene Zausniewski[1], *1. Case Western Reserve University, Cleveland, Ohio, United States, 2. Case Western Reserve University, Parma, Ohio, United States*

Over 25% of custodial grandmothers report elevated depressive symptoms, which may affect situational appraisals and learning/retaining new information, and thus the effectiveness of cognitive-behavioral interventions. We examined the effect of depressive symptoms on self-appraised stress and reward associated with caregiving to co-residential grandchildren in a sample of 342 grandmothers who participated in a nationwide behavioral RCT testing two methods of stress reduction. Participants completed a baseline questionnaire, one of 2 cognitive-behavioral interventions (guided journaling or journaling with Resourcefulness Skills Training ©), and 3 subsequent questionnaires over 6 months. We analyzed self-appraised stress and reward with RM-ANOVAs to evaluate whether level of depressive symptoms (CES-D below-16, 16-29, 30+) affected the effectiveness of each arm with regard to self-appraised stress and reward. We found differences by depressive symptom category and interaction effects of depressive symptoms by arm in self-appraised stress. The below-16 group had relatively constant appraised stress over time, but the 16-29 and 30+ groups had significant decreases in stress over time. The Resourcefulness Skills Training © group had an average decrease in stress of .68 over time compared to .2 points for the journal-only group; there were no intervention effects in the below-16 group. The highest symptom group showed a stronger effect for the journal-only intervention, perhaps reflecting the challenges in learning and applying new skills. Self-appraised reward increased over time across groups. Participants' level of depressive symptoms have significant effects on the effectiveness of interventions and should be taken into consideration when designing studies and analyzing effectiveness.

GENETIC RISK FOR ADHD ON LATER LIFE EMOTIONAL AND COGNITIVE HEALTH: TESTING MECHANISMS OF EFFECT

Thalida Arpawong, and Jimi Huh, *University of Southern California, Los Angeles, California, United States*

Attention Deficit Hyperactivity Disorder (ADHD) is associated with emotional regulation and cognitive processing challenges throughout life. Not well-understood is how ADHD genetic risk (ADHD-GR) affects depressive symptoms (DepSx) and cognitive functioning in older age. Furthermore, less is known about the mechanisms through which some individuals show better outcomes despite higher ADHD-GR. We evaluated potential mechanisms using the Health and Retirement Study with data from 7,871 European Americans (EAs) and 1,226 African Americans (AAs), ages 50-93, and ADHD-GR calculated from a mixed ancestry genomewide scan. Mediators included closeness of parental relationships during childhood, sense of purpose in life in adulthood, and educational attainment. Outcomes included validated scales for DepSx and cognitive functioning. Structural equation models were stratified by race/ethnicity due to potential differences in genetic effects, adjusted for age, gender, ancestry, and health conditions with DepSx and genetic risk for dementia with cognitive functioning. Among EAs, ADHD-GR significantly predicted lower sense of purpose ($p<.05$) and worse parental relationships ($p<.001$), with higher levels of both, in turn, predicting less DepSx (p's< 0.01). ADHD-GR also showed significant direct effects on DepSx ($p<.01$), controlling for mediators. Additionally, ADHD-GR predicted less education ($p<.001$), but more education predicted better cognitive functioning ($p< 0.001$). No relationships with ADHD-GR were significant among AAs. Findings imply that among EAs, mediators could be targets to mitigate negative effects on psychological and cognitive health, two hallmark challenges for individuals with ADHD. More work is needed to characterize ADHD-GR on outcomes among older AAs.

HEARING LOSS AND ITS CONSEQUENCES FOR SPOUSAL MENTAL HEALTH: EVIDENCE FROM THE HEALTH AND RETIREMENT STUDY

Jessica West, Sherri Smith, and Matthew Dupre, *Duke University, Durham, North Carolina, United States*

Hearing loss (HL) is an increasingly prevalent chronic stressor among older adults and is associated with numerous adverse health outcomes. The life course perspective and stress process framework highlight that an individual's stressors may have a short and/or long-term impact on the health of others. However, little is known about how HL influences the proliferation of stress within married couples. Drawing on nationally-representative data from 11 waves (1998-2018) of the Health and Retirement Study (n=9,000 individuals, 4,500 couples), we use age-based mixed models to examine how one's own HL, spouse's HL, or both spouses have HL shape the level and changes in depressive symptoms. For men, we find that their wives' HL, their own HL, and both spouses having HL are each associated with an increase in depressive symptoms—and that the associations persist as spouses age. For women, we find that their own HL and both spouses having HL is associated with an increase in depressive symptoms. Furthermore, we find that the differences in women's depressive symptoms between spouses who both have HL and those who do not have HL significantly declines with age. We also find no evidence to suggest that husbands' HL is associated with wives' depressive symptoms. Together, these findings suggest that the connections between spouses' HL and their depressive symptoms are a dynamic process that unfolds differently by gender over time. Interventions that recognize the proliferation of stress associated with HL may help both individuals with HL and their spouses reduce their depressive symptoms.

LONG-TERM GENDERED PATHWAYS OF RELIGIOUS INVOLVEMENT POST WIDOWHOOD

Frances Hawes[1], and Jane Tavares[2], *1. University of Wisconsin-Eau Claire, Eau Claire, Wisconsin, United States, 2. University of Massachusetts Boston, Boston, Massachusetts, United States*

Widowhood is associated with decreased emotional well-being, particularly increased depression. Prior research suggests that religiosity may help improve mental health among widowed individuals. However, longitudinal studies exploring the role of religiosity on emotional well-being among widowed older adults is lacking, as are studies which examine different dimensions of religiosity. This longitudinal study analyzed data from the 2006-2018 waves of the nationally representative Health and Retirement Study (HRS). Ordinary least squares (OLS) regression analysis was used to examine the relationship between widowhood and depression as well as the role of religiosity as a moderator of this association. Analysis was stratified by gender to further explore these interactions. Results show that men and women show similar levels of depression at widowhood, but men are far less likely to be depressed prior to widowhood. Women also show a better recovery pattern over time post-widowhood. Furthermore, religiosity (particularly attending church) is an effective way of coping with widowhood and mitigating depression for both genders. However, men are significantly less religious than women. This study highlights the long-term effects of widowhood on depressive symptomology among older adults. Practical implications of this study include intervention development around increased screening and treatment for depression for widowed older adults (in particular, for widowers) as well as connecting this vulnerable population with resources. These findings may also inform program outreach (such as hospice bereavement services) that aim to facilitate healthy grieving among widowed older adults.

SESSION 5150 (PAPER)

LONELINESS

FACTORS THAT PREDICT LONELINESS FOR MIDDLE-AGED AND OLDER ADULTS DURING THE COVID-19 PANDEMIC

Angela Curl, and Katie Wolf, *Miami University, Oxford, Ohio, United States*

The Protection Motivation Theory (Eberhardt & Ling, 2021; Rogers, 1975) describes factors that influence intention and engagement in preventive health behaviors, including knowledge/experience, threat appraisal, and coping/efficacy appraisal. Public health responses to the covid-19 pandemic were designed to increase knowledge, emphasize potential severity of being infected, and promote preventive health behaviors – all with the goal of reducing infection transmission. However, these efforts may have inadvertently increased loneliness, particularly for older adults. This study used 2020 Health and Retirement Study data (N=1,687 adults over age 50) to examine predictors of loneliness based on the PMT framework, controlling for demographic factors and 2016 loneliness scores. Structural Equation Model results indicate that being at higher risk for covid-19 complications and death was associated with lower feelings of control over health (B=-.09), greater likelihood of knowing someone who died from covid-19 (B = .20), and higher overall concerns about covid-19 (B=.12), all p<.01. Higher concerns about covid-19 and knowing someone who died from covid-19 were associated with more protective behaviors (B=.41, p<.01; B=.05, p<.05; respectively). Not knowing someone who died of COVID-19, and lower perceived control over health and social life were all significantly associated with higher loneliness scores. These results suggest that interventions that promote perceived control over one's health and social life may be effective in reducing feelings of loneliness in this population, and that feelings of control over health also increases preventive health behaviors that reduce the risk of covid-19 infection.

LONELINESS IN COMMUNITY-DWELLING US OLDER LATINX ADULTS

David Camacho[1], Kelly Pacheco[2], Todd Becker[3], Cary Reid[4], and Elaine Wethington[5], *1. University of Maryland, Baltimore, Norwalk, California, United States, 2. New York University, New York City, New York, United States, 3. University of Maryland, Baltimore, Baltimore, Maryland, United States, 4. Weill Cornell Medicine, New York City, New York, United States, 5. Cornell, Ithaca, New York, United States*

Loneliness is a critical public health problem yet little is known about older Latinx's experiences with loneliness. We conducted narrative interviews (Cultural Formulation Interview), with 17 Spanish-speaking Latinx (60 years+) living with loneliness (based on 3-item Loneliness scale) in New York or Los Angeles. Interviewers were bilingual (English/Spanish) gerontological social workers with training in qualitative methods, culturally-sensitive clinical research and elicitation of "sensitive data". Our thematic analysis was informed by Biopsychosocial and Minority Stress Models, and our gerontological clinical experience with Latinx groups. Most participants immigrated from Mexico, Dominican Republic, Ecuador or Uruguay and lived in the US for more than 20 years. Interviews ranged from 60 to 120 minutes. Most participants described comorbid depression or pain. A substantial majority (82%) had never discussed feelings of loneliness with family or friends. No participant reported seeking professional help to address loneliness. Other identified themes demonstrated how cultural and contextual factors shape loneliness: 1) Descriptions and interpretations rooted in familism and views of aging ("it seems I no longer matter to my children"); 2) perceived causes e.g. discrimination, family conflict, bereavements, immigrant stress, violence; 3) religious and cognitive coping to mitigate loneliness ("I pray that God gives me strength, "I befriend loneliness"); and 4) psychosocial functioning impact ("there is no reason to live"). Our findings support development of culturally congruent loneliness prevention and treatment practices for older Latinx adults. Future quantitative research should explore the association of cultural and minority stress factors related to loneliness in diverse samples of older Latinx.

NETWORK SIZE, SOCIAL ACCOMPANIMENT, AND GENDER: PROTECTIVE OR RISK FACTOR FOR REAL-TIME LONELINESS, AND FOR WHOM?

Ellen Compernolle[1], and Alyssa Goldman[2], *1. NORC at the University of Chicago, Chicago, Illinois, United States, 2. Boston College, Chestnut Hill, Massachusetts, United States*

Large personal networks are a key marker of social integration that protect against loneliness. Yet how such social integration shapes loneliness on a momentary basis remains unclear. This study examines (1) the role of personal network size in shaping older adults' momentary loneliness, (2) how momentary social accompaniment modifies this association (protective or risk factor), and (3) whether this moderation varies by gender. We use three waves of ecological momentary assessments (n = 12,251) and personal network data collected from 333 older adults as part of the Chicago Health and Activity in Real-Time (CHART). Findings from multilevel regression models suggest that older adults with large social networks experience greater intensity loneliness when momentarily alone compared to those with smaller social networks. This association is also more pronounced among men compared to women. Results support our deviation-from-baseline hypothesis, which is further supported by additional analyses that find a similar association between more frequent interaction with network ties and heightened loneliness when alone. Additional analyses provide insight into observed gender differences as well: women's networks and momentary social company tend to be familial ties characterized by caregiving, compared to men's ties, which are characterized as peers or companions. Here, moments of momentary social isolation may be a welcome reprieve from otherwise demanding social relationships ("tethering"). We conclude that extending the well-documented links between global measures of social integration and loneliness into a real-time framework offers novel insight into existing, high-level trends in loneliness among older adults.

POST-TRAUMATIC STRESS AND LONELINESS AMONG OLDER PUERTO RICANS: HOW DOES DISCRIMINATION MATTER?

Kaipeng Wang[1], Daniel Vélez Ortiz[2], Lisa Colón[3], and Fei Sun[2], *1. University of Denver, Denver, Colorado, United States, 2. Michigan State University, East Lansing, Michigan, United States, 3. Washington State University, Pullman, Washington, United States*

Loneliness is associated with worse mental health conditions, more functional limitations, and higher mortality among older adults. Almost one third older Puerto Ricans have experienced loneliness. Research has shown that post-traumatic stress has been associated with higher risk of loneliness among older adults; however, such an association has not been examined among Puerto Ricans despite their high prevalence of post-traumatic stress disorder. In addition, perceived discrimination, a critical risk factor of social isolation, is likely to reduce help-seeking behaviors and aggregate loneliness among individuals who have experienced trauma. Nonetheless, few studies have focused on the moderating role of perceived discrimination on the association between post-traumatic stress and loneliness. This study examines the association between post-traumatic stress and loneliness and whether that association differs by everyday perceived discrimination among older Puerto Ricans. Data were collected from 304 Puerto Ricans aged 60 and above living in the Greater Boston area who responded to questionnaires. We used ordinary least squares regression to examine the association between post-traumatic stress, perceived everyday discrimination, and loneliness. We found that post-traumatic stress was significantly associated with higher levels of loneliness; however, the association differed by perceived everyday discrimination. The association between post-traumatic stress and loneliness was stronger for those that perceived a higher level of everyday discrimination. Findings underscored the role that perceived discrimination plays in exacerbating loneliness among older Puerto Ricans experiencing post-traumatic stress and have clinical and public health implications for service delivery and mental health promotion among older Puerto Ricans.

SOCIAL ISOLATION AND LONELINESS AMONG OLDER ADULTS IN SUBSIDIZED SENIOR HOUSING: DOES IMMIGRATION STATUS MATTER?

Chung Hyeon Jeong[1], Jihye Baek[2], ByeongJu Ryu[3], Jina Park[2], BoRin Kim[1], and Sojung Park[2], *1. University of New Hampshire, Durham, New Hampshire, United States, 2. Washington University in St. Louis, St. Louis, Missouri, United States,*
3. Chuncheon Hyoja Social Welfare Center, Chuncheon-si, Kangwon-do, Republic of Korea

Older immigrants are at increased risk for social isolation and loneliness due to cultural and linguistic barrier to forming social networks. The vulnerability to social isolation could be exacerbated by the gaps between older immigrants' cultural expectations on social relations and actual social connectivity. Guided by the cognitive discrepancy model of loneliness, this study examined how social isolation influences loneliness among low-income older residents living in subsidized senior housing and if the relation varies by immigration status. Survey data were collected in 2019 and 2020 from 231 residents in subsidized senior housing communities located in St. Louis and Chicago. Social isolation was measured by frequency of social contacts, accounting for the types of relationships (family vs. friends) and the modes of contacts (in-person vs. remote). Loneliness was measured by the Revised University of California Los Angeles loneliness scale. Perceived quality of friendship was also included in the analytic models. The results of multiple linear regression showed that having positive friendship (b=-1.00, p<.001) and more frequent in-person contacts with friends (b=-1.29, p<.001) were negatively associated with loneliness, respectively. A significant moderating effect was found that older immigrants felt less lonely than non-immigrant counterparts when they had more in-person family contacts (b=-1.09, p<.05). The results suggest that the impacts of social isolation on loneliness among senior housing residents could differ depending on immigration status. The findings of this study could contribute to developing culturally sensitive interventions to enhance social connectedness and reduce loneliness among older immigrants in subsidized senior housing.

SESSION 5160 (SYMPOSIUM)

METAMORPHOSES: THE CONTINUING EVOLUTION AND ADAPTATION OF THE SAVVY CAREGIVER PROGRAM

Chair: Kenneth Hepburn Discussant: Joseph Gaugler

This symposium traces the nearly 30 years of development projects, trials, and transformations that continue to occur in efforts to make an evidence-based psychoeducation program (Savvy Caregiver) available to family members and friends who provide care to community-dwelling persons living with dementia illnesses. Savvy seeks to enhance caregivers' knowledge and skills for providing care and to enhance their competence and confidence (sense of mastery) in being able to guide their persons through days that are as safe, calm, and pleasant as possible. Over this period of time, Savvy has clarified its target participant group (focusing on primary caregivers rather than larger family groups), moved from having concurrent sessions for caregivers and persons living with dementia, continued to develop strategies that enable broad implementation while maintaining program fidelity, demonstrated the effectiveness of a synchronous/asynchronous online version that extends program reach (Tele-Savvy), and is currently exploring in an ongoing pilot how best to deliver a fully asynchronous version of the program that employs continuing education principles (Tele-Savvy@Home). The individual presentations will describe the main developmental milestones (investigator led to protocol-trained to online trained interventionist; in-person to synchronous/asynchronous to fully asynchronous) and the structural adaptations that enabled them. Particular emphasis will be placed on design decisions linked to maintaining a psychoeducational orientation and to program emphasis on developing or strengthening caregivers' self-efficacy for providing effective day-to-day care. Savvy's experience may help investigators in designing new interventions, particularly online interventions or in considering augmentation or delivery platform change of established interventions.

HISTORY: MINNESOTA FAMILY WORKSHOP TO SAVVY CAREGIVER: CENTRALITY OF SELF-EFFICACY

Kenneth Hepburn, *Emory University, Atlanta, Georgia, United States*

This presentation will trace the development of the Savvy Caregiver program from its beginnings as the Center for Nursing Research-supported Minnesota Family Workshop (1993; PI: Sharon Ostwald) through a further test as the Partners in Caregiving Program (1997; PIs: Hepburn 1RO1NR04517-01) to the Alzheimer's Association-supported Savvy program (1997; PIs Hepburn & Lewis). Three main developments occurred over this period: the program solidified its identity as a caregiver training program and its mechanism of action as that of self-efficacy development through an active learning approach; it sharpened its focus by concentrating on the principal family caregiver (moving away from a broader family approach and eliminating concurrent care recipient programming); and it developed interventionist training materials and programs to enable broader reach. Since 2002, Savvy has enjoyed wide dissemination as an evidence-based in-person psychoeducation program, fostered by support to sponsoring organizations by the Administration on Community Living.

TELE-SAVVY: CHALLENGES AND OPPORTUNITIES OF A SYNCHRONOUS/ASYNCHRONOUS PROGRAM

Mariya Kovaleva, *University of Nebraska Medical Center, Omaha, Nebraska, United States*

This presentation will trace the development of the Savvy Caregiver program from its beginnings as the Center for Nursing Research-supported Minnesota Family Workshop (1993; PI: Sharon Ostwald) through a further test as the Partners in Caregiving Program (1997; PIs: Hepburn 1RO1NR04517-01) to the Alzheimer's Association-supported Savvy program (1997; PIs Hepburn & Lewis). Three main developments occurred over this period: the program solidified its identity as a caregiver training program and its mechanism of action as that of self-efficacy development through an active learning approach; it sharpened its focus by concentrating on the principal family caregiver (moving away from a broader family approach and eliminating concurrent care recipient programming); and it developed interventionist training materials and programs to enable broader reach. Since 2002, Savvy has enjoyed wide dissemination as an evidence-based in-person psychoeducation program, fostered by support to sponsoring organizations by the Administration on Community Living.

TELE-SAVVY@HOME: CONVERTING TO A COMPLETELY ASYNCHRONOUS DELIVERY APPROACH

Fayron Epps, *Emory University, Fairburn, Georgia, United States*

It is well established that family caregiving is taxing and stressful. Group-based psychoeducational programs such as the Tele-Savvy program demonstrated that the acquisition of skills, knowledge, and caregiving mastery can ameliorate caregiving stress – and enhance PLWD quality of life. Many factors, however, preclude caregivers' attendance in the synchronous portions of Tele-Savvy limiting the program's scalability. To make Tele-Savvy more accessible and available to a growing number of dementia family caregivers, we designed a fully asynchronous version of the Tele-Savvy program, Tele-Savvy@Home. To accomplish this, we consulted facilitators and caregivers who participated in Tele-Savvy. We also reviewed the existing curriculum, re-wrote portions, reordered modules, and created new videos to cover synchronous content. In addition, we partnered with education design specialists to create interactive and reflection exercises to maintain a psychoeducation orientation and strengthen caregivers' self-efficacy. This strategy may help investigators in their augmentation of the delivery strategies of established interventions.

BRINGING INTERACTIVITY TO FULLY ASYNCHRONOUS PROGRAMS

Carolyn Clevenger, *Emory University, Atlanta, Georgia, United States*

Asynchronous online learning brings both new opportunities as well as challenges to an asynchronous psychoeducation program like Tele-Savvy@Home. While asynchronous learning offers engagement flexibility for time-strapped family caregivers, a lack of scheduled meetings represents a lack of contact and interactivity, threatens accountability, and produces a high incompletion rate. To engage participants in the next generation of this asynchronous, self-paced course, we have implemented a small cohort structure (10 participants each) and created a combination of automated prompts and optional touchpoints. The cohort structure and touchpoints mimic important shared and active learning components of the facilitated sessions. Prompts include weekly messages that nudge learners with reminders of their ideal progress point and offer value propositions for staying on-time. A pacing guide allows caregivers to build the course into their schedule in advance of the course's start. Optional touchpoints include unit-by-unit post-tests, a cohort-based discussion board, and free text reflective exercises.

SESSION 5170 (SYMPOSIUM)

SOCIAL HEALTH IN THE CASE OF DEMENTIA: AN INTERNATIONAL PERSPECTIVE

Chair: Karin Wolf-Ostermann Co-Chair:
Myrra Vernooij-Dassen Discussant: Rene Melis

Dementia is one of the major age-related societal challenges and causes enormous demands for persons living with dementia (PlwD) and their families. We do not understand the origins of this multifactorial syndrome and there is still no cure for dementia. New thinking by the exploration of paradigms has scope to improve knowledge about this complex condition. Social health can be understood as a driver for stimulating the use of cognitive reserve through active facilitation and utilization of the individual's capacities. It allows to slow cognitive impairment or to maintain cognitive functioning in old age and therefore seems to be a promising approach to a better understanding of the developmental mechanism of dementia.In this international symposium we therefore aim to explore the role of social health in the onset and progress of dementia. The first presentation will present a new framework on understanding social health in dementia. The second presentation will describe convoys of care in a family based culturally sensitive ADRD caregiving intervention reducing care burden and family conflicts. The third presentation reports on the role of immune system and neurodegeneration markers in the association between social health and cognitive brain aging in older adults. The final presentation presents newly derived results from a mixed research synthesis on underlying mechanisms of the interrelation of social health and cognitive functioning, elaborated by the international SHARED-consortium. Our discussant will synthesize the research findings and lead a discussion of future directions for research and practice to successfully fight challenges in dementia care.

CONCEPTUAL ADVANCEMENT FOR SOCIAL HEALTH IN DEMENTIA RESEARCH

Myrra Vernooij-Dassen[1], Eline Verspoor[1], Marieke Perry[1], and Karin Wolf-Ostermann[2], *1. Radboud University, Nijmegen, Gelderland, Netherlands, 2. University of Bremen, Bremen, Bremen, Germany*

The lack of conceptual clarity on social health in dementia research hinders its articulation. We aim to apply concept advancement for social health to provide conceptual clarity by building from a conceptual meaning to domains. The procedure is underpinned by theoretical models and epidemiological evidence on the relation between social heath and cognitive functioning.This led to considering social health as a reciprocal relational concept that refers to the influence that an individual has on others (social environment), and vice versa. We distinguished three domains defining the individual level, representing the social competences of the individual, and three domains defining the social environmental level (structure , function and appraisal of the relationship. We hypothesize that social health acts as a driver for stimulating the use of cognitive reserve. This conceptual advancement promotes developments that integrate neurobiological and social sciences and new interventions to support older people with and without dementia.

CONVOYS OF CARE

Toni Antonucci[1], and Kristine Ajrouch[2], *1. University of Michigan, Ann Arbor, Michigan, United States, 2. Eastern Michigan University, Ypsilnati, Michigan, United States*

Many existing Alzheimer's disease (AD) caregiving interventions focus narrowly on thechallenges and needs of a primary caregiver rather than the family systems in which they areembedded. We advance a family systems framework by invoking convoys of caregiving to adaptan existing AD caregiver intervention to Middle Eastern/Arab American families in metroDetroit (N=56). The composition of caregiving networks is described, followed by assessment ofcare burden, depressive symptoms, care satisfaction and family conflict. Results show thatsiblings and children are the predominate support network members who accompanied theprimary caregiver to the program. Paired t-tests show that care burden and family conflictdecreased while caregiving satisfaction increased following program participation. Depressivesymptoms did not change. Findings illuminate how convoys of care may serve as valuablesupport resources, yet may also be the source of stress and conflict.

SOCIAL HEALTH AND IMMUNE SYSTEM IMBALANCE: SEX-SPECIFIC ASSOCIATIONS AND CAUSAL LINKS TO BRAIN AGING

Isabelle van der Velpen[1], Amber Yaqub[1], Meike Vernooij[1], Marieke Perry[2], Myrra Vernooij-Dassen[2], Mohsen Ghanbari[1], Arfan Ikram[1], and Rene Melis[3], *1. Erasmus MC, Rotterdam, Zuid-Holland, Netherlands, 2. Radboud University, Nijmegen, Gelderland, Netherlands, 3. Radboud university medical center, NIjmegen, Gelderland, Netherlands*

Background: We explored whether the balance between innate and adaptive immune system links social health to cognitive brain aging in community-dwelling older adults.

Methods: Social health markers (social support, marital status, loneliness) were measured in the Rotterdam Study in 2002-2008. Balance of the immune system was assessed using white blood-cell-based indices (neutrophil-to-lymphocyte ratio (NLR), platelet-to-lymphocyte ratio (PLR), systemic immune-inflammation index (SII)) during the same visit. Cognitive function and total brain volume were measured at the 2009-2014 follow-up visit.

Results: In 8375 adults (mean age 65.7, 57% female), never married participants had higher NLR, PLR and SII compared to married peers, indicating imbalance towards innate immunity. Widowed/divorced males, but not females, had higher NLR, PLR and SII. Immune system balance did not mediate associations between social health and cognitive brain aging. Discussion: Social health is sex-differentially associated with immune system balance, but does not link to cognitive brain aging through mediation.

MAPPING THE INTERPLAY OF SOCIAL HEALTH AND COGNITIVE FUNCTIONING: A MIXED RESEARCH KNOWLEDGE SYNTHESIS

Henrik Wiegelmann[1], Imke Seifert[1], Marta Lenart-Bugla[2], Mateusz Łuc[2], Ansgar Gerhardus[1], Dorota Szcześniak[2], Joanna Rymaszewska[2], and Karin Wolf-Ostermann[1], *1. University of Bremen, Bremen, Bremen, Germany, 2. Wroclaw Medical University, Wroclaw, Dolnoslaskie, Poland*

Introduction: Dementia is a syndrome with complex underlying bio-psycho-social mechanisms relevant for prevention and intervention. This work presents a mixed research knowledge synthesis, mapping the multidimensional interplay of social health and cognitive functioning in dementia.

Methods: Data integration from 1) systematic review, 2) group model building workshops, (3) iterative integration of multi-national cohort studies (4) ongoing revisions of the social health concept via expert discussions.

Results: The map comprises more than 50 markers, clustered in six domains (social health, psychological pathways, physiological pathways, health behavior pathways, brain/cognitive reserve, cognitive functioning). The social health domain is structured in six sub-domains representing a novel conceptual understanding. Three pathways (physiological, psychological, health behavior) reflect principal mechanisms connecting social health with brain/cognitive reserve and cognitive functioning.

Conclusion: The map depicts dynamic relationships between social health and cognitive functioning that can serve as a basis for recommendations, both for prevention and for improved dementia care.

SESSION 6000 (POSTER)

AGHE POSTER SESSION I

Explore innovative age-friendly, intergenerational, dementia-inclusive, and other approaches to gerontology education.

CONNECTING GENERATIONS AND PRESERVING LIVED EXPERIENCES: AN ILLINOIS AGE-FRIENDLY INITIATIVE

Alyssa Stanfield[1], Matthew Splitstone[2], George Mois[3], Chelsey Byers[4], and Wendy Rogers[5], *1. University of Illinois--Urbana-Champaign, Champaign, Illinois, United States, 2. University of Illinois--Urbana-Champaign, Urbana Champaign, Illinois, United States, 3. University of Illinois Urbana-Champaign, Urbana Champaign,* *Illinois, United States, 4. University of Illinois Extension, Champaign, Illinois, United States, 5. University of Illinois Urbana Champaign, Champaign, Illinois, United States*

The University of Illinois Urbana-Champaign was recently designated an age-friendly university (AFU).Our AFU program coordinated by CHART (Collaborations in Health, Aging, Research, and Technology) collaborates with our campus University of Illinois Extension office. We are partnering with a student organization called Sage to engage undergraduate students in AFU principles (i.e., promote intergenerational learning and increase the understanding of students of longevity divide). Sage is a social venture run by the Illinois chapter of the global nonprofit organization called Enactus, a social entrepreneurship organization. Sage was established in the spring of 2019 by students who noticed discomfort and lack of understanding among their fellow students of the older generations. By fostering communication, Sage aims to combat ageist social processes, reduce social isolation, and increase mutual understanding and access to the often undervalued wisdom of older adults. Sage helps facilitate life review and develops intergenerational relationships by pairing older adults with college students who listen to and capture their stories through writing to boost the morale and self-confidence of participants. The stories and wisdom they share are then preserved through the production of a cherished legacy booklet or digital media. CHART and campus Extension services support the Sage efforts by assisting with materials development and recruiting older adults from the community to participate. We will share our lessons learned to encourage the development of similar programs at other universities.

DISCUSSION OF AGE-FRIENDLY UNIVERSITY PRINCIPLES WITH OLDER LEARNERS

Emiko Takagi, and Madeleine Marroquin-Serrano, *San Francisco State University, San Francisco, California, United States*

The purpose of this project was to study how older learners think a university campus currently meets the 10 Age-Friendly University principles and what they see as potential steps to create an age-friendly campus community. Online focus group interviews were conducted with 17 members of Osher Lifelong Learning Institute at San Francisco State University in 2020. The participants were 60 years or older, and the majority were female and non-Hispanic white. The study participants received information about the 10 Age-Friendly University principles presented by the Age-Friendly University Global Network and were asked to discuss their thoughts about how the university satisfies these principles. The interview recordings were transcribed for the thematic analysis of qualitative data. The analysis yielded three themes. The first theme described the diversity of older adults' learning needs and desires that the university must recognize and accommodate. The second theme represented older adults' sense of optimism and anxiety about intergenerational learning. The third theme highlighted the challenges older adults tend to experience in accessing information, educational programs, and/or university facilities. The interviews with older learners were found valuable and indispensable in the work of Age-Friendly University assessments. The presentation is focused on the discussion regarding how older adults' voices can be incorporated in the assessments and ways in which higher education institutions should combat ageism on and off campus as part of work to address the issues identified in this study.

"DEMENTIA-FRIENDLY": WHAT DOES IT MEAN TO UNDERGRADUATE STUDENTS?

Nasreen Sadeq, *University of South Florida, Tampa, Florida, United States*

Experiential learning assignments may be a potential method of educating undergraduate students about relevant issues in gerontology. Experiential learning involves applying knowledge learned in the classroom to real-world situations and requires students to engage in reflection. The current study explores undergraduate students' perspectives on what it means to be "dementia-friendly" through an activity completed outside of the classroom. Students enrolled in an Alzheimer's Disease Management course completed a module about quality of life, which included information about dementia-friendly communities. Then, students visited a location of their choice that is often frequented by older adults. Based on what they learned in class, they explored the location and documented observations about its dementia-friendly characteristics, or lack thereof. Following their visit, students wrote a reflection on their experience and suggested ways to improve dementia-friendliness. Consensual qualitative methods were used to explore themes in student responses. Among students (N=56), the majority visited grocery or big-box stores, followed by retail shops and restaurants. The three most common themes that emerged about essential dementia-friendly characteristics were 1) availability of helpful people, 2) easy to read signs, and 3) easy to navigate with few fall hazards. Themes from students' suggestions for improving dementia-friendliness included 1) items with larger font sizes, 2) providing staff with dementia training, and 3) more amenities (e.g., store maps, personal shoppers). Student reflections suggested that the assignment also increased awareness and empathy about challenges faced by older adults who wish to age in place.

DISMANTLING AGEISM: EXPLORING PERSONAL AND SOCIETAL ATTITUDES ABOUT AGING IN UNDERGRADUATE CLASS ACTIVITIES

Erica Srinivasan, *University of Wisconsin, La Crosse, La Crosse, Wisconsin, United States*

Ageism and fear of aging are influenced by both personal and societal attitudes about aging. Ageist beliefs reflected in society or in individuals can impact both our own aging process and how we treat others (Cooney et al, 2020). Thus, it is imperative to explore personal and societal attitudes about aging. In this poster, themes will be presented from a study on two class activities that explore ageism and attitudes about aging, as well as directions for these activities. Students (n=34) in an undergraduate college class were asked to describe their thoughts on aging in 6 words. They were next prompted, with no word limit, to describe fears and what they look forward to about aging. Content analysis of responses revealed themes including the complexity of aging, fears about dementia, physical changes, and the unknown nature of life, and positive interest in career and family goals. In a second activity, based off the AARP social experiment in which millennials were asked "what do you consider to be old?," students asked peers "what image comes to mind when I say "old person?" and "what three words come to mind when I say old person?" Content analysis of responses included themes relating primarily to negative stereotypes, such as "confused and nursing home," with some positive associations, such as "grandparents or wisdom." Both activities prompted rich discussion about the connection between fears of aging and ageism, the importance of addressing ageism and of exploring both positive and challenging aspects of personal aging.

LET'S PLAY TOGETHER: INTERGENERATIONAL EDUCATION BY CO-DESIGN ESCAPE GAME WITH OLDER ADULTS

Li-Chuan Liu, *National Taitung University, Taitung, Taitung, Taiwan (Republic of China)*

People always think that the older adults are only suitable for participating in activities and games suitable for older adults, and cannot complete games with young people, such as escape game. However, if we can understand the characteristics and needs of the elderly, we find that the older adults still have mobility and vitality to participate in games with young people. Through the intergenerational learning of university's students and the older adults, we use design thinking and PDCA as class frameworks, and let two groups can jointly together to design escape game for the older adults. During the planning stage, the survey and interview of older adults, game design training; the practical operation in the implementation stage; the team discussion and correction in the reflection stage; and the sharing with older adults in the re-action stage (celebration). As a result, these processes allow students and older adults to communicate and share life experiences and wisdom. In one hand, students have a better understanding and concerns about older adults, and they find that the older adults also have vitality and enthusiasm; on the other hand, older adults also more understand the life of students, and feel the creativity and investment of students. In other words, both groups have changed their cognition to each other, and discovered the possibility of mutual cooperation and communication.

BREATHING LIFE INTO CONVERSATIONS ON DEATH: USING A DEATH CAFÉ MODEL IN A SERVICE-LEARNING PROJECT

Marjorie Getz, *Methodist College, Peoria, Illinois, United States*

This poster presentation describes a project from an upper-level course on death and dying (part of a gerontology program at a small Midwest college). The course derives from the work of Phillipe Ariès's book, The Hour of Our Death. Ariès traced five patterns across time and showed why death had become an uncomfortable truth for those of us living now. In essence, death has been banished from our daily lives. Other research suggests that younger healthcare professionals are particularly uncomfortable interacting with dying clients and may withdraw from them at this important life juncture. Finally, frustration with textbook development of cultural approaches to dying and death (often varied cultural groups, e.g., Asian Americans, are lumped together as if all Asian-Americans share death related practices) led to design of this unique service-learning project. Students, and community members who are experts on various faith/cultural practices take part in a modified death café. Students from an OLLI program are invited to participate, too. We report on qualitative data taken from student reflections. Content analyses of reflective essays identified these themes: (a) new insights/questions about death encounters/attitudes/practices in America (b) willingness to assimilate and accommodate various aspects of other cultural approaches to death into one's own philosophy; (c) feelings of accomplishment/awareness of new skills in providing community-based support to people isolated during the pandemic; (d) understandings related to the importance/value of community service and civic engagement; and (e) new found comfort in openly discussing death concepts in this supportive environment.

IMPROVING MEDICAL STUDENT RECOGNITION AND UNDERSTANDING OF MORAL INJURY IN MILITARY VETERANS

Maribel Rodriguez-Gonzalez[1], Michael Alan Silverman[2], Maura Miller[3], Sandra DiScala[4], Mythili Bharadwaj[4], and Anthony Beazley[4], *1. Florida Atlantic University, West Palm Beach, Florida, United States, 2. FAU-West Palm Beach VA Medical Center, West Palm Beach, Florida, United States, 3. West Palm Beach VA Medical Center, Jupiter, Florida, United States, 4. West Palm Beach VA Medical Center, West Palm Beach, Florida, United States*

Developing a curriculum for medical students is essential in teaching specific skill sets to better care for patients. There are 18,000,000 living military Veterans in America with unique needs not usually included in medical school curriculum. Military personnel are trained to kill or neutralize the enemy, a doctrine that goes against the moral, religious, and societal principle of thou shalt not kill. Combat Veterans are frequently placed in circumstances where they are forced to commit or participate in acts that go against their moral beliefs leading to a dimensional problem called Moral Injury (an affliction of the soul) with accompanying psychological, behavioral, social, and symptoms such as lack of trust, spiritual distress, fatalism, regret, depression, self-loathing, and apathy, etc. and can be a significant problem encountered in older Veterans precipitated by the normative changes of aging. Discussion with more than one hundred second- and third-year medical students over a 3-year period showed that the students were unfamiliar with Moral Injury. The Geriatrics Department at the West Palm Beach VA Medical Center has created an educational module for medical students that focuses on 1) recognizing the symptoms of Mora Injury, 2) how to approach and converse with Veterans including specific questions to ask and what not to say, 3) the importance of a team approach including a chaplain, 4) interventions such as providing forgiveness and life review, and 5) being cognizant of the trust issues of older LGBTQ Veterans. The response of the medical students has been both positive and enthusiastic.

SKILL BUILDING BLOCKS: ASYNCHRONOUS ONLINE LEARNING THROUGH INTERACTIVE THEMATIC INSTRUCTION

Harvey Sterns[1], and Vicki de Klerk-Rubin[2], *1. The University of Akron, Akron, Ohio, United States, 2. Validation Training Institute, Pleasant Hill, Oregon, United States*

Whether professional or as a family carer, interactions with an older adult living with or without cognitive decline should be person-centered. Learning behavioral skills requires more than watching a demonstration or cognitive learning; it requires practice, feedback and more practice. Online learning has become the best way to reach carers of older adults, partially due to the COVID pandemic and partially due to time, money and energy resources being stretched to their limits. The Validation Training Institute has developed 6 self-directed, online Skill Building Blocks that uses thematic instruction strategy, interactive exercises, and videos demonstrating why each skill is important and how to best utilize the skill in real life situations. Learners have completed pre and post-questionnaires using the Likert scale and the IMMS (Instructional Material Motivation Survey) which measures attention, relevance, confidence, and satisfaction. An online focus group of participants concluded the data collection process. Techniques taught through Skill Building Blocks proved to be relevant to the learners' life experience. There was effective retention and transfer of skills, and the training proved to be motivating for continued application in the real world. Learners expressed confidence and satisfaction with the user-friendly, thematic design of each block.

AFTER THE STORM: SOCIAL WORK STUDENTS ASSISTING WITH FEMA DISASTER RELIEF FOR OLDER ADULTS

Joy Ernst, *Wayne State University, Detroit, Michigan, United States*

This poster describes a partnership during Fall 2021 between the Wayne State School of Social Work and the Federal Emergency Management Agency (FEMA) to assist older adults whose homes sustained damage during flooding in June 2021. This short-term project helped people access resources to repair and restore damaged homes, repair, or replace mechanical and electrical systems, deal with mold and other health hazards, and replace their personal belongings. Social work students trained by FEMA made over 700 outreach calls to homeowners whose applications for relief were rejected. The students worked with the homeowners to facilitate access to help that either resulted in the approval of their FEMA application (due to assistance with technical issues such as missing documentation or errors in the application) or connected them with alternative sources of help and support. A focus group with students provided insights on their motivations, training experiences, issues affecting the applicants, and skills developed. While FEMA-required training offered little relevant assistance, SSW staff and faculty overseeing the program provided ongoing support that students considered vital as they worked to assist applicants. Some homes were extensively damaged and resources available from FEMA were insufficient. Some homeowners suspected the students were scammers; students also learned of exploitation by contractors. Students honed empathy, reflection, and supportive listening skills as they heard stressors associated with maintaining their homes amidst losses due to covid and their knowledge of community resources expanded. Lessons learned to aid in future efforts to assist in disaster relief are described.

AGE-FRIENDLY CAMPUS PRACTICES IN HIGHER EDUCATION: A HEAT MAP VIEW

Janelle Fassi[1], Celeste Beaulieu[2], Lauren Bowen[2], Joann Montepare[3], Susan Whitbourne[4], and Nina Silverstein[2], *1. University of Massachusetts Boston, Goffstown, New Hampshire, United States, 2. University of Massachusetts Boston, Boston, Massachusetts, United States, 3. Lasell University, Newton, Massachusetts, United States, 4. University of Massachusetts Amherst, Amherst, Massachusetts, United States*

The Age-Friendly University (AFU) initiative aims to increase the participation of age-diverse older adults in higher education communities. The present study investigated age-friendly practices across 23 institutions in the United States. The ICCS Inventory (Silverstein et al., 2022), which identifies 192 potential age-friendly campus practices was completed by administrators representing major campus units. A heat map was used to graphically represent age-friendly practices and identify where universities differed in the presence of those practices. Heat map findings indicated campuses are low in some auxiliary services that assist retired faculty and staff. However, campuses consistently gave retired faculty and staff access to university library services. Campuses also had limited age-friendly teaching and learning services. None of the campuses reported having resources to help faculty deliver teaching materials in formats specifically geared toward older learners. In addition, none of the campuses reported having teaching and learning staff visiting campus departments to provide resources for older learners, and very few campuses offered courses that focused on aging and age diversity issues. Common age-friendly practices were seen with respect to providing instructional technology support for faculty/staff/students and community partnerships for intergenerational activities. Physical environment and personnel evidenced the most frequent age-friendly practices likely because they are mandated by the ADA (e.g., clear signage, handicapped parking close to buildings, spaces free of obstacles, training in ageism as a form of discrimination). Overall, the present study highlighted the areas where college campuses are most age inclusive, while also revealing areas for improvement in age inclusive practices.

EVALUATING THE EFFECTIVENESS OF AN ONLINE TRAINING COURSE FOR MEETING NEEDS ASSOCIATED WITH CAREGIVING BURDEN

Shera Hosseini, Lorraine Carter, Donna Thomson, and Michelle Howard, *McMaster University, Hamilton, Ontario, Canada*

Informal caregivers make up a critical part of long-term support in the communities due to their important role in caring for older adults living at home. Modern-day caregivers are facing greater responsibility and burden for managing their care recipients. The present study aimed to explore the effect of a caregiving training program in alleviating caregiver burden. This program included four standalone online modules each with specific foci. Completion of activities across the modules allowed for the creation of a Caregiver Action Plan which offered a personal and practical resource to the informal caregivers. This evaluation study was qualitative and a used thematic analysis method of data analysis. Data stemmed from semi-structured interviews with the caregivers and their reflections on the program's discussion board. Most caregivers provided care for persons with dementia. Interviews with the family caregivers were conducted, transcribed, and thematically analyzed. Themes were identified through constant comparison and in an iterative process. The family caregivers demonstrated consensus on the efficacy of the program in raising competence and confidence and contributing to ameliorating burden levels. Important themes were identified in association with areas for which the caregivers needed support: Early dementia education, planning for future care, learning about navigating healthcare systems, peer support, enhancing self-care, and coping with emotional burden and self-blame. The findings will be informative in shaping the program based on the caregiver's identified needs through addressing those areas that they would need support. These findings may offer recommendations to other programs designed to support the family caregivers.

COMBATING STIGMA: AN EDUCATIONAL RESOURCE ON SUBSTANCE USE DISORDER IN OLDER ADULTS

Marissa Mackiewicz, Patricia Slattum, and Leland Waters, *Virginia Commonwealth University, Richmond, Virginia, United States*

Substance Use Disorder (SUD) affects people from all walks of life and age groups. Special considerations for older adults with SUD should be made secondary to the unique pathophysiological and socio-economic complexities of aging populations. Successful SUD treatment and recovery depends on access to essential support systems comprised of interprofessional teams as well as family, friends, and caregivers. Education on SUD for healthcare providers, caregivers and the community is a key component for combating the national opioid epidemic and the stigma that can be a barrier to recovery. A ten-minute video and an accompanying discussion guide were developed to present to clinical faculty and students participating in an interprofessional care coordination wellness clinic servicing low-income older adults living independently in the community setting. The video was designed to highlight stigma and ageism facing older adults with SUD and serve as the basis for discussion among learners. The process for creating and evaluating the video and discussion guide will be shared including the role of older adults with lived experience of SUD in the process. Information will be provided on SUD as a chronic disease and the importance of interprofessional and individualized patient care in recovery. Participants will be able to identify the significance of SUD related stigma in providing and seeking care, asses the role of mental/behavioral health in SUD, and learn about treatment options for SUD. This will allow for better identification of characteristics of older adult populations that place them at greater harm from the consequences SUD.

TUTORIAL-STYLE EDUCATION FOR UNDERGRADUATES IN AGING

Karley Deason, Nasreen Sadeq, and Brianne Stanback, *University of South Florida, Tampa, Florida, United States*

At almost every university, there is an option for undergraduates to enroll in directed readings or research, independent studies, or some other form of tutorial-style education, although not much is known about them or best practices associated with them for undergraduate students interested in aging. This project reviews available literature about tutorial-style education and describes the multidimensions involved in these learning experiences. Search phrases such as "history of Oxford tutorials", "tutorial classes", and "student traits in tutorials" were used in Google Scholar to find literature, returning 142 articles. Articles were included if the literature was published in a periodical, findings were not redundant, and measures connected to the objectives of this project, and, by these criteria, ten articles comprised the final sample for review. Student characteristics, instructors, and other factors, like the time intensity of the tutorial course and the student's connection to the subject area, have been found to impact tutorial-style education. The review is the first of its kind to use its findings to propose a set of best practices to enhance the experience for students interested in aging, including the fit of student and instructor, skillsets of successful students, and modalities, and advance a research agenda to better understand and communicate practices in tutorial-style education for undergraduates in aging.

CREATING AN AGE-FRIENDLY UNIVERSITY: THE CASE OF ST. CLOUD STATE UNIVERSITY (SCSU)

Phyllis Greenberg[1], Rona Karasik[2], Jessica VanderWerf[2], Claudia Burgos Zuniga[2], and Maria Kroeber[2], *1. St. Cloud State University, St Cloud, Minnesota, United States, 2. St. Cloud State University, St. Cloud, Minnesota, United States*

As universities seek ways to address decreasing enrollments and enhance Diversity, Equity, and Inclusion (DEI) initiatives, the concept of Age-Friendly Universities (AFU) has gained momentum. The AFU Global Movement is a way to situate a university to explore means to increase student enrollments, and expand DEI Initiatives to include age. This poster details the steps taken by St. Cloud State University, a comprehensive Minnesota State university, to become designated as an AFU, as well as the unique challenges encountered. Actions taken both before and after being designated as an Age Friendly University (December, 2021) are discussed. Pre-designation steps included evaluating the campus' current age friendliness, gathering university and community support at all levels, participating as a "champion" in the UMass-Boston & LaSalle University's Age-Friendly University Inventory and Campus Climate survey, and piggy-backing on Minnesota's Age-Friendly State and the local community's Age-Friendly initiatives. The SCSU Gerontology program was awarded a grant from the MinnState Innovation Fund to explore ways of "Creating an Age-Friendly SCSU." The grantors saw this as a potential template for other universities in the system who were seeking to expand their student base. Post benefits, challenges, strategies and next steps working towards meeting the 10 Principles of an Age-Friendly University are also discussed.

USING CONNECTED LEARNING THEORY GUIDED ADOPTION IN SUCCESSFUL IMPLEMENTATION OF 4MS AGE-FRIENDLY CARE

Leah Tobey[1], Danette Scherer[2], and Robin McAtee[3], *1. University of Arkansas for Medical Sciences/AR Geriatric Education Collaborative, Little Rock, Arkansas, United States, 2. UAMS: AR Geriatric Education Collaborative, Little Rock, Arkansas, United States, 3. University of Arkansas for Medical Sciences, Little Rock, Arkansas, United States*

As one of the HRSA funded Geriatric Workforce Enhancement recipients, the Arkansas Geriatric Education Collaborative worked with the Reynolds Institute on Aging Thomas and Lyons Longevity Clinic to implement Age

Friendly care. An adult learning theory was used to develop trainings on the 4M's of Age-Friendly Healthcare and to pursue Age-Friendly Certification from The Institute for Healthcare Improvement. The Connected Learning Theory is a proven method to reliably help a trainee's adoption of new principles and ideas by connecting familiar relationships which are easily recognized. This theory supports various learner pathways and proposes that students learn best when they form familiar connections to the materials. In an effort to provide enhanced training to healthcare professionals who were already familiar with much of the content, associations were made between M&M's candy with each of the 4Ms, What Matters, Mobility, Mind and Medications of Age-Friendly Care. Baseline and 6-months post training data on two Merit-Based Incentive Payment Systems (MIPS) measures, depression and falls risk screening, were used to evaluate outcomes. Staff were satisfied with the 4Ms Age-Friendly Framework and found it easily applicable to their older adult patient workflow. MIPS evaluation of data showed significant changes in depression screens with a 23% improvement and a 3% improvement in screenings for future fall risk 6 months after training. This clinic achieved Level I Age-Friendly Certification in June 2021. Although the staff were already specialists in geriatrics, the training increased application of the 4 M's, improved staff acceptance, and improved knowledge via M&M connections.

THE EFFECT OF COMMUNICATION SKILLS TRAINING FOR NURSING STUDENTS BY AUGMENTED REALITY SIMULATION SYSTEM

Masaki Kobayashi[1], Miyuki Iwamoto[2], Saki Une[3], Ryo Kurazume[4], Atsushi Nakazawa[2], and Miwako Honda[3], *1. Rochester Regional Health System, Rochester, New York, United States, 2. Kyoto University, Kyoto, Kyoto, Japan, 3. National Hospital Organization Tokyo Medical Center, Tokyo, Tokyo, Japan, 4. Kyushu University, Fukuoka, Fukuoka, Japan*

Background: Educational methods for improving communication with dementia patients are lacking. Our study aimed to evaluate the efficacy of simulated communication skills training for nursing students using augmented reality (AR).

Methods: A randomized controlled study. 25 nursing students enrolled and learned standardized multimodal communication skills using textbooks. Participants were randomly assigned to AR training or conventional mannequin training group and each had one-hour training of basic nursing care. The mannequin of AR group was superimposed a computer graphic of an elderly woman's face, which reacts to participants' communication. Further, participants' gaze and voice were evaluated by artificial intelligence (AI) and the participants received real-time feedback to their head-mounted display. The conventional group had the self-training with nursing mannequins. Participants performed basic nursing care to simulated patients before and after training, which were video-recorded by eye-tracking cameras and fixed cameras, then the videos were analyzed by AI. The primary outcome was the proportion of eye contact, verbal, and multimodal communication time during the care to simulated patients. Additionally, participants' empathy was evaluated by the Jefferson Scale.

Results: The interactive communication in AR group significantly increased than conventional group (eye contact 13.6% versus 4.4%, verbal communication 27.7% versus 20.1%, multimodal communication 9.6% versus 3.8%, P< 0.05, respectively). The empathy score significantly increased in AR group, whereas it decreased in conventional group [Mean (SD): 9.1 (6.6) versus -1.3 (3.8), P< 0.01].

Conclusions: The simulated communication skills training for nursing students using AR was associated with increased interactive communication skills and empathy to patients.

MOVING FROM ENDORSEMENT TO ACTION: ALIGNING AFU EFFORTS WITH UNIVERSITY STRATEGIC PLANS AND GOALS

Sarah Walsh[1], Andrea Zakrajsek[1], Cassandra Barragan[1], and Stephanie P. Wladkowski[2], *1. Eastern Michigan University, Ypsilanti, Michigan, United States, 2. Bowling Green State University, Bowling Green, Ohio, United States*

The Age-Friendly University global initiative has the opportunity to unite nations around the world towards making higher education spaces inclusive of older adults. Once a university joins the AFU Global Network and endorses the 10 guiding principles, the real work of living up to the principles begins. Each institution has unique geographical, political, social, and financial characteristics that require tailored approaches to this work. At our regional comprehensive university, we completed three separate analyses (external, internal, future directions) as part of our Environmental Scan. The goal of the Environmental Scan was to understand the initial strengths, weaknesses, and opportunities to age-friendliness and inclusiveness for older learners within our campus community. We utilized a multi-pronged data collection approach, including individual stakeholder interviews, online surveys of older leaners, policy analysis, and internal and external audits. Many aspects of data collection for the environmental scan occurred concurrently with data analysis. Data from each of the eight data collection methods were used to generate key findings and recommendations and will be presented. Furthermore, we found that aligning our recommendations with the University's marketing and enrollment efforts as well as the University's goals relating to diversity, equity and inclusion allowed for greater administrative support for strategies to increase age-friendliness on campus. with implications for similar work at other institutions. The Age-Friendly University global initiative has the opportunity to better support the inclusion of older adults in higher education. Our Environmental Scan of age-friendliness, from inception to completion will apply to institutions across the globe.

SESSION 6010 (POSTER)

BIOLOGY OF AGING (BS)

BDNF VAL66MET MODERATES THE EFFECTS OF HYPERTENSION ON EXECUTIVE FUNCTIONING IN OLDER ADULTS DIAGNOSED WITH AMCI

Peter Louras[1], Lisa Brown[2], Rowena Gomez[2], Stacie Warren[2], and Kaci Fairchild[3], *1. VA Palo Alto Health Care System, Palo Alto, California, United States, 2. Palo Alto University, Palo Alto, California, United States, 3. VA*

Palo Alto Healthcare System, Palo Alto, California, United States

Brain-derived neurotrophic factor (BDNF) has a demonstrated role in promoting memory functions and neuronal survival. A common variant in the BDNF gene, the Val66Met polymorphism, has been found to reduce BDNF expression and increase vulnerability to neurocognitive impairments and age-related cognitive declines. Research suggests that BDNF Val66Met may be associated with hypertension, a well-established risk factor for health and brain functioning across the lifespan. While BDNF is most studied for its effect on learning and memory, its role in moderating other cognitive domains is not as well understood, especially those most affected by hypertension. Furthermore, no study to date has investigated these relationships exclusively with older adults and those at increased risk for cognitive decline. Therefore, the aim of this study was to investigate the effect of BDNF Val66Met and hypertension on the executive function ability of older adults (mean age 71.3±9.2 years) diagnosed with amnestic Mild Cognitive Impairment (aMCI) (N = 108). Results showed that BDNF Val66Met moderated the relationship between hypertension and executive functioning, such that hypertensive carriers of the BDNF Met allele performed significantly worse compared to Val-Val homozygotes, and independent to the effects of aging. These results indicate that genetic and vascular risk interactions can predispose older adults with aMCI to impairments in multiple cognitive domains, and potentially increase susceptibility to further declines or conversion to dementia. These findings have implications for future research on dementia disease pathology, and highlight the importance of strategies that target fixed and modifiable risk factors to promote cognitive resilience.

EXOME-WIDE STUDY IDENTIFIED 12 PLEIOTROPIC LOCI ASSOCIATED WITH ALZHEIMER'S AND CARDIOVASCULAR DISEASE RISKS

Yury Loika, Elena Loiko, Konstantin Arbeev, Eric Stallard, Anatoliy Yashin, Irina Culminskaya, and Alexander Kulminski, *Duke University, Durham, North Carolina, United States*

Health of brain, heart and blood vessels are closely connected, which means that Alzheimer's (AD) and cardiovascular (CVD) diseases may have overlapping etiologies including genetic component. Most of previous genetic association studies considered different traits (AD, CVD, and their risk factors) separately. The analysis of pleiotropic predisposition to these traits may shed light on the trait-specific mechanisms in protection against AD. We carried out pair-wise pleiotropic exome-wide association study (~250K common genetic variants) in predisposition to AD and each of 17 traits in a sample of 118K individuals from UK biobank. The analysis included seven qualitative traits (CVD, coronary-heart disease, type 2 diabetes, stroke, myocardial infarction, heart failure and hypertension), as well as their 10 risk factors (blood glucose, body-mass index, height, weight, 4 lipid traits, systolic and diastolic blood pressure). Fisher's method and omnibus test were used in pleiotropic analyses. In addition to the APOE-TOMM40 locus, the analysis identified 12 genetic loci in which genetic polymorphisms demonstrated significant associations with AD at $p \le 5\times10\text{-}4$ and pleiotropic associations at genome-wide level, $p \le 5\times10\text{-}8$. The identified genes are involved in processes of phosphorylation; regulation of cell growth, differentiation, and brain development; signal transduction and neurotransmission; mitochondrial and cytoskeleton organization; regulation of gene expression, apoptotic processes, and adaptive immune response. Our results provide novel evidence supporting the hypothesis of complex pleiotropic mechanisms contributing to the development and progression of AD and provide more insights into understanding of underlying biological functions and regulatory mechanisms behind these effects.

REGULATION OF NEURONAL MITOCHONDRIAL BIOENERGETICS BY LIPID METABOLITES UPREGULATED IN DEMENTIA

Stephanie Heimler[1], K. Allison Amick[2], Jaclyn Bergstrom[3], Mohit Jain[3], and Anthony Molina[4], *1. UC San Diego School of Medicine - Division of Geriatrics, Gerontology, and Palliative Care, LA JOLLA, California, United States, 2. Wake Forest School of Medicine, Winston-Salem, North Carolina, United States, 3. UC San Diego School of Medicine, La Jolla, California, United States, 4. UC San Diego School of Medicine - Division of Geriatrics, Gerontology, and Palliative Care, La Jolla, California, United States*

Mitochondrial dysfunction occurs early in Alzheimer's disease (AD) progression and is evident in the Central Nervous System (CNS) and peripheral circulating cells. While there is evidence indicating that bioenergetic decline can drive the early pathogenesis of AD, little is known about the extracellular factors that alter neuronal bioenergetic capacity. We hypothesized that circulating metabolites contribute to neuronal bioenergetic decline associated with AD. Using a cohort comprised of participants with normal cognition, mild cognitive impairment, and dementia, we show that human serum harbors circulating, non-cellular factors capable of mediating neuronal bioenergetic differences according to the cognitive status of the serum donor. We developed a novel screening-based approach to identify candidate "mito-active" lipid metabolites in human serum that could mediate differences in bioenergetic capacity. Among these, Nervonic Acid and 15-epi-PGA1 were predicted to be mitochondrial inhibitors upregulated in participants with dementia. Neurons exposed to physiologically-relevant ranges of these molecules in-vitro exhibited a dose-dependent reduction in maximal mitochondrial respiration. We found that 500ug/mL of Nervonic Acid and 9ug/mL of 15-epi-PGA1 reduced maximal mitochondrial respiration by 62.3% and 63.3%, respectively, thereby validating our screening and prediction approach. Future experiments may be directed towards investigating if and how these and other mito-active metabolites of interest cross the blood-brain barrier to meaningfully affect AD. Furthermore, identified mito-active molecules can be investigated in other clinical cohorts to examine their role/s in multiple age-related or neurological conditions. This work expands our mechanistic understanding of how extrinsic factors associated with age and cognitive status contribute to neuronal bioenergetic decline.

AN OPTIMIZED MOUSE PARABIOSIS PROTOCOL FOR INVESTIGATION OF AGING AND REJUVENATIVE MECHANISMS

Sonia Rodriguez, Chase Carver, Katayoun Ayasoufi, Felicia Duke Boynton, and Marissa Schafer, *Mayo Clinic, Rochester, Minnesota, United States*

Surgical parabiosis is widely used to study the mechanistic influence of the circulating milieu on aging and regeneration.

This powerful model presents diverse complications based on age, strain, sex, and other experimental parameters. In young (Y) and old (O) male and female C57BL6 mice, we optimized heterochronic (n=12) and isochronic (n=10 Y-Y, n=7 O-O) parabiosis. Throughout protocol development, we identified several complications including variable responses to anesthesia, external and internal dehiscence, dehydration, and weight loss. We identified and implemented solutions during surgical and post-surgical periods, including titrated anesthesia, reinforced internal sutures, topical agents to promote wound healing, and increased supplementation. By consistently adopting protocol changes we were able to significantly increase survival. Separately, we confirmed the time course of chimerism in heterochronic pairs of C57BL6 and Tg(act-EGFP)Y01Osb (eGFP) mice. Baseline and longitudinal blood samples were collected via tail vein. Flow cytometry was used to visualize GFP-positive cells from the parabiont blood sample. Through blood analysis we found that chimerism occurs as early as 2 days post-operatively. Exploitation of our optimized protocol may enable others to efficiently adopt the surgical parabiosis model to dynamically study mechanisms of aging and regeneration.

EPIGENETIC AGING OF THE DEMOGRAPHICALLY NONAGING NAKED MOLE RAT

Csaba Kerepesi, *Institute for Computer Science and Control (SZTAKI), Budapest, Budapest, Hungary*

The naked mole-rat (NMR) is an exceptionally long-lived rodent that shows no increase of mortality with age, defining it as a demographically non-aging mammal. Here, we perform bisulfite sequencing of the blood of>100 NMRs, assessing>3 million common CpG sites. Unsupervised clustering based on sites whose methylation correlates with age reveals an age-related methylome remodeling, and we also observe a methylome information loss, suggesting that NMRs age. We develop an epigenetic aging clock that accurately predicts the NMR age. We show that these animals age much slower than mice and much faster than humans, consistent with their known maximum lifespans. Interestingly, patterns of age-related changes of clock sites in Tert and Prpf19 differ between NMRs and mice, but there are also sites conserved between the two species. Together, the data indicate that NMRs, like other mammals, epigenetically age even in the absence of demographic aging of this species.

IMPACT OF COMBINATIONS OF THE APOE Ɛ4 ALLELE AND TOMM40-APOC1 VARIANTS ON SURVIVAL TO OLDER AGES AND ALZHEIMER'S RISK

Alexander Kulminski[1], Ethan Jain-Washburn[2], Ian Philipp[1], Konstantin Arbeev[1], Eric Stallard[1], Mary Feitosa[3], Nicole Schupf[4], and Kaare Christensen[5], *1. Duke University, Durham, North Carolina, United States, 2. DUKE UNIVERSITY, Durham, North Carolina, United States, 3. Washington University, St Louis, Missouri, United States, 4. Columbia University, New York, New York, United States, 5. Southern Denmark University, Odense, Syddanmark, Denmark*

Multifactorial diseases, health-related traits, and lifespan are polygenic phenotypes with complex genetic architectures. Polygenicity implies that multiple variants can impact the risks of these phenotypes independently or jointly. Recently, we showed that carriers of minor alleles of rs429358 (APOE ε4 encoding polymorphism), rs2075650 (TOMM40), and rs12721046 (APOC1) polymorphisms have up to 4.4 times higher risk of Alzheimer's disease (AD) than APOE ε4 carriers without the minor alleles of rs2075650 and rs12721046. Here, we examined the chances of living to older ages—85 years and above—for carriers of compound genotypes combining these three polymorphisms using data from the Long Life Family Study, Framingham Heart Study, Cardiovascular Health Study, and UK Biobank. Consistent with their higher AD risk, carriers of the APOE ε4 allele with one or two minor alleles of rs2075650 and rs12721046 had 24.3% lower log odds of living to 85+ years (β=-0.243, p=2.22×10-2) than APOE ε4 carriers without either minor allele. Counterintuitively, AD did not mediate this risk. With AD-affected subjects excluded from the analysis, the effect size for the log odds of living to 85+ years (β=-0.352, p=2.35×10-3) was 1.45 times larger for APOE ε4 carriers with one or two minor alleles of rs2075650 and rs12721046. The chances of survival could be associated with lipid- and immunity-related mechanisms, whereas the risk of AD may be associated with amyloid-β-related mechanisms, among others. Targeting heterogeneous polygenic profiles of individuals at higher risks of multifactorial phenotypes may be a promising strategy for translating genetic discoveries to health care.

CONVERGENT CELL NONAUTONOMOUS PATHWAYS REWIRE METABOLISM TO SLOW AGING

Scott Leiser, Shijiao Huang, Hillary Miller, Safa Beydoun, Elizabeth Dean, Hyo Choi, Ajay Bhat, and Marshall Howington, *University of Michigan, Ann Arbor, Michigan, United States*

An organism's ability to perceive and respond to changes in its environment is crucial for its health and survival. Our approach to identify molecular mechanisms of aging is to focus on common mechanisms downstream of multiple pathways. This approach led to our discovery of a gene, flavin-containing monooxygenase (fmo)-2, that is both necessary and sufficient to increase lifespan and healthspan downstream of several longevity interventions, including dietary restriction and hypoxia. Surprisingly, we also find that in both hypoxia and dietary restriction models, fmo-2 is induced by cell non-autonomous signaling pathways, consistent with the worms' perceiving the stress (e.g. low oxygen, lack of food) and changing physiology as a result. Our current work focuses on 1) the signaling networks that regulate stress perception and integrate multiple signals to change physiology, and 2) the mechanism of FMO-2-mediated longevity. Our new data suggest that these cell non autonomous networks pathways utilize both overlapping and distinct signaling mechanisms to converge on upregulation of the same gene. They also suggest that these pathways can be manipulated by small molecule drugs to increase lifespan by "tricking" the organism into activating stress response networks. We further find that FMO enzyme expression has a drastic effect on endogenous metabolism, primarily through tryptophan and one carbon metabolism. Ultimately, we aim to leverage our results in a translational framework to identify key signals, genes, and mechanisms where organisms respond to the perception of environmental stress to improve health and slow aging.

INFLAMM-AGING IS ASSOCIATED WITH PRO-INFLAMMATORY PROGRAMMING OF INNATE IMMUNE CELLS IN THE COLON

Ji Yeon Noh[1], Hongying Wang[1], Yuhua Farnell[2], Xiao-Di Tan[3], Gus Wright[4], Andrew Hillhouse[4], and Yuxiang Sun[1], *1. Texas A&M University, College Station, Texas, United States, 2. Texas A&M AgriLife Research, Texas A&M University, College Station, Texas, United States, 3. Ann & Robert H. Lurie Children's Hospital of Chicago, Feinberg School of Medicine, Northwestern University, Chicago, Illinois, United States, 4. College of Veterinary Medicine & Biomedical Sciences, Texas A&M University, College Station, Texas, United States*

Chronic low-grade inflammation is prevalent in aging, which is called inflamm-aging. Immune cells are important mediator of inflammatory state of host and the innate immunity is the first responder to various insults. Gastrointestinal track, especially colon, is the site where immune cells are abundant. Aging is associated with increased gut dysbiosis and functional decline. We hypothesize that colonic innate immune cells contribute to the age-associated inflammation in the colon. We found that macrophages in colon mucosa are elevated in aging, and it is accompanied by pro-inflammatory cytokine expression and increased gut permeability. Specifically, we used flow cytometry to assess colonic innate immune cells collected from 5-, 7-, 14-, 19-, 24-, and 28-month-old mice. Aging significantly increased the populations of pro-inflammatory cytokine producing innate immune cells in the colon, including neutrophils, dendritic cells, monocytes and macrophages. Interestingly, the infiltrating Ly6Chi macrophages and pro-inflammatory CD11c+ macrophages were much higher, while anti-inflammatory CD206+ macrophages were decreased in colon of the aged mice. In line with the immune profile, aged mice showed increased gut permeability tested by fluorescein isothiocyanate-dextran, and the gene expressions of gap junction proteins in the colon were decreased, supporting increased gut permeability in the aged mice. Collectively, our results suggest that innate immune cells play an importance role in age-associated gut inflammation; targeting the innate immune cells in the colon may present a novel therapeutic strategy for prevention and treatment of aging leaky gut.

CELLULAR RESPIRATION AND RESILIENCE AS A POTENTIAL BIOLOGICAL MECHANISM DRIVING SEX DIFFERENCES IN AGING

Adam Salmon[1], and Daniel Adekunbi[2], *1. The University of Texas Health Science Center at San Antonio, San Antonio, Texas, United States, 2. University of Wyoming, Laramie, Wyoming, United States*

There are substantial differences in the progression of aging between males and females including in progression and prevalence of disease and longevity. Not all can be explained solely by sex-specific endocrine regulation and growing evidence suggests there are basic biological and genetic differences in sex that drive disparity in physiological function. In this study, we describe metabolic differences at the cellular level that both define some of these biological differences as well as provide a potential mechanism for delineating relevant molecular mechanisms of aging. Using HET3 mice, a genetically heterogeneous model with a consistent female advantage in longevity, we show that primary fibroblast lines retain functional metabolic characteristics, including mitochondrial response and stress resilience, which are representative of the sex of the donor animal. These differences persist even after several rounds of passage using standard culturing techniques suggesting these differences are not driven by direct impact of circulating sex hormones. Moreover, we find that differences in these cellular responses have some predictive power to determine both sex- and individual-specific responses to physiological challenge including obesity and longevity. In addition, we are able to use this model to delineate how donor sex affects cellular responses within defined pillars of aging including proteostasis, metabolic function, and adaption to stress. Overall, our model then provides valuable in defining the cellular responses that contribute to the mammalian aging process.

THE FOXO3 LONGEVITY GENOTYPE PROTECTS AGAINST MECHANISMS OF CELLULAR AGING IN OKINAWANS

Trevor Torioge[1], D. Craig Willcox[2], Michio Shimabukuro[3], Timothy Donlon[2], Randi Chen[2], Richard Allsopp[4], and Bradley Willcox[2], *1. John A. Burns School of Medicine, University of Hawaii, Manoa, Honolulu, Hawaii, United States, 2. Kuakini Medical Center, Honolulu, Hawaii, United States, 3. Fukushima Medical University, Fukushima City, Fukushima, Japan, 4. University of Hawaii, Honolulu, Hawaii, United States*

The genetic association of FOXO3 genotypes with human longevity is well established, although the mechanism is not fully understood. We now report on the relationship of the FOXO3 longevity variant rs2802292 with telomere length, telomerase activity, FOXO3 expression and inflammatory cytokine levels in men and women. In agreement with earlier work, the FOXO3 longevity variant conferred protection against telomere shortening of peripheral blood mononuclear cells from adults aged 55 and older. This was accompanied by higher levels of telomerase activity in carriers of the longevity-associated FOXO3 G-allele (P=0.015). FOXO3 mRNA expression increased slightly with age in both young (P=0.02) and old (P=0.08) G-allele carriers. Older female G-allele carriers displayed a modest decline in levels of pro-inflammatory cytokine IL-6 with age (P=0.07). In contrast, older male G-allele carriers displayed an age-dependent increase in levels of anti-inflammatory cytokine IL-10 with age (P=0.04). Thus, FOXO3 may act through several different pro-longevity mechanisms, which may differ by age and sex.

LATE-LIFE MORTALITY GWAS IN FLIES IDENTIFIES DIABETES AND OBESITY REGULATED TO REGULATE MORTALITY AND RESILIENCE

Tyler Hilsabeck[1], Sudipta Bar[2], Kenneth Wilson[2], Jennifer Beck[3], Christopher Nelson[3], Rachel Brem[4], and Pankaj Kapahi[2], *1. Buck Institute, Santa Rosa, California, United States, 2. Buck Institute for Research on Aging, Novato, California, United States, 3. Buck Institute, Novato, California, United States, 4. University of California at Berkeley, Novato, California, United States*

Variations in rate of aging in geneticaly heterogenious populations supports the hypothesis that aging is at least partially genetically regulated. However, genetically identical individuals also vary in their time of death. We have observed in D. melanogaster that this variation is genotype-dependent, as specific genotypes have characteristic survival curve shapes that are largely reproducible. Typical aging studies reduce a strain's lifespan down to a population-level value, i.e. mean lifespan. While these metrics can represent the trends in a population, they are unable to encapsulate the variation in the aging of individuals from the same distinct population. Instead, we used two values that characterize the logistic fit of a strain's mortality late in life: the risk of initial mortality (α) and the rate of aging (β). To identify regulators of the rate of aging, we performed a Genome-Wide Association Study (GWAS) of β for 160 different fly strains from the DGRP collection on two different diets late in life. This approach identified the candidate gene Diabetes and Obesity-Regulated (DOR), which has known roles in stress response, autophagy, and senescence, as having a role in the late-life mortality. DOR inhibition leads to a significant increase in late-life mortality that is preceded by a reduction in healthspan-related traits. Further, germline-specific inhibition is sufficient to increase senescence-related factors and shorten lifespan. We conclude that a decrease in DOR, a conserved gene, compromises an organism's resilience through increased inflammation, senescence, and increased mortality, providing a potential target for bolstering the decline seen in human aging.

VITAMIN D DEFICIENCY AND FASTER EPIGENETIC AGING: RESULTS FROM THE BERLIN AGING STUDY II (BASE-II)

Valentin Vetter[1], Yasmine Sommerer[2], Christian Kalies[3], Dominik Spira[1], Lars Bertram[2], and Ilja Demuth[4], *1. Charité - Universitätsmedizin Berlin, Berlin, Berlin, Germany, 2. University of Lübeck, Lübeck, Schleswig-Holstein, Germany, 3. Charité – Universitätsmedizin Berlin, Berlin, Berlin, Germany, 4. Charité Universitätsmedizin Berlin, Berlin, Berlin, Germany*

Particularly older people are at risk for deficient vitamin D levels, as their capability for cutaneous synthetization is lower and they are often less exposed to sunlight. However, the resulting impact on one individual's health is not fully understood. To examine potential consequences of low vitamin D levels for health of older people, we examined its relationship with a DNA related biomarker of aging, DNA methylation age acceleration (DNAmAA). Several epigenetic clocks, that are used to estimate this parameter from methylation fractions of specific cytosine-phosphate-guanine sites, are available and differ in aspects of aging they represent best. Five clocks, 7-CpG clock, Horvath's clock, Hannum's clock, PhenoAge, and GrimAge, were available in the longitudinal BASE-II cohort (n=1,100) at follow-up examination. DNAmAA estimated from 7-CpG clock and GrimAge was associated with vitamin D levels in covariate adjusted regression analysis. Additionally, a quasi-interventional study design was employed and showed 2.6 year lower 7-CpG DNAmAA (p=0.011) and 1.3-year lower Horvath DNAmAA (p=0.042) in vitamin D deficient participants that chose to start vitamin D supplementation during the follow-up period of 7.4 ± 1.5 years compared to a matched control-group of participants with untreated vitamin D deficiency. No statistically significant difference was found between sufficiently treated participants with vitamin D deficiency and a matched group of participants that reached sufficient vitamin D level without supplementation. Although validation of our results in a randomized controlled trial is needed, our findings suggest, that vitamin D deficiency associated higher rates of epigenetic aging can potentially be reversed through supplementation.

SHORT TELOMERES ASSOCIATE WITH HYPERPHOSPHORYLATED TAU BURDEN IN PRIMARY AGE-RELATED TAUOPATHY

Corey McMillan[1], Bandita Adhikari[1], Kurt Farrell[2], David Wolk[1], PART Working Group[2], Edward Lee[1], John Crary[2], and F. Bradley Johnson[1], *1. University of Pennsylvania, Philadelphia, Pennsylvania, United States, 2. Icahn School of Medicine at Mount Sinai, New York City, New York, United States*

Aging is a major risk factor for hyperphosphorylated tau burden (p-tau). Telomeres lengths (TL) shorten with age and various sources of DNA damage, thus provide a measure of biological age. Additionally, DNA methylation (DNAm) changes over time and may contribute to changes in TL. We hypothesize that shorter TL will be associated with increased risk of p-tau burden and that this process may be mediated by DNAm. We extracted DNA from frontal cortex of 113 individuals (Age=87.3 + 9.3; 37% Female) that met neuropathological criteria for primary age-related tauopathy (PART), characterized by p-tau in the absence of amyloid pathology. We measured mean TL using qPCR to determine the copy number of telomere repeat DNA in comparison to a single copy gene. We also measured DNA methylation using the Illumina MethylationEPIC Kit for ~850K CpGs. P-tau was measured in medial temporal cortex using an Aperio Digital Pathology Slide Scanner. Linear regression revealed that shorter TL was associated with increased p-tau burden (B=-0.28; p=-.003), including adjustment for age (B=0.003; p=0.003). eWAS identified six CpGs associated with TL (all q< 0.05). Causal mediation analyses identified that two of these CpGs mediate the TL and p-tau association: proportion mediated by cg08701686 (UNC5D) and cg24533059 (near IFNGR1 and OLIG3) was 32.5% and 48.6%, respectively. Shorter TL is associated with increased p-tau pathological burden in PART and may be mediated in part by DNAm at particular loci. These findings support the concept that biological aging, as measured with TL and DNAm, may contribute to tauopathy beyond chronological aging.

SPERMIDINE TOXICITY IN MITOCHONDRIAL DNA-DEFICIENT SACCHAROMYCES CEREVISIAE

Wei-Hsuan Su, Omar Ocegueda, Catherine Choi, Jessica Smith, Kelsey Lee, Yihan Wan, Jacqueline Yao, and Sam Schriner, *University of California, Irvine, Irvine, California, United States*

Mitochondrial dysfunction is thought to play a significant role in aging and in manyhuman diseases. Over the last 20 years or so, a number of drugs have been found toextend lifespan in model organisms. Using ethidium bromide to deplete the yeastSaccharomyces cerevisiae of its mitochondrial DNA (mtDNA), we evaluated thedependence on functional mitochondrial in the action of five of these lifespan-extending compounds; dinitrophenol, metformin, rapamycin, resveratrol, andspermidine. None of them extended lifespan in mtDNA-deficient cells, demonstratinga requirement for functional mitochondria in their action. However, we found thatspermidine significantly shortened lifespan in these cells, decreasing the medianlifespan from 6 days to 4 days. Despite this, spermidine, nor any of the othercompounds tested, had any effect of growth rates in mtDNA-deficient cells. Spermidine is thought to extend lifespan through the induction of autophagy. Wepredict that spermidine shortened lifespan in mtDNA-deficient cells through anincreased need for ATP, for which these cells were not able to provide. Given thatmitochondrial dysfunction might be a common feature of aging and disease, ourresults suggest that if spermidine were used as an anti-aging treatment in humans, itmay be harmful.

ETHNICITY-SPECIFIC EXTREME LONGEVITY VARIANTS IN A CONSORTIUM OF FOUR CENTENARIAN STUDIES

Harold Bae[1], Anastasia Gurinovich[2], Zeyuan Song[3], Cristina Giuliani[4], Marianne Nygaard[5], Nir Barzilai[6], Annibale Puca[7], and Paola Sebastiani[2], *1. Oregon State University, Corvallis, Oregon, United States, 2. Tufts Medical Center, Boston, Massachusetts, United States, 3. Boston University, Boston, Massachusetts, United States, 4. University of Bologna, Bologna, Emilia-Romagna, Italy, 5. University of Southern Denmark, Odense, Syddanmark, Denmark, 6. Albert Einstein College of Medicine, Bronz, New York, United States, 7. IRCCS Multimedica, Milan, Lombardia, Italy*

It has been shown that some longevity variants including the APOE variants have ethnicity-specific effects on EL within European ethnicities. The goal of the present study is to identify genetic variants whose effects vary by ethnicity by conducting a genome-wide association study of extreme longevity (EL: defined as living past the age at which less than 1% individuals from the 1900 - 1920 birth year cohorts survived) that includes the SNP-by-ethnicity interaction terms using a consortium of four centenarian studies: the New England Centenarian Study, the Long Life Family Study, the Southern Italian Centenarian Study, and the Longevity Gene Project. We used the Uniform Manifold Approximation and Projection (UMAP), a non-linear dimension reduction technique, to identify distinct ethnic clusters. The UMAP analysis revealed four distinct ethnic groups (Danish, Italian, Ashkenazi Jewish, and middle European) in the aggregated data set with 2223 cases and 5673 controls. Using a mixed effects logistic model with SNP-by-ethnicity interaction terms, we found 29 loci, in which the test of any interaction effect produced p< 10-5. The results showed that some variants had ethnicity-specific effects on EL. We sought for replication in two independent studies of longevity: the Danish Longevity Study and the Italian Longevity Study. In the Italian Longevity Study, rs7907949 (PFKP), rs11667516 (intergenic: RAB11B;MARCHF2), rs13245505 (intergenic: ZC3HC1;KLHDC10) replicated with a nominal significance level of 0.05. In the Danish Longevity Study, rs79853795 (PLCB1) and rs4072601 (SLC39A11) replicated. Future drug development should account for ethnic-specific differences in the genetic effects for higher efficacy for more diverse populations.

EVALUATING T-CELL AGE-RELATED IMMUNE PHENOTYPES IN THE CONTEXT OF BIOLOGICAL AGING IN HEALTH AND RETIREMENT STUDY

Ramya Ramasubramanian[1], Helen Meier[2], Sithara Vivek[3], Eric Klopack[4], Eileen Crimmins[5], Jessica Faul[2], Janko Nikolich-Žugich[6], and Bharat Thyagarajan[3], *1. University of Minnesota Twin Cities, Minneapolis, Minnesota, United States, 2. University of Michigan, Ann Arbor, Michigan, United States, 3. University of Minnesota Twin Cities, MINNEAPOLIS, Minnesota, United States, 4. University of Southern California, Leonard Davis School of Gerontology, Los Angeles, California, United States, 5. University of Southern California, Los Angeles, California, United States, 6. University of Arizona, Tucson, Arizona, United States*

Cellular changes in the adaptive immune system accompanies the aging process and contributes to an age-related immune phenotype (ARIP) characterized by decrease in naïve T (TN) cells and increase in memory T (TM) cells. However, a population level marker of ARIP associated with biological aging and age-related chronic conditions has not been evaluated previously. We developed two ARIP measures based on well understood age related changes in T cell distribution: TN/ (TCM (Central Memory) + TEM (Effector Memory) + TEFF (Effector)) or TN/ TM in CD4+ and CD8+ T cells. We compared them with more commonly used ARIP measures such as CD4/CD8 ratio and CD8+ TN cells by evaluating associations with chronological age and phenotypic age using linear regression and association with multimorbidity using multinomial logistic regression. CD8+ TN and TN/TM had the strongest inverse association with chronological age (beta estimates: -3.41, -3.61; p-value< 0.0001). CD4+ TN/TM had the strongest inverse association with phenotypic age (beta estimate = -0.74; p-value < 0.0001) after adjustment for age, sex, race and CMV serostatus. CD4+ TN/TM was inversely associated with co-occurring chronic conditions (odds ratio for 2 conditions and 3 conditions vs. 0 conditions: 0.74 (95%CI: 0.63-0.86) and 0.75 (95% CI: 0.63-0.90), respectively) after adjustment for age, sex, race, CMV serostatus, smoking, and BMI. CD4+ TN/TM had a stronger association with phenotypic age and age-related morbidity compared to other ARIP measures. Future longitudinal studies can help us evaluate if CD4+ TN/TM can predict risk of aging related outcomes.

MEGA-ANALYSIS OF A CONSORTIUM OF FOUR CENTENARIAN STUDIES IDENTIFIES NOVEL EXTREME LONGEVITY VARIANTS

Harold Bae[1], Anastasia Gurinovich[2], Zeyuan Song[3], Anastasia Leshchyk[3], Mengze Li[3], Nir Barzilai[4], Thomas Perls[3], and Paola Sebastiani[2], *1. Oregon State University, Corvallis, Oregon, United States, 2. Tufts Medical Center, Boston, Massachusetts, United States, 3. Boston University, Boston, Massachusetts, United States, 4. Albert Einstein College of Medicine, Bronz, New York, United States*

The meta-analysis of extreme longevity (EL) conducted in 2017 using a consortium of four longevity studies—the New England Centenarian Study (NECS), the Long Life Family Study (LLFS), the Southern Italian Centenarian Study (SICS), and the Longevity Gene Project (LGP)—confirmed previous associations with APOE alleles and identified additional candidate genes. The current study builds upon this work. Using an aggregated set of the four studies (mega-analysis), we sought to identify additional longevity variants. The current study includes 234 additional cases with a total of 2304 cases (median age=103, age range=[96, 119]), defined as living past the age at which less than 1% individuals from the 1900 - 1920 birth year cohorts survived and approximately 6,000 controls. Approximately 10 million genotyped and imputed

SNPs that passed imputation quality score threshold of 0.7 and that had a minor allele count of 3 or greater were analyzed. We ran a mixed effects logistic model for EL adjusting for sex, top principal components, indicator for living in Denmark, indicator for living in Italy, and the genetic relationship matrix. The analysis identified 21 novel loci that are genome-wide significant, both common and rare, and these loci were not previously published. The genome-wide significant loci include genes such as ADGRL2 (p=6.46-15), HLA-DPA1 (p=1.06-8), GRK5 (p=2.01-8), TECTB (p=3.38-8), KCNQ1 (p=7.53-10), TEAD2 (p=9.53-10), and several intergenic regions. We are currently in the process of seeking replication of the top results in independent cohorts.

MEDICAL MORBIDITY RISK IN A SAMPLE OF OLDER WOMEN WITH BINGE EATING

Savannah Hooper[1], Victoria Marshall[1], Preston Bridges[2], Sara Espinoza[3], Pamela Keel[4], Andrea LaCroix[5], Nicolas Musi[1], and Lisa Kilpela[1], *1. UT Health Science Center San Antonio, San Antonio, Texas, United States, 2. The University of Texas Health Science Center San Antonio, San Antonio, Texas, United States, 3. Sam and Ann Barshop Institute, UT Health San Antonio, San Antonio, Texas, United States, 4. Florida State University, Tallahassee, Florida, United States, 5. University of California, San Diego, La Jolla, California, United States*

Binge eating (BE; consuming an abnormally large amount of food in one sitting while feeling out of control) is the most common form of disordered eating among older women, and aging may confer greater risk for medical morbidities. While the clinical phenotype of older women with BE is unknown, understanding health impacts of BE on the aging process is important. The objective of this study was to describe physiological characteristics of older women (aged 60+) with clinical levels of BE (i.e., ≥weekly episodes). Participants (N = 21; M age = 66.0±4.59) underwent a DEXA, indirect calorimetry, anthropometric measurements, and fasting blood labs. 76% of participants reported a BE age of onset in midlife or later (age 42+); the sample mean BMI was 35.08±8.64, with an average waist-to-hip ratio of 0.90±.047. DEXA scans indicated 90.48% were classified as overweight or obese. Using age- and gender-matched norms, mean fat percentile was 84.75±17.43; mean total body fat percentage was 47.0±4.5. Mean Resting Energy Expenditure (kcal/lean mass) was 34.2±3.71; average respiratory quotient was 0.81±0.06. HbA1c values indicated that 61.90% had pre-diabetes or diabetes; 47.61% had high fasting blood glucose and 76% had high LDL cholesterol. Mean bone mineral density (BMD) fell within a healthy range (1.11 g/cm2±.14); 33.33% had a BMD z-score of less than zero. Cardiovascular comorbidities were rare in this sample (9.5% had standard hypertension). Overall, metabolic disturbances were prevalent, while a minority had cardiovascular or skeletal morbidities. Findings suggest that BE may interfere with healthy aging predominantly through metabolic morbidities.

THE TOLL OF BINGE EATING ON AGING: THE PHYSICAL FUNCTIONING OF OLDER WOMEN WITH WEEKLY BINGE EATING

Savannah Hooper[1], Victoria Marshall[1], Preston Bridges[2], Sara Espinoza[3], Pamela Keel[4], Andrea LaCroix[5], Nicolas Musi[1], and Lisa Kilpela[1], *1. UT Health Science Center San Antonio, San Antonio, Texas, United States, 2. The University of Texas Health Science Center San Antonio, San Antonio, Texas, United States, 3. Sam and Ann Barshop Institute, UT Health San Antonio, San Antonio, Texas, United States, 4. Florida State University, Tallahassee, Florida, United States, 5. University of California, San Diego, La Jolla, California, United States*

Binge eating (BE) is defined as eating an unusually large amount of food while feeling a loss of control; BE prevalence rates range from 12-26% in older adult women. BE is closely linked with obesity, depression, and poor micronutrient intake, as well as with cardiovascular issues and pain in younger populations. Among older adults, such morbidities can negatively affect quality of life and mobility. Yet, little is known about the toll of BE on the aging body in terms of physical function. Thus, the current investigation assessed the physical functioning of older women (60+ years) with clinical levels of BE (i.e., ≥weekly BE). Participants (N = 21) underwent several physical function tests including lower extremity functioning (Short Physical Performance Battery; SPPB), endurance (Six-Minute Walk Test), and grip strength. The majority of participants (76%) had a BE age of onset in midlife or later (age 42+). The average BMI was 35.08±8.64, and 90.48% met criteria for overweight or obesity. On the SPPB, 47.62% scored < 10, suggesting mobility limitations and predicting all-cause mortality. Most women (90.48%) scored >1SD below the age/gender matched norm on the Six-Minute Walk Test (*M*=355.96±67.04) while 61.9% scored >1SD below the norm for grip strength (*M*=24.91±6.40). Results indicate that older women struggling with BE also demonstrate diminished physical functioning, which confers risk for future health problems and poorer quality of life. Our findings suggest that intervention development for older populations struggling with BE may need to incorporate physical rehabilitation to promote healthy aging in this population.

IDENTIFICATION AND INVESTIGATION OF SENESCENT CELLS IN SKELETAL MUSCLE AGING

Xu Zhang, Leena Habiballa, Zaira Aversa, Yan Er Ng, Joao Passos, and Nathan LeBrasseur, *Mayo Clinic, Rochester, Minnesota, United States*

Skeletal muscle aging is marked by the loss and atrophy of resident fibers, and the accumulation of functionally diverse cell types including fibroblasts, adipocytes, and immune cells. Senescent cells amass in multiple tissues with advancing age where they contribute to aging, chronic disease, and physical decline. The role of senescence in mediating muscle aging has become a popular and sometimes contentious topic. However, to date, this concept has not been methodically tested. In this study, we characterized the changes in cell abundance and, importantly, cell-specific transcriptional profiles with skeletal muscle aging using scRNAseq. Interestingly, we identified a small population of p16 positive fibro-adipogenic progenitors (FAPs) which, upon further investigation using immunohistochemical methods, were found to express other senescence markers. This subpopulation of FAPs did not exhibit elevation in p21 levels with age. Instead, terminally differentiated myofibers were the source of the p21 increase. Myofibers with high p21 expression exhibit a strong inflammatory phenotype, which includes activated p53 signaling pathways together with strong cytokine-cytokine receptor interactions. We further identified large amounts of cross-talk between different cell types, suggesting that senescent FAPs and myofibers could contribute to skeletal muscle aging in a paracrine manner. Importantly, these observations in mice were confirmed in human samples, suggesting the strong translational power of these findings.

IDENTIFICATION AND INVESTIGATION OF SENESCENT CELLS IN SKELETAL MUSCLE AGING

Xu Zhang, Leena Habiballa, Zaira Aversa, Yan Er Ng, Joao Passos, and Nathan LeBrasseur, *Mayo Clinic, Rochester, Minnesota, United States*

Skeletal muscle aging is marked by the loss and atrophy of resident fibers, and the accumulation of functionally diverse cell types including fibroblasts, adipocytes, and immune cells. SESSION 6050 (POSTER)

BIOLOGY OF AGING: BEHAVIORAL AND SOCIAL SCIENCES SECTION I

C-REACTIVE PROTEIN AND BRAIN MORPHOLOGY

Rahul Pearce[1], Lisa Eyler[1], Tyler Bell[2], Jeremy Elman[1], Christine Fennema-Notestine[3], Donald Hagler[1], Carol Franz[1], and William Kremen[1], *1. University of California San Diego, La Jolla, California, United States, 2. University of California, San Diego, La Jolla, California, United States, 3. University of California San Diego, San Diego, California, United States*

The process by which aging leads to increased risk for Alzheimer's disease and dementia is not entirely understood, but one hypothesized contributor is the occurrence of low-grade inflammation in older age. In this study, we examined how peripheral levels of C-reactive protein (CRP), a measure of systemic inflammation, relate to brain structure and diffusion in a group of older adult men. After excluding twenty-seven participants for confounding medical conditions, we analyzed a final sample of 426 community-dwelling men from the Vietnam Era Twin Study of Aging, who were assessed at average age 68 for plasma levels of CRP and underwent structural and diffusion brain imaging. Linear mixed models adjusting for family relatedness, age, medical morbidity, and BMI examined associations of CRP with whole brain volume, whole gray and white matter volumes, global fractional anisotropy (FA), and global mean diffusivity (MD). Higher CRP was related to lower whole brain volume (β = -.13, p = .006), including lower whole white matter volume (β = -.22, p <.001) but not whole gray matter volume (p = .08). Higher CRP was related to lower global FA (β = -.51, p = .012) but not global MD (p = .203). Regionally, a relationship of higher CRP to lower FA was found in the anterior thalamic radiation (β = -.51, p = .010), which is implicated in a variety of higher order cognitive processes. These results suggest a link between peripheral inflammation and lower white matter integrity in older adult men, the implications of which for cognitive aging and dementia should be further explored.

SOCIODEMOGRAPHIC DIFFERENCES IN IMMUNOSENESCENCE IN OLDER AGE: EVIDENCE FROM THE HEALTH AND RETIREMENT STUDY

Grace Noppert[1], Rebecca Stebbins[2], Jennifer Dowd[3], and Allison Aiello[4], *1. University of Michigan, Ann Arbor, Michigan, United States, 2. King's College London, London, England, United Kingdom, 3. Leverhulme Centre for Demographic Science, University of Oxford, Oxford, England, United Kingdom, 4. Carolina Population Center, University of North Carolina at Chapel Hill, Chapel Hill, North Carolina, United States*

Population patterns of immunosenescence are not well described. We characterized markers of immunosenescence and assessed sociodemographic differences in a population of individuals ages 56 years and older using newly released venous blood data from the nationally representative U.S. Health and Retirement Study (HRS) (n=8,400). Median values of the CD8+:CD4+, effector memory (em)RA:naïve CD4+ and emRA:naïve CD8+ T cell ratios were higher among older participants (more aged immune profile) and were lower among those with additional educational attainment (less aged immune profile). Racialized minority populations had immune markers suggestive of a more aged immune profile: Hispanics had a CD8+:CD4+ median value of 0.37 (95% CI: 0.35, 0.39) compared to Whites (0.30, 95% CI: 0.29, 0.31). Blacks had the highest median value of the emRA:naive CD4+ ratio (0.08; 95% CI: 0.07, 0.09) compared to Whites (0.03; 95% CI: 0.028, 0.033). Our regression analyses showed that race/ethnicity and education were associated with large differences in T-cell markers of aging, which were orders of magnitude greater than age. By standardizing regression coefficients to estimate years of immunological aging, we found that each additional level of education was associated with roughly an additional decade of immunological age, and racialized minorities had on average an immunological age two to four decades higher than Whites. As one of the first large-scale population-based investigations of immunosenescence, our study advances understanding of the immune mechanisms underlying age-related disease, with implications for risks such as vulnerability to novel pathogens (e.g., SARS-CoV-2).

INVESTIGATING LINKS BETWEEN CHILDHOOD HEALTH AND FAMILY LIFE AND ACCELERATED BIOLOGICAL AGING

Marina Larkina, and Jacqui Smith, *University of Michigan, Ann Arbor, Michigan, United States*

An epigenetic clock measure, DNA methylation (DNAm) PhenoAge, differentiates individual aging trajectories and has been shown to predict mortality and morbidities. Despite suggestions that early-life experiences may shape epigenetic aging, little is known to date about specific risk and protective factors. We use data from Health and Retirement Study (HRS) to investigate the role of childhood factors, including health and family financial situation, in epigenetic age acceleration. The sample (N = 3952, M age = 64, range 50-100) included participants from the HRS 2016 Venous Blood Study and those, who reported about their childhood health and family. Using logistic regression, we predicted DNAm PhenoAge acceleration, calculated as the residuals resulting from regressing DNAm PhenoAge on chronological age and coded as 0 or 1 (1 = positive values, faster epigenetic aging rate). Participants with more years of education were less likely to have accelerated epigenetic aging (OR: 0.963, 95%CI[0.941-0.985], p < .001). However, self-reported chronic illnesses before age 16 (15 possible conditions), self-rated childhood health, and family financial situation before age 16 were not associated with accelerated aging. In addition, men had higher likelihood of accelerated aging than women (OR: 1.145, 95%CI[1.007-1.301], p < .05). Race/ethnicity and age cohort (e.g., being younger or older age 65) were not significant predictors. Our results highlight that investigation of relation between childhood disadvantages and DNAm PhenoAge acceleration might need to include other indicators (e.g., residential history). Future work is needed also to identify life course moderators of the clock efficacy.

GENETIC ARCHITECTURE OF SUBJECTIVE HEALTH: RELATIONSHIP WITH PHYSICAL HEALTH, COGNITION, AND DEPRESSION.

Deborah Finkel[1], and Margaret Gatz[2], *1. Indiana University Southeast, New Albany, Indiana, United States, 2. University of Southern California, Los Angeles, California, United States*

The fact that self-rated health (SH) predicts mortality and a variety of other health outcomes independent of objective health measures generates questions about mechanisms and etiologies. SH can be considered an indicator of physical health, per se, resulting from active cognitive processing of explicit information about one's own health and intuitive knowledge of symptoms and physical sensations. The extent to which SH taps shared cultural ideas about health should be reflected in estimates of the shared environmental component of variance (C). SH has also been associated with emotional health measures, such as neuroticism and depression. Previous analyses have been limited by sex (only women), sample size, age (range = 63-76), and failure to include cognitive function. The current analysis used data from 8291 adults ranging in age from 22 to 102 from the international Interplay of Genes and Environment Across Multiple Studies (IGEMS) consortium to investigate the genetic architecture of SH. Genetic influences on self-rated health (SRH) were investigated in the context of CIRS (Cumulative Illness Rating Scale), MMSE (Mini-Mental Status Exam), and depression (CES-D or CAMDEX). Independent pathways modeling indicated that all genetic variance for SRH was shared with CIRS, MMSE, and depression. Comparison of groups older and younger than 74 indicated age differences in genetic architecture of SRH. Evidence suggests that the discordance between objective and subjective health increases in late adulthood, possibly as a result of greater emphasis on psychological rather than physical components of subjective health assessments by older adults.

TOWARD A NEUROECOLOGICAL MODEL OF FINANCIAL CAPACITY AMONG OLDER ADULTS

Michael Barnett[1], Samuel Van Vleet[2], Kailee Prentice[1], Annika Wurm[1], Danica Bass[1], Yenifer Morales Mejia[1], Jeanné Dube[1], and Samuel Van Vleet[2], *1. The University of Texas at Tyler, Tyler, Texas, United States, 2. Miami University, Oxford, Ohio, United States*

In recent decades, technology has changed how individuals interact with their money and with each other. A combination of financial vulnerability and low technological literacy puts many older adults at risk for identity theft, fraud, and financial exploitation. We reviewed the literature on financial capacity, financial exploitation, and digital literacy. Extant models and measures of financial capacity among older adults emphasize numeracy and basic functional skills, such as writing checks and counting change; these may not reflect the digital nature of contemporary financial activity. We propose the neuroecological model of financial capacity among older adults. This function-led model contends that financial capacity consists of neurocognitive abilities to make sound financial decisions in a complex environment, to use technology to monitor and carry out financial activities, and the ability to protect personal information and guard against fraud. This points to a need for more ecologically valid measures of financial capacity and vulnerability to financial exploitation that addresses the role of technology in everyday financial activities.

SESSION 6060 (POSTER)

ALZHEIMER'S DISEASE AND RELATED DEMENTIAS (SRPP)

PLACE OF DEATH FOR PEOPLE WITH DEMENTIA: EVIDENCE FROM THE CDC WONDER MORTALITY DATA

Takashi Amano, *Rutgers University-Newark, Newark, New Jersey, United States*

Previous studies have found that patients with dementia experience poorer end-of-life care compared to patients with cancer. Dying in the preferred place has become a common measure of the quality of end-of-life care, and it has been consistently reported that the majority of people prefer to die at home. Thus, this study examines whether dying from dementia is a significant determinant of the place of death in mortalities among older adults. The Mortality Data on Center for Disease Control and Prevention (CDC) Wide-ranging Online Data for Epidemiologic Research (WONDER) between 2010 and 2019 were utilized. This study examined whether dying from dementia was associated with place of death (hospital, home, hospice facility, nursing home/long-term care facility) among deaths at 65 years or older. A multinomial logistic regression analysis was performed to estimate the association adjusted for covariates. We analyzed a total of 15,855,034 death records of which 12.34% were dementia deaths. The percentage of deaths at nursing homes was higher in deaths from dementia (56.5%) than other deaths (21.85%), whereas percentages of death at home were similar (20.7% for dementia death and 29.1% for other deaths). Multinomial logistic regression revealed that dementia deaths were 2.74 times more likely to occur at nursing homes than at hospitals compared to other deaths. Results suggest that dementia deaths are more likely to occur at nursing homes/long-term care facilities than other deaths. Further research should investigate the ways to improve the quality of end-of-life care for people with dementia in nursing homes/long-term care facilities.

GOOD ALZHEIMER'S CARE DEFINED BY FAMILY CAREGIVERS AND FORMAL CAREGIVERS IN KOREA

Gawon Chung, *Korean Women's Development Institute, Seoul, Seoul-t'ukpyolsi, Republic of Korea*

The purpose of this study is to explore the meaning of good Alzheimer’s care and the policy needs from the perspective of family caregivers and formal caregivers(in long-term care settings) in Korea and to provide policy suggestions to mainstream "care" and "caregivers" into the Korean National Dementia Plan. By using mixed methods, the Korean Government's policy efforts under the National Dementia Plan to respond to the issue based on Alzheimer’s patients' individual needs and care environments and to alleviate family’s caregiving burden are analyzed. Also, the formal caregivers’ working conditions, difficulties, and the level of knowledge/expertise are examined to find out whether they are well prepared for providing good Alzheimer’s care. The findings reveal that both family caregivers and formal caregivers desire Alzheimer’s care experts’ consulting and honest communication among the care triads. Family caregivers want formal caregivers not to infantilize the patients, to provide more cognitive services based on their individual history and characteristics. Also, the vulnerabilities of patients' spouses are identified that in many cases there is no one other than the spouse who can provide care for the patient, their self-rated health status is poorer, and their tendency to seek professional help is relatively lower. Formal caregivers want the Alzheimer’s patient-formal caregiver ratios to be lowered for better care and their Alzheimer’s care expertise to be acknowledged and properly compensated. Thus, it is crucial to reflect the experiences of the care triads(patients, family caregivers, and formal caregivers) in the Korean National Dementia Plan more rigorously.

LEARN, PLAN, DO: PUBLIC HEALTH PLANNING TO ADDRESS DEMENTIA AND CAREGIVING

Talyah Sands[1], Priya Shah[1], Kelsey Donnellan[2], and Heidi Holt[3], *1. Association of State and Territorial Health Officials, Arlington, Virginia, United States, 2. Assoc. of State and Territorial Health Officials (ASTHO), Arlington, Virginia, United States, 3. CDC, Atlanta, Georgia, United States*

To respond to growing rates of dementia, as well as emerging scientific evidence, there is an urgent need for states to leverage public health strategies to reduce the risk of dementia, promote early detection, and prevent avoidable health issues related to dementia as well as systematically support dementia caregiving. The BOLD Infrastructure for Alzheimer’s Act passed into law on December 31, 2018. The law is designed to promote implementation of CDC’s Healthy Brain Initiative State and Local Public Health Partnerships to Address Dementia: The 2018-2023 Road Map Series and the Healthy Brain Initiative Road Map for Indian Country. Its goal is to create jurisdiction infrastructure and promote planning and action to address dementia across the life-course. With support from CDC, the Association of State and Territorial Health Officials developed an e-learning module to guide public health departments on engaging partners in jurisdiction planning on dementia. The module aligns with the Healthy Brain Initiative Road Map and offers approaches to operationalize health equity throughout its resources. During this session, presenters will overview the module contents and detail the process developed to help jurisdictions assess their dementia and caregiving needs, prioritize actions from the Road Map, and create an action plan. They will also share examples of state planning efforts. Participants will learn how to get started with their own planning process using the tools offered in the module and examples from other states. This presentation complements Tools to Support Needs Assessments on Dementia, Cognitive Health, and Caregiving, abstract ID 1226183.

LEVERAGING NATURAL LANGUAGE PROCESSING TO IDENTIFY CAREGIVER AVAILABILITY FOR PATIENTS WITH ALZHEIMER'S DISEASE

Elham Mahmoudi, Wenbo Wu, Cyrus Najarian, James Aikens, Julie Bynum, and Vinod Vydiswaran, *University of Michigan, Ann Arbor, Michigan, United States*

Identifying caregiver availability for patients with Alzheimer’s disease and related dementia (ADRD) can inform healthcare systems and hospital administrations on appropriate discharge planning. However, caregiver availability data is not systematically collected in the healthcare system. Our objective was to use medical notes (from physicians, nurses, or social workers) to assess caregiver availability and types of caregivers for hospitalized patients with ADRD. We used 2016-2019 telephone-encounter notes from a single institution. Rule-based natural language processing (NLP) was used to develop an algorithm to identify whether the patient (1) resides at home; (2) resides at an institution; (3) has a formal caregiver; and (4) has an informal caregiver. We evaluated the data at the note level and used chart abstraction as the “gold standard.” We examined the validity of the algorithm for both training (n=749) and test sets (n=227). Our results indicated a high level of accuracy and reliability for identifying an informal caregiver (F1=0.942; accuracy=0.947, sensitivity=0.970, and specificity=0.928). Identifying whether the patient lived at an institution was the least reliable measure (F1=0.638, accuracy=0.899, sensitivity=0.512, specificity=0.978). The most common causes of misclassifications were: (1) incomplete or misspelled names of the facilities; (2) past/uncertain/undecided situations; (3) lack of specificity; (4) use of uncommon abbreviations; and (5) irregular use of templates. Our NLP algorithm was able to identify whether the patient lived at home vs. an institution and whether the patient had a formal or informal caregiver. There is merit in continuing the NLP approach to identify more granular, caregiver-related information (e.g., hours available).

THE SENIOR COMPANION PROGRAM PLUS: A PROMISING LAY PROVIDER MODEL FOR ADRD FAMILY CAREGIVING

Ling Xu[1], Noelle Fields[2], Ishan Williams[3], Joseph Gaugler[4], and Daisha Cipher[2], *1. University of Texas at Arlington, Arlington, Texas, United States, 2. The University of Texas at Arlington, Arlington, Texas, United States, 3. University of Virginia, School of Nursing, Charlottesville, Virginia, United States, 4. University of Minnesota, Minneapolis, Minnesota, United States*

Considerable disparities exist in the prevalence of Alzheimer's Disease and related dementia (ADRD) in older African American (AA) populations compared to older white populations. Given the need for caregiver interventions for family caregivers from racial and ethnic minority groups that hold potential for translation, implementation, and sustainability in their communities, peer-led, lay provider models may offer promise. We developed the Senior Companion Program Plus (SCP Plus), a peer-led psychoeducational program for AA family caregivers (CGs) provided by Senior Companions (SCs). Guided by sociocultural stress and coping model, the study was a randomized controlled trial that assessed the effects of SCP Plus on AA ADRD family caregivers' stress and burden, coping skills, and social support. Although COVID-19 ended the trial early, study participants included Senior Companion-Caregiver dyads (N=20). Friedman tests for non-normally distributed variables, one-way repeated measures ANOVA for normally distributed variables, and post hoc between group significance tests were conducted. CGs in SCP Plus group reported significantly decreased caregiving burden ($F(2,6) = 17.65$, $p = 0.003$) especially between pre- and follow up-tests, as well as increased coping skills, especially at post-test ($F(2,6) = 4.93$, $p = 0.05$), satisfaction with social support ($\chi2(2) = 6.53$, $p = 0.04$), and positive aspect of caregiving ($\chi2(2) = 6.53$, $p = 0.04$) (especially between pre- and post-tests as well as between pre- and follow up-tests). Implications for future research are offered as well as lessons learned for culturally congruent, lay provider interventions for ADRD family caregivers.

EFFICACY OF A BRAIN HEALTH PROGRAM FOR OLDER MICHIGANDERS: SINGLE-GROUP DESIGN FINDINGS

Ha-Neul Kim, Fei Sun, and Paul Freddolino, *Michigan State University, East Lansing, Michigan, United States*

This study aims to examine the effectiveness of a brain health education intervention addressing four areas: dementia false beliefs, Alzheimer's disease knowledge, confidence in managing cognitive changes, and dementia worries among older adults. A quasi-experimental design was used with 6 groups of participants of older adults in Michigan who received the intervention over an 8-week period via Zoom. Participants (n=39) included male = 8, female = 31; Caucasian = 19, African American = 20 that were 60 or older (M = 71.74, SD = 6.80). Participants' MoCA score ranged from 18 to 30 (M = 26.36, SD = 2.43). Paired t-tests were used to compare pre-post differences on four main areas. At post-test, participants reported decreased false beliefs to dementia ($p<.001$); increased Alzheimer's disease knowledge ($p=.003$); and improved confidence in managing cognitive changes ($p=.018$) compared to their baseline scores. However, although the mean score of 'dementia worries' decreased on post-test (pre-test: 15.67, post-test: 14.53), it did not show statistical significance ($p=.33$). The 8-week brain health intervention showed a positive impact on lessening participants' false beliefs on dementia, and enhancing knowledge of Alzheimer's disease and confidence in managing their cognitive changes. The findings of this study laid the groundwork for future studies that use a larger sample size and randomized control trial design to test brain health education programs among older adults.

QUALITY CARE AND CONFLICTING RIGHTS AMONG RESIDENTS WITH DEMENTIA, FAMILIES, AND STAFF IN LONG-TERM CARE FACILITIES

Angela Perone, *University of California - Berkeley, Berkeley, California, United States*

Conflicting rights between residents with dementia and staff pose unique problems for quality of care in long-term care (LTC) facilities. Residents relying on staff for care may be afraid to express concerns. A disproportionate female (and often women of color) staff may be exposed to discrimination that stems from a resident's loss of executive functioning and inability to control emotions. Family often find themselves somewhere in the middle. This study, thus, poses two research questions: (1) How do residents, families, and LTC staff understand their rights when conflicts arise between residents with dementia and staff?; (2) How can we leverage collective expertise of residents, families, and LTC staff to deliver a more holistic approach for addressing these conflicts? To answer these questions, I employed a multimethod qualitative design using semi-structured interviews (n=90) and participant observation (n=8 months). Building on legal consciousness theory—which explains how individuals invoke (or do not invoke) legal principles to define everyday experiences—findings revealed that staff rarely invoked legal framings to describe interactions whereas residents readily invoked rights rhetoric. Families mostly avoided rights rhetoric and instead focused on storytelling. All groups (residents, staff, and families) employed an array of emotional literacy and life experiences to navigate conflicts that coalesced around empathy. This paper concludes with research, policy, and practice suggestions for invoking principles of empathy to advance quality of care for residents with dementia by improving interactions among residents, staff, and family and workforce conditions for staff that flow from these interactions.

EXPLORING RACIAL DISPARITIES IN AD/ADRD RISK: EVERYDAY DISCRIMINATION AS A SOCIAL STRESSOR

Katharine Gary, Masudul Hoque, and Igor Akushevich, *Duke University, Durham, North Carolina, United States*

Using evidence from the Health and Retirement Study (HRS), we explore racial disparities in Alzheimer's Disease and Related Dementia (AD/ADRD) risk. From a stress process perspective, there is substantial evidence in the literature that everyday discrimination is a chronic strain for Black individuals that acts as a social determinant of illness. However, few studies have examined specific relationships between this social stressor, race and AD/ADRD risk. Using generalized linear regression and Cox proportional hazard models, we explored racial differences in exposure and vulnerability to everyday discrimination. Results suggest that Black individuals experience more frequent exposure to everyday discrimination than their counterparts, and this chronic strain predicts AD/ADRD risk. However, contrary to the stress process model, White respondents were more vulnerable to the effect of everyday discrimination on AD/ADRD risk. Racial bias from medical professionals during the diagnostic process as well as mortality selection bias may explain these unexpected findings, especially given that racial minorities who experience high rates of everyday discrimination may not live long enough to reach the average age of diagnosis. These results provide further evidence that discrimination is a key factor in explaining racial disparities in late-life disorders, while also taking into consideration that many racial minorities with high rates of this type of stress may not survive to late-life.

LOS ANGELES COUNTY BOLD INITIATIVE: LAYING THE GROUNDWORK FOR STRATEGIC PLANNING ON DEMENTIA

Tony Kuo[1], Noel Barragan[2], Mariana Reyes[2], Mateeha Zafar[3], Cinthie Lopez Paz[3], and Ariane Thomas[2], *1. University of California, Los Angeles, Los Angeles, California, United States, 2. Los Angeles County Department of Public Health, Los Angeles, California, United States, 3. Los Angeles County Department of Workforce Development, Aging and Community Services, Los Angeles, California, United States*

Funded by the Centers for Disease Control and Prevention's Building Our Largest Dementia Public Health Program through U.S. Congressional appropriations for the BOLD Infrastructure for Alzheimer's Act, the Los Angeles County BOLD initiative (LA BOLD) was established in 2021 with the goal of addressing the silent but burgeoning epidemic of Alzheimer's disease and related dementias (ADRD) in Los Angeles County (LAC). In 2019, approximately 166,857 LAC residents were living with Alzheimer's disease; this number is expected to increase 150% by 2040. The initiative brings together a diverse group of multi-sector stakeholders, including two Area Agencies on Aging, two major academic centers, the largest Medicaid health plan in the region, the county's safety net health agency (Public Health, Health Services, Mental Health), and other key community partners. The primary objectives of LA BOLD are: (i) establish a countywide coalition to address ADRD locally, and (ii) develop a strategic plan to guide the coalition's efforts. The present study describes the first year of this initiative, highlighting the formation of the coalition's steering group, identifying the three focus areas for strategic planning – risk reduction, early detection, advance care planning – and sharing lessons learned from navigating the contextual realities of ADRD care and prevention in LAC's diverse communities. Data and program accomplishments for this early phase of LA BOLD are discussed within the context of medical advancement, the financial realities of ADRD programming and services, and the geopolitical factors that are being considered as part of the strategic planning and implementation processes.

UTILIZING BOOT CAMP TRANSLATION TO ENCOURAGE HISPANIC/LATINX PARTICIPATION IN ALZHEIMER'S RESEARCH

Stacey Moeller[1], Samantha John[1], and Luis Medina[2], *1. University of Nevada, Las Vegas, Las Vegas, Nevada, United States, 2. University of Houston, Department of Psychology, Houston, Texas, United States*

Hispanic/Latinx (H/L) individuals are 50% more likely to develop Alzheimer's disease (AD), relative to non-Hispanic whites. Despite higher prevalence rates and earlier age of onset, H/L individuals are underrepresented in aging and AD research. The Engaging Communities of Hispanics for Aging Research (ECHAR) Network is an interdisciplinary, multi-site project that aims to address these disparities. ECHAR uses Boot Camp Translation (BCT), a community-based participatory research (CBPR) approach that partners research faculty and medical experts with community stakeholders to translate medical jargon into action-based, locally-relevant messages. Researchers at University of Nevada, Las Vegas recruited 14 community members to participate in an AD-specific BCT. The process was completed between June 2021 through January 2022 to identify: 1) key messages, 2) target audience(s), and 3) dissemination strategies. BCT members identified three messages to reflect community concerns and highlight values: 1) "Amar es saber" ("To love is to know"), which acknowledges the importance of family and addresses cultural norms that may discourage disease conversations; 2) "The community cares. Let's talk."; and 3) "Podemos afrontar el Alzheimer juntos." ("We can face Alzheimer's disease together."). Target audiences include younger and middle-age adults who may be or become caregivers and local non-profit and community organizations. Members identified social media, community education events, community influencers, and educational products as dissemination strategies. BCT is an effective tool for engaging local communities and exploring Hispanic/Latinx beliefs and attitudes toward AD. It leverages community member expertise to create meaningful, tailored, and culturally-relevant messages that address health disparities and encourage action.

RESULTS FROM A PLATFORM-BASED CLINICAL TRIAL FOR PERSONS DIAGNOSED WITH MILD COGNITIVE IMPAIRMENT

Allison Gibson, Caitlin Pope, Kelly Parsons, Elizabeth Rhodus, Mark Huffmyer, Julia Johnston, and Gregory Jicha, *University of Kentucky, Lexington, Kentucky, United States*

The process of receiving a diagnosis of mild cognitive impairment (MCI) is overwhelming. Individuals may experience adaptive or maladaptive responses to the diagnosis. Five specific areas of maladaptive response were previously identified, including 1) failure to plan for future decline, 2) decreased compliance and interaction with medical care providers, 3) decreased confidence and reduced social engagement, 4) increased physical limitations and mobility, and 5) decreased medication compliance. This pilot study reports on the delivery of the platform-based trial for persons diagnosed with MCI with survey data and qualitative focus groups data (n=38). The study consisted of a single-site platform trial examining the intervention group. Using this approach allowed the participants to explore different biopsychosocial arms of the intervention. Second, the platform design allowed researchers to determine the effects of the interventions on patient help-seeking and adherence behavior in real-world care. Feasibility, opportunities, and challenges will be discussed. Opportunities include the group's cohesion with the group-based intervention, which increased engagement for study group participation. Additionally, participants were most susceptive to intervention components that were novel (i.e., mindfulness) and administered by a professional (i.e., pharmacist, physical therapist) as opposed to self-facilitated activities. Challenges include frequency of study visits, the study partner requirement, and the in-person delivery of the intervention. These challenges were further compounded by the COVID-19 pandemic. Findings from this study offer considerations in implementing support programming and clinical research for persons diagnosed with MCI. The presentation will also include discussion on COVID-19 pandemic-related protocol modifications of this intervention study.

BUILDING A COUNTYWIDE ALZHEIMER'S DISEASE AND RELATED DEMENTIA RESOURCE INVENTORY

Mariana Reyes[1], Noel Barragan[1], Tony Kuo[2], and Ariane Thomas[1], *1. Los Angeles County Department of Public Health, Los Angeles, California, United States, 2. University of California, Los Angeles, Los Angeles, California, United States*

As a BOLD Public Health Program grantee, the Los Angeles County (LAC) Department of Public Health (DPH) was funded to translate national ADRD priorities to the local level. Guided by the social ecological framework, DPH aims to address ADRD by engaging a multi-pronged approach that meaningfully considers the intersection of social, political, and environmental realities when developing and implementing key strategies. As part of this effort, DPH developed a resource inventory and simultaneously created a dedicated website to host and disseminate this information. The target audience for this resource inventory includes the general public; people living with ADRD and their caregivers and families; health professionals; and community-based and allied health professionals. The resource inventory encompasses a wide range of educational information, training materials, local programs, and services related to ADRD such as trainings for healthcare providers to strengthen their knowledge and ability in screening and diagnosing ADRD and legal/financial planning tips for caregivers. In developing the inventory's scope, DPH relied on multi-sector partners to understand the needs of LAC's diverse communities especially keeping in mind communities disproportionately impacted by ADRD (e.g., Black and Latinx communities). Stakeholders highlighted the need to ensure that resources addressed both ADRD topics and critical community needs related to the social determinants of health. The final inventory drew extensively from a wide range of existing national, state, and local resources. This presentation will outline DPH's resource inventory development process and share how results will be used to identify resource gaps and inform local ADRD-focused efforts.

THE IMPACT OF A FACILITATED DISCUSSION SERIES IN IMPROVING DEMENTIA CAREGIVER STRESS, RESILIENCY, AND WELL-BEING

Robin Bonifas[1], and Wendy Cohen[2], *1. Indiana State University, Terre Haute, Indiana, United States, 2. Duet: Partners in Health & Aging, PHOENIX, Arizona, United States*

Emotional stress stemming from the complex grief associated with dementia care takes a greater toll on a family caregiver's health than the physical effort of providing care. Finding Meaning and Hope, a 10-week workshop for caregivers of persons with dementia designed to promote understanding of grief and teach self-care concepts that mitigate stress. Each session features a video of a dementia care expert sharing strategies, followed by a facilitator-led discussion. Home practice activities help caregivers incorporate focal self-care strategies into their lives. This evaluation research assessed the association between workshop participation and caregiver outcomes in stress and well-being. 208 caregivers, 83 percent age 60 and older, completed the workshops between 2019 and 2021. Two standardized instruments were administered before and after workshop participation: the 12-item Caregiver Self-Assessment Questionnaire (American Medical Association, 2015) and the 11-item Sense of Competence Questionnaire (Vernooij-Dassen, 2008). Multivariate Linear Regression was used to assess factors associated with participant outcomes. Participation in more than half the sessions had a positive impact on stress management, emotional well-being, and coping, but fewer gains were made by caregivers with health limitations and those who began the workshops with lower emotional well-being ($F = 15.923$, $p < .001$). Given that family caregivers' mental and emotional health has been negatively impacted by the COVID-19 pandemic (Czeisler et al. 2020), strategies to manage stress and bolster well-being are vital in enabling them to continue care provision when isolation may exacerbate the challenges they encounter. Finding Meaning and Hope offers a promising approach.

THE ROAD MAP STRATEGIST INITIATIVE: A NATIONWIDE EFFORT TO BUILD LOCAL PUBLIC HEALTH CAPACITY ON DEMENTIA

Meghan Fadel[1], Peter Holtgrave[2], Shelby Roberts[3], Eva Jackson[3], John Shean[3], Lisa Garbarino[4], and Lisa McGuire[5], *1. Alzheimer's Association, Albany, New York, United States, 2. National Association of County and City Health Officials (NACCHO), Washington, District of Columbia, United States, 3. Alzheimer's Association, Chicago, Illinois, United States, 4. Centers for Disease Control and Prevention, Atlanta, Georgia, United States, 5. CDC, Atlanta, Georgia, United States*

The Road Map Strategist Initiative is a nationwide effort to build local health department (LHD) capacity to address cognitive health and dementia. Through a collaboration between the Alzheimer's Association and the National Association of County and City Health Officials (NACCHO), the initiative aims to make policy, systems, and environmental change, with a focus on health equity. Participating health departments receive funding, training, and technical assistance to establish a part-time Healthy Brain Initiative (HBI) Road Map Strategist, a public health professional serving as a system change agent. With support and education from the program sponsors, Road Map Strategists conduct a community health needs assessment, train LHD staff and leadership, and collaborate with community partners to implement and accelerate public health actions on dementia. Actions taken by the Road Map Strategists are informed by the Healthy Brain Initiative's State and Local Public Health Partnerships to Address Dementia, The 2018-2023 Road Map. Presenters will share lessons learned from the first cohort of eight (8) LHDs during each stage of the initiative, with a focus on approaches used for Road Map implementation efforts in their communities. This session will share evaluation findings on successes and barriers for changing health department capacity to support local dementia efforts. Data from key indicators related to knowledge gain and capacity change will be shared, including the way LHD characteristics influenced success. The session will also cover effective approaches toward advancing health equity in dementia in local communities and plans for future iterations of the initiative.

SESSION 6070 (POSTER)

ALZHEIMER'S DISEASE, FAMILY CAREGIVING, AND SOCIAL RELATIONSHIPS

CORRELATIONS OF GPS-BASED COMMUNITY MOBILITY METRICS BETWEEN PERSONS WITH DEMENTIA AND FAMILY CAREGIVERS

Jane Chung, Joseph Boyle, and David Wheeler, *Virginia Commonwealth University, Richmond, Virginia, United States*

Currently, the majority of dementia care is provided at home by informal caregivers. Most informal caregivers share a routine with their loved ones and change their activity patterns to adapt to a new routine of persons with dementia (PWDs). Given the dementia caregiving context, caregivers' mobility behaviors and PWDs' mobility may be positively associated. This study aimed to characterize patterns of GPS-derived community mobility in dementia dyads and examine relationships between PWDs' and caregivers' mobility patterns. Six dyads wore a GPS data logger inside and outside the home for 8-11 days. Twelve participants generated valid GPS track files (N=110). Four temporal and spatial mobility metrics were derived from GPS data (total distance, time use, median speed, and convex hull area). Then we calculated Pearson correlation coefficients between PWDs and their caregivers over all tracks. All dyads made active out-of-home trips, indicated by mean daily distance (range: 6,198 - 115,592m for PWDs; 5,125 - 108,857m for caregivers). Median speed of movement ranged from 0.09 to 1.29 km/hour for PWDs, and from 0.21 to 0.97 km/hour for caregivers. The mean size of convex hull over the monitoring period indicates a limited space usage level in both PWDs and caregivers, meaning restricted community mobility despite relatively large distance trips. The correlation coefficient was positive and significant for each metric ($r = 0.70$-0.97, $p < .001$). These results suggest substantial agreement in the mobility metrics between PWD and their caregivers, indicating a high level of dyadic effects of a partner's experience of community mobility.

SOCIAL CONNECTIVITY IS ASSOCIATED WITH INCREASED PERFORMANCE ON MEDIAL TEMPORAL LOBE FUNCTION IN OLDER AFRICAN AMERICANS

Genesis Tan[1], Zuzanna Osiecka[1], Bernadette Fausto[1], Darlingtina Esiaka[2], and Mark Gluck[1], *1. Rutgers University - Newark, Newark, New Jersey, United States, 2. Robert Wood Johnson Medical School, Rutgers University, Newark, New Jersey, United States*

Research links social connectivity to cognitive function in older adults. However, many of the studies relating social connectivity to cognitive function focused on global cognition—orientation/attention, memory, verbal fluency, language, and visuospatial ability domains. In this study, we aimed to assess the association of social connectivity with generalization, a domain of cognition which relies on hippocampal function, in a population of older African Americans residing in the Greater Newark area. Specifically, we examined the impact of social connectivity on generalization using sensitive measures that tap into medial temporal lobe (MTL) function. Participants (N = 74; M = 73.84) from an ongoing study, Pathways to Healthy Aging in African Americans—a Rutgers University-Newark community partnership fostered over 16 years of community engagement, health education, and public service—responded to measures of cognitive function, social network, social engagement, mental health, and demographic details. Also, they completed a task-based functional Magnetic Resonance Imaging. Results showed that marital status was negatively associated with MTL function, with those that are either single, divorced, or separated outperforming those that are married. Similarly, depressive symptoms had a negative association with MTL function. Further, the linear combination of social network variables and covariates significantly predicted MTL function. Our findings illuminate the benefits of social connectivity and resources on cognitive skills, and amplify the need to study the brain in the social context.

EXAMINING SUBJECTIVE BURDEN AMONG SPOUSAL CAREGIVERS OF PARTNERS WITH DEMENTIA: THE IMPACT ON MARITAL QUALITY

Jeremy Yorgason, and Avalon White, *Brigham Young University, Provo, Utah, United States*

Although sometimes caregiving is associated with closeness in marriage, at other times the stresses may affect marriage relationships negatively. In the current study we explore how caring for a partner with dementia, and subjective burden are associated with marital quality. We further explore how dementia care and subjective burden might interact (suggesting a pileup of stress) to affect marital quality. Using data from 1,066 spousal caregivers that participated in the NSOC study and their corresponding care recipients from the NHATS study, the current analysis explored cross-sectional associations between spousal caregiving (primary vs. Secondary caregiver, subjective burden, gender, age, education) and partner care recipient characteristics (dementia classification, household income) predicting positive and negative marital quality. Results suggested that dementia classification and subjective burden were associated with lower positive marital quality and higher negative marital quality. The relationship between subjective burden and positive marital quality was moderated by whether or not the care recipient had dementia. Specifically, when dementia was present, the negative association between subjective burden and positive marital quality was stronger. Spousal caregivers often carry substantial burden to help their partners with activities of daily living. Care provision can alter the marriage relationship in negative ways when perceived burden is high. The current study suggests that the negative association between burden and positive marital quality is even stronger when caring for a spouse with dementia. Gender differences need further exploration, as well as how these patterns play out in early vs. later stages of dementia and across time.

A MOBILE MUSIC APPLICATION FOR CAREGIVERS OF PERSONS WITH DEMENTIA: A USABILITY TESTING STUDY

Cassidy Doyle[1], Debra Dobbs[1], Kelly Wiechart[2], Rohan Wadhwa[1], and Hongdao Meng[1], *1. University of South Florida, Tampa, Florida, United States, 2. KellyW Consulting, Tampa, Florida, United States*

More than 11 million Americans spend an average of 26.3 hours caring for a person with dementia (PWD). Managing behavioral and psychological symptoms of dementia (BPSD) is a significant source of caregiver stress. Music-based interventions (MBIs) have been shown to be a pleasant activity enjoyed by both PWD and their caregivers, with the potential to help alleviate BPSD. However, current commercial music streaming services are not designed for families coping with dementia due to subscription and/or network connection requirements. This mixed-methods usability study tested caregivers' experience with an open-source Android application (MUsic to Support Engagement and Resilience, or MUSER) as a potential platform for home-based MBI delivered by caregivers of PWD. In-lab and in-home testing sessions were conducted with 6 caregivers (2 former and 4 current caregivers, 1 male and 5 females). Semi-structured interviews were conducted before and after the in-home testing period between July and November 2021 to better understand User Experiences (UX). Family caregivers had a mean age of 57.8 (SD=26.2, range 20-77). The main themes identified from the interviews included ease of use, device and music preferences, and prior experience with technology. Overall, users reported high satisfaction and would recommend the application to other caregivers. Users reported that listening to music on the app elicited positive emotional effects (e.g., calmness and relaxation). The MUSER mobile music application can be used by caregivers to deliver MBI in the community. Future research should test whether a caregiver-delivered MBI would be efficacious in reducing BPSD among PWD.

CARE TO PLAN: TAILORING RESOURCES FOR DEMENTIA CAREGIVERS ACROSS A HEALTH SYSTEM

Ashley Millenbah[1], Katie Louwagie[1], Zachary Baker[2], Christine Jensen[3], and Joseph Gaugler[1], *1. University of Minnesota, Minneapolis, Minnesota, United States, 2. Arizona State University, Tempe, Arizona, United States, 3. Riverside Center for Excellence in Aging and Lifelong Health, Williamsburg, Virginia, United States*

Each day, millions of persons with Alzheimer's disease or related dementias (ADRD) rely on family members for necessary care and support. While there are many well-documented interventions to support ADRD caregivers, they lack individualization for specific caregiver needs and contexts. Care to Plan (CtP) was designed to address this gap in tailoring recommendations to support caregivers. After a Phase I pilot, CtP was refined and implemented within a moderately sized health system in the eastern US. A mixed-methods randomized controlled trial aimed to provide insights into the efficacy, acceptability, and utility of CtP. Twenty-two caregivers were randomly assigned to the treatment group (to review the CtP tool with a senior care navigator) and 21 were assigned to receive usual care. After completion of usual care procedures, 7 participants joined a waitlist control group, following treatment procedures. Three- and six-month outcomes included caregiver self-efficacy and distress, caregiver use of recommended support, and service utilization by the person with memory loss. Most caregivers were white (81%), female (74%), and cared for a parent (56%) or spouse (35%). The majority of caregivers agreed that the tool was helpful (70%) and would recommend it to other caregivers (83%). While 48% of caregivers felt that resources provided by the tool were not new to them, the checklist scores and interviews indicate that the senior care navigators were valuable in discussing the recommendations. Phase II findings will guide future evaluation and dissemination, and inform future models of CtP for health system usage.

MINDFULNESS AND CAREGIVING EXPERIENCE IN ADRD CAREGIVERS

Magdalena Tolea[1], Iris Cohen[1], Simone Camacho[2], and James Galvin[3], *1. University of Miami Miller School of Medicine, Boca Raton, Florida, United States, 2. University of Miami Miller School of Medicine, Boynton Beach, Florida, United States, 3. University of Miami School of Medicine, Miami, Florida, United States*

Mindfulness (being present in the moment without judgement) has been linked to greater caregiver emotional health. Recent mindfulness-based interventions report improved coping skills, mood, and reduced stress in dementia caregivers. In this cross-sectional study of 141 ADRD caregivers, we assessed whether the relationship between caregiver mindfulness and caregiver experience varies by caregiver gender, relationship to patient (spouse-vs-child), etiology (AD-vs-LBD), or stage (MCI-vs-dementia). A stratified univariate analytic approach was used. Four mindfulness parameters (AMPS scale) were used: global score (GS), decentering (F1), positive (F2), and negative emotional regulation (F3). Outcomes included positive and negative appraisals of caregiving (PANAC), preparedness, care confidence, and depression. GS was linked to positive outcomes in male (rPANAC+=0.32/p=0.005), spouse caregivers (rPANAC+)=0.32/p=0.006) of ADRD patients regardless of etiology (rPANAC+=0.31/p=0.013 for AD; rconfidence=0.31/p=0.036 for LBD) and stage (rPANAC+=0.33/p=0.010 and rpreparedness=0.38,/p=0.008 for MCI; rPANAC+=0.29/p=0.011 and rconfidence=0.31/p=0.007 for dementia). Inverse relationships were observed with negative outcomes in male (rPANAC-=-0.46/p=0.002 and rdepression=-0.41/p=0.005), spouse caregivers (rPANAC-=-0.25/p=0.035 and rdepression=-0.30/p=0.009) of AD patients (rPANAC-=-0.25/p=0.043 and rdepression=-0.33/p=0.009) in early stages (rdepression=-0.41/p=0.001). F2 contributed to most relationships, with F3 and F1 significant in some but not all caregiver groups. Specifically, male spouse caregivers of AD patients regardless of stage may benefit from full-scope (F1-F3) programs while those of LBD patients from programs focused on improving emotional regulation (F2-F3). Wives of AD and LBD patients may in turn benefit from programs to improve positive emotional regulation (F2). Findings suggest that tailoring mindfulness-based interventions to specific caregiver groups may be effective in improving caregiver experience and mood.

POLICIES AND PERSPECTIVES AROUND SEXUAL ACTIVITIES AMONG RESIDENTS WITH COGNITIVE IMPAIRMENT OR DEMENTIA IN LTC

Mijin Jeong, and Sarah Jen, *University of Kansas, Lawrence, Kansas, United States*

Many older adults remain sexually interested and active in later life. However, little is known about how sexual policies and practices in skilled-nursing facilities (SNF) address sexual activities of residents with cognitive impairment and dementia. This study seeks to identify the current sexual policies and staff's perspectives related to residents with cognitive impairment or dementia in SNFs in Kansas. Online surveys and mailed surveys were distributed to administrators from all 364 SNFs in Kansas in June 2020. 60 long-term care facilities (16.5%) answered the survey. Of 60 survey respondents, 22 facilities (36.7%) have a policy addressing sexual expression and 19 of those policies (94.7%) address issues related to cognitive impairment, competency, or dementia. 77.4% had trained their staff on the impact on sexual expression for those with cognitive impairment or dementia once or more than once during the past year. 73.3% of administrators stated that their staff would respond differently to sexual expression among individuals with dementia or cognitive impairment compared to other residents, often noting issues related to consent and capacity. 55.2% reported any sexual expression among residents with dementia within the past year. Findings indicated that there is a lack of overall sexual policies, but those that exist are likely to address residents with cognitive impairment or dementia. Although there is evidence of training and attention to issues related to sexual expression in individuals with dementia or cognitive impairment, there is a need for further efforts to establish practice norms and policies around more complex or nuanced situations.

SESSION 6080 (POSTER)

BIOBEHAVIORAL HEALTH

PSYCHOLOGICAL DISORDERS LINKED TO OSTEOPOROSIS IN A POPULATION-BASED COHORT STUDY

Kanya Godde Chrisco, Margaret Gough Courtney, Josephine Roberts, and Yadira Quintero, *University of La Verne, La Verne, California, United States*

Psychosocial disorders can stem from or have profound effects on one's health, having been linked to many negative health outcomes. In this study, we hypothesize psychological disorders are associated with a higher risk osteoporosis diagnosis. Self-reported information from years 2012-2016 of the public-use, longitudinal cohort-based Health and Retirement Study, was evaluated from 11,716 American respondents aged 50-90 years old. The odds of scores on the Center for Epidemiological Studies Depression (CESD) scale, and broader psychological disorders (emotional, nervous, psychiatric) on osteoporosis diagnosis (outcome), were estimated with a logistic regression using survey weights, while controlling for sex, logged age, education level, race/ethnicity, family structure during childhood (number of adults), having thyroid disease, allostatic load, and body weight. A McFadden's R2 (0.18) shows the model fits relatively well. The results demonstrate that as CESD score goes up, there is a 10% increase in odds (OR = 1.1, $P < 0.001$) of an osteoporosis diagnosis. Similarly, if a respondent reported a doctor told them they had other psychological disorders, the odds of an osteoporosis diagnosis increased by 52% (OR = 1.52, $P < 0.001$). It is unknown whether the components of broader psychological disorders are caused by decreased quality of life and/or other limitations from osteoporosis or if they contribute to bone health changes in this sample, or both. However, as CESD is a short-term measure (reflecting on the week prior) it is deduced to be as a result of a decreased quality of life associated with some cases of osteoporosis.

SYMPTOMS CONTRIBUTING TO SLEEP PROBLEMS IN OLDER ADULTS WITH TYPE 2 DIABETES

Min Jung Kim[1], Cynthia Fritschi[2], and Eunhee Cho[1], *1. College of Nursing, Yonsei University, Seoul, Seoul-t'ukpyolsi, Republic of Korea, 2. University of Illinois Chicago, Chicago, Illinois, United States*

Sleep problems are common in older adults. Those with diabetes are more vulnerable to sleep disorders since diabetes-specific symptoms can interfere with sleep quality. Yet little is known which diabetes symptoms most strongly affect sleep in older adults. This study aimed to examine the associations between diabetes symptoms and sleep and to identity the symptoms that most strongly disrupt sleep in older adults in the United States. Diabetes symptoms were assessed using the Diabetes Symptom Checklist-Revised. Sleep impairment and sleep disturbance were self-reported using The Patient-Reported Outcomes Measurement Information System. Demographic (age, sex, race/ethnicity) and other variables (body mass index, depressive symptoms, diabetes duration, glycemic control) were also assessed. Multivariate regression analyses were used with standardized coefficients. A total of 82 adults aged ≥ 60 years were included (mean age = 68.32 ± 5.29 years, White 76.83%, female 56.1%). After controlling for demographic and other variables, increased hypoglycemia ($\beta = .35$), hyperglycemia ($\beta = .38$), fatigue ($\beta = .65$), cognitive ($\beta = .48$), and ophthalmologic ($\beta = .25$) symptoms and neurological pain ($\beta = .42$) significantly increased sleep impairment. Of these, fatigue was the strongest contributor to sleep impairment. Similarly, increased hyperglycemia symptoms ($\beta = .30$), fatigue ($\beta = .34$), and neurological pain ($\beta = .37$) significantly increased sleep disturbance while neurological pain was the strongest contributor. To improve sleep quality of older adults with diabetes, their diabetes symptoms should be comprehensively assessed, and potential contributor to poor sleep such as increased fatigue and neurological pain should be addressed.

EXERCISE BEHAVIOR IS DETERMINED BY PANDEMIC DISTRESS AND TASK BURDEN AMONG CAREGIVERS OF OLDER ADULTS

Donya Nemati, NiCole Keith, and Navin Kaushal, *Indiana University, Indianapolis, Indiana, United States*

Background: Caregivers who have dependents with dementia are at a much higher risk of heart disease and mental illnesses compared with non-dementia caregivers. Consequently, these outcomes have been exacerbated by societal barriers that resulted from the pandemic. Engaging in regular physical activity at a moderate-to-vigorous level (MVPA) is beneficial for caregivers has it has been shown to prevent several adverse health outcomes. However, pandemic-related (COVID-19) distress likely worsened caregiver burden which in turn compromised their MVPA levels. The purpose of this study was to understand how caregiving burden impacts MVPA when accounting for physical activity determinants from an augmented Theory of Planned Behavior (TPB) model.

Methods: Participants (n=127) were caregivers for older adults (65+) who have dementia. Participants completed measures of MVPA (behavior), TPB, pandemic-related distress (COVID Caregiver Risk Index) and burden scale for family caregivers. The study was investigated using a structural equation model.

Results: Participants were 45.5 (SD=3.4) years old, 76.4% female. Attitudes (β=.22, p=.012) and perceived behavioral control (β=.19, p<.001) predicted intention. Attitudes and perceived behavioral control mediated the relationship between past behavior and intention (β=.17, p=.02). Covid distress predicted caregiver burden (β=.35, p<.001), and caregiver burden mediated the effects between distress and behavior (β=-.12, p=.01).

Conclusions: Caregiver burden findings suggest that societal changes and demographic-specific burdens related to caregivers need to be considered for caregivers with dependents who have dementia. Taken together, exercise programs that focus on traditional behavioral determinants also need to include specific approaches to buffer caregiving burden experienced in this demographic.

CHRONIC CONDITIONS AND MORTALITY: MODERATION BY SELF-RATED HEALTH

Lauren Voss[1], Elizabeth Teas[2], and Elliot Friedman[1], *1. Purdue University, West Lafayette, Indiana, United States, 2. Purdue University, Lafayette, Indiana, United States*

Chronic conditions become more common with age and greater numbers and severity of chronic conditions, in turn, increase the risk of mortality. However, individuals with similar disease burden often have different mortality rates. The purpose of the present study is to examine potential explanations for divergent mortality outcomes. Self-rated health (SRH), or perceptions of one's own health, consistently predicts mortality. Thus, we hypothesized that participants' SRH would modify the association between chronic conditions and mortality. Data were from the second wave of the Midlife in the US (MIDUS study, N=5,524). Mortality data were collected through 2018. Chronic conditions were measured in two different ways. To assess disease severity, each chronic condition was weighted by its propensity to cause disability; these were then summed. The second was a count of chronic conditions, a common measure in many studies. SRH was measured on a scale of 1-5 (1 = poor, 5 = excellent). Results from logistic regression models showed probability of mortality increased significantly with greater disease burden (measured both as counts and severity of conditions) and decreased with higher ratings of SRH. Importantly, compared to lower ratings, higher ratings on SRH were associated with lower probability of mortality at the same levels of disease severity. In fact, participants who rated their health as excellent showed no increase in probability of mortality with increasing number or severity of conditions. Overall, this study suggests that even in the context of chronic diseases, positive perceptions of health predict greater longevity.

REMOTE ELECTRONIC DATA CAPTURE OF MEDICATION USE AND AGITATION SYMPTOMS IN OLDER ADULTS WITH MCI OR DEMENTIA

Wan-Tai Au-Yeung[1], Lyndsey Miller[2], Sarah Gothard[2], Allison Lindauer[2], and Jeffrey Kaye[2], *1. Oregon Health and Science University, Portland, Oregon, United States, 2. Oregon Health & Science University, Portland, Oregon, United States*

Timely and objective knowledge regarding behavioral and psychological symptoms (BPS) in older adults with cognitive impairment or dementia residing in the community setting is challenging to obtain. The Monitoring Dementia-Related Agitation using Technology Evaluation (MODERATE) Study aims to identify longitudinal changes of agitation and related symptoms for dyads living at home with dementia. To date, MODERATE has enrolled seven dyads (a person living with MCI or dementia and a spousal caregiver). The mean age of the participants is 75.7 (8.5) years, the age of the spousal caregivers is 71.0 (6.0) years, and 5 out of 7 of the participants with MCI or dementia are male. We created an online survey, which is sent weekly to the caregivers, to inquire of any changes in medication and frequency of symptoms of agitation experienced by the persons with MCI or dementia in the past week. As of 02/22/2022, 102 weekly surveys (mean per participant = 14.6) were sent out via email; 99 responses were returned (response rate of 97.1%). One caregiver used a personal computer (PC) only, 2 used smartphone only and 4 used both PC and smartphone to complete the surveys. The median time to complete the online survey was 3.83 minutes with IQR 1.72 – 9.14 minutes. "Complaining, negativism, refusal to follow directions" were the most commonly reported agitated behaviors reported (43% of surveys). Caregivers can provide regular detailed symptom profiles and medication reports online. This approach may be used for more timely and informative management of BPS in dementia.

SESSION 6090 (POSTER)

COVID-19 PANDEMIC

THE IMPACT OF COVID-19 ON SERVICE USAGE IN A RURAL "VILLAGE"

Joonyoung Cho[1], Ruth Dunkle[2], and Julie Tarr[3], *1. University of Michigan-Ann Arbor, Ann Arbor, Michigan, United States, 2. University of Michigan, Ann Arbor, Michigan, United States, 3. ShareCare of Leelanau, Leland, Michigan, United States*

The Covid-19 pandemic disrupted service access and use for many older adults aging in place. This study focuses on understanding how a rural "Village", where services are primarily provided by volunteers to older adults, adjusted to Covid-19. The sample is drawn from service users of at least one or more services between January and October 2020 (N=233). Survey and qualitative data were gathered via telephone-interview (N=80). This study examined (1) the impact of Covid-19 on service use and ability to stay at home, 2) services offered, and 3) changes to day to day life. In the sample, 53.75% is 80+ in age, 70% female, and 43.75% lived alone. 15% of respondents reported reduction in service used, 10% an increase, 65% no change, and 6.25% used no services. Some services such as rides to medical care, and grocery delivery increased, other services (e.g., caregiving) were reduced. 26.24% respondents believed that the organization's services helped them stay at home during Covid-19. Other services were developed to better serve older adults such as phone reassurance and expansion of delivery of medication and food. Open ended responses identified how Covid-19 impacted day to day life. While many reported negative ways such as changing mental health perspectives and limiting medical care, others report life being more peaceful and providing time to enjoy nature. Findings provide an understanding that services while disrupted continued for one volunteer organization with some service users showing resilience in their day to day lives.

ASSOCIATIONS BETWEEN COVID-19 VACCINE HESITANCY AND SOCIOSPATIAL FACTORS IN NYC TRANSIT WORKERS 50 YEARS AND OLDER

Gabriella Meltzer[1], Jordan Harris[2], Michelle Heffner[3], Paula Lanternier[4], Robyn Gershon[5], and Alexis Merdjanoff[5], *1. Columbia University, New York, New York, United States, 2. Purdue University, West Lafayette, Indiana, United States, 3. Colorado State University, Fort Collins, Colorado, United States, 4. University of Texas at Austin, Austin, Texas, United States, 5. New York University School of Global Public Health, New York, New York, United States*

This analysis aimed to investigate how age, race/ethnicity, and geographical location contributed to vaccine hesitancy in a sample of New York City (NYC) Metropolitan Transit Authority (MTA) workers. Transport Workers Union, Local 100 members completed online surveys in August 2020 about their COVID-19 history, workplace protections and policies, fear of COVID-19 exposure, vaccination attitudes, and sociodemographic and health characteristics. We conducted univariate and bivariate analyses, followed by multivariate logistic regression, to determine the association between respondent age (younger than 50 vs. 50+) and vaccine hesitancy (willing vs. unwilling/unsure). We also produced spatial visualizations to examine these factors by participants' zip codes. Of 645 respondents, 59% were 50 years or older, 53% were non-White, and 71% expressed vaccine hesitancy. MTA workers ages 50+ were 46% less likely to be vaccine hesitant than their younger counterparts (OR 0.64; 95% CI 0.42, 0.97). Compared to Whites, non-Whites (OR 3.95; 95% 2.44, 6.39) and those who did not report their race (OR 3.10; 95% CI 1.87, 5.12) were significantly more likely to be vaccine hesitant. Those who were not concerned about contracting COVID-19 in the community had 1.83 greater odds (95% CI 1.12, 2.98) of being vaccine hesitant than those who were concerned. Spatial visualizations revealed that the oldest respondents tended to reside in Queens. Zip codes with high vaccine hesitancy were clustered in Brooklyn, where non-White respondents tended to reside. The trends observed in COVID-19 vaccine hesitancy based on race and age persist in a population of high risk, non-healthcare essential workers.

COVID-19 CASE AND MORTALITY RATES IN GREEN HOUSES AND TRADITIONAL NURSING HOMES IN NEW YORK STATE

Yuchi Young[1], Ashley Shayya[1], Thomas O'Grady[1], and Ya-Mei Chen[2], *1. SUNY at Albany School of Public Health, Rensselaer, New York, United States, 2. National Taiwan University, Taipei City, Taipei, Taiwan (Republic of China)*

Introduction. Green Houses (GHs) have features that distinguish them from traditional nursing homes (NHs) including small size, home-like settings, humane model of care, and a sense of community. Literature shows these features have contributed to lower staff turnover, higher resident satisfaction, and lower COVID-19 case and mortality rates. Few studies use longitudinal data to quantify the differences between GHs and NHs by examining COVID-19 case and mortality rates. Methods. Nursing Home COVID-19 Data from CMS were used to compare case and mortality rates between GHs (n=4) and NHs (n=614) from 5/2020 to 1/2022. Case and mortality rates were calculated for GHs and NHs. Incidence rate ratio (IRR) of case and mortality rates were provided. Results. The preliminary results indicate GHs have lower COVID-19 case (3.76 vs. 6.8 per 1,000 resident weeks) and mortality rates (0.35 vs 1.21 per 1,000 resident weeks) compared to NHs. The IRR for COVID-19 cases is significantly higher in NHs compared to GHs (IRR = 1.8; 95% CI 1.55, 2.11), likewise, for mortality (IRR = 3.45; 95% CI 2.09, 5.75). Conclusions. The findings illuminate key differences in COVID-19 case and mortality rates among GHs and NHs. Factors such as GH size and their unique care model may contribute to the differences observed in COVID-19 case and mortality rates when compared to NHs. Future studies may include facility or resident characteristics in the study design.

POST-COVID-19 ASSESSMENT: HEALTH LITERACY AND PREVENTION PRACTICES IN LTC FACILITIES IN INDIA: PROVIDER PERSPECTIVE

Shantha Balaswamy[1], Raja Samuel[2], and Rufus Singh[2], *1. Ohio State University, Dublin, Ohio, United States, 2. Madras School of Social Work, Chennai, Tamil Nadu, India*

There were no governmental issued guidelines directed specifically towards Long-Term Care residential facilities (LTCF) for older adults in India during COVID-19 pandemic (Rajagopalan 2020) and no data has been collected on care for resident in NGO's and private facilities (WHO, 2021). Further, studies of level of knowledge of providers on health indicators of residents, health literacy and risks factors of contracting the virus is absent. In India, older adults who live in LTCF have higher rates of chronic diseases (hypertension, diabetes, respiratory, heart problems), live in crowded communal space, less access to medical care for underlying health conditions, and have untrained, multiple caregivers, thereby putting them at increased risk for exposure and contracting the COVID-19 virus, and significant risk of infection, illness and mortality. LTCF includes NGO's, government funded old age homes and private paid retirement homes and is considered a multi-residence housing facility. This exploratory study, using online survey of providers of approximately 125 LTC facilities, examines the providers general health literacy level, prevention practices at their facility interventions, demands and rewards of caring for residents during COVID. Preliminary results: less than 20% of providers tracked prevalence of illness, health symptoms, infection rate, hospitalization, mortality rate, or post-recovery. Majority reported difficulty in accessing vaccination, getting residents vaccinated, and accessing resources (food/ medicine/sanitizers) and problem coordinating care due to staffing shortage. Only a small percent use and track health and psychological assessments of residents. Findings have implications for advocating for standardization care and support National and State LTCF policy.

NURSING HOME ADMINISTRATOR EXPERIENCES DURING COVID-19: AN EXPLORATORY STUDY

Susanny Beltran[1], Jennifer Wagner[2], and Vivian Miller[2], *1. University of Central Florida, Orlando, Florida, United States, 2. Bowling Green State University, Bowling Green, Ohio, United States*

Nursing homes have been the epicenter for the COVID-19 pandemic; 149,107 residents and over 2,200 staff have died of COVID-19. In addition to the loss of lives, 99% of nursing homes report staffing shortages. Various exploratory studies have emerged gathering the experiences of frontline nursing home staff during COVID-19, however less is known about the experiences of Nursing Home Administrators (NHA) responsible for overseeing personnel and operating a facility in line with shifting state and federal mandates. Thus, this study explores the experiences of NHA during the pandemic. A cross-sectional online survey was conducted. In addition to demographic and facility-level questions, open-ended questions explored prior training on infection prevention, day-to-day operational challenges, needs, and considerations of leaving their role as administrator. The total sample (N=60) included 47 NHA of record and 13 assistant administrators/other; 53% worked in corporate NHs and 23% were part of continuing care retirement communities. Respondents report prior infection prevention training, but indicate it was not adequate preparation for COVID-19. Moreover, administrators describe challenges in recruiting and retaining staff, and in supporting staff mental health needs (e.g., burnout, PTSD). The majority of NHAs endorse a desire to step away from their role, but indicate a commitment to residents keeps them from resigning. Findings indicate that NHAs, like other members of the NH team, have experienced the effects of COVID-19, and point to specific training and support needs to equip NHAs for work in the context of this pandemic and future emergencies.

RESEARCH, (UN)INTERRUPTED? EFFECTS OF THE PANDEMIC ON A 1 YEAR FOLLOW-UP TO AN ONLINE RCT

Alexandra Jeanblanc[1], Carol Musil[1], Christopher Burant[2], and Jaclene Zausniewski[1], *1. Case Western Reserve University, Cleveland, Ohio, United States, 2. Case Western Reserve University, Parma, Ohio, United States*

The pandemic profoundly disrupted research, largely due to the interruption of data collection. Our online-only behavioral RCT, evaluating two methods of stress-reduction for grandmothers with co-resident grandchildren, completed the originally planned 4 data collection points prior to the pandemic. When it began, we were in the process of collecting a 5th questionnaire (Q5) from a sample of 152. Our pre-existing work from home policies allowed us to continue data collection uninterrupted.Of 152 potential grandmothers, 51 (58 eligible) grandmothers completed Q5 prior to the pandemic and 62 (94 eligible) completed it after it began, (total N=113, 74.43% response rate. We compared Q5 responses pre/post pandemic, finding no significant differences on resilience, mindfulness/decentering, subjective support, instrumental support, or the friendship scale. Post-pandemic participants had significantly lower scores on the social resourcefulness subscale (t=-1.723, p=.044), but not personal or overall resourcefulness. They reported more depressive symptoms for the CES-D positive affect and depressed affect subscales (t=1.997, p=.048; t=1.673, p=.049). The post-pandemic sample reported worse self-rated health over the last year (t=2.753, p=.003) and worse overall health (t=1.781, t=.039).The higher levels of depressive symptoms, worse self-reported health, and lower social resourcefulness aligns with pandemic-related changes observed by other studies. We did not need to adapt our research procedures for the pandemic and, due to the lower post-pandemic response rate, our subsamples were of relatively equal size. Consequently, it is likely that the differences we observe here are real and reflect the negative effect of the pandemic on individual health and psychosocial well-being.

WHAT DO LONG-TERM CARE LEADERS SAY ABOUT THEIR PREPAREDNESS FOR COVID-19? A QUALITATIVE STUDY

Darren Liu[1], Sandi Lane[2], Betty Burston[3], and Robert Rados[4], *1. West Virginia University, Morgantown, West Virginia, United States, 2. Appalachian State University, Boone, North Carolina, United States, 3. University of Nevada Las Vegas, Nevada, Las Vegas, Nevada, United States, 4. Southern Illinois University Carbondale, Carbondale, Illinois, United States*

The post-acute and long-term care (PALTC) sector has, in some respects, served as the epicenter in the U.S. during the COVID-19 pandemic. Many decisions were carried out by administrative and/or clinical leaders during this pandemic. The decisions were made based on their professional experiences, and recommendations by the Centers for Medicare & Medicaid Services (CMS). However, little research has reported on the perspective of those administrators who took the lead during this most difficult time. This study aims to understand how responses and decisions were formed during COVID-19 to ensure resources were available protect staff and residents. Accordingly, this study tried to answer two key questions: 1) What did the PALTC administrative and clinical leaderships learn? 2) What can we do better not if, but when COVID ever "…hits again?" We interviewed nursing home and/or assisted living administrators in two conveniently selected states: Pennsylvania and North Carolina. These interviews (each of which took about 30 minutes) were conducted over Zoom using structured and open-ended questions. The transcripts were entered and analyzed using NVivo – a qualitative data analysis software. The results revealed several themes including communications, relationship building, experience as an administrator, fears and resilience, as well as successful activities to support their staffs such as recognition, bonuses, and food bags prepared for their family. The findings highlight some important administrators' thoughts which recommend key future strategies. These include whether preparedness assets, knowledge, resources, and policies were adequate and where the future efforts should focus.

APPLYING A COLLABORATIVE, INTERDISCIPLINARY APPROACH TO INCREASE COVID-19 VACCINE EQUITY, ACCESS, AND CONFIDENCE

Alice Prendergast[1], and Kristi Fuller[2], *1. Georgia Health Policy Center, Georgia State University, Atlanta, Georgia, United States, 2. Georgia State University, Atlanta, Georgia, United States*

The COVID-19 pandemic has impacted the health and well-being of older adults, people with disabilities, and caregivers in myriad ways. Subgroups of these populations, particularly people of color, experience higher rates of infection and mortality from COVID-19, and are also at increased risk for social disconnection, depression, economic hardship, and a host of other adverse outcomes brought on or exacerbated by the pandemic. COVID-19 vaccines are effective in preventing serious illness and play an important role in protecting vulnerable groups, yet uptake varies considerably across communities and health disparities are growing. Researchers from the Georgia Health Policy Center conducted a mixed-methods study involving a literature review, secondary data analysis, and focus groups to gather information about drivers of vaccine hesitancy and inequity. The team partnered with a multiagency collaborative, branding firm, and subject matter experts to synthesize and apply findings in the development of a statewide, multichannel vaccine communications campaign. In this session, researchers will provide an overview of the study, highlight key findings, and discuss lessons learned throughout this complex, collaborative project.

COVID-19 CASES AND DEATHS IN NURSING HOMES: ROLE OF QUALITY IN MULTIPLE WAVES

Xiaochuan Wang, and Camilo Osorio Castaneda, *University of Central Florida, Orlando, Florida, United States*

The COVID-19 pandemic has disproportionally impacted nursing homes in the United States. As of February 2022, nursing homes have reported over 980,000 resident cases and nearly 150,000 resident deaths, accounting for a high share of total COVID-19 cases and deaths in the U.S. Earlier studies have identified various factors that relate to nursing homes' vulnerability to COVID-19 (e.g., ownership status, facility size). Quality has a critical role in affecting nursing home COVID-19 outcomes. However, research on this topic has been relatively limited and inconsistent. Using publicly available data from CMS COVID-19 Nursing Home Dataset, Nursing Home Compare, Long-Term Care Focus, and The New York Times, this study examines the role of nursing home quality (e.g., infection control deficiency, quality of care deficiency, and five-star quality rating) on COVID-19 resident cases and deaths during multiple waves. Of the over 15,000 nursing homes examined, approximately 64% have had at least one infection control deficiency and 82% have had at least one quality of care deficiency during the two years preceding the COVID-19 pandemic. Results from regression models indicate that the likelihood of having at least one case is more related to facility and resident characteristics (e.g., facility size, percentage of Medicaid residents) and environmental factors (e.g., county case rates) than quality indicators. Whereas the roles of quality on the odds of having resident deaths, and the magnitude of resident cases and deaths, are more consistent in the later waves of the pandemic. Implications for future research and practice will be discussed.

COMMUNICATION DURING COVID-19: A COMPARISON BETWEEN INSTITUTIONALIZED AND COMMUNITY DWELLING OLDER ADULTS

Victoria Dube[1], Mollie George[1], Sarah Hubner[2], and Julie Blaskewicz Boron[3], *1. University of Nebraska at Omaha, Omaha, Nebraska, United States, 2. University of Nebraska Omaha, Omaha, Nebraska, United States, 3. University of Nebraska, Omaha, Omaha, Nebraska, United States*

COVID-19 has created communication and socialization challenges for many older adults (OAs) living in community or institutional settings (CECs, IECs respectively) and their essential contacts (ECs). An essential contact is someone who provides emotional, physical, and social support for an older adult. While social distancing measures have decreased the spread and infection rate, these measures have placed strain upon communication and socialization needed for wellbeing which may increase the risk of loneliness and subsequently depression, cognitive functioning, and mortality among OAs. This study compared how general, in-person, and distanced communication between CECs and IECs has changed due to COVID-19. Self-identified ECs to OAs (N=546) completed a Qualtrics questionnaire via Amazon Mechanical Turk. Respondents (Age Range: 19-77; Mean=44.3; SD=14.2) were generally female (54.8%), white (81.0%), and CECs (57.3%). Pearson chi-square was used to evaluate the association between EC and communication type. Phi and Cramer's V were used to measure effect size. IECs were significantly more likely than CECs to report much less general (41.6% vs. 10.7; medium effect) and in-person (60.0% vs. 22.4%; medium effect) social interaction due to COVID-19. IECs were significantly more likely to report much more distanced communication than CECs (42.8% vs 5.2%; small effect). Overall, this suggests community dwelling OAs' communication and socialization were less impacted by COVID-19 distancing than institutionalized OAs. Thus, institutionalized OAs may be at greater risk for negative effects of social distancing. Future efforts need to focus on prioritizing ways for institutionalized adults to communicate with their ECs if social distancing is needed.

THE ASSOCIATION BETWEEN CHRONIC LUNG CONDITIONS AND COVID-19 MORTALITY AMONG 65+ IN CONNECTICUT AND RHODE ISLAND

Taylor Jansen, Chae Man Lee, Shu Xu, YanJhu Su, Nina Silverstein, and Beth Dugan, *University of Massachusetts Boston, Boston, Massachusetts, United States*

Older adults aged 65 and older have accounted for 81% of all deaths from COVID-19 in the US. Individuals with chronic lung diseases have higher risk for severe COVID-19 and death. The aim of this research is to examine the association between town-level rates of asthma and COPD and deaths from COVID-19 in 208 towns in Connecticut and Rhode Island. This study utilized data from multiple publicly available datasets: the public health departments of Connecticut and Rhode Island, the 2021 Connecticut and 2020 Rhode Island Healthy Aging Data Reports (www.healthyagingdatareports.org), and the Census Bureau's 2014-2018 American Community Survey (ACS). A multi-step analysis was conducted to examine the association between town-level chronic lung conditions and COVID-19 mortality. Bivariate correlations and mapping found strong, positive associations between town-level asthma prevalence and COVID-19 mortality (rs [206] = 0.15; P = .03) and

COPD prevalence and COVID-19 mortality (rs [206] = 0.15; P = .03). After controlling for town-level factors associated with chronic lung conditions and COVID-19 mortality, linear regression models did not find support for an association between chronic lung conditions and COVID-19 mortality. However, town-level factors like percentage of the 65+ African American population (β: 0.19, SE: 249.18, p= .02) and 65+ with low educational attainment (β: 0.45, SE: 278.98, p= .001) were significant predictors of COVID-19 mortality. This research adds to the current knowledge base that high rates of racial minorities and low education among the 65+ population are significant predictors of town level COVID-19 mortality.

SENIOR CENTER RESPONSE TO COVID-19: INVOLVEMENT WITH VACCINE DISTRIBUTION

Ceara Somerville, Caitlin Coyle, and Jan Mutchler, *University of Massachusetts Boston, Boston, Massachusetts, United States*

In early 2021, access to a COVID-19 vaccine was prioritized for older adults and people with multiple co-morbidities. Between high demand, emerging supply, and new systems for booking a vaccine appointment, many people had challenges getting an appointment. Senior centers became a crucial resource for access to the vaccine and additional information about its efficacy and safety. This poster presents survey data collected from 282 senior centers in Massachusetts regarding their involvement with the COVID-19 vaccine distribution in 2021. Nearly all senior centers reported making vaccine appointments on behalf of residents and were responsible for over 166,000 appointments made. Nearly 100,000 hours were spent by senior center staff or volunteers to make appointments. About a third of senior centers participated in hosting nearly 2,000 vaccine clinics, which vaccinated over 175,000 adults. Respondents reported challenges faced during the booking process, including the length of time and the developing technologies to book an appointment. Almost two-thirds of senior centers reported assisting community members under age 60, operating beyond the traditional scope of their services. Other assistance provided by senior centers included providing information about eligibility and guidelines (84%), information about vaccine efficacy and safety (62%), offering transportation to appointments (70%), and providing physical assistance for appointments (31%). Evidence from this poster emphasizes the important role that senior centers play in the community, not just for older adults but also for the community at large.

MEANING IN CHALLENGING TIMES: SENSE OF MEANING SUPPORTS COPING WITH PANDEMIC STRESSES

Katherine Kero[1], Anja Podlesek[2], and Voyko Kavcic[1], *1. Wayne State University, Detroit, Michigan, United States, 2. University of Ljubljana, Ljubljana, Ljubljana, Slovenia*

The COVID-19 pandemic created disruptions in daily life and trauma for many individuals. Traumatic experiences often trigger reflection on meaning in life (MIL), which may result in either resilience or despair. The purpose of this study was to evaluate the role of MIL in mediating the relationship between COVID-related stressors and well-being outcomes. Further, age-related differences in MIL were examined. Web-based surveys were completed by 831 Slovenian participants in April of 2020. Demographic data; perceptions of stressors related to lacking necessities, movement restrictions, and concerns at home; MIL; perceived overall health status; anxiety; emotional state; and perceived stress were measured. Overall, a moderately strong sense of MIL (M = 5.0, SD = 0.74, range 1-7) was reported by participants. Older age was a significant predictor of greater MIL, (B = 0.098, SE = .036, p < .01). Older adults also experienced less perceived stress, negative emotions, and home-related stressors compared to younger adults, but greater stress from lacking necessities (p < .05). MIL partially mediated the relationship between stressors and well-being outcomes, especially stressors related to lacking necessities and concerns at home (13-27% mediation) and outcomes of anxiety, perceived stress, and negative emotions. A strong sense of MIL was associated with improved well-being and a buffering of the effects of pandemic-related stressors. Older adults were less vulnerable to stress and had a greater sense of MIL than younger individuals. Public health initiatives and media may help improve resilience to pandemic trauma by emphasizing the collective meaning in challenging situations.

UNDERSTANDING OLDER HEALTH CARE WORKERS' BURNOUT DURING COVID-19

Jihee Woo[1], and Rafael Engel[2], *1. University of Minnesota, St. Paul, Minnesota, United States, 2. University of Pittsburgh, Pittsburgh, Pennsylvania, United States*

The prolonged battle against the COVID-19 pandemic has left many health care workers physically, mentally, and emotionally exhausted, exacerbating burnout that was already endemic in the healthcare sector. Burnout places not only an individual's well-being but patient care at risk. In this study, we examine protective and risk factors contributing to burnout specifically among older health care workers during COVID-19. We address these questions using data collected from an online survey conducted on health care workers employed at hospitals in Pittsburgh, Pennsylvania in February 2022. Health care workers ages 50 and older (n=165) –a subset of surveyed health care workers– were included in the analytic sample. Participants were asked a series of questions about burnout, mental health, workplace stressors, intent to leave the job, and demographics. Participants were predominantly female (88%) and white (91%) with a mean age of 57.2 years. Almost 70% were registered nurses and the remaining were service, clerical, and technical workers; the mean years of work experience was 21.5 years. Most participants (77%) experienced moderate levels of burnout. Preliminary regression analysis suggests that perceived inadequate staffing (β=2.12, p<.001) and workplace discrimination (β=1.23, p=.001) were positively associated with burnout while job autonomy (β=-1.77, p<.05) and schedule flexibility (β=-.2.09, p=.001) were negatively associated with burnout. Burnout was in turn positively associated with depression, anxiety, and intent to leave the job. These findings demonstrate the need for workplace support to address older health care workers' burnout, better accommodate their needs, and keep them safe and healthy in their jobs.

SESSION 6100 (POSTER)

COVID-19, ACUTE, AND END-OF-LIFE CARE

CLINICAL CHARACTERISTICS AND MORTALITY IN ADULTS 85 YEARS AND OLDER HOSPITALIZED WITH SARS-COV-2

Valerie Danesh[1], Jinmyoung Cho[2], Kristen Tecson[3], and Alan Stevens[4], *1. Baylor Scott & White Health, Dallas, Texas, United States, 2. Baylor Scott & White Health,* *Temple, Texas, United States, 3. Baylor Scott & White Research Institute, Dallas, Texas, United States, 4. Baylor Scott and White Health, Temple, Texas, United States*

Severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) places older adults at increased risk of hospitalization and mortality due to coronavirus disease 2019 (COVID-19). To date, research and regulatory data describe adults 65 years and older, with few reporting on characteristics specific to older adults 85 and older ("oldest-old"). A consecutive 12-month case series including 1,510 oldest-old patients hospitalized with SARS-CoV-2 is presented to describe clinical characteristics, Intensive Care Unit (ICU) utilization and in-hospital mortality from 26 urban, suburban and rural-serving hospitals in an integrated health system in Texas. Known predictors of poor prognosis in COVID-19 include older age, male sex, metabolic risk factors (dyslipidemia, obesity, diabetes) and respiratory failure requiring oxygen support. Compared with hospitalized patients < 85 years, oldest-old patients more often had 4+ chronic conditions (31% vs 12%, p< 0.0001), but less often had metabolic risk factors associated with increased risk for mechanical ventilation and mortality. Specifically, diabetes prevalence was similar between age groups (27% oldest-old vs 30%, NS), while obesity prevalence was lower (18% oldest-old vs 55%, p< 0.0001). Oxygen support requirements were largely similar to the general population, with 4 of 5 hospitalized patients requiring oxygenation support. Of 1,510 oldest-old patients hospitalized for SARS-CoV-2, 269 (18%) required admission to an ICU, 1,206 (80%) required oxygen support, and 1,221 (81%) survived. Following hospitalization, 78% required supportive care, including hospice (15%). Hospitalization characteristics across the lifespan suggest an accelerated and compounded need for ICU recovery and post-hospitalization rehabilitation attributed to the COVID-19 pandemic.

IMMUNE RESPONSES TO MODERNA COVID-19 MRNA VACCINE IN FRAIL NURSING HOME PATIENTS

Charles Semelka[1], John Sanders[1], and Martha Alexander-Miller[2], *1. Wake Forest School of Medicine, Winston Salem, North Carolina, United States, 2. Wake Forest School of Medicine, Winston-Salem, North Carolina, United States*

Prior COVID-19 mRNA vaccine trials included healthy older adults, but mRNA vaccine responses were not studied in frail older adults. We postulated that frailty was associated with immune responses of reduced quality and quantity following mRNA vaccination. A cohort of 15 older adults in a retirement facility were followed from the first Moderna mRNA-1273 vaccine dose in February 2021 with blood collections at baseline and weeks 4 (boost), 6, 18 and 28. Outcomes were IgG titers to SARS-CoV-2 Spike protein with secondary outcomes of T cell responses. Statistical analysis used log transformed geometric mean antibody titers in multivariable regression models with clinical predictors including, age, sex, prior infection status, and clinical frailty scale (CFS) score. Cellular immune response analysis used multivariable regression for function and phenotyping of T cell subsets. All participants with median (IQR) age: 90 years (84, 96) and CFS score: moderately frail 6 (5, 7) generated robust antibody responses with mean peak titer levels 10-fold higher than baseline. In the adjusted model, individuals with severely frail scores CFS=7 had lower antibody levels compared to mildly frail CFS=5, OR: 0.55 (0.35, 0.87) p=0.017. Both chronological age and sex had non-significant relationships with antibody titers. Spike peptide specific CD4 cells and T follicular helper cells were significantly decreased in more frail individuals (p=0.011 and p=0.008 respectively), though the relationship with antibody titers was non-significant. Frailty scores were a better predictor than age for serologic and cellular immune responses to COVID-19 mRNA vaccination in very old adults.

DEPRESSION, ANXIETY, STRESS, AND HEADACHE IN BRAZILIAN OLDER PEOPLE IN THE CONTEXT OF THE COVID-19 INFODEMIC

Alexandre Bulgarelli[1], Camila Mello Dos Santos[1], Ricardo Cavalcante[2], and Karla Frichembruder[1], *1. University of Rio Grande do Sul, PORTO ALEGRE, Rio Grande do Sul, Brazil, 2. Federal University of Juiz de Fora, PORTO ALEGRE, Rio Grande do Sul, Brazil*

Objective: The aim of the present study was to analyze the prevalence and factors associated with headaches in Brazilian older people in the context of COVID-19 Infodemic.

Methods: This is a cross-sectional study carried out with 3,307 older Brazilians through a virtual questionnaire, self-completed using a cell phone, tablet, or computer with internet access. The questionnaire was composed of the Geriatric Depression Scale(GDS), Geriatric Anxiety Inventory(GAI), and the Perceived Stress Scale (PSS). Data collection was developed between June 2020 and January 2021. The analysis model consisted of variables distributed into four blocks: exogenous variables, primary determinants, health behaviors, and health conditions. It was used the Goodness-of-fit test to assess the quality of fit of the final model. Poisson regression with robust variance was used to estimate the associations.

Results: The prevalence of headache was 31.7% (CI 95%: 30 – 33). This outcome was associated with the use of psychotropic drugs (p < 0,001), concern with information about COVID-19(p < 0,001), symptoms of depression and anxiety(p < 0,001), and perception of stress(p < 0,001).

Conclusion: Anxiety, depression, and stress are thought to be associated with headaches in older adults who are exposed to excess information and fake news about COVID-19. It is considered that in the COVID-19 Infodemic scenario, headache in older people who have access to information is an important marker of mental health associated with suggestions of depression, anxiety, and stress.

SHARED DECISION-MAKING WITH COST INFORMATION IN THE CONTEXT OF AGE-FRIENDLY CARE

Nicole Iny, *FAIR Health, New York, New York, United States*

The proposed poster session will explore shared decision making—the patient-clinician communication to decide on tests, treatment and care based on clinical evidence, balancing risks and outcomes with patient and caregiver preferences and values—and how evidence-based strategies, such as shared decision-making tools, or decision aids, can support older adults and their caregivers/care partners as they navigate the healthcare system. Notably, the session will share findings from FAIR Health's grant-funded initiatives to advance shared decision making through decision aids, which combine clinical and cost information for specific clinical scenarios, and are freely available for consumers on fairhealthconsumer.org and for healthcare providers on fairhealthprovider.org. As such, the session will offer diverse perspectives and a unique spotlight on the financial and patient- and caregiver-centered aspects of healthcare decision making. Through FAIR Health's needs assessment for a current project funded by The John A. Hartford Foundation, which has as its goal to advance shared decision making among older adults with serious illness and family caregivers, FAIR Health collected qualitative feedback from older patients, family caregivers and healthcare providers regarding perspectives on navigating the healthcare system. Through a national survey of older patients and family caregivers, FAIR Health found that: (1) though a significant proportion of older adults consider healthcare costs to be an important factor when making healthcare decisions, more than a third have difficulty getting such cost information; and (2) family caregivers/care partners expressed an appetite and need for healthcare information, resources and tools that facilitate better decisions about their care receiver's care.

WHAT IS THIS COVID? COMMUNITY PERCEPTIONS OF COVID-19

Karen Kopera-Frye, and JoJo Delgado, *New Mexico State University, Las Cruces, New Mexico, United States*

The COVID pandemic was complicated by the varied amounts and sources of information available on what exactly COVID was, e.g., CDC website, social media; some fact-based and some not. The purpose of the project was to learn how people defined COVID. The surveyed sample consisted of 155 community dwellers (M age = 45.7 years), with above average education, primarily female (66%), and slightly over one-half identifying as Caucasian and approximately 40% Latinx. The sample were all residents of the Southern Border region, having very high rates of COVID infection in this area, and a statewide mask mandate both inside and outside. The open-ended question inquiring "What is COVID?" was answered by the respondents and thematic analysis focused on two dimensions: 1) was the response factual or not (incorrect in some manner); and 2) the definition of COVID in terms of a virus, flu, etc. Interestingly, despite the median education being around 15 years, 44.5% of the sample gave an incorrect definition of COVID. The three most predominant themes emerging from the definitions were (in descending order): 1) a virus with specific facts noted; 2) a disease/infection; and 3) an affective reaction such as annoying. The results highlight the diverse conceptualizations in a very high-risk area, especially focused on oftentimes an incorrect understanding of COVID.

A DATA-BASED PROPOSITION FOR THE CREATION OF NEW ICD-10 DIAGNOSIS CODES FOR POST-ACUTE SEPSIS SURVIVORS

Sungho Oh[1], Melissa O'Connor[2], Michael Stawnychy[3], Yolanda Barrón[4], Patrik Garren[1], Elaine Sang[1], and Kathryn Bowles[3], *1. University of Pennsylvania, Philadelphia, Pennsylvania, United States, 2. Villanova University, M. Louise Fitzpatrick College of Nursing, Villanova, Pennsylvania, United States, 3. University of Pennsylvania School of Nursing, Philadelphia, Pennsylvania, United States, 4. Visiting Nurse Service of New York, New York, New York, United States*

Sepsis survivors have the second highest readmission rate among Medicare beneficiaries, next to heart failure. I-TRANSFER is an implementation science study to improve transitions and reduce readmissions among sepsis survivors transitioning from acute to home health care (HHC). A total of 63 semi-structured interviews were conducted with stakeholders among 12 hospitals and 5 affiliated home health agencies (HHAs). The purpose of this secondary analysis was to: 1) examine how the sepsis diagnosis is reflected in HHC documentation, 2) identify barriers in sepsis information transfer to HHC, 3) recommend a documentation strategy to enhance information transfer and HHC documentation. We analyzed the diagnosis coding within a national OASIS dataset and eight I-TRANSFER interviews with hospitalists, documentation specialists, and HHC coders. Findings include: a) sepsis diagnoses were nearly invisible in HHC records being documented for only 10% of 165,000 sepsis survivors transitioned to HHC, b) sepsis information in referral documentation can be unclear to HHC coders, c) the lack of sepsis diagnosis documentation might make HHC clinicians unaware of the patient's risk for readmission, d) HHC coders recommended improved language in the acute care discharge summary to link the need for HHC to sepsis, thereby supporting the use of ICD-10 sepsis 'A' codes in HHC. The use of terms, such as "History of Sepsis" or "Sepsis Resolved," leads to HHC using non-specific codes, thus is not recommended. We highlight the need for new ICD-10 codes for "Sepsis Aftercare" and "Post-Sepsis Syndrome" to clearly communicate and document the needs of sepsis survivors.

CORRELATIONS BETWEEN OLDER PATIENTS' FIRST COVID-19 VACCINATION TIMING AND MEDICATION ADHERENCE

Thomas Marano[1], Renae Smith-ray[2], Clifford Jones[3], Balamurugan Sivakolunthuvel[3], Linda Schultz[3], Michael Taitel[4], and Kevin Leung[3], *1. AllazoHealth, Forest Hills, New York, United States, 2. Walgreen Co., Deerfield, Illinois, United States, 3. AllazoHealth, New York, New York, United States, 4. Walgreen Co, Deerfield, Illinois, United States*

Medication adherence and COVID-19 vaccinations are both essential to improving health outcomes and avoiding hospitalizations. When vaccines first became available in early 2021, the CDC recommended prompt vaccination for patients age 65-and-over. Vaccine hesitant older adults are among those at the highest risk for severe outcomes from a COVID-19 infection. A retrospective study was conducted using prescription and vaccine claims data from a pharmacy chain. Patients were included if they: 1) were age 65+ as of 1/1/21; 2) had at least two prescriptions of RAS antagonists, non-insulin anti-diabetics, or statins (in 2021); and 3) received at least two doses of mRNA COVID-19 vaccine between 1/1/21 and 9/21/21. Patients were then split into two evenly-distributed groups based on the number of days into 2021 when they received their first vaccine dose. The outcome was the proportion of optimally adherent patients (PDC ≥ 80%) by condition as of 12/31/21. Two-proportion z-tests were performed comparing the adherent proportions of the "earlier to vaccinate" group versus the "later to vaccinate" group as of 12/31/21. Age groups analyzed were "65-74" and "75+". The proportion of adherent patients as of 12/31/21 in the "Earlier to Vaccinate" group is higher than those in the "Later to Vaccinate" group for all three adherence metrics by 4.4% (65 to 74) and 2.2% (75+, p=0.00108*) for Diabetes, by 5.1% and 2.6% for Hypertension, and by 6.0% and 3.9% for Statins (*all other p< 0.00001). The timeliness of a patient's first COVID-19 vaccination dose was predictive of medication adherence in 2021.

REAL-WORLD EFFECTIVENESS ENHANCED INFLUENZA VACCINES IN OLDER ADULTS DURING THREE CONSECUTIVE INFLUENZA SEASONS: 2017–2020

Ian McGovern, *Seqirus (A CSL Company), Summit, New Jersey, United States*

Unenhanced influenza vaccines often fail to elicit adequate immune responses in adults ≥65 years due to immunosenescence. Enhanced influenza vaccines, MF59-adjuvanted trivalent inactivated influenza vaccine (aTIV) and high-dose vaccine (HD-TIV), were specifically developed to overcome this problem. The relative vaccine effectiveness (rVE) of aTIV vs HD-TIV and standard, egg-derived quadrivalent influenza vaccines (QIVe) was estimated in 3 retrospective cohort studies during the 2017-2020 US influenza seasons. Influenza-related medical encounters (IRMEs) were identified using diagnostic codes specific to influenza disease (ICD J09*-J11*) from a dataset that integrated electronic primary care medical records with pharmacy and medical claims. rVE was estimated using propensity score methods adjusting for variables including age, sex, race, ethnicity, geographic location, week of vaccination, frailty and health status. Subgroup analyses included specific age groups and those with high-risk medical conditions. aTIV demonstrated a consistent benefit over QIVe and HD-TIV across all three seasons in the overall study populations, and greater rVE versus QIVe was consistently observed over all three seasons in all age subgroups as well (65-74, 75-84, 85+). aIIV3 was comparable to HD-TIV and more effective than QIVe in a subgroup with high-risk medical conditions. These findings lend further support to the use of aTIV to prevent influenza-related medical encounters in older individuals.

REGIONAL VARIATION IN COVID-19 MITIGATION PRACTICES AMONG HOME- AND COMMUNITY-BASED LONG-TERM CARE PROVIDERS

Jessica Lendon, Christine Caffrey, Priyanka Singh, Zhaohui Lu, and Sengupta Manisha, *National Center for Health Statistics, Hyattsville, Maryland, United States*

Residential care communities (RCC) and adult day services centers (ADSC) were greatly impacted by COVID-19. As state-regulated home- and community-based care settings (HCBSs), they experienced changing regulations, outbreaks among care recipients and staff, and new challenges to safely provide services. Using a nationally representative sample of over 11,600 RCCs and census of nearly 5,500 ADSCs from the 2020 National Post-acute and Long-term Care Study, this study examined the prevalence and regional variation (p<.05) of practices to mitigate COVID-19. Preliminary data show that most RCCs (87%) and ADSCs (72%) screened for symptoms. Most RCCs limited communal activities (83%) and ADSCs reduced hours or temporarily closed (73%). More RCCs used video telemedicine than audio-only (40% vs 34%) to assess, diagnose, or treat users. However, more ADSCs used audio-only than video telemedicine (25% vs 17%). Over 80% of all providers always or sometimes imposed in-person restrictions on family, visitors, volunteers, and non-essential services providers. More ADSCs in the Midwest (82%) and South (80%) screened symptoms than Northeast (68%) and more ADSCs in the Midwest (85%) limited hours/temporarily closed than Northeast (72%). More RCCs in the Midwest (43%) and South (41%) used video telemedicine than Northeast (36%); however, a lower percentage of ADSCs in the Midwest (9%) and South (12%) used video telemedicine than Northeast (25%). Results show a variety of experiences in the first year of the COVID-19 pandemic among these two HCBSs. Practices to mitigate COVID-19 while continuing to provide needed services were common, with some differences across settings and US regions.

ANXIETY IN COMMUNITY-DWELLING OLDER ADULTS AND ITS RELATED FACTORS DURING THE COVID-19 PANDEMIC

Yu Ma[1], Chieko Greiner[2], and Hirochika Ryuno[3], *1. Kobe University, Kobe, Hyogo, Japan, 2. Kobe University, Kobe-city, Hyogo, Japan, 3. Kobe University, Kobe city, Osaka, Japan*

The rate of infection and magnitude of the effects of the coronavirus disease 2019 (COVID-19) pandemic has far exceeded the realm of what most people had previously experienced in their lives. There is an urgent need to ensure that strategies are in place to prevent and reduce anxiety in older adults. The present study aimed to assess anxiety in community-dwelling older adults and the related factors during the COVID-19 pandemic in Japan. A community-based cross-sectional study was completed in July 2021. The Japanese version of the Geriatric Anxiety Inventory was used to screen for anxiety symptoms. Demographical data and data for the following five other factors were collected: loneliness, mental well-being, perceived social support, coping behaviors to COVID-19, and fear of COVID-19. The association between anxiety and potential predictors was analyzed using binomial logistic regression. A total of 385 participants aged 65 to 86 years were included in the present study. 17% developed anxiety symptoms. Factors associated with anxiety were age, living alone, loneliness, significant people support, fear of COVID-19, and health monitoring as a COVID-19 coping behavior. Older age, living alone, and significant people support were associated with lower anxiety, and loneliness, fear of COVID-19, and health monitoring as a COVID-19 behavior were associated with higher anxiety in community-dwelling older adults during the COVID-19 pandemic. These findings can help to develop effective measures for reducing anxiety and will support the development of a psychological intervention for tackling the mental health of community-dwelling older adults during the COVID-19 pandemic.

PROFILE OF COMMUNITY-DWELLING OLDER ADULTS ONE YEAR INTO COVID-19

Helen Lach[1], Devita Stallings[1], Janice Palmer[2], and Rebecca Lorenz[3], *1. Saint Louis University, St. Louis, Missouri, United States, 2. Webster University, St. Louis, Missouri, United States, 3. University at Buffalo, Buffalo, New York, United States*

We surveyed community-dwelling older adults in 2020, primarily in the Midwest, to learn about their experiences during the initial months of the COVID-19 pandemic. In summer 2021, we collected quantitative and qualitative one-year follow-up data on 118 participants from the original cohort who agreed to be contacted later (n=246;

48% response rate). Respondents included mostly women (75.2%), White (95%) with a mean age of 76.4 years and 15 mean years of education; half were married (49.5), and 40.7% lived alone. Compared to 2020, participants had a higher mean score on the CESD10 (9.76 vs. 6.97); although self-rated health and quality of life scores were similar (94-95% good-excellent). Mean scores on the Brief Resilient Scale were similar. In this group, 99.3% had been vaccinated, and had a concern score of 3.7 out of 5 that there would be more COVID outbreaks. Themes from their reported adaptations during the pandemic included taking steps for physical and mental self-care, maintaining connections with others, and finding credible sources of information. Connecting with others online was the biggest technological change during this time, and the computer was the most valued technology. These educated, middle class older adults continued to adapt to the COVID-19 pandemic, but those who did not respond to the second survey may have had more health or mental health challenges. These findings suggest a need for health care providers to screen older adults for depression so that early interventions can take place.

TRIPLE MALADY: OLDER PERSONS WITH MENTAL ILLNESSES AND COVID- 19: INSIGHTS FROM A PSYCHOGERIATRIC CLINIC IN NIGERIA

Olubukola Omobowale[1], Olufisayo Elugbadebo[2], and Oluwagbemiga Oyinlola[3], *1. University of Ibadan, Nigeria, Ibadan, Oyo, Nigeria, 2. College of Medicine, University of Ibadan, Ibadan, Oyo, Nigeria, 3. University College Hospital, Ibadan, Ibadan, Oyo, Nigeria*

Background Older persons with mental illnesses have been differentially affected by COVID-19 because of reduced access to routine health care, the adverse social impacts of the preventive strategies, and inadequate knowledge of the ongoing COVID -19 pandemic.Adequate knowledge is crucial to ensuring adherence to the right preventive practices among older persons.

Methods A hospital-based comparative study was conducted among older persons attending the Psychogeriatric and Healthy Ageing clinics of the Geriatric Centre, University College Hospital, Ibadan. Data were gathered with a semi-structured interviewer administered questionnaire and SPSS version 23 was used to analyze the data. The level of significance was set at 5%.

Results A total of 390 respondents aged 60 and above were sampled in the two groups: 195 with a psychiatric diagnosis (PD) and 195 with a non-psychiatric diagnosis (nPD). Their mean age was PD: 72.2 (±7.4) years and nPD: 71.0 (±8.0) years. About 14.9% had dementia and mild cognitive impairment; 14.6% psychotic disorders; 13.8% mood disorders and 6.6% anxiety and somatoform disorders. The majority were aware of the ongoing pandemic (PD: 95.9%; nPD: 96.4%). The use of facemask (PD: 89.7%; nPD: 86.7%) was the commonest preventive practice. Male gender (OR:2.09, CI; 1.14-3.86, p= 0.018) and education (OR: 5.10, CI; 1.15-22.67, p= 0.032) were predictors among PD and nPD respectively.

Conclusion: Older persons with psychiatric diagnoses have gaps in their knowledge of COVID-19 compared to those without symptoms. Health education about the ongoing pandemic and prevention programs targeting the older population with mental illnesses would be beneficial.

SHOT ON THE SPOT VACCINATION COMMUNITY OUTREACH

Alissa McIntyre[1], Rebecca Allen[2], Brian Cox[3], Loretta Wilson[4], Pamela Payne-Foster[5], JoAnn S. Oliver[6], Yan Luo[7], and Hee Lee[8], *1. University of Alabama, Tuscaloosa, Alabama, United States, 2. The University of Alabama, TUSCALOOSA, Alabama, United States, 3. Alabama Research Institute of Aging, Tuscaloosa, Alabama, United States, 4. Rural Alabama Prevention Center, Eutaw, Alabama, United States, 5. Rural Health Institute/Community Rural Medicine, Tuscaloosa, Alabama, United States, 6. Capstone College of Nursing, Tuscaloosa, Alabama, United States, 7. The University of Alabama, Tuscaloosa, Alabama, United States, 8. University of Alabama, Birmingham, Alabama, United States*

Due to the COVID-19 pandemic disproportionately affecting Black communities, The University of Alabama (UA) partnered with the Rural Alabama Prevention Center (RAPC), a community-based healthcare organization to improve the vaccination rate from 34% vaccinated Alabama Black Belt residents to 70% over a year. Health literacy training is provided to community health workers and students who, along with the team members, volunteer at pop-up Shot on the Spot vaccination sites to administer surveys collecting demographics and vaccine hesitancy data. Team members provide health literacy information and answer questions non-vaccinated individuals have. This vaccination intervention has led to drastic rate increases, such as, Choctaw County having a 36.6% increase since the beginning of the project in August (30.7% to 67.30%). However, some counties have low vaccination rate changes, such as, Crenshaw County with a rate change of 15.4% (19.5% to 34.90%). Notably, the Alabama Black Belt currently stands at a higher vaccination rate compared to Tuscaloosa County (UA's location), only having a rate of 44.3%. Within one year, there have been a total of 44 administered first and second vaccine doses and 435 booster doses, resulting in 50.24% vaccinated Black Belt residents. As the virus evolved into different variants, team members were able to observe an increase in administered booster doses in congruence with the rise of a new coronavirus variant. The partnership formed between RAPC and UA scientists and students is an important step in improving vaccination rates and building community research on minority and diverse populations.

OLDER ADULT'S SEPSIS CARE: CROSSING THE CONTINUUM: LESSONS LEARNED, OPPORTUNITIES PRESENTED

Teresa Cranston, Joseph Kontra, and Lanyce Roldan, *Penn Medicine Lancaster General Health, Lancaster, Pennsylvania, United States*

Sepsis is the body's overwhelming response to infection that can lead to tissue damage, organ failure, and death. Delays in identification and treatment are associated with increased morbidity and mortality especially for older adults. It is key that clinicians practice collaboration and communication when diagnosing & treating patients that may have a different presentation. The Continuous Monitoring Unit

(CMU) consists of RNs, who monitor the Sepsis Dashboards 24 hours/7 days a week. These nurses evaluate all BPA data points. They dismiss the irrelevant and align the significant while looking for possible notes of infection. They act upon the BPA when the patient meets criteria. They collaborates with the provider to initiate recommended sepsis care. Once the sepsis diagnosis is confirmed, the CMU RN communicate with inpatient nursing via EMR shift reporting and Care planning tools. Nursing utilizes these tools for daily rounds with the health care team communicating patient discharge needs. Identifying the Sepsis survivor on admission allows for early sepsis survivor education, discharge preparation and outpatient follow up referrals. Case Management utilizes an electronic application for outpatient referrals and includes a Sepsis Survivorship alert. Community resources, alert to a sepsis diagnosis will follow up within 24-48 hours of discharge to insure that the patient is having a smooth transition. Referred providers can escalate care to the PCP for early intervention therefore reducing worsening state or readmission. Specifically, our home care agency monitors the patient closely upon discharge due to the sepsis survivor's tenuous state and reinforces sepsis education.

A NURSING HOME–BASED COVID-19-ONLY REHAB PROGRAM: VARIABLES RELATED TO SUCCESSFUL COMMUNITY DISCHARGE

Orah Burack[1], Joann Reinhardt[1], Wingyun Mak[2], and Ruth Spinner[1], *1. The New Jewish Home, New York, New York, United States, 2. The New Jewish Home Research Institute on Aging, New York, New York, United States*

Many COVID-19 patients continue to test positive for COVID-19 beyond the typical quarantine period. Persistent positive testing complicated hospital discharges to nursing home (NH) based rehabilitation facilities when (in May 2020) New York State (NYS) required a negative COVID result prior to NH admissions. To meet the needs of medically stable persistent positive patients, NYS approved 19 NHs as COVID-only facilities (COF). These facilities provided rehabilitation services and allowed hospitals to regain critical space for incoming acute care patients. In the present study we describe the (1) establishment of a 100 bed COF, (2) patients admitted to the COF and care provided, and (3) predictors of successful discharge to the community.Information on the establishment of the COF was obtained from interviews with NH leadership and clinical staff. Patient, treatment, and outcome data were obtained from the NH's electronic health record. Of 319 COF admissions over four months, 54% were female and the mean age was 80 years (SD=10.56). 51% had cognitive impairment and the mean number of comorbidities was 6.75 (SD=2.47). All patients received physical and occupational therapy while 37% received speech therapy. Medical treatment included: anticoagulants (52%), oxygen (37%), antibiotics (35%), inhaler/nebulizers (31%), and oral steroids (15%). 59% of COF stays resulted in successful community discharges. This outcome was more likely for patients who had fewer comorbidities, less speech therapy, and did not require antibiotics. Implications for COVID care as well as leveraging NH potential during crisis will be discussed.

FILE OF LIFE: OLDER ADULT PERSPECTIVES AND SUGGESTIONS TO INCREASE FOL USAGE

Kaye Dandrea, Teresa Williams, and Marilyn Gugliucci, *University of New England College of Osteopathic Medicine, Biddeford, Maine, United States*

IntroductionIn a home emergency, an accurate patient medical history is vital for proper medical decision-making. One method to provide medical information in an emergency is through the FILE OF LIFE™ (FOL); a document distributed by local medical centers and public service organizations completed by community adults and placed on their refrigerator in a magnetic folder. To date, there was no known study, until this one, conducted with older adults to check the FOL design suitability for older adults; the goal of this project. MethodsOlder adults were recruited through the UNE COM Geriatrics Education Mentor (GEM) program for this pilot qualitative research. Twenty-one GEMs volunteered to participate in five 90-minute focus groups. Questions were specific for each section - Patient Identifiers, Emergency Contacts, Medical Data, Medical Conditions, Allergies, and Medical Insurance Information, and the usability of the FOL. Qualitative content analysis followed by NVivo 12+ analysis applied inter-rater reliability methods and changes for each FOL section were based on reaching data saturation. ResultsFILE OF LIFE™ comments (N=328) were coded to the following themes: Layout, Font Size, Spacing, and Section Ordering. Sections were edited accordingly with "Identifiers," Medical Data, Medical Conditions, Allergies, and Emergency Contacts requiring substantive changes. Other minor changes were made throughout the form. ConclusionFurther research will ensure efficient usability by older adults and emergency response personnel. The FILE OF LIFE™, although a trusted resource for older community dwelling residents, has a chance to increase usability by incorporating the suggested changes from this research.

REIMAGINING END OF LIFE: ALTERNATIVE APPROACHES TO SERIOUS ILLNESS CARE CONVERSATIONS

Maresi Berry-Stoelzle[1], Cristina Ortiz[2], Jessica Trepanier[1], Sarah Murray[1], Melissa Steffen[1], Bruce Alexander[3], and Kenda Stewart Steffensmeier[1], *1. Iowa City VA HCS, Iowa City, Iowa, United States, 2. University of Iowa VA, Iowa City, Iowa, United States, 3. Iowa City VA Health Care System, Iowa City, Iowa, United States*

Serious illness care conversations are intended to document and protect patients' medical treatment wishes. In the outpatient management of chronic diseases, it has been difficult to pinpoint ideal timing for these conversations. The goal of this project is to analyze current practice within a VA health care system for identifying and referring veterans for palliative care services in the last years of life. To develop a targeted intervention, we relied on different forms of information to identify life events which should trigger a goals of care conversation, possibly even a formal palliative care referral. This study describes how we operationalized knowledge gained from: 1) Veteran community members via a project-dedicated engagement panel, 2) semi-structured interviews with providers, and 3) review of patients' clinic notes written by clinicians during the last 5 years of life. Tapping into the knowledge and experience of multiple parties provided nuance and complexity to our approach to intervention development. From the Veteran community member engagement panel, we learned that trusting relationships were essential. Providers emphasized that having enough time during appointments and timing of the conversation during a patient's disease trajectory were important. Finally, chart review indicated a need for broaching serious illness conversations early and throughout the duration of their care. The goal of an earlier intervention is to engage veterans when they are medically stable and prior to prolonged hospitalization. These findings structured our ongoing intervention that focuses on identifying and reaching out to Veterans with serious illnesses.

FEASIBILITY OF ECOLOGICAL MOMENTARY ASSESSMENT OF SURROGATES FOR COGNITIVELY IMPAIRED ICU PATIENTS: A PILOT STUDY

Tracy Taylor[1], Emily Burke[2], James Slaven[3], Bruce Pfeffer[4], Shelley Varner Perez[4], Sarah Banks[5], and Alexia Torke[2], *1. Regenstrief Institute, Inc., North Vernon, Indiana, United States, 2. Indiana University (IU) Center for Aging Research, Regenstrief Institute, Inc., Indianapolis, Indiana, United States, 3. Indiana University, Indianapolis, Indiana, United States, 4. Indiana University Health, Indianapolis, Indiana, United States, 5. Indiana University School of Medicine, Indianapolis, Indiana, United States*

We explore the feasibility of ecological momentary assessment (EMA) with surrogate decision makers (SDMs) of critically ill hospitalized adults, to obtain in-the-moment participant-reported data. In this small pilot, 23 SDMs were approached. 82.6% were white, 53.9% were female, and 53.9% were 55 years and older. 25% were spouse or partner, 25% were adult children, 30% were parents, and 20% were other relations. Average ICU length of stay was 13.46 days (range 1.73-77.79). 13 SDMs enrolled (56.52%). Using Twilio, an automated text was sent to SDMs containing a secure link to the surveys. Up to five questions about anxiety, depression, distress, communication, and spiritual well-being were sent up to twice per day. Most participants (84.62%) completed EMA surveys for 5 or more days. Most SDMs stated that the surveys were not burdensome. Of those who declined participation (n= 10), accessibility to a smartphone, stress, and availability to complete texted surveys were noted as barriers to participation. The data suggest that EMA is a valuable tool to inform clinical interventionists and care providers interacting with SDMs. Future research will assess EMA with a larger group of SDMs, utilizing questions that help identify gaps in communication and opportunities to provide support to SDMs. Although surrogates are often under high stress in the ICU setting, they are willing to provide real-time EMA feedback on their experiences. EMA can provide a "just in time" option for research and clinical intervention that focuses on bridging gaps that may contribute to better outcomes for SDMs.

SESSION 6110 (POSTER)

DEMENTIA CARE

THE RISK OF DEMENTIA AMONG INDIVIDUALS WITH DEPRESSION AFTER A TRAUMATIC BRAIN INJURY

Joan Ashby[1], Miriam Nuno[1], Beatrice Ugiliweneza[2], Maya Deshmukh[1], and Maxwell Boakye[3], *1. University of California, Davis/Davis, Davis, California, United States, 2. Univerisity of Louisville, Louisville, Kentucky, United States, 3. Univerisity of Louisville/Louisville, Louisville, Kentucky, United States*

Although traumatic brain injury (TBI) has been found to be associated with dementia and depression, large-scale studies of US non-Veteran populations are limited. This study assesses the role of depression on dementia risk after TBI. Data was analyzed from 80,423 individuals with TBI age 55+ in the IBM MarketScan Commercial Claims and Encounter Database and the Medicare Supplemental Database between January 1, 2000 and December 31, 2019. Dementia diagnosis was captured from inpatient or outpatient visits with a "wash out" period of one year. Depression was defined based on documented diagnosis and/or the prescription of antidepressants. The median age was 69 years, 51% female, with a majority covered by Medicaid (51%). 62% of TBIs were moderate/severe and 16% mild. 44,234 (55.1%) individuals were diagnosed with depression with a median of 2.1 months after TBI and 24.4 months prior to dementia. Depression rates differed by sex (female: 54%, male: 44%, $p< 0.0001$) and insurance (Commercial: 36%, Medicaid: 49%, $p< 0.0001$). The median time to dementia was 158 months. The median time to dementia was 128 months among those with depression, while patients without depression did not reach this estimate within 250 months of follow-up ($p< 0.0001$). The risk of dementia increased significantly over time after depression among patients with TBI. This study provides evidence to support that depression after TBI represents a symptom of TBI rather than a prodrome of dementia. Future research will investigate the role of depression in the risk of dementia by race/ethnicity, insurance status, and TBI severity.

DOES THE MICROBIOME INFLUENCE THE DEVELOPMENT OF DEMENTIA IN OLDER ADULTS?

Naomi Tesema, Kristen Wroblewski, Jayant Pinto, and Martha McClintock, *University of Chicago, Chicago, Illinois, United States*

Some data implicate microbes in the pathogenesis of Alzheimer's Disease and Related Dementias (ADRD). Whether the use of antibiotics predisposes to ADRD remains unknown. To investigate the relationship between antibiotics and subsequent cognitive function, we analyzed data from a longitudinal, nationally representative sample of older US adults (N=2,906, the National Social Life, Health and Aging Project). The use of antibiotic medications was collected by home interview at baseline. Five years later, cognition was assessed using a survey adapted version of the Montreal Cognitive Assessment (MoCA). Additionally, ADRD status was measured by a report of a physician's diagnosis (self or proxy). The association between baseline antibiotic use and an interval dementia diagnosis/MoCA scores was tested using multivariate logistic regression, controlling for age, sex, race and ethnicity, education, co-morbidities (modified Charlson Comorbidity Index), and cognition at baseline (Short Portable Mental Status Questionnaire). Older US adults who used antibiotics had lower MoCA-SA scores at 5-year follow-up (OR=3.94, 95% CI= 1.79-8.66). However, the use of antibiotics did not predict a subsequent diagnosis of dementia (OR=1.48, 95% CI= 0.44-4.95). Thus, antibiotic use may cause deleterious effects on cognitive function, but does not appear to have a clinical impact in terms of diagnosis of dementia. Further study of the role of microbes and drugs that modulate them may be useful in understanding ADRD.

TAI CHI OR CONVENTIONAL EXERCISE ON PHYSICAL PERFORMANCE, SLEEP, AND QUALITY OF LIFE IN OLDER PEOPLE WITH DEMENTIA

Ran Gao[1], Chieko Greiner[2], Hirochika Ryuno[3], and shuhong Gao[4], *1. Kobe University, Kobe, Hyogo, Japan, 2. Kobe University, Kobe-city, Hyogo, Japan, 3. Kobe University, Kobe city, Osaka, Japan, 4. Hainan nursing home, Haikou city, Hainan, China (People's Republic)*

Aims: This study was to compare the therapeutic efficacy of Tai chi and conventional exercise on physical performance, sleep efficiency and quality of life among older people with dementia.

Methods: Eighty-one elderly mild to moderate older people with dementia living in a nursing home in China were screened and randomized to three groups. The intervention groups received a 12-week Tai chi or conventional exercise intervention. Participants were assessed at baseline, week 6, and week 12 between December 2020 and July 2021. The primary outcome was short physical performance battery, secondary outcomes including the sleep efficiency and quality of life. Generalized estimating equations and one-way analysis of variance were the main statistical tests.

Results: The mean age was 80.7 (SD 7.7) years and 74.1% of participants were women. Analysis indicated that there was a significant difference in both intervention groups in short physical performance battery, sleep efficiency and quality of life relative to control from 0-12 weeks, and the Tai chi group had a substantial advantage over the conventional exercise group.

Conclusions: Tai chi and conventional exercise could improve physical performance, sleep efficiency and quality of life in older people with dementia. Furthermore, Tai chi could be a more effective approach to improve physical performance.

VALIDITY AND RELIABILITY OF THE ROWLAND UNIVERSAL DEMENTIA ASSESSMENT SCALE: IMPLICATIONS OF AN INDONESIAN STUDY

Renata Komalasari, and Elias Mpofu, *University of North Texas, Denton, Texas, United States*

Standardized dementia screening self-report assessments from developing countries are increasingly adopted in developing countries. Yet the cross-cultural transportability of dementia screening tools cannot be assumed. The Southeast Asia region has one of the fast-growing geriatric populations but no locally developed or validated measures of cognitive decline among older adults. This study aimed to determine the validity and reliability of scores from the Rowland Universal Dementia Assessment Scale (RUDAS) for use in the multiethnic older adult population in Indonesia. Participants were 135 Indonesian older adults (females = 61.5%, males = 38.5%; age range = 60-82) who were patients of a geriatric nursing centre. They completed the Indonesian translation of the Rowland Universal Dementia Assessment Scale (RUDAS-Ina). Exploratory factor analysis and confirmatory factor analysis of the scores yielded two factors explaining a total of 55.13% (the first factor explained 38.18%; the second factor explained 16.96%) of the variance for the entire set of variables. The reliability of scores from the RUDAS-Ina was marginally satisfactory (Cronbach α = .61), suggesting a need for locally developed measures for use with the Indonesian geriatric population. Future studies should consider the feasibility of developing and calibrating an adapted RUDAS to the Indonesian setting, which also may be studied in other Southeast Asian countries.

INCIDENCE AND ASSOCIATED FACTORS OF DEMENTIA IN PEOPLE WITH SCHIZOPHRENIA: A POPULATION-BASED COHORT STUDY

Yingyang Zhang, Pengcheng Wang, Jennifer Y.M. Tang, Gloria H.Y. Wong, and Hao Luo, *The University of Hong Kong, Hong Kong, Hong Kong*

Existing evidence suggests that people with schizophrenia may have an increased risk of dementia. This study aimed to quantify the incidence of dementia and examine putative risk factors associated with dementia in people with schizophrenia. This is a cohort study using population-based electronic health records of people who visited public hospitals in Hong Kong. We included participants (≥ 45 years) with schizophrenia diagnosis between 2009 to 2018 without dementia and followed them until March 2021. Incidence of dementia was calculated, and Cox proportional hazard regression was utilized to estimate hazard ratios of dementia, adjusting for covariates. A total of 20,901 individuals (mean [SD] age, 58.4 [10.3] years, 55.7% were women) were followed for 154,630 person-years (median [interquartile range] follow-up, 7.6 [4.7-10.3] years). The incidence of dementia was 5.1 [95% CI, 4.7-5.4] per 1000 person-years (those aged 45-64: 2.0 [1.8-2.3]; those 65 and above: 17.0 [15.6-18.5] per 1000 person-years). Factors independently associated with all-cause dementia were age (Hazard Ratio, 1.11 [95% CI, 1.10-1.11]), diabetes (1.62 [1.36-1.93]), bipolar disorders with at least five-year duration (2.12 [1.50-3.01]), and schizophrenia duration (1.02 [1.01-1.04]). Stratified analysis indicated that the association of these factors with dementia had differences in different sex and age groups. The incidence of dementia after schizophrenia diagnosis was high and two risk factors of dementia that are different from the well-established ones were identified.

PEOPLE LIVING WITH DEMENTIA GUIDED THE WAY: ADAPTIVE STAKEHOLDER ENGAGEMENT TO DESIGN A PRAGMATIC CLINICAL TRIAL

Michael Lepore, *University of Maryland School of Nursing, Baltimore, Maryland, United States*

Research on non-pharmacologic interventions for people living with dementia (PLWD) has shown many benefits, but healthcare systems do not offer these interventions widely. To strengthen understanding of the real-world effectiveness of evidence-based non-pharmacologic interventions for PLWD requires a pragmatic approach to trialing interventions in the contexts of healthcare systems where they are standardly delivered. Designing pragmatic trials with the engagement of primary stakeholders can support trial feasibility and meaningful outcome measurement, but little evidence is available on approaches for engaging PLWD in designing pragmatic trials. This longitudinal case study introduces adaptive stakeholder engagement, a three-phase approach to engaging PLWD in planning a pragmatic trial. First, a multistakeholder workshop including PLWD was held where participants prioritized topics for research, including research on the impact of increasing social activity. Second, an evidence-based non-pharmacological intervention that addresses this priority area was piloted with PLWD and qualitative feedback was collected from PLWD over the course of intervention piloting to inform the trial design. Finally, PLWD were engaged in facilitated monthly meetings to provide input on the pragmatic trial design. In addition to informing intervention selection, input collected from PLWD informed the pragmatic trial in several ways, including approaches to PLWD recruitment, disclosure of research to PLWD, and intervention orientation processes. The adaptive stakeholder engagement model involved PLWD in different roles, as workshop participants, intervention participants, and trial advisors. This model enabled PLWD to be engaged in priority setting, infrastructure development, and trial protocol design, and may be useful for researchers planning future pragmatic trials.

THE PRESCRIPTION DRUG LANDSCAPE OF ALZHEIMER'S DISEASE AND RELATED DEMENTIAS

Lauren Bangerter[1], Callahan Clark[2], Megan Jarvis[3], Emma Coates[4], Natalie Sheils[5], Alyssa Wong[4], and Ken Cohen[2], *1. United Health Group, Edina, Minnesota, United States, 2. United Health Group, Minnetonka, Minnesota, United States, 3. Optum Labs, Minnetonka, Minnesota, United States, 4. UnitedHealth Group, Minnetonka, Minnesota, United States, 5. United Health Group, Eden Prarie, Minnesota, United States*

Alzheimer's Disease and Related Dementias (ADRDs) are debilitating conditions that impact cognition and function of nearly 5 million adults in the U.S. This study describes the landscape of prescription drugs to treat cognitive and behavioral symptoms of ADRD among Medicare Advantage Part D enrollees with ADRD (Dementia, Alzheimer's Disease, Parkinson's, Frontotemporal Dementia, Lewy Body, Vascular Dementia, or Mild Cognitive Impairment). We assessed prevalence of prescription fills in the years pre- and post-ADRD diagnosis. Prescription fills to manage cognitive symptoms, were assessed by acetylcholinesterase inhibitors and NMDA receptor antagonists. Prescription fills to manage behavioral and psychological symptoms of dementia were assessed by antipsychotics, mood stabilizers and anticonvulsants, antidepressants, sedative-hypnotic z-drugs, and benzodiazepines. The final sample (N=161,368) consisted of 79.2% white, 62.2% female with median age 83 (IQR 77-89). Most drug fills increased from pre-diagnosis year to post diagnosis year including Acetylcholinesterase inhibitor (15.3% to 35.5%), NMDA Receptor Antagonists (5.8% to 16.6%), mood stabilizers and anticonvulsants (15.8% to 18.2%), and antidepressants (19.4% to 24.2%). Benzodiazepine use remained stable (13.0% to 13.6%) as did Sedative hypnotic z- drugs (1.9% 1.8%). Results reveal polypharmacy (median of 11 prescriptions post-ADRD diagnosis) and high healthcare utilization (median of 10 specialty types visited post-ADRD diagnosis). This study shows discrepancies between real-world pharmacologic ADRD management and evidence-based practices. This work highlights the need for innovative care models that simultaneously address polypharmacy and optimally coordinated care for people with ADRD.

DELIRIUM-LIKE BEHAVIORAL SYMPTOMATOLOGY IN COMMUNITY-DWELLING OLDER ADULTS WITH DEMENTIA

Jasmine Vickers[1], Danny Wang[2], and Carolyn Pickering[2], *1. University of Alabama at Birmingham, Birmingham, Alabama, United States, 2. The University of Alabama at Birmingham, Birmingham, Alabama, United States*

Delirium, a sudden and acute confusional state, is known to be more prevalent and deleterious in older adults with dementia; yet the literature on estimates of delirium in community-dwelling older adults with dementia is scarce. The aim of this study was to determine the patterns and frequency of delirium-like symptoms in community-dwelling older adults with dementia, as reported by their caregivers (n=50) in a 21-day diary study (n=1389 diaries). Caregiver reports of severity scores of care-recipient behaviors that were one standard deviation above the mean were considered outliers, representing a sudden and acute change. Caregivers that reported outlier scores for two consecutive days were considered delirium-like symptoms. Descriptive statistics were used to determine the number of caregivers who reported delirium-like symptoms and the percentage of days with symptoms present. Additionally, chi-square tests and Independent samples T-test were used to determine the associations between delirium-like symptoms and participant characteristics. Caregivers were predominately White/Caucasian (89%), female (94%), and a son/daughter (60%) of the care-recipient. Caregivers had an average age of 52.6 years and were caregiving an average of 3.9 years. The care-recipients had dementia for an average of 4.3 years. Caregivers reported delirium-like symptoms for 12(24%) care-recipients and this rate was consistent with previous research findings. Caregivers reported delirium-like symptoms, on average, for 6.9 days (33%) of the 21-day diary period. More research is needed to understand the occurrence and patterns of delirium in community-dwelling older adults with dementia to improve home care services, outpatient services, and support for caregivers.

UTILIZATION TRENDS OF GLUCOSE-LOWERING DRUGS FOR TYPE 2 DIABETES IN OLDER ADULTS WITH AND WITHOUT DEMENTIA

Chandrasekar Gopalakrishnan[1], Dae Kim[2], and Elisabetta Patorno[3], *1. Brigham and Women's Hosp./ Harvard Medical School, Boston, Massachusetts, United States, 2. Hebrew SeniorLife, Boston, Massachusetts, United States, 3. Brigham and Women's Hospital, Harvard Medical School, Boston, Massachusetts, United States*

Dementia is an important consideration in the therapeutic management of older adults with type 2 diabetes (T2D). Given the recent availability of numerous second-line therapeutic agents, there is limited evidence on uptake of these newer medications by dementia status. Using Medicare fee-for-service data from 2013-18, we identified a cohort of patients with T2D who initiated a glucose-lowering drug (N=3,355,725; mean [SD] age, 74.8 (6.9) years) and stratified our analysis based on the presence of a diagnosis for dementia in the year prior to treatment initiation. Amongst patients with dementia (N=511,835; mean [SD] age, 79.9 (7.7) years), metformin use remained stable from 25.8% to 24.8%, whereas sulfonylureas (20% to 17.5%) and insulin (31.8% to 26.2%) use declined. Amongst patients without dementia (N=2,843,890; mean [SD] age, 73.8 (6.3) years), metformin (31.7% to 24.7%), sulfonylurea (22.1% to 19.4%) and insulin use (18.7% to 14.6%) decreased. DPP-4i and glitazones use remained largely stable whereas the use of newer agents such as SGLT-2i and GLP-1 RA increased steadily in both patients with and without dementia though the uptake was much higher in patients without dementia. By the end of 2018, 19.6% of patients initiated either a SGLT-2i or a GLP-1 RA amongst those without dementia whereas only 11.1% did so amongst those with dementia. In conclusion, older medications such as metformin, sulfonylureas and insulin accounted for about two-thirds of initiated glucose-lowering medications and were more frequently used by patients with dementia, though their use declined steadily over time with the availability of newer agents.

QUALITY OF LIFE PREDICTS END-OF-LIFE CARE TRANSITIONS AMONGS PERSONS WITH DEMENTIA OVER NINE YEARS

Suzanne Sullivan, Chin-Shang Li, and Yu-Ping Chang,
University at Buffalo, Buffalo, New York, United States

Physical, financial, and emotional burdens are profound and affect the quality-of-life of persons with dementia (PWD) and their caregivers, particularly as cognitive decline accelerates and death approaches, which leads to burdensome, non-beneficial transitions in care that can lead to further decline of PWD. Measures of quality-of-life for PWD and their caregivers include important physical, psychological/cognitive, existential, caregiving burden, and socio-demographic factors that may be useful for predicting and preventing these end-of-life transitions. This secondary data analysis of the National Health and Aging and Trends Study (NHATS) linked to the National Study of Caregiving (NSOC) investigates the relationship between quality-of-life factors and end-of-life care transition (overnight hospitalization, hospice use, and place of death) over nine years (2011-2019) among caregiver/PWD dyads using multivariable logistic regression for hospice and place of death and multivariable logistic regression with generalized estimating equations for longitudinal overnight hospitalizations. Overnight hospitalizations are predicted by overall health (p=0.048), pain (p=0.016), and having a regular doctor (p=0.012). Predictors of hospice include health prevents enjoying life (p=0.0002) and receiving food stamps (p=0.008). Place of death is predicted by PWD needing >30 mins to fall asleep (p=0.007), dementia status (p=0.015), health preventing enjoying life (p=0.0005), race (p=0.033), and census division (p=0.012). End-of-life care transitions can be predicted far in advance by quality-of-life and socio-demographic factors of PWD and their caregivers. With this knowledge it may be possible to develop upstream interventions to facilitate appropriate transitions and improve end-of-life quality-of-life far in advance of avoidable care transitions of PWD.

ACCEPTABILITY OF A TAILORED MUSIC LISTENING INTERVENTION FOR SLEEP IN OLDER ADULTS WITH DEMENTIA

Sophia Geisser[1], Isabella Ciccone[1], Justine Sefcik[2], Nancy Hodgson[3], and Darina Petrovsky[1], *1. Rutgers, The State University of New Jersey, New Brunswick, New Jersey, United States, 2. Drexel University, Philadelphia, Pennsylvania, United States, 3. University of Pennsylvania, Philadelphia, Pennsylvania, United States*

There is a lack of non-pharmacological interventions aimed at improving sleep disturbances among persons living with dementia (PLWD). In this randomized clinical trial, we examined the acceptability of a tailored music listening intervention on sleep disturbances in PLWD. We recruited 33 PLWD age >60 and their care partners (‘dyad’); 30 dyads completed the study. Dyads were randomly assigned to a wait-list control or intervention group, which included listening to tailored sleep-inducing music 30 minutes every night for 4 weeks. Acceptability outcomes included a questionnaire of perceived benefits and satisfaction with study participation; and a single item examining the PLWD’s level of enjoyment while listening to music. In addition, we conducted semi-structured exit interviews. We used descriptive statistics and conventional content analysis to examine the qualitative data. Most PLWD and care partners identified themselves as female, Black and non-Hispanic. One third responded that the study benefited care partners (n=11, 36.7%) and helped improve PLWD quality of life (n=11, 37.9%). The majority (n=28, 93.3%) felt that this study was clearly explained to them, while a third felt that the study required too much work (n=10, 33.3%). Most dyads enjoyed listening to music that was selected for them (n=38, 93.3%) and reported that the intervention and music selection was acceptable. We identified four themes regarding the music selections: music was relaxing, enjoyable, promoted sleep, and brought back memories. Overall, this intervention shows promise for decreasing sleep disturbances among PLWD. Future studies involving music interventions for sleep should examine the mechanism of action.

ASSOCIATION OF HBA1C WITH BEHAVIORAL SYMPTOMS OF DEMENTIA IN VA NURSING HOME RESIDENTS WITH DIABETES (2013–2019)

Alexandra Lee[1], Ying Shi[2], Matthew Growdon[2], Kristine Yaffe[2], Kenneth Covinsky[2], and Sei Lee[2], *1. University of California, San Francisco, San Francisco, California, United States, 2. UCSF, San Francisco, California, United States*

For people with dementia, behavioral symptoms of dementia are often signs of distress and may be caused by pain, confusion, agitation, or negative moods. In people with diabetes, pain, confusion, and agitation may result from aspects of diabetes management, including poor glycemic control, episodes of very low or high blood sugar (hypo- and hyperglycemia), insulin injections, or fingerstick pricks to check blood glucose. Few studies have examined how diabetes control contributes to behavioral symptoms of dementia. We conducted a retrospective study in VA nursing home (NH) residents aged 65+ with both dementia and diabetes, and a NH stay>45 days. We used the second assessment of the Minimum Dataset (MDS 3.0) to identify behavioral symptoms of verbal or physical outbursts during the prior 7 days. We conducted mixed-effects logistic regression, with clustering by NH facility. The 5060 residents were overwhelmingly male (99%), had an average age of 78, with mean HbA1c was 7.1 (standard deviation 1.6). The overall prevalence of any behavioral symptoms was 16.7%. Compared to residents with HbA1c < 6%, behavioral symptoms were slightly more common among residents with HbA1c 6-7%, 7-8%, and >9%, but not statistically significantly different. Behavioral symptoms were significantly more common in residents with HbA1c 8-9% (prevalence 19.6%) than in residents with HbA1c < 6% (prevalence 15.5%; odd ratios adjusted for NH facility: 1.35, 95% confidence interval: 1.05-1.75). Additional research is needed to determine which aspects of diabetes management may be contributing to excess risk of behavioral symptoms of dementia.

COSTS OF DEMENTIA CARE AND EARLY-STAGE PREVENTIVE NURSING: A COMPARATIVE BIG DATA STUDY IN OSAKA

XUJING HU[1], Reiko Kanaya[2], Ryohei Yamamoto[1], Hiroshi Toki[3], Yasushi Takeya[1], and Miyae Yamakawa[1], *1. Osaka University, Suita, Osaka, Japan, 2. Osaka University, Osaka, Osaka, Japan, 3. Health and Counseling Center, Suita, Osaka, Japan*

Data show a substantial increase in the costs of dementia care nationally and globally. We assessed the factors increasing financial pressure, and found an association between the costs and the severity of dementia. We suggest that early diagnosis and preventive nursing care can reduce the deterioration associated with dementia, and therefore the overall costs of dementia care. The purpose of this study was to determine the relationship between the costs of dementia care and early-stage preventive nursing care in a sample of people with dementia aged 65 to 85 years, using the Medical Care Insurance and Osaka Prefecture Long-Term Care Insurance Database (N = 17973). We found that early care might have a significant effect on formal care costs in the early period of dementia but did not influence the medical care costs of dementia. During the first 5 years, the long-term care costs of people with dementia with an initial care level of Support 1/2 (one type of care level of Japanese long-term care insurance system, and the participants receive preventive services) were $4,389, while people with an initial care level of Care 1/2 (the other type of care level, and the participants receive nursing services) were $12,333. About 20% of people who received preventive care recovered, suggesting that preventive nursing care can restore the ability of people with early-stage dementia. This might be the reason for the reduction in long-term care costs. This research provides a basis for supporting preventive nursing care and extending healthy lifespans.

PAIN IN PERSONS WITH DEMENTIA AND APATHY IN NURSING HOMES

Yo-Jen Liao[1], and Ying-Ling Jao[2], *1. Pennsylvania State University, Pennsylvania State University, Pennsylvania, United States, 2. Pennsylvania State University, University Park, Pennsylvania, United States*

Apathy and pain commonly occur in persons with dementia and significantly impact their quality of life. However, communication barriers in persons with dementia make pain assessment challenging. Apathy further complicates pain management in dementia due to decreased facial expression and verbal communication. This study aims to examine pain management in persons with dementia and apathy. This descriptive study included 13 residents with dementia and apathy from two nursing homes in Pennsylvania. Data on pain, pain-related diagnoses, and treatments were extracted from medical records. Participants' mean age was 90 years old, and their mean apathy level was 54.6. All 13 participants had pain-related diagnoses with an average of 3.1 pain-related diagnoses (range=1-7). Four participants (30.7%) had pain reported in their medical records with osteoarthritis being the most common diagnosis (38.5%). Eight participants (61.5%) had pain-related diagnoses but did not have regular pain medication administered, and 3 of them (37.5%) had pain reported. In addition, five participants had one or more acute pain-related diagnoses, including surgery, fractures, and falls, and only 2 (40%) of them had pain reported. The average number of prescribed pain medications was 0.4 and 1.1 for regularly administered and as-needed medications, respectively. Acetaminophen was the most common administered medication. Overall, the results pointed out the potential issue that pain may be underrecognized and undermanaged in this population. More research is needed to examine the pain assessment and treatment in this population to promote pain management in persons with dementia and apathy.

REJECTION OF CARE AND AGGRESSION AMONG OLDER VETERANS WITH DEMENTIA WITH AND WITHOUT POSTTRAUMATIC STRESS DISORDER

Bada Kang[1], Wei Pan[2], Michele Karel[3], Kirsten Corazzini[4], and Eleanor McConnell[2], *1. Yonsei University, Seoul, Seoul-t'ukpyolsi, Republic of Korea, 2. Duke University, Durham, North Carolina, United States, 3. VA Central Office, Washington, Washington, United States, 4. University of New Hampshire, Durham, New Hampshire, United States*

Veterans with co-occurring dementia and posttraumatic stress disorder (PTSD) living in residential long-term care encounter a range of physical and social stimuli, which may trigger trauma-related distress that can be exacerbated and manifested with care rejection and aggression. Yet, it is largely unknown how PTSD influences manifestation of care rejection and aggression in older veterans with dementia. Guided by the need-driven dementia-compromised model, this study examined the moderation effect of PTSD on pathways from background factors, and interpersonal triggers to care rejection and aggression among veterans with dementia with and without co-occurring PTSD. In this secondary analysis study, a multi-group structural equation modeling was conducted using program evaluation data of 315 veterans with dementia from the STAR-VA behavioral intervention implemented in 76 Veterans Health Administration-operated nursing homes. Although no moderation effect of PTSD on the overall model was found, findings revealed distinct patterns of relationships among background factors, interpersonal triggers, and care rejection and aggression between veterans with dementia with and without PTSD. The magnitude of the direct effects of interpersonal triggers on care rejection was greater in veterans with PTSD. Findings on the indirect effect of depression via interpersonal triggers on care rejection and direct effect of functional status on aggression only in veterans with PTSD implies that different mechanisms may underlie distressed behavior depending upon whether or not a veteran has PTSD. This study also underscores the importance of an enhanced focus on trauma-informed care, and individualized multi-component symptom management approach for veterans with dementia and PTSD.

USE OF HIGH COST CARE AMONG VETERANS WITH COMORBID MENTAL ILLNESS AND ALZHEIMER'S DISEASE AND RELATED DEMENTIAS

Katherine Miller[1], and Megan Shepherd-Banigan[2], *1. University of Pennsylvania, Durham, Pennsylvania, United States, 2. Durham VA Medical Center, Durham, North Carolina, United States*

As Vietnam-era Veterans age, VA faces a growing need to manage aging-related conditions, such as Alzheimer's disease and other dementia (ADRD), for this complex patient population. ADRD is of particular concern as military related factors, such as psychiatric illnesses, increase ADRD likelihood and complicate care management. In particular, decreasing use of low value care (e.g., emergency department (ED) care) is one approach to promote appropriate supportive care for Veterans with comorbid ADRD and psychiatric illness, but is understudied. We describe differences in potentially low value health care among older Veterans with ADRD 12 months after a new ADRD diagnosis. We compare Veterans with mental illness (MI) pre-ADRD diagnosis (major depressive disorder, post-traumatic stress disorder, or generalized anxiety disorder) to those without pre-existing MI. Potentially low value care includes ED use, hospitalization, and 30-day readmissions 12 months after a new ADRD diagnosis. Compared to Veterans with no pre-existing MI, Veterans with pre-existing MI are more likely to be younger (79 vs. 82 years old), male, married, White, Hispanic. In the year after new ADRD diagnosis, 16.9%, 21.6% and 2.6% of Veterans with MI had any ED visit, hospitalization, and 30-day readmission, respectively. In contrast, only 7.3%, 9.5%, and 0.9% of Veterans without pre-existing MI had any ED visit, hospitalization, and 30-day readmission, respectively. Our findings suggest that reducing low-value care may be an appropriate intervention target to improve care quality for Veterans with ADRD and mental illness.

DIFFERENCES IN NEUROPSYCHIATRIC SYMPTOMS AMONG RACIAL AND ETHNIC GROUPS LIVING WITH DEMENTIA IN HOME HEALTHCARE

Rebecca Lassell[1], Kimberly Convery[1], Jason Fletcher[1], Tracy Chippendale[1], Shih-Yin Lin[1], Tessa Jones[1], Aditi Durga[1], and Abraham Brody[2], *1. New York University, New York, New York, United States, 2. HIGN at the NYU Rory Meyers College of Nursing, New York, New York, United States*

The relationship between dementia and neuropsychiatric symptoms is well documented. Yet, little is known about the prevalence of neuropsychiatric symptoms among diverse homebound persons living with dementia. Guided by an intersectionality framework we asked: 1) Is there an association between the presence of individual neuropsychiatric symptoms and racial and ethnic groups? 2) If so, do these symptoms differ by dementia stage among groups? We conducted a cross-sectional study of n=190 receiving skilled home healthcare in Utah, New York, and New Jersey and enrolled in the DSM-H trial. We prospectively measured symptom prevalence with the Neuropsychiatric Inventory Questionnaire and dementia stage using the Quick Dementia Rating System. We performed Chi-square tests to determine the association of individual symptom prevalence with race and ethnicity and cross tabs to descriptively stratify individual symptom prevalence by dementia stage among groups. Participants were 11.9% Hispanic, 28% non-Hispanic Black, 56.1% non-Hispanic white (white). The prevalence of delusions was significantly higher in Hispanic and non-Hispanic Black groups than whites (41.7% & 41.8% vs. 22.5%) and elation/euphoria in Hispanic and non-Hispanic Black groups than whites (20.8% &12.7% vs. 5.4%). Delusions were most prevalent in non-Hispanic Black groups with mild dementia (53.8%) and Hispanics with moderate dementia (50.1%), while elation/euphoria was most prevalent for Hispanics with severe dementia (33.3%). Other neuropsychiatric symptoms showed no significant differences. These findings expand our knowledge of differences in neuropsychiatric symptoms among racial and ethnic persons living with dementia, which can inform future studies and targeted interventions that address disparities and improve care.

DEMENTIA CARE IN THE LAST YEAR OF LIFE: EXPERIENCES IN A COMMUNITY PRACTICE

Mairead Bartley[1], Jennifer Manggaard[2], Karen Fischer[2], Diane Holland[2], and Paul Takahashi[2], *1. Mayo Clinic Rochester, Rochester, Minnesota, United States, 2. Mayo Clinic, Rochester, Minnesota, United States*

Objectives: People with dementia often have high care needs at end of life. We compared care delivery in the last year of life for people living with dementia in the community (home/assisted living facilities, ALF) to those in skilled nursing facilities (SNF).

Methods: This was a retrospective study of people who died with a diagnosis of dementia in the community compared with SNF between 2013 and 2018. Primary outcomes of hospitalizations/ED visits in the last year of life were measured. Secondary outcomes included advance care planning (ACP) completion, hospice enrollment, provider visits and ICU admissions.

Results: Of 1203 people with dementia, 581 (48.3%) were living in a SNF and 622 (51.7%) in the home/ALF. At least one hospitalization was recorded for 70.7% in the home/ALF compared with 50.8% in the SNF ($p< 0.01$), similar to ED visits (80.2% versus 58% in home/ALF and SNF groups, respectively, $p< 0.01$). People in the SNF had more provider visits (median 9 (IQR 6, 12) compared with 5 (IQR 3,9) in the home/ALF group ($p< 0.01$). There was no ACP for

12% of those in the home/ALF, compared with 4.6% in the SNF(p< 0.01). Approximately half (56.5%) in the SNF were enrolled in hospice compared with 68.3% in the home/ALF group (p< 0.01), Median time in hospice was 26.5 days in the SNF versus 30 days in the home/ALF (p=0.67).

Conclusions: People living with dementia have frequent acute care utilization in the last year of life. Hospice care was more common in the home/ALF. Time in hospice was short.

DEMENTIA AND THE ROLE OF EVIDENCE-BASED GUIDELINES IN PRIMARY CARE: RESULTS OF A CLUSTER RANDOMIZED CONTROLLED TRIAL

Sonia Lech[1], Julie L. O'Sullivan[2], Robert P. Spang[3], Jan-Niklas Voigt-Antons[4], Paul Gellert[1], and Johanna Nordheim[1], *1. Charité – Universitätsmedizin Berlin, Berlin, Berlin, Germany, 2. Charité-Universitätsmedizin Berlin, Berlin, Berlin, Germany, 3. Technische Universität Berlin, Berlin, Berlin, Germany, 4. University of Applied Sciences Hamm-Lippstadt, Hamm, Nordrhein-Westfalen, Germany*

General practitioners (GPs) play a key role in the care of people with dementia (PwD). However, the potentials of evidence-based dementia guidelines in primary care remain unclear. The main objective of the present study was to examine the role of guideline-based dementia care in general practices and to evaluate the effectiveness of a tablet-based intervention aiming at improving guideline-based care. A two arm, cluster-randomized controlled trial (cRCT) with an intervention group (tablet-based intervention) and a control group (treatment as usual) was conducted from April 15, 2018, to July 31, 2021, in Berlin and the surrounding area. Primary outcome was defined as adherence to dementia guideline recommendations after 9 months. Secondary outcomes included various health outcomes assessed in PwD (e.g., quality of life). Linear Mixed Models were used to analyse cross sectional baseline data. Primary and secondary outcomes were analysed by intention-to-treat analysis and using Mixed Models. Data of N = 28 GPs and N = 91 PwD was analysed. PwD were on average 80.5 years old (SD = 6.3), 59% were female. Self-reported overall guideline adherence of GPs was on average 71% (SD = 19.4, range: 25–100). Further, lower guideline adherence was found to be significantly associated with higher numbers of patients ($\gamma 10 = -5.58$, CI = – 10.97, – 0.19, p = .04). The effectiveness of the cRCT is still under evaluation. Final results will be presented and discussed at the GSA Annual Scientific Meeting. Further, implications and conclusions of the trial will be provided.

FORECASTING PREVALENCE AND MORTALITY OF ALZHEIMER'S DISEASE AND RELATED DEMENTIAS USING PARTITIONING MODELS

Igor Akushevich[1], Arseniy Yashkin[1], Mikhail Kovtun[2], Julia Kravchenko[3], Konstantin Arbeev[1], and Anatoliy Yashin[1], *1. Duke University, Durham, North Carolina, United States, 2. Duke university, Durham, North Carolina, United States, 3. Duke University School of Medicine, Durham, North Carolina, United States*

A forecasting model for prevalence and mortality based on a trend partitioning approach which models trends in age-adjusted prevalence and incidence-based mortality in terms of changes in interpretable epidemiologic quantities such as disease incidence and survival, is developed and applied to generate forecasts of Alzheimer's disease (AD) and related dementia (ADRD) prevalence and mortality up to 2035 using health data drawn from a 5% sample of the total Medicare population. Forecasts are generated for entire AD population and for unique subgroups characterized by age groups and the presence of high-impact health conditions (stroke, traumatic brain injury, pneumonia, hypertension, diabetes) prior to AD diagnosis. Then methodology using B-splines in key time points allows is used to analyze scenarios of possible interventions focused on the prevention and treatment of AD/ADRD. Prevalence of AD/ADRD is predicted to be stable between 2017 and 2035 primarily due to a decline in prevalence of pre-AD/ADRD-diagnosis stroke. Mortality, on the other hand, is predicted to increase. In all cases the resulting patterns come from a trade-off of two disadvantageous processes: increased incidence and disimproving survival. The projections are constructed with the assumption that future trends represent a superposition of historic trends in different time periods taken with weights. Sensitivity to assumptions on choice of specific weights are studied, and the approach to choose an optimal combination of weights and therefore, to minimize uncertainties of future forecasts of AD/ADRD prevalence and mortality is suggested and discussed.

SESSION 6120 (POSTER)

DIVERSITY, EQUITY, INCLUSION, AND ACCESSIBILITY

RETURN MIGRATION AND AGING OF JAPANESE INDIVIDUALS LIVING IN GREATER NEW YORK: A QUANTITATIVE ANALYSIS

Itsuko Toyama[1], and Taeko Nakashima[2], *1. St. Andrew's University, Izumi City, Osaka, Japan, 2. Nihon Fukushi University, Handa-city, Aichi, Japan*

Our previous quantitative research studies have revealed that large numbers of older Japanese individuals living in overseas communities either maintain hope of receiving culture-oriented care or harbor aspirations of returning to Japan to live out their final days. Presently, by analyzing a quantitative research study on older Japanese individuals living in Greater New York in 2018, we clarify the characteristics of those individuals who have decided to return to Japan. In the research study, 2,057 questionnaires were distributed, and the overall return rate was 29.7%. Respondents were divided into three groups based on their answers regarding their intentions for the location of their final abode: the United States, Japan, or indecisive. We performed a multinomial logistic regression analysis based on age, gender, immigration status, having children in the United States, and academic background. The following is a summary of the findings: (1) as participants aged, the ratio of selecting either "Japan" or "indecisive" as opposed to "the United States" decreased, (2) compared to those holding citizenship, individuals with permanent residence selected both "Japan" and "indecisive" at greater rates (by approximately 3 times and 8.7 times, respectively); (3) compared to those having children in the United States, individuals without children in the United States selected both

"Japan" and "indecisive" at greater rates (by approximately 1.8 times and 2.2 times, respectively); (4) individuals with a graduate career displayed a tendency to select "the United States," and (5) gender and language proficiency were not critical attributes in determining the likelihood of selecting "Japan."

BUILDING CAPACITY FOR PATIENT-CENTERED OUTCOMES RESEARCH IN THE AGING RESEARCH COMMUNITY

Taylor Gray[1], Sophia Webber[2], and Erin McGaffigan[3], *1. UMass Boston, Waltham, Massachusetts, United States, 2. University of Wisconsin- Madison, Madison, Wisconsin, United States, 3. UMASS Boston Gerontology Institute, North Reading, Massachusetts, United States*

Patient-centered outcomes research (PCOR) models are increasingly used to ensure stakeholders inform evidence-based systems of care. Unfortunately, older adults, especially those of low income, frailty, and color, are often left out of PCOR, leading to continued health and service disparities. The Aging PCOR Learning Collaborative was funded by the Patient-Centered Outcomes Research Institute in 2020 to conduct a series of multi-media education, training, and mentoring activities to change how older adults are viewed and engaged in research. This project was strongly guided by multiple advisory structures, including two stakeholder advisory boards, two older adult paid advisors, and two student advisors, all of whom assumed an integral role in the design and implementation of project activities, dissemination of products, and analysis and reporting of evaluation methods. Project staff applied a multi-domain evaluation framework to analyze data relevant to these activities, which demonstrated the effective role of advisory structures and the project's reach to over 300 older adults, researchers, funders, and academic leaders. This session will review the steps required to implement these activities as well as our project reach, outputs, and mid-term outcomes, providing one of the first glimpses into how to measure this significant shift in research paradigm.

THE RELATIONSHIP BETWEEN HEALTHCARE STEREOTYPE THREAT AND ADVANCE CARE PLANNING AMONG HISPANIC PATIENTS

Valeria Cardenas[1], Aaron Storms[2], Sindy Lomeli[3], Carin van Zyl[4], and Susan Enguidanos[3], *1. University of Southern California, San Diego , California, United States, 2. Keck School of Medicine of USC, Los Angeles, California, United States, 3. University of Southern California, Los Angeles, California, United States, 4. USC, Los Angeles, California, United States*

Experiencing ethnic/racial stereotype threat, the psychological experience of confronting stereotypes in the healthcare system, has been found to negatively impact healthcare outcomes (e.g. dissatisfaction with healthcare, poorer mental and physical health, higher physician distrust). Few studies have examined healthcare stereotype threat among Hispanics, and no study has tested how it might impact advance care planning outcomes among Hispanic hospitalized patients. This study aims to examine the relationship between healthcare stereotype threat and advance care planning activities among Hispanic hospitalized patients. We analyzed secondary data collected from a feasibility study of a palliative care educational intervention among 50 Spanish-speaking, Hispanic patients, over the age of 40, who were hospitalized in a large public hospital. Fifty percent had discussed future care if they were to become seriously ill, 18% had written instructions about their care (living will or advance directive), and 32% had a durable power of attorney (proxy) for healthcare. Results of logistic regressions revealed that greater healthcare stereotype threat scores were associated with lower odds of having discussed future care or medical treatment with others (OR=0.49, p=.03). However, healthcare stereotype threat scores were not associated with having provided written instructions about future medical care (OR=0.44; p=0.07), or with having a durable power of attorney for healthcare (OR=0.89; p=0.76). Future research should investigate ways to improve the cultural sensitivity in broaching discussions of future medical treatment among seriously ill patients. Additionally, more research and attention to policy implication are needed to reduce racial stereotype threat experienced in the healthcare system.

EXPERIENCE OF UNFAIR TREATMENT IN HEALTHCARE SETTING AND RELATED STRESS AMONG OLDER AMERICANS: RACIAL/ETHNIC GAPS

Eun-Hye Yi[1], Michin Hong[2], and Cherish Bolton[1], *1. Indiana State University, Terre Haute, Indiana, United States, 2. Indiana University, Indianapolis, Indiana, United States*

Guided by the intersectionality framework, this study examined the experience of unfair treatment in healthcare settings over lifetime and related stress. A subsample drawn from the California Health and Interview Survey 2017, including residents age 55 or higher, was used (N=12,261). Significant differences existed in unfair treatment and corresponding stress among racial/ethnic groups, including Whites, African Americans (AA), Hispanics, and Asian Americans (AS). Using weighted chi-square tests, we found that most Whites (75.99%) never experienced unfair treatment, while around 60% of AA answered never. Whites tended to feel extreme stress more when mistreated (23.47%) than Hispanics (14.83%) and AS (15.69%). Weighted logistic regression analyses revealed that younger older adults with lower mental health were more likely to experience unfair treatment across all race/ethnic groups. Intersectional factors contributing to unfair treatment experience were identified for each race/ethnic group. Being a female, living in poverty, poor health, being a naturalized citizen, and living in an urban area were factors for Whites while having higher education was a factor for AA. Mental health was associated with extreme stress for the unfair treatment in all racial/ethnic groups. Different contributors to the stress were found by race/ethnicity. Gender, poverty, citizenship, and length of staying in the U.S. were significant for Whites. For AA, poverty, healthcare insurance, and obesity were significant, and for AS, physical health and obesity were. This study highlights the importance of culturally/ethnically sensitive approaches shaping interventions and policies to enhance awareness about unfair treatment and preventing discrimination toward diverse older adults.

RACIAL DISCRIMINATION IN HEALTHCARE SETTINGS OF OLDER ADULTS: SUBJECTIVE REASONS AND CONTRIBUTORS

Eun-Hye Yi[1], Michin Hong[2], and Cherish Bolton[1], *1. Indiana State University, Terre Haute, Indiana, United States, 2. Indiana University, Indianapolis, Indiana, United States*

Racism is prevalent in the United States; however, literature exploring racial discrimination experienced by older adults is still limited. The current study examined subjective reasons for discrimination and compared race/ethnic groups. Then, we examined the contributors to racial discrimination in healthcare settings. An older adult sample aged 55 or higher was drawn from California Health and Interview Survey 2017 for analysis (N=12,261). African Americans were the highest (13.06%) among five racial-ethnic groups who reported racial discrimination experienced in a lifetime in getting medical care, while Whites were the lowest (1.57%). Perceived reasons for discrimination were significantly different by racial/ethnic group. Only 3.5% of Whites perceived they were discriminated against due to their race, whereas racial/ethnic minorities perceived the main reason for discrimination was their race/skin color (African American: 55.43%, Others: 24.06%, Asian Americans: 20.26%, Hispanics: 18.22%). The weighted logistic regression analyses revealed that being a racial/ethnic minority, economic status, mental health status, citizenship, the length of living in the United States, and age were significantly associated with the experience of racial discrimination of older people. Analyses by race/ethnic groups found different contributors. For example, poverty was the most prominent factor in racial discrimination for Whites, while education was for African Americans. This study identified an apparent gap in lifetime discrimination toward racial/ethnic minority older people. Also, we found racial discrimination experience combined with systematic barriers. The findings of this study support the need for interventions for race/ethnicity-based trauma of older people and anti-racism framework education for healthcare professionals and researchers.

FORMAL AND INFORMAL VOLUNTEERING AMONG OLDER ADULTS: ASSOCIATIONS WITH HEALTH OUTCOMES ACROSS SEXUAL ORIENTATIONS

Joseph Frey[1], Huei-Wern Shen[1], and Yi Wang[2], *1. University of North Texas, Denton, Texas, United States, 2. University of Iowa, Iowa City, Iowa, United States*

Volunteering is associated with positive physical and mental health outcomes among older adults. However, little is known about the impact of volunteering on health among older lesbian, gay, and bisexual (LGB) Americans. Using nationally representative 2016 Health and Retirement Study data, the present study explored associations between volunteering and health outcomes (i.e., self-rated health, current memory rating) across sexual orientations among older Americans. Two types of volunteering were considered in the study—formal volunteering (doing unpaid work for religious, educational, health-related, or other charitable organizations) and informal volunteering (providing unpaid help to friends, neighbors, or relatives who do not co-reside). We included 235 (5.7%) respondents who self-identified as LGB or something else, and 3,894 (94.3%) heterosexual-identified respondents. Controlling for health-related variables (e.g., ADLs/IADLs), SES (e.g., income), contextual features (e.g., urban/rural), and sociodemographics (e.g., age, gender, race), results from eight stratified OLS regression models showed that for heterosexual-identified older adults, both formal and informal volunteering promoted self-rated health ($p<.001$, respectively) and memory rating ($p<.001$, respectively). However, for LGB-identified older adults, only informal volunteering was detected to increase memory rating ($p<.038$). Findings suggest that the well-documented health benefits of formal volunteering may not be supported in the LGB population. The current theoretical model and discourse about productive aging should be modified to be more inclusive with respect to sexual orientation. Further research identifying the pathways (e.g., identity-related stigmatization and discrimination) between various types of volunteering and health outcomes among older LGB adults is urged and possible directions will be discussed.

BARRIERS TO VACCINE UPTAKE IDENTIFIED BY COMMUNITY-BASED ORGANIZATIONS FOR INSITUTIONALLY UNDERSERVED GROUPS

Tracy Wharton[1], Emily Costello[2], Vincent Lafronza[3], and Oscar Espinosa[3], *1. National Network of Public Health Institutes, Kensington, Maryland, United States, 2. National Network of Public Health Institutes, Atlanta, Georgia, United States, 3. National Network of Public Health Institutes, Washington, District of Columbia, United States*

Through a competitive proposal process for a recent funding opportunity, 38 community based organizations submitted proposals that addressed vaccine hesitancy among adults who are members of racial or ethnic minority communities. Proposals were required to include discussion of barriers identified in the community of focus and evidence to support all assertions. Submissions ranged from single employee projects to large collaborative networks, and were submitted from all regions of the US, including both tribal and territorial areas, including more than 45 ethnic and language groups. Barriers were coded by two reviewers and six (6) primary themes were identified: access related to transportation, distance, or time; lack of culturally responsive materials or sensitivity of providers; structural issues such as poor data collection, historical inequity, mistrust, or systemic racism; messages coming from untrusted sources; misinformation or no information available; and differing cultural perspectives. The most commonly identified issues were related to mistrust, historical structural issues or fear and racism (n=23), and lack of access due to transportation, distance, or time (n=17). This group of proposals for funding represent a small cross-section of communities who continue to have significant pockets of unvaccinated persons. While it is possible to see themes for barriers that are encountered in increasing vaccination rates among adults, communities demonstrate extremely nuanced realities, filtered through a range of culturally and paradigmatically different ways of knowing. Success in public health initiatives requires intensive focus on the variance across these different perspectives and careful attention to appropriately focus outreach and messaging.

EMBRACING GENDER DIVERSITY: REIMAGINING HEALTH AND HEALTH EQUITY FOR TRANSGENDER OLDER ADULTS

Teri Kennedy[1], Courtney Marsh[2], Quinnlyn Walcott[1], Paddy Qiu[3], Angela Li[1], and Sally Maliski[1], *1. The University of Kansas Medical Center, Kansas City, Kansas, United States, 2. The University of Kansas Medical Center, Overland Park, Kansas, United States, 3. The University of Kansas, Lawrence, Kansas, United States*

This presentation will share results of in-depth focus groups exploring eight transgender older adults' (TOAs) experiences of health and healthcare and related themes, explain weathering and factors contributing to health and healthcare disparities, and apply the Sexual and Gender Minority Health Disparities Research Framework to explore strategies to address individual, interpersonal, community, and societal factors to foster health and health equity. TOAs represent an underserved population at elevated risk for lower socioeconomic status, higher rates of disability and chronic illness, and poorer overall physical and mental health compared to their non-transgender LGBQ and cisgender peers. Due to their unique life experiences including difficult decisions about "coming out" and transitioning, lack of acceptance of being transgender, and physiological impacts of hormonal and surgical treatments, transgender individuals experience long-term chronic stress and accumulate health-related risks as they age, contributing to significant health disparities. Higher levels of illness, disability, and premature death among historically disadvantaged groups can be explained by weathering, the accumulated impact of social disadvantages and socio-political inequalities over the life course producing premature biological aging. A 2019 systematic review of LGBTQ aging literature found that only 10% of studies included trans-identified participants and few addressed the needs of transgender older adults. Understanding the lived experiences of TOAs including healthcare access and receipt, and psychological, social, and financial experiences across the life course, is crucial to understanding current disparities in health and healthcare, developing strategies to improve care and reduce inequities, and fostering health and health equity of transgender older adults.

EFFECTIVENESS OF A HUMAN RIGHTS–BASED APPROACH ONLINE PROGRAM FOR GERONTOLOGICAL SOCIAL WORKERS

Minhong Lee[1], An Sok[2], and Kyeongmo Kim[3], *1. Dong-eui University, Busan, Pusan-jikhalsi, Republic of Korea, 2. Daegu University, Gyeongsan City, Kyongsang-bukto, Republic of Korea, 3. Virginia Commonwealth University, Richmond, Virginia, United States*

The human rights perspective is emphasized through the social work code of ethics and practice principles. However, the efforts to improve the human rights perspective of social workers were insufficient in gerontological social work education in South Korea. Thus, the study aimed to prove the effects of a human rights-based approach intervention for gerontological social workers, which consisted of nine online sessions using Zoom. PI developed the program based on McPherson's integrated framework for Human Rights Practice in Social Work. A quasi-experimental design was used. The experimental group consisted of 36 social workers, and the control group was 31 social workers at senior centers. The pre-post tests for the experimental group and posttest for the control group were conducted. The sociodemographic characteristics of the two groups were equivalent. The key measure was the Human Rights Lens in Social Work (HRLSW) scale consisting of two sub-dimensions: social problems as rights violations and clients as experiencing rights violations.The effect sizes of the online program's effects on the social worker's rights-based perspective were large over .90. In addition, the degrees two dimensions of the HRLSW at the posttest were significantly higher than those of the control group (social problems as rights violations: $d = 1.04$, $p < .001$; clients as experiencing rights violations: $d=0.98$, $p<.001$). Based on the findings of this study, the implications of human rights education and training were discussed to improve the human rights-based perspective of gerontological social workers.

SESSION 6130 (POSTER)

EDUCATION AND TRAINING

AGEISM, CONTACT, AND OLDER ADULT ADLS RELATE TO MENTAL HEALTH TRAINEES' INTEREST IN GEROPSYCHOLOGY

Grace I. L. Caskie[1], Abigail Voelkner[1], MaryAnn Sutton[2], Anastasia Canell[3], and Eve Root[1], *1. Lehigh University, Bethlehem, Pennsylvania, United States, 2. UPMC Psychological Associates, Harrisburg, Pennsylvania, United States, 3. Lehigh University, Mineola, New York, United States*

Despite growing demand, few mental healthcare professionals specialize in clinical work with older adults. A better understanding of factors related to geropsychology interest may increase the pipeline of future geropsychologists. Graduate-level trainees (N=460; 67.4% doctoral; age=21-64) completed the Fraboni Scale of Ageism, Contact with Older Adults Scale, six indicators of interest in work with older adults, and an imagined "typical" older adult's ability to complete activities of daily living (ADLs). 60% imagined full ADL independence. Between 14.1%-25.7% expressed strong interest in education/training related to treating older adults and having some older adult clients; only 6.7% planned to specialize in clinical work with older adults. In regression analyses (R-squared=16%-32%), more ageist attitudes, less contact, and being a master's trainee were related to less interest. ADL status was significant only for interest in specialization; imagining more ADL-dependence related to higher interest in specializing in older adults. ADL status significantly moderated the relation of contact to interest in learning about issues related to older adults; ADL-based differences in interest were non-significant at low and average contact, but at high contact, interest in learning about older adults was significantly higher when the older adult was imagined as ADL-dependent rather than ADL-independent. Findings may indicate benevolent ageism partially motivates trainees' interest in learning about/working with older adults whom they imagine need more help with basic tasks of daily living. Increasing contact, reducing ageist attitudes, and providing more clinical opportunities with older adults may facilitate trainees' readiness and interest in future clinical work with older adults.

ACCEPTABILITY AND FEASIBILITY OF A CAREGIVER FINANCIAL PREPAREDNESS PROGRAM

Lauren Stratton[1], Claire Grant[2], Monica Moreno[1], Kerry Lanigan[1], Katherine Judge[3], and Sam Fazio[1], *1. Alzheimer's Association, Chicago, Illinois, United States, 2. Cleveland State University, Cleveland Heights, Ohio, United States, 3. Cleveland State University, Cleveland, Ohio, United States*

Caregivers are often financially impacted, through health care costs, long-term care costs, and decreased income. A financial literacy program, Managing Money: A Caregiver's Guide to Finances, was developed to provide information on financial impacts in caregiving. The virtual program was delivered synchronously with a live presenter through an online platform and was rated with high acceptability. The virtual program was then shifted to an online format. Changes included removing the live presenter and group format in favor of a voiceover and self-paced movement, the addition of videos, and online resources. The asynchronous, self-paced online delivery of the program was evaluated through a survey of 146 caregivers. Participants had a mean age of 45.85 (SD=5.65); 55% female; 75% White; 46% cared for their grandparent and 45% to their parent. A Likert scale was utilized to indicate satisfaction with the program (1=strongly disagree, 5=strongly agree). Overall, participants indicated that the program provided important information on managing money (M=3.97, SD=.83); helped to understand the content (M=3.89, SD=.91); was easy to read and understand (M=3.99, SD=.90); and would recommend the program (M=3.91, SD=.84). The explanation of content areas were rated on a Likert scale (1=poor, 4=excellent); participants rated areas including having conversations about finances (M=3.05, SD=.80); avoiding financial fraud and abuse (M=2.98, SD=.81); covering care costs (M=2.98, SD=.81); and organizing legal plans (M=3.09, SD=.80). Participants reported no difficulties that needed to be resolved when moving through the program. Overall, both the virtual and online formats were acceptable and feasible to caregiving populations.

EXPLORING HEALTHCARE WORKERS' GERIATRIC EDUCATION AND SUBSEQUENT COMMUNICATION WITH OLDER ADULTS

Tina McQuaid, *University of Guelph, Mississauga, Ontario, Canada*

Research shows that older adults are living longer than ever, are the fastest growing population, and can have increasingly complex health-related issues. However, the health knowledge and literacy of older adults can be limited, and these adults may have difficulty understanding the terminology that healthcare workers use to communicate with them about their health. For impoverished older adults especially, this can contribute to poor health decisions and decreased care. Given this, educating healthcare practitioners to communicate effectively with older adults becomes essential to older patients' quality of care. Using predominantly North American studies of healthcare workers' practices, education, and their interactions with older adults (aged 65-85, primarily), this review paper finds that: i) older adults are responsible for their communication with healthcare workers, but practitioners, because of their implied authority, control the narrative, and therefore it is necessary for them to become more educated in communicating with older adults; ii) some current communication practices by healthcare workers (with older adults) are not reflective of sufficient care; and iii) new gerontology education can foster increased empathy and shared communication practices among healthcare workers, and this can aid patients to better control and have confidence in their healthcare decisions. Social and cultural factors that may explain the health literacy divide in older adults are discussed, as are recommendations and best practices for healthcare workers working with older adults.

EDUCATIONAL PREPAREDNESS IN MEETING THE NEEDS OF AN AGING POPULATION

Donnette Narine[1], Abigail Helsinger[2], Phyllis Cummins[3], Rita Karam[4], Wonmai Punksungka[5], Jenna Kramer[6], and Takashi Yamashita[7], *1. University of Maryland, Baltimore, Baltimore, Maryland, United States, 2. Miami University, Oxford, Ohio, United States, 3. Miami University, Oxford, Ohio, United States, 4. RAND Corporation, Santa Monica, California, United States, 5. University of Maryland - Baltimore County, Baltimore, Maryland, United States, 6. RAND Corporation, Arlington, Virginia, United States, 7. University of Maryland, Baltimore County, Baltimore, Maryland, United States*

Community colleges play an important role in training adults in healthcare-related occupations, such as nurses and medical technicians, to meet the needs of an aging population in the U.S. In addition, community colleges with open access policies, have a long-standing record of serving a diverse population, including students of all ages. However, the relatively low program completion rates (e.g., about 30% in Ohio) are of concern in general, and among older students in particular. One of the reasons for the low completion rate is the lack of postsecondary education readiness or basic skills, such as literacy, numeracy, and digital skills. The COVID-19 pandemic has created additional challenges, including faculty shortages, lack of internet access, poor digital skills, and transitions to online classes. This study examined characteristics of health-related occupational programs at community colleges located in Washington, Indiana, and Ohio, focusing on adult student characteristics, and their administrators' and faculty's views on basic skills and program completion. In addition, potential employers were interviewed regarding the skill expectations of community college hires. Using the semi-structured qualitative interview, community college administrators, faculty, and potential employers reported that numeracy skills, excellent grammar, and critical thinking skills are important to succeed both in the classroom and in the workplace. Creating a supportive atmosphere in the classroom and providing tutoring, either by the instructor or at a tutoring center, are also important for student success. More detailed results as well as other policy implications are discussed in this study.

EVALUATION OF FALL RISK PREVENTION EDUCATION THROUGH AGE-FRIENDLY PARTNERSHIPS

Solymar Rivera-Torres[1], and Jennifer Severance[2], *1. University of North Texas, Denton, Krum, Texas, United States, 2. UNTHSC-TCOM, Fort Worth, Texas, United States*

Falls in the home and community environments are the leading cause of injuries and long-term disabilities for the aging population. This study examines the outcomes of a partnership among an academic institution, government agency, community nonprofit, and emergency services organization to expand access to a fall prevention training program by targeting delivery in postal codes identified as underserved with high rates of falls emergencies (hot spots) and non-high rates (non-hot spots). A total of 354 adults aged 50 and older participated in a fall prevention education program, with 188 (53%) participants completing at least five sessions (completers), of which 35% resided in hot spot areas. Descriptive statistics for frequency, percentage, mean, and standard deviations values were calculated for demographic variables. A paired t-test analysis was conducted to compare initial and final scores for self-assessed general health and fall efficacy programs. The paired sample t-test statistics revealed significant improvements in fall efficacy for completers in hot spots ($t = -6.23$; $p < 0.001$) and non-hot spots areas ($t = -11.17$; $p < 0.001$). No statistical differences ($p > 0.05$) were observed between the initial and final scores of the self-assessed general health for completers in hot spots and non-hot spot areas. Cross-sector collaboration to deliver targeted falls prevention training at various community locations can effectively reach underserved, at-risk older adults, although additional retention strategies must be considered. In conclusion, identifying at-risk older adults to mobilize partnerships, limited resources can be allocated towards improving retention and program outcomes of community-based fall prevention education.

IMPROVING THE PERFORMANCE OF COMMUNITY HEALTH WORKERS IN A BEHAVIORAL LIFESTYLE INTERVENTION FOR OLDER ADULTS

Xinran Liu[1], Yuxin Lin[2], Sara Baumann[1], and Steven Albert[1], *1. University of Pittsburgh, Pittsburgh, Pennsylvania, United States, 2. Peking University Health Science Center, Beijing, Beijing, China (People's Republic)*

Community health workers (CHWs) play essential roles in implementing community-based behavioral lifestyle interventions. This qualitative analysis aimed to explore what program factors and CHW characteristics would help improve CHW performance in the Mobility and Vitality Lifestyle Program (MOVE UP), a community-based behavioral weight-management intervention for improving mobility among overweight or obese older adults. The MOVE UP program was implemented from January 2015 to June 2019 at 23 community-based sites in Pittsburgh, Pennsylvania. Trained and supported CHWs delivered 32 group sessions over 13 months. We collected data from semi-structured interviews with 21 CHWs and 14 community key informants (community site directors or coordinators); seven focus group discussions with participants from 9 sites, and 124 pieces of graduation advice provided by MOVE UP graduates for future participants; onsite CHW performance observation at 18 sites, and 124 meeting memos of support phone calls with CHWs. Interviews and focus groups were audio-recorded and transcribed verbatim. All data were thematically analyzed in a deductive approach, using the CHW generic logic model. Emerging themes were: Trained CHWs still require onsite support by experienced CHWs or training staff to deliver the first session; Participants need a Q&A session by specialists to address their questions beyond CHWs' knowledge; Desirable CHW characteristics could increase CHWs' relation and accessibility to participants, such as the same age group, similar weight loss experience, and living or working in the same community. These findings provide important insight as to recruiting and supporting CHWs in a community-based behavioral lifestyle intervention for older adults.

WORKFORCE DEVELOPMENT: AGING NETWORK CARE MANAGERS AS BEHAVIORAL HEALTH PROVIDERS FOR OLDER ADULTS IN COMMUNITIES

Mbita Mbao[1], and Bronwyn Keefe[2], *1. Salem State University, Salem, Massachusetts, United States, 2. Boston University, Boston, Massachusetts, United States*

Background and Objectives: The population of older adults (65 and over) continues to increase with projections of one in five by 2030. Furthermore, one in four older adults have a behavioral health problem, and over 63% are not receiving behavioral health (BH) services. Many older adults living in the community depend on aging networks for home- and community-based services. However, most care managers' current education and training do not cover the skills and competencies to provide adequate care for older adults with BH needs. This study aimed to evaluate the effectiveness of a training intervention on the perceived self-efficacy of care managers working with older adults with BH issues in the aging network. Research Design and

Methods: The study used a quasi-experimental design with a pre-and post-tests approach. The study used convenience sampling (n=90).

Results: We found a significant difference in the mean self-efficacy scores related to working with clients with mental health problems between pre-test (M=62.31, SD=10.11) and post-test (M=65.88, SD=7.40). In addition, results indicated a significant difference in the mean self-efficacy score between the pre-test (M=59.81, SD=10.68) and post-test (M=65.60, SD=9.85) related to working with clients with substance use problems. Discussion and Implications: The study found that self-efficacy was higher at post-test than pre-test. In addition, there was no difference in the self-efficacy scores of those participants who had previously completed a mental health course or certification and those who had not.

KNOWLEDGE DEFICITS ABOUT THE SAFE USE OF PRESCRIPTION OPIOIDS AND NALOXONE IN OLDER ADULTS IN ARKANSAS

Patricia Savary, Gohar Azhar, Naomi Amstrong, Regina Gibson, Elizabeth Eoff, Amanda Pangle, Robin McAtee, and Jeanne Wei, *University of Arkansas for Medical Sciences, Little Rock, Arkansas, United States*

Older adults might be more likely to experience adverse effects of opioid medications, or accidental overdose because of age-related multi-morbidities and polypharmacy. Arkansas has the second highest legal opioid prescription rate in the nation hence disseminating information to older individuals is key in fighting the opioid epidemic. As part of an Opioid Prevention for Aging and Longevity Program, we conducted a community-based, cross-sectional, anonymous survey of individuals >59 years about opioids, the common side effects and use of naloxone. The total N was 304, and the response per item varied from 236-298. Respondents' knowledge was strongest for preventative safety measures: to avoid drinking alcohol when using opioids 90.94% and to lock opioids in a secure location when children are nearby (89.49%). About three-quarters of respondents correctly identified medications classified as opioid (70.34%) or non-opioid (74.48%). Similarly, 75.36% recognized a non-opioid, ibuprofen, as the appropriate pain medication for back pain. The side effects of opioids not as well recognized. Sleepiness and trouble driving was the best understood side effect (72.18%). In contrast, the side-effect of constipation was correctly identified in just 34.17% of responses and trouble urinating in only 26.79%. In addition, a key emergency safety measure in case of opioid over-dose was far less known: Only 63.98% were able to correctly identify naloxone as an antidote for opioid overdose.Older adults exhibited gaps in knowledge about the common side effects of prescription opioids and were unaware of the life-saving role of naloxone in reversing the effects of opioid overdose.

IMPACT OF AN ONLINE EMOTION-FOCUSED COMMUNICATION TRAINING ON STAFF KNOWLEDGE AND SELF-EFFICACY

Katherine Abbott[1], Allison Heid[2], Megan Kelley[1], Alexandra Heppner[1], and Kimberly Van Haitsma[3], *1. Miami University, Oxford, Ohio, United States, 2. Ardmore, Pennsylvania, United States, 3. Pennsylvania State University, University Park, Pennsylvania, United States*

The way we respond emotionally to others can impact how we provide care. Emotional intelligence is vital for care team members whose entire day involves interacting with other people. We have developed an interactive, online, self-paced course for people providing care to others with the specific goal of increasing awareness of emotions and helping to identify emotions in others. The training is supported by research indicating that individuals who can better manage their own emotions are better positioned to manage behaviors and emotions in others. The central concept of the training is to build relationships that enhance person-centered care through increasing care providers' emotional intelligence. These skills allow care providers to better manage their own behavior and emotions, which results in improved quality of their care work. The purpose of this study was to assess the knowledge, self-efficacy, acceptability, and appropriateness of the online training. The data for this study came from n = 130 individuals (19% direct care worker, 16% activities, 13% health care provider, and 12% case manager) who completed assessments pre-and post-training. Knowledge of emotion-focused communication strategies and self-efficacy in using emotion-focused communication strategies both increased significantly with training (t(129) = -5.40 p < .001 and t(124) = -6.42 p < .001). In addition, high levels of acceptability, appropriateness, and satisfaction were reported. Findings indicate the benefits of online training for emotion-focused communication for caregivers. The discussion will focus on recommendations for practice, policy, and research.

SESSION 6140 (POSTER)

HEALTH INEQUITIES, DISPARITIES, AND PERSON-CENTERED CARE

DOES AGEISM ACCELERATE BIOLOGICAL AGING

Mingxin Liu, Alan Cohen, Tamas Fulop, Véronique Legault, Carine Betrisey, and Melanie Levasseur, *Université de Sherbrooke, Sherbrooke, Quebec, Canada*

Defined as, "stereotype, prejudice, and discrimination directly towards people because of their age", ageism may contribute to adverse health outcomes, accelerate aging process, and increase the burden on health and social services. Little is known about the ageism impact on biological aging. Secondary analysis of the American Health and Retirement Study (2012 and 2016 waves) was carried out. Participants were asked: the self-perception of aging (SPA), the causes of receiving discrimination, including ageism as one of the causes, and the frequency of receiving such discrimination. The aging rate was measured using two distinct measurements: homeostatic dysregulation (using Mahalanobis distance on 44 biomarkers, n= 9934, 2016 wave) and epigenetic aging clocks (n=4018, 2016 wave). The influence of perceived ageism (current or previous waves) on the aging rate was modelled with linear models using biological aging (aka. homeostatic dysregulation and epigenetic age) as the dependent variable (outcome), ageism as the exposure, with considering confounders: sex, depressive symptom. The results show that more negative SPA, either from the previous (2012) or the same wave (2016), is associated with elevated homeostatic dysregulation (e.g. the slope increases from 1.20 to 1.34, p< 0.001, previous wave) and increasing epigenetic age (e.g. DNAm PhenoAge, the slope increases from 53.81 to 61.14, p< 0.001, current wave). The association between the ageism receiving frequency and biological aging is similar but less significant. The results demonstrate that ageism is associated with accelerated biological aging. More interventions are called to combat ageism and foster the health and wellbeing of the older adults.

ASSOCIATION BETWEEN PERCEIVED CONTROL AND COGNITIVE FUNCTION AMONG STROKE SURVIVORS IN CHINA: A LONGITUDINAL STUDY

Zhijian Liu[1], Huanzhi Zhu[1], Jing Wang[2], Bei Wu[3], Qin Wang[4], and Juan Li[5], *1. Naval Military Medical University, Shanghai, Shanghai, China (People's Republic), 2. University of North Carolina at Chapel Hill, Chapel Hill, North Carolina, United States, 3. New York University, New York, New York, United States, 4. Linyi People's Hospital, Linyi, Shandong, China (People's Republic), 5. Huashan Hospital affiliated to*

Fudan University, Shanghai, Shanghai, China (People's Republic)

This study explored the association between perceived control and cognitive function among stroke survivors in China. We conducted a longitudinal study and assessed perceived control (by Perceived Control in Health Care Questionnaire) and cognitive function (by Montreal Cognitive Assessment, MoCA) of 231 stroke survivors at the acute stage, 3, 6 months after onset from two stroke centers in Shanghai and Linyi from June to December 2020. General linear mixed model was used for analysis. Perceived control was at a moderate level, and the average score of MoCA showed cognitive impairment at 3 waves. Both perceived control and cognitive function improved with time. Perceived control was positively associated with cognitive function (β=0.08, $p < 0.001$). After controlling for stroke severity, risk factors of cognitive impairment, age, gender, and education, the association was still significant (β=0.04, $p < 0.001$). These findings suggest that perceived control may be a potential target in cognitive interventions for stroke survivors.

DIFFERENCES IN COMMUNITY AND PROVIDER STAKEHOLDERS' PERCEPTIONS ON BRAIN HEALTH SERVICE GAPS AND SCREENING NEEDS

Annie Rhodes, Lana Sargent, and Faika Zanjani, *Virginia Commonwealth University, Richmond, Virginia*

Introduction: Alzheimer's Disease and Related Dementias (ADRD) management and prevention is a priority for providers and community members. Aligning perceptions regarding resources and screening supports person-centered care while addressing the increased dementia burden attributed to systemic inequity and health disparities. This project aimed to identify needs in lower-income diverse populations. Research Question: What are the differences in perceived service gaps and screening preferences for brain health and ADRD?

Methods: A convenience sample of 15 providers and 20 community stakeholders (55+) completed a 2021 survey about Richmond's service gaps and screening needs for brain health and ADRD.

Results: 40% of providers were ADRD focused, 65% of community members reported a memory concern. Overall, providers reported fewer service gaps: Administration on Aging Service Gaps 46.7%/75%, Caregiving gaps 80%/85%, Specialty Health gaps: 53.3%/80%. Clinical ADRD gaps 73.3%/80%, Memory Case Management gaps 86.7%/90%, Memory Social Services gaps 33.3%/90%, Memory Screening gaps 53.3%/85%. Provider and Community stakeholders were more aligned regarding screenings that should be included in a brain health/ADRD management program: Advance Care Planning screening: 80%/80%, Caregiving Status screening: 93.3%/90%, Memory Loss screening: Lifestyle Risk screening: 100%/95%, Cognitive-Comorbidity Risks screening: 100%/75%, Psychosocial Risks screening:100%/100%, Depression screening 100%/100%, Clinical Health screening 73.3%/90%, Substance Use Disorder screening 86%/75%, Sleep Problem screening 93%/75%

Conclusion: Although there were areas in which both providers and community members aligned, results show that providers underestimate brain health/ADRD service gaps experienced by the community. Both groups are amenable to comprehensive screening for services. However, providers are interested in more expansive ADRD screeners.

CROSS-CULTURAL DIFFERENCES IN AGE ESTIMATION AND AGE BIAS

Hannah Benz, Hailey Scherer, Gustavo Rodriguez, and Jenessa Steele, *Radford University, Radford, Virginia*

Our society is aging rapidly with older adults composing a continuously growing proportion of the population. This expected shift in population age is likely going to carry societal consequences, such as an increase in age discrimination. Previous research has shown that ageism (the systematic stereotyping and categorizing of people based on their age) is the most experienced kind of prejudice across Europe, with individualistic, industrialized countries like the USA and Germany showing greater levels of age bias towards the elderly. The current study aimed to investigate cross-cultural differences in age estimation and attitudes towards older adults. Pilot measures included 102 participants (65 American, 37 German) who estimated the age of 12 male celebrities representing three different age groups (young, middle, and older adult) and completed the Fraboni Scale of Ageism (FSA), a survey measurement investigating ageism. Although the Fraboni scale has been validated in other countries, it has not yet been translated to German, nor tested on a primarily German-speaking population. Preliminary analyses showed that both the original FSA scale and the German translation were reliable (αOriginal = 0.909, αGerman = 0.703), however, t-test revealed significant differences between the FSA mean scores of the original scale ($M = 1.78$, $SD = .34$) and the translated version ($M = 3.15$, $SD = .28$), $t(100) = -20.90$, $p < .001$. The researchers are currently recruiting 400 additional participants to explore the effects of culture, race, and participant age on age estimation and further validate the German translation of the scale.

INCLUSION OF ETHNICALLY DIVERSE POPULATIONS IN CLINICAL TRIALS OF HEALTHSPAN: IMPLICATIONS FROM THE SALSA STUDY

Sara Espinoza, Tiffany Cortes, and Helen Hazuda, *UT Health San Antonio, San Antonio, Texas, United States*

Background: Geroscience-guided clinical trials focused on healthspan may seek to enroll older adults initially free of chronic diseases and disability. Here we examine healthspan in the San Antonio Longitudinal Study of Aging (SALSA), a cohort of 749 community-dwelling older (65+ years) Mexican Americans (MA) and European Americans (EA), and describe prevalence and characteristics associated with poor healthspan.

Methods: Poor healthspan was defined at the SALSA baseline exam as presence of any one of: 1) chronic disease (diabetes, myocardial infarction, congestive heart failure, stroke, chronic obstructive pulmonary disease, or cancer);

2) dependence in basic or instrumental activities of daily living; or 3) mini mental state exam score < 18. Frailty was defined by Fried phenotype criteria. The association of poor healthspan with age, sex, ethnic group, socioeconomic status (SES), and frailty was assessed using chi-square or t-tests.

Results: 544 (72.6%) participants met criteria for poor healthspan, which was associated with older age (69.6 ±3.4 vs. 69.3 ±3.4, $p < 0.05$), male sex (77.3% vs. 69.2%, $p < 0.05$), MA ethnicity (77.4% vs. 67.3%, $p < 0.05$), lower income (11.3 ±3.1 vs. 12.2 ±2.9, $p < 0.001$ and education (10.4 ±4.6 vs. 12.7 ±3.2, < 0.0001), and frailty (95.5% vs. 4.6%, $p < 0.001$).

Conclusion: Poor healthspan was highly prevalent (>70%) in SALSA and associated with MA ethnicity, low SES, and frailty. Geroscience-guided clinical trials of potential interventions to improve healthspan by preventing chronic diseases and disability may under-represent individuals of ethnic minority background and lower SES and, thereby, jeopardize generalizability of the findings to the broader population.

LIVING WITH MULTIMORBIDITY: SHARED EXPERIENCES OF PATIENTS, FAMILY CAREGIVERS, AND HEALTHCARE PROFESSIONALS

Anna Peeler[1], Katie Nelson[2], Sarah Badawi[2], Lara Street[3], David Hager[3], Patricia Davidson[4], and Binu Koirala[2], *1. Johns Hopkins University School of Nursing, Baltimore, Maryland, United States, 2. Johns Hopkins University, Baltimore, Maryland, United States, 3. Johns Hopkins Hospital, Baltimore, Maryland, United States, 4. University of Wollongong, Wollongong, New South Wales, Australia*

Over 50% of patients in intermediate care units (IMCU) present with multimorbidity, two or more chronic conditions. Balancing the effects of multimorbidity and their treatments with quality-of-life can be a challenge. This experience-based co-design project aimed to elicit experiences of patients, family caregivers, and healthcare professionals in IMCU, in the context of challenges and intricacies of multimorbidity management, to inform the development of a symptom management toolkit. Patients aged 55 years and older were recruited and interviewed in person. Healthcare professionals working in IMCU (i.e., physicians, nurses, respiratory therapists, social workers, etc.) were recruited and interviewed virtually. Participants were asked questions about their role in recognizing and treating symptoms, factors affecting quality of life, symptom burden and trajectory over time, and symptom management strategies that have and have not worked. An inductive thematic analysis approach was used for data analysis. Twenty-three interviews were conducted: 9 patients, 2 family-caregivers, and 12 healthcare professionals. Patients' mean age was 67.5 (± 6.5) years, over half (n=5) were Black or Hispanic, and average number of multimorbidity was 3.67. Five major themes emerged: 1) importance of patient-provider relationship; 2) open and honest communication; 3) accessibility of resources during hospitalization and at discharge; 4) caregiver support, training, and education; and 5) care-coordination and follow-up care. Patients, caregivers, and healthcare professionals often have different priorities for multimorbidity management, treatment, and education. However, given the growing population of patients experiencing multimorbidity, it is imperative to identify shared priorities and target holistic interventions considering their experiences to enhance outcomes.

PATIENT PARTICIPATION IN HEALTHCARE ACTIVITIES: NURSES' AND PATIENTS' PERSPECTIVES IN TAIWAN

Hsueh-Fen Kao[1], Chang-Chiao Hung[2], Bih-O Lee[3], Su-Ling Tsai[2], and Oscar Moreno[4], *1. The University of Texas at El Paso, El Paso, Texas, United States, 2. Chung-Gung University of Science and Technology, Puzi City, Chiayi, Taiwan (Republic of China), 3. Kaohsiung Medical University, Kaohsiung, Kaohsiung, Taiwan (Republic of China), 4. M B Care Home Health, LLC, El Paso, Texas, United States*

Patient participation in healthcare activities is key to producing successful patient-centered care. However, little is known about both nurses' and patients' perspectives regarding patient participation in East Asia. This paper compared and contrasted perspectives of patient participation in healthcare activities between nurses and patients (age=61.53 ±8.75), using a qualitative study with a purposive sample of 39 nurses and 15 patients. Inclusion criteria for patient participants were: (1) speaking Mandarin Chinese or Taiwanese dialect, (2) aged 20 or older, (3) hospitalized at the unit for at least 3 days, (4) able to provide written informed consent, and (5) well enough to endure 40–50 minutes of individual interview. A semi-structured interview was applied to focus groups for nurses, and to face-to-face interviews for patients to prevent nosocomial infection. Content analysis was utilized to analyze the data, common themes and subthemes were identified showing three similarities in perspectives between nurses and patients—authoritative culture, participation behaviors, and obstacles to participation, as well as two differences—sources of acquiring patient-related health information, and responsible party. Nurses and patients did not entirely view participation in healthcare activities congruently. Relevant clinical practices are also suggested, including respecting patients' autonomy, nurses' using layman's language for explanations, patients' understanding the meaning behind their participation behaviors, recognizing obstacles faced in enhancing patient participation with adjusted nursing workload, actively providing needed health information, and leading patients to realize that they will be responsible for their health behaviors after discharge.

PLACE-BASED HEALTH DISPARITIES: FUNCTIONAL DISABILITY IN APPALACHIAN WEST VIRGINIA

Carly Pullen, Kareem Ibrahim-Bacha, and Julie Hicks Patrick, *West Virginia University, Morgantown, West Virginia, United States*

Place-based health disparities contribute to disability across the lifespan. Additional examinations of contributors to morbidity and disability at mid-and late-life are needed to inform policies and programs. Using data from the 2020 Centers for Disease Control and Prevention's (CDC) Behavioral Risk Factor Surveillance System (BRFSS), we examine some of the social determinants of health (e.g., age, gender, education, income) as predictors of access to health care and predictors of functional ability. The study included 5,880 adults living in

West Virginia all between the ages of 18 to 65+ years. Access to healthcare was indexed by three variables, including whether one had medical insurance, saw personal physicians, and avoided medical treatment due to cost. Functional ability was indexed by reports of difficulty in three ADLs and the number of chronic health conditions. Although most paths were significant, our initial model fit the data poorly, X2 (DF = 39, N =5880) = 2503.6, p < .001, CFI = .70, RMSEA = 1.0. We re-ran the model, using age as a moderator. In this set of analyses, the model fit well for middle-aged and older adults, but a different set of predictors characterized the relations for younger adults. Our results suggest that policies and programs that increase medical access for current middle-aged and older adults might decrease functional disability. Moreover, as younger adults age into midlife, they enter with lower economic and educational resources, further exacerbating their lack of access to health care and increasing disability.

A LONGITUDINAL INQUIRY OF PATIENT-PROVIDER RELATIONSHIPS AMONG AN UNDERSTUDIED GERIATRIC POPULATION

Rosana Bravo[1], and Angela Gutierrez[2], *1. Western University of Health Sciences, Pomona, California, United States, 2. Ohio University, Heritage College of Osteopathic Medicine, Athens, Ohio, United States*

Patient-provider relationships have a direct impact on patient outcomes. This study explored patient-provider relationships among an understudied geriatric population of color— foreign-born Latinos¬ participating in an all-inclusive specialized program aimed at controlling patients' costs and enhancing access to care. Thirteen older adult Latinos with multimorbidities from nine Program of All-Inclusive Care for the Elderly (PACE) centers in Southern California were recruited. Researchers conducted three in-depth interviews in Spanish with each participant (39 interviews total) over 13 months. The first interviews were conducted face-to-face and lasted one hour on average. Subsequent interviews were conducted over the phone (Range: 60-90 minutes). Data were analyzed using codes, identifying categories and themes. The concepts of time and trust were used to analyze the process of relationship development and to capture changes over time. The patient-provider relationship developed on a continuum across time and trust, establishing three stages to the patient-provider relationship. In the first stage emerged the concept of el buen doctor (the good doctor). In the second stage, trust was perceived to have been established, and was only strengthened as the doctor continued to demonstrate trustworthy characteristics over time. The third stage embodied all that a person of trust was plus an additional advocacy dimension. The longitudinal and specialized geriatric program design illuminated the nature of quality of care and patients' perceptions on relationship development over time. Controlling patient/provider costs and enhancing access to care in an all-inclusive program are beneficial in enhancing patient-provider relationships.

ADVANCE CARE PLANNING FOR SPANISH-LANGUAGE SPEAKERS: PATIENT, FAMILY, AND INTERPRETER PERSPECTIVES

Geraldine Puerto[1], Germán Chiriboga[1], Susan DeSanto-Madeya[2], Vennesa Duodu[1], Dulce Cruz-Oliver[3], and Jennifer Tjia[1], *1. University of Massachusetts Chan Medical School, Worcester, Massachusetts, United States, 2. University of Rhode Island, Providence, Rhode Island, United States, 3. Johns Hopkins Medical School, Baltimore, Maryland, United States*

Language access is a challenge to advance care planning (ACP). Spanish-language speakers are the largest non-English speaking population in the US. While ACP tools have been translated into Spanish, it is unclear how heterogeneity in country of origin may affect the generalizability of translations across diverse US Spanish-speaking populations. The study objective is to describe challenges and facilitators to ACP for diverse populations of Spanish-language speakers. We conducted 3 focus groups with a total of 29 participants from members of Spanish-language speaking communities whose countries of origin were predominantly from the Caribbean, Central, and South America. Eligibility included being 18 years or older, being a native Spanish-speaker, and having direct experience with ACP as a patient, caregiver, or medical interpreter. We conducted thematic analysis with axial coding. Themes include: 1. Linguistic Challenges with Current ACP Translations; 2. Effect of Country of Origin and Culture on ACP Understanding; 3. Impact of Local Healthcare System Cultural on ACP; and 4. Need for ACP to be Normalized into the Local Community. ACP is both a cultural practice and a clinical practice. Recommendations for improving ACP completion for non-English speakers extend far beyond translation, since simply translating ACP tools without a cultural context is neither equitable nor inclusive. A key step is normalizing ACP into the local community. Understanding the intersection of local healthcare systems of ACP practice with the patient's and family's cultures of origin will facilitate introducing ACP in a culturally sensitive manner.

COLORECTAL CANCER SCREENING (CRC) DISPARITIES: A ZIP CODE–LEVEL ANALYSIS

Roshni Singh, Carla Parraga, Rachel Lin, Leonardo Tamariz, and Ana Palacio, *University of Miami Miller School of Medicine, Miami, Florida, United States*

CRC is the third leading cause of cancer-related deaths among older adults in the US. CRC screening can prevent disease by early identification, yet there are disparities in CRC screening. This study aimed to determine the impact of race, social determinants, and geographic location at zip-codes level on CRC screening.We conducted a retrospective cross-sectional study of CRC screening among different races, evaluating the relationship with the social deprivation index (SDI) and annual income as health determinant factors using the public available data of 2016-2019 CDC 500 cities project and PLACES project 2020 database combined with 2019 American Community Survey for zip code-based analysis. We conducted a multivariate analysis and a confirmatory factor analysis among race, income, lack of health insurance, access to check-up visits and SDI. Increasing SDI tertile increased the likelihood of being Black and Hispanic and having lower median household income ($p< 0.01$). Lack of health insurance and lower regular checkup visits were less common in the third tertile of SDI ($p< 0.01$). The multivariate analysis showed that being black, Hispanic, having a lower income, not having health insurance, not having regular check-ups and SDI were related to decreased screening. In the confirmatory factor analysis, the variables most associated with decreased screening are SDI and access to health insurance.Race, SDI, insurance status, socioeconomic status, all impact CRC screenings, but the two most important factors are SDI and access to healthcare. These data may help implement interventions that specifically target these barriers to promote CRC screenings within disadvantaged communities.

ETHNORACIAL DIFFERENCES IN HOME HEALTHCARE USE: FINDINGS FROM THE NATIONAL HEALTH AND RETIREMENT STUDY

Adam Simning[1], Jinjiao Wang[2], Thomas Caprio[1], Brian McGarry[1], and Yue Li[1], *1. University of Rochester, Rochester, New York, United States, 2. University of Rochester School of Nursing, Rochester, New York, United States*

This study seeks to identify ethnoracial differences in self-reported home health care (HHC) use among older adults. To do so, we examined 8,817 people aged 65 and older from the 2016 wave of the Health and Retirement Study (HRS), a nationally representative survey of older adults in the U.S. The dependent variable was whether HRS participants reported any HHC service use in the past two years. The primary independent variable was ethnoracial grouping, which included non-Hispanic White, non-Hispanic Black, and Hispanic groups. Multivariable logistic regressions stratified by ethnoracial grouping identified correlates of HHC use. We found that HHC use was more prevalent among non-Hispanic Blacks (14.9%) than in non-Hispanic Whites (10.1%) or Hispanics (10.7%). For all ethnoracial groups, increasing age, dementia, activities of daily living impairment, medical comorbidity (except for Hispanics), and hospitalization (in the past two years) were associated with an increased likelihood of HHC use. In addition, we identified ethnoracial differences in the correlates of HHC use. Among non-Hispanic Whites, more formal education and Medicaid insurance were associated with a higher likelihood of using HHC. For non-Hispanic Blacks, residing in rural areas was associated with a decreased likelihood of HHC use, whereas being single and living alone were associated with an increased likelihood of HHC use. This study thereby identified notable ethnoracial differences in the correlates of HHC use among older adults.

PERSON-CENTERED CARE: WHY TAKING INDIVIDUALS' CARE PREFERENCES INTO ACCOUNT MATTERS

Frances Hawes[1], Jane Tavares[2], Marc Cohen[2], and Ann Hwang[3], *1. University of Wisconsin-Eau Claire, Eau Claire, Wisconsin, United States, 2. University of Massachusetts Boston, Boston, Massachusetts, United States, 3. Harvard, Cambridge, Massachusetts, United States*

Person-centered care has been recognized as an integral part of a high-quality health care system. Utilizing the 2014 to 2018 waves of the Health and Retirement Study, we explore trends in person-centered care among those 50 and older by examining the extent to which they feel their care preferences are being taken into account, that is, that they are being heard by providers. We analyze the impact of not receiving person-centered care on health care utilization, health outcomes, and preventative care utilization. One-third of respondents reported that their care preferences were “sometimes” or “never” considered. Findings show that wealth and racial disparities in person-centered care are worsening over time. From 2014 to 2018, the percentage of non-Hispanic White respondents who reported that their care preferences were never taken into account decreased while the percentage for Hispanic and non-Hispanic Black individuals increased. Similar trends were seen for low-income individuals. Having a usual source of care was associated with a greater likelihood of having care preferences considered as well as significantly better control of chronic condition and greater use of preventive care. When care preferences are not being taken into account, there is less utilization of health care services, less preventive care usage, poorer control of chronic conditions, and increased risk for higher health care costs. These findings highlight the importance of assuring that people feel listened to by health care providers and emphasize a need for strategies to advance person-centered care for people of color and low-income populations.

SYSTEMATIC EXCLUSION AT STUDY COMMENCEMENT MASKS EARLIER MENOPAUSE FOR BLACK WOMEN IN THE STUDY OF WOMEN’S HEALTH ACROSS THE NATION (SWAN)

Alexis Reeves[1], Michael Elliott[2], Carrie Karvonen-Gutierriez[2], and Sioban Harlow[2], *1. Stanford University, School of Medicine, Berkeley, California, United States, 2. University of Michigan, Ann Arbor, Michigan, United States*

Assumptions regarding “normative” aging, including average age at onset of disease, are often based on White populations. However, evidence suggests that Black and Hispanic populations may experience “weathering” or accelerated health declines compared to Whites due to the cumulative impact of social and economic marginalization. If “weathering” leads to a differential probability of inclusion into a cohort study, it will likely misinform understanding of aging in minoritized populations. Using SWAN, a longitudinal multi-ethnic cohort of midlife women, and its cross-sectional screening study, we quantified the extent of potential selection bias at study commencement and re-estimated racial/ethnic differences in age at menopause, the main outcome of SWAN, with adjustment for various forms of potential selection bias. Left truncation was corrected for using inverse probability weighting and right censoring using multiple imputation. Two selection mechanisms were identified, eligibility and participation. Black and Hispanic women had the lowest probability of eligibility stemming from a high prevalence of surgical menopause. Their eligibility rates decreased with increasing age faster than in White women. Correcting for selection biases showed that uncorrected analyses overestimated of the median age of menopause in Black and Hispanic women, thereby underestimating racial/ethnic disparities. After adjustment, Black women had earlier natural and surgical menopause (average 1.2 years) versus White women. Overall, this study found that failure to account for different forms of selection can lead to mis-estimation of racial/ethnic disparities in health and aging. Selection bias is particularly acute at study commencement, and particularly affects minoritized populations.

VOICES OF OUR ELDERS: ATTITUDES, BELIEFS, AND PERSPECTIVES ABOUT RESEARCH IN MINORITY OLDER ADULTS

Trudy Gaillard[1], Donna Shambley-Ebron[2], Giovanni Garcia[1], Ryan Romero[1], Donna Neff[3], Phildra Swagger[3], Dawn Gardier[1], and Fern Webb[4], *1. Florida International University, Miami, Florida, United States, 2. University of Cincinnati, Cincinnati, Ohio, United States, 3. University of Central Florida, Orlando, Florida, United States, 4. University of Florida (UF) College of Medicine, Jacksonville, Jacksonville,, Florida, United States*

The U.S. Census Bureau projects that the numbers of adults 65 and older will double from 46 million in 2020 to 90 million by 2050, thus representing the fastest growing segment of the population. However, older adults, especially those from minority groups, remain underrepresented in clinical research. It is imperative to understand what older adults believe about research and research participation to enhance recruitment efforts. The aim of this presentation is to present preliminary findings from our qualitative study which explored the attitudes, beliefs, and perspectives of older minority adults regarding research and research participation. We conducted 12 focus groups via Zoom, in South Florida with minority adults (African American, Caribbean, Hispanic) over the age of 65 (N=49). An interview guide was used to query the participants about their attitudes, beliefs, and perspectives of research and research participation. Focus groups were video-recorded and transcribed. NVivo software was used for data management and analysis. We found that participants: 1) thought research was necessary to expand understanding and knowledge of health conditions; 2) stated research should be conducted by trusted scientific institutions; 3) relied heavily on their adult children for advice regarding research participation; 4) expressed reluctancy regarding invasive procedures; and 5) were influenced by personal experiences when considering research participation. Our preliminary findings suggest that older minority adults believe in the value of research, however, may be hesitant about participating. We propose continued strategies aimed at increasing engagement of minority older adults into health research.

RURAL LIVING AND DISABILITY IN OLDER ADULTS: THE ROLE OF ALTERNATIVE SUPPORT RESOURCES AS MEDIATORS

Bernard Steinman[1], and Daniel Barbakoff[2], *1. University of Wyoming, Laramie, Wyoming, United States, 2. Weill Cornell Medical College, New York, New York, United States*

Rural communities are often characterized by sparse service environments offering limited care, services, and conveniences that help with daily activities. In lieu of community services that target older adults to assist with aging-in-place, alternative supportive features, including environmental modification and informal social networks may be especially important in rural settings to preserve functional independence. The purpose of this study was to assess the role of alternative support resources as potential mediators between service environments and Activities of Daily Living (ADL) functioning of older adults living in rural settings. Data from the National Health and Aging Trends Study (NHATS) were analyzed. Guided by the International Classification of Functioning, Disability and Health, regression models included covariates for sociodemographics, chronic conditions, mobility functioning, and participation. Service environments were quantified using a measure of the number of services (e.g., help with bathing) available in communities. Two potentially important support features were tested as mediators. Environmental modification was operationalized using indicators of whether homes had been modified (e.g., with features such as grab bars). Size and quality of individuals' social networks were calculated using indicators of whom participants spoke to about important things in their life. Measures of ADLs served as key dependent variables. Results suggest a negative statistical relationship between service environments and disability that is explained in part by the availability of alternative support resources. Implications are that older adults who live in rural communities may often benefit by employing home modifications and relying on informal care options to meet their needs.

DEPRESSION IS ASSOCIATED WITH POORER CLINICAL FUNCTIONING AMONG HISPANIC OLDER ADULTS

Andres Duarte[1], Dilianna Padron[1], Joanna Gonzalez[2], Patricia Garcia[3], Lisandra Mendoza[4], Ranjan Duara[2], and Miriam Rodriguez[1], *1. Albizu University, Miami, Florida, United States, 2. Mt. Sinai Medical Center, Miami Beach, Florida, United States, 3. Rehabilitation Hospital of Indiana, Indianapolis, Indiana, United States, 4. Department of Veterans Affairs Bay Pines, Cape Coral, Florida, United States*

Objective: The aim of the current study was to examine associations between depression and clinical functioning among a multi-ethnic sample.

Methods: 35 cognitively normal and Mild Cognitive Impairment (MCI) participants were included and self-identified as Hispanic or white non-Hispanic (WNH). The Hispanic group (n=18), had a mean age of 70.83 (SD=7.66) and 15.59 mean years of education (SD= 3.43). The WNH group (n=17) had a mean age of 71.76 (SD=6.9) and 16.81 mean years of education (SD=2.59). Subjects were given the Alzheimer's disease Cooperative Study (ADCS) ADL inventory, the modified Clinical Dementia Rating scale (mCDR), and the Geriatric Depression Scale (GDS). Linear regressions were conducted to analyze the predictive associations between GDS scores and ADL functioning while controlling for the effect of diagnosis and age.

Results: Among Hispanics, the overall regression was significant (R2 = .622, F(2,17)= 12.32, p<.001). Higher GDS scores was found to significantly predict worse mCDR scores (β = .676, p<.001) when controlling for the effects other factors. When examining ADCS-ADL scores, the overall model was also found to be significant (R2= .413, F(2,17)=5.28, p<.05). Higher GDS scores significantly predicted worse ADCS-ADL scores (β = =.652, p<.01) when controlling for the effects of other factors. Diagnosis and age did not significant predict ADL scores. Among the WNH group, the regression model was not significant and depression was not a significant predictor of ADL functioning.

Conclusions: The results suggest Hispanics are more vulnerable to the effects of depression on ADL function which has important implications for AD diagnosis.

ADDRESSING ALZHEIMER’S DISPARITIES AMONG BLACK POPULATIONS WITH BRAINGUIDE BY USAGAINSTALZHEIMER’S

Brooks Kenny, *UsAgainstAlzheimer's, Kensington, Maryland, United States*

Older, Black Americans are disproportionately impacted by Alzheimer’s disease (AD), accounting for 15% (~1 million) of all individuals aged 65+ living with AD (5.8 million). Stigma, fear, and gaps in education contribute to 60% of undetected AD cases. In Georgia, AD remains the 6th leading cause of death. By 2029, cases are projected to spike by 46%, from 130,000 to 190,000. Given these alarming statistics and in response to AD health disparities in this population, UsAgainstAlzheimer’s, in partnership with community leaders and organizations, launched a pilot outreach program to promote AD prevention and brain health awareness in Atlanta. Program goals included: increasing knowledge about brain health, emphasizing the importance of early detection and diagnosis, raise awareness of BrainGuide™ by UsAgainstAlzheimer’s and other brain health resources, and develop a network of organizations for ongoing collaboration, awareness, and education. Program strategies included accessing highly saturated, faith-based spaces like mega churches, circulating key messaging through paid and earned media, and hosting widely received community webinars. UsAgainstAlzheimer’s collected participant feedback and examined BrainGuide website traffic to evaluate the effectiveness of community engagement on increasing brain health awareness and addressing AD stigma in Atlanta. Preliminary findings indicate a 96% increase in BrainGuide traffic from Atlanta and 70% increased engagement with BrainGuide resources, compared to the national average. UsAgainstAlzheimer’s’ pilot program suggests that brain health promotion, grounded in community engagement from trusted influencers, has potential to raise brain health awareness and empower people to take action. Further research and learnings are required to determine program scalability.

SOCIAL EPIGENETICS OF RACIAL DISPARITIES IN AGING

Isabel Yannatos[1], Sharon Xie[1], Rebecca Brown[2], and Corey McMillan[1], *1. University of Pennsylvania, Philadelphia, Pennsylvania, United States, 2. University of Pennsylvania School of Medicine, Philadelphia, Pennsylvania, United States*

Racial disparities in many aging-related health outcomes are persistent and pervasive among older Americans. There are well-documented inequities in social and physical environmental exposures which may contribute to these disparities, but we lack understanding of the biological intermediates by which environmental exposures affect disparate health outcomes. DNA methylation (DNAm) aging captures the residual between biological age, robustly measured by GrimAge and Dunedin Pace of Aging methylation (DPoAm), and chronological age. We hypothesize that neighborhood social environment and air pollution exposures contribute to racial disparities in DNAm aging. We performed retrospective cross-sectional analyses among non-Hispanic participants (N=2611 White, N=639 Black) in the Health and Retirement Study whose 2016 DNAm age is linked to survey responses and geographic data. We observed Black individuals have significantly accelerated DNAm aging on average compared to White individuals according to GrimAge (599%) and DPoAm (498%). We implemented linear regression models and Kittagawa-Blinder-Oaxaca decomposition to identify exposures that contribute to this disparity. Exposure measures include census-tract-level Social Deprivation Index, perceived social stress, particulate matter (PM2.5), nitrogen dioxide, and ozone. Individual-level determinants include socioeconomic status, healthcare access, health status, and health behaviors. Results suggest these individual-level factors account for ~43% of the disparity in GrimAge and ~34% in DPoAm. Higher neighborhood socioeconomic deprivation for Black participants significantly contributes to the disparity in GrimAge, while greater vulnerability to PM2.5 contributes to the disparity in DPoAm. DNAm aging may play a role in the environment “getting under the skin” and contributing to age-related health disparities between Black and White Americans.

SESSION 6150 (POSTER)

IMPROVING ADRD CARE THROUGH MEASUREMENT, ASSESSMENT, AND METHODS

SACCADES TO SCREEN AND ASSESS COGNITIVE IMPAIRMENT IN OLDER ADULTS: A SYSTEMATIC REVIEW AND META-ANALYSIS

Qiaoqin Wan, Shifang Zhang, xiuxiu huang, and Xiaoyan Zhao, *Peking University, Beijing, Beijing, China (People's Republic)*

Objective: To systematically summarize the evidence of saccade as a screening and assessing for patients with mild cognitive impairment (MCI) and dementia.

Methods: English databases including PubMed, EMBASE, the Cochrane Library, Web of science, and PsycINFO and Chinese databases including CNKI, Wanfang and VIP were searched. Studies that analyzed the metrics of saccade in people with health cognition, MCI, or dementia were included. The quality of the included studies was evaluated with Cross-sectional/ Prevalence Study Quality from Agency for Healthcare Research and Quality (AHRQ). Study characteristics, participants' characteristics, sample size, saccade procedure, and metrics were extracted from the included studies.

Results: Twenty-two studies involving 1595 participants were included. Meta-analysis showed that peak velocity (SMD= -0.27°/s, 95% CI (-0.44, -0.11), latency (SMD=-0.36ms , 95%CI (-0.51,-0.20), and accuracy rate (SMD=0.42%, 95%CI (0.17,0.68) of prosaccade between older adults with and without cognitive impairment had significant difference. The performance in latency (SMD=-0.56ms, 95%CI(-0.72,-0.39), accuracy rate (SMD=1.32%, 95%CI(1.07,1.56), and corrected errors (SMD=1.23%, 95%CI(0.98,1.47) of antisaccade in people with health cognition was better than that in older adults with cognitive impairment. The results of subgroup analysis revealed that the accuracy rate of prosaccade, latency and accuracy rate of antisaccade demonstrated crucial difference between health older adults and people with MCI, while only accuracy rate of antisaccade showed significant difference between people with MCI and dementia.

Conclusions: The metrics of saccade, especially antisaccade, can be a potential screening and assessing tool for MCI and dementia in elderly persons.

AUTOMATIC CLASSIFICATION OF ADRD CAREGIVERS' ONLINE INFORMATION WANTS: A MACHINE LEARNING APPROACH

Yuelyu Ji[1], Ning Zou[1], Bo Xie[2], Daqing He[1], and Zhendong Wang[1], *1. University of Pittsburgh, Pittsburgh, Pennsylvania, United States, 2. The University of Texas at Austin, Austin, Texas, United States*

Social media platforms are used by caregivers for persons with Alzheimer's Disease and its Related Dementias (ADRD) to obtain care information. Understanding what types of information caregivers want is critical to developing interventions to provide tailored information. Existing research on caregivers' information wants has relied primarily on manual data analysis, unable to handle the vast amount of data available on social media. In our prior work, we adapted the validated Health Information Wants (HIW) framework to the ADRD caregiving context, forming the HIW-ADRD framework that includes 7 types of information commonly wanted by caregivers. Our longer-term goal is to develop machine algorithms that use the HIW-ADRD framework to automatically classify caregivers' information wants from vast social media posts. Towards this end, we first scrapped posts from ADRD-related subgroups on Reddit, a popular social media platform. We then used few-shot learning, a machine learning method, to extract HIW from the posts. Using questions with question marks as a primary indicator for HIW, we filtered out those sentences and their corresponding background information. Next, we combined the questions and their background information as summaries of the posts. Finally, we sent the summaries to a classification model that classified these summaries based on HIW categories. We used 200 annotated posts to train the model, then tested it on 16779 posts. The evaluation results showed that our model achieved 62.35% in accuracy. These findings provide preliminary evidence for both the deep learning process and the algorithms. This study has implications for future research.

HEALTH SURVEILLANCE OF PERSONS LIVING WITH DEMENTIA AND CAREGIVER DYADS

Annie Robitaille[1], Neil Drummond[2], Linda Garcia[1], Himasara Marasinghe[3], and David Barber[4], *1. University of Ottawa, Ottawa, Ontario, Canada, 2. University of Alberta, Edmonton, Alberta, Canada, 3. University of Calgary, Calgary, Alberta, Canada, 4. Queen's University, Kingston, Ontario, Canada*

The relationship between individuals living with dementia and their caregivers is important and can impact their dementia journey. However, limited national longitudinal data exists about the caregiver-person living with dementia dyad. Availability of such data would provide important information about joint trajectories and help to better identify the needs of caregivers and persons living with dementia across the dementia journey. The objective of this study was to develop a linked national longitudinal database of persons living with dementia and their caregivers. The Canadian Primary Care Sentinel Surveillance Network (CPCSSN) extracts and de-identifies clinical data from electronic medical records (EMR) from approximately 2 million patients across Canada. CPCSSN data is used to identify persons living with dementia and caregivers willing to participate in the study. CPCSSN data from participating dyads are linked (e.g., chronic and mental health conditions, diagnoses, laboratory test results) and additional information about the experiences of persons living with dementia and their caregivers (e.g., ethnicity, amount and type of care provided, burden, availability of support) are collected yearly using surveys. The growing database contains linked, de-identified, comprehensive information about persons living with dementia and their caregivers that will become a rich source of data for researchers, clinicians, and policymakers. Specifics around how the database was developed, and lessons learned will be discussed as these findings can be used as a template to develop similar linked health surveillance databases.

NORMALIZING COGNITIVE EVALUATIONS IN ADULTS: GETTING PEOPLE IN THE SCREENING PIPELINE EARLY

Laura Mehegan, and Chuck Raineville, *AARP, Washington, District of Columbia, United States*

To understand how adults and healthcare providers perceive a dementia diagnosis and cognitive evaluations, AARP fielded a nationally representative survey of adults aged 40 and older (N=3,022) along with a companion survey of healthcare providers in a position to diagnose dementia (N=500). Like healthcare providers, Americans aged 40 and older understand the benefits of diagnosing dementia at an early stage, 81% agree that early detection would motivate them to engage in healthier behaviors to slow the progression of the disease. Adults look to healthcare providers as authorities to determine when a cognitive evaluation should be triggered with 63% saying they would get an evaluation if their doctor recommended it and 49% of healthcare providers saying evaluations should be done if the doctor feels it is necessary and 39% saying it should be done yearly beginning at age 65. The research also showed that most adults (76%) want to know if they have dementia. Additionally, majorities of adults would engage in healthy behaviors if they knew it's good for their brain health. Given the desire to prevent and improve outcomes, routine screening for cognitive function should be as commonplace as getting a screening colonoscopy. Unlike a colonoscopy, routine screening for cognitive function is not a normalized process yet. Data from both populations suggest an opportunity for routine evaluation due to a shared understanding of the long and short-term benefits of screening.

INVOLVING PERSONS LIVING WITH DEMENTIA AS KEY STAKEHOLDERS: RESEARCH "WITH" RATHER THAN RESEARCH "ON"

Ashlee Cordell[1], Christa Wilk[1], Silvia Orsulic-Jeras[1], Sara Powers[2], Farida Ejaz[1], and Beth Sanders[3], *1. Benjamin Rose Institute on Aging, Cleveland, Ohio, United States, 2.*

The Benjamin Rose Institute on Aging, Cleveland, Ohio, United States, 3. LifeBio, MARYSVILLE, Ohio, United States

Involving persons living with dementia (PLWD) as members of the research team is an important step in establishing an environment of conducting research "with" as opposed to research "on". Emerging research is also capturing PLWDs' lived experiences to inform product development. This presentation highlights the importance of conducting product development research with PLWD as key stakeholders and the valuable insight they provide to researchers and developers. Five community-dwelling PLWD with varying diagnoses (60% mild cognitive impairment; 20% Alzheimer's Disease; 20% mixed dementia) and tMMSE scores ranging from 22-26 (Mean=25) participated in two rounds (9 months apart) of 60-minute-long virtual focus groups via Zoom to test multiple versions of LifeBio MemoryTM: an app-based product designed for PLWD which utilizes advanced technology to improve an existing life story intervention. In Time 1, PLWD provided feedback on prototypes of the app and associated training that was used to inform the final product. In Time 2, participants reviewed the final product. A thematic analysis was conducted at each time point to inform further development of the app. Findings determined the following themes: 1) life stories can help with providing better person-centered care, 2) potentially sensitive topics require more training, 3) simple and clear instructions are vital for success. Topics further discussed in this presentation will include PLWDs': 1) thoughts on the concept of LifeBio and its adaptation, 2) comfort with answering life story interview questions, 3) opinions on dementia-friendly materials, and 4) reactions to the use of app-based technology.

ADJUSTING FOR COUNTRY-LEVEL VARIATION IN DEMENTIA PREVALENCE WITH CLASSIFICATION ALGORITHMS IN SHARE

Matthias Klee[1], Kenneth Langa[2], and Anja Leist[3], *1. University of Luxembourg, Esch-sur-Alzette, Not Applicable, Luxembourg, 2. University of Michigan, Ann Arbor, Michigan, United States, 3. University of Luxembourg, Esch-sur-Alzette, Grevenmacher, Luxembourg*

Background. Population-level dementia prevalence depends on societal factors and individual-level risk and protective factors. To improve our understanding of how these factors interact, we can use cross-national surveys such as the Survey of Health, Ageing and Retirement in Europe (SHARE). However, in absence of validated cognitive assessments, adjusting for underdiagnosis of dementia is needed. The present study sought to explore the usefulness of the Langa-Weir and alternative algorithms to detect probable dementia while accounting for country-level variation in estimated prevalence and underdiagnosis of dementia.Method. Data from 57,880 respondents aged 60 years and older to wave 7 of SHARE (2017) with non-missing data on variables related to sociodemographics and cognition were used. Adaptations of the Langa-Weir classification algorithm were compared to a weighted logistic regression model and an XGBoost classifier applying the synthetic minority oversampling technique. Different specifications of algorithms were tested globally and for individual countries and compared with the World Alzheimer's Report (2015)'s country-level projections of dementia prevalence for 2018. Results. All algorithms accurately classified self-reported diagnosis of dementia (accuracy = 0.90-0.96), with the Langa-Weir classification based on recall and a cutoff reflecting country-specific prevalence outperforming other algorithms regarding compensation of underdiagnosis. Algorithmically detected probable dementia is associated with newly self-reported dementia diagnosis, drop-out and death two years later. Discussion. Identifying probable dementia through classification algorithms can increase statistical power and improve validity in cross-national investigations. Further research is needed to replicate the findings in validated cognitive assessments and to identify causes of cross-national variation in dementia underdiagnosis.

SESSION 6160 (POSTER)

KNOWLEDGE AND COMMUNICATION AS ADRD INTERVENTIONS

NONVERBAL STRATEGIES TO ENHANCE PERSON-CENTERED COMMUNICATION WITH PEOPLE LIVING WITH DEMENTIA

Emma Bender, Marie Savundranayagam, Laura Murray, and Joseph Orange, *Western University, London, Ontario, Canada*

Many people living with dementia experience difficulties comprehending language, and benefit from nonverbal communication (NVC). Yet, little published empirical evidence exists for care partners regarding NVC strategies that support person-centered communication with perons living with dementia. This study aimed to determine whether NVC strategies used by personal support workers accompany verbal communication demonstrating person-centered communication indicators (facilitation, negotiation, recognition, validation). Secondary data analysis of video-recorded interactions (n=40) between personal support workers and simulated persons living with dementia was conducted. The recordings were transcribed according to communication-units, which were coded for person-centered communication and NVC, using a novel coding system consisting of ten NVC strategies. The overlap between NVC strategies and verbal person-centered communication was examined. Findings revealed that personal support workers frequently accompany verbal person-centered communication with NVC strategies. Out of 1848 communication-units in which person-centered verbal communication was used, 69% overlapped with NVC strategies. Gaze overlapped with all person-centered communication indicators frequently, both individually (40% – 49% of overlapping communication-units) and when combined with touch (13-24%). Gestures using objects (with and without gaze) frequently accompanied facilitation (17%) and negotiation (21%), while positive facial expressions (with and without gaze) were commonly found in recognition (16%) and validation (16%). The use of NVC strategies which support person-centered communication may lead to communication enhancement, in turn improving interactions and relationships between persons living with dementia and their care partners.

FEASIBILITY OF THE ACTPLAN PROGRAM FOR AFRICAN-AMERICAN DEMENTIA CAREGIVERS: A SELF-DIRECTED MULTIMEDIA DELIVERY

Yashika Watkins[1], Rita Tharpe[2], Neelum Aggarwal[3], and Gloria Bonner[4], *1. Chicago State University, Cliffside Park, New Jersey, United States, 2. ACTPlan Study, Chicago, Illinois, United States, 3. Rush University, Chicago, Illinois, United States, 4. University of Illinois at Chicago College of Nursing, Chicago, Illinois, United States*

African Americans (AA) are less likely than White Americans to complete advance care plans or end-of-life treatment documents. They face significantly greater risk of Alzheimer's Disease, a silent epidemic for this population, and other dementias. The healthcare system's lack of dementia support for AAs contributes to disparate care. A four-session caregiver group education program was conducted on advance care planning for AA dementia family providers. The program was based on Kolb's Experiential Learning Model and initially found effective in an R01 study using in-person delivery by a professional. The present pilot assessed feasibility of delivering the program in a self-directed multimedia format without professional facilitation, using Session 1 on tube feeding decisions as the test session. Twenty-six AA dementia caregivers completed the session in groups of 5 to 8 at a church equipped with a large TV screen. On-screen prompts guided navigation through the program which included recorded lecture, slides, short videos on decision-making, and group discussions. Using quantitative and qualitative methods, pre-and post-survey instruments were administered and interviews conducted. Usability ratings averaged 84%. Knowledge and self-efficacy gains exceeded those of the R01, with a 35% increase in correct responses on knowledge items, versus 18% for the R01 subjects; and increase in perceived decisional self-efficacy of 31% versus 30% for the R01 subjects. Qualitative feedback was universally positive. These findings confirm the feasibility of the self-guided multimedia approach to delivery of the program. A large RCT is planned which, if successful, will support wide dissemination to AA caregivers in need.

DOES KNOWLEDGE MATTER? AN INVESTIGATION INTO KNOWLEDGE OF ALZHEIMER'S DISEASE AND CAREGIVER BURDEN

Kaitlin Grelle, Kristen Hardin-Sigler, and Rebecca Deason, *Texas State University, San Marcos, Texas, United States*

A caregiver for someone with Alzheimer's disease often experiences burden, which can negatively impact their own physical and mental health, social participation and network, and financial stability (Chaio et al.; 2015, George & Gwyther, 1986). There is much interest in determining how to mitigate burden and studies suggest knowledge of the disease and recognizing positive aspects of caregiving may help reduce burden (Abdollahpour et al., 2018; Graham et al., 1997). The purpose of this study was to better understand how certain caregiver characteristics may impact burden. Participants (N=112) completed questionnaires regarding burden, disease knowledge, specific characteristics, and their caregiver experience. Pearson's correlations were conducted to examine the relationship between knowledge, burden, and caregiver characteristics. There was no significant correlation between burden and knowledge ($p = .457$), but burden was significantly correlated with positive aspects of caregiving ($p < .001$) and life satisfaction ($p < .001$). To better understand how well these two variables predicted burden, a multiple regression was conducted, $R^2 = .352$, $F(2, 90) = 24.48$, $p < .001$. Our findings provide further evidence that a focus on the positive aspects of caregiving and higher levels of life satisfaction are predictors of reduced caregiver burden. Some prior studies suggested knowledge of Alzheimer's disease led to decreased burden, whereas other studies found more knowledge increased anxiety, thus increased burden (Zawadzki et al., 2011). Our failure to find a correlation between knowledge and burden levels suggests this relationship may not be straightforward and future research needs to explore more specific aspects of this question.

IDENTIFYING GAPS AND MISCONCEPTIONS AND EXAMINING PREDICTORS OF ALZHEIMER'S DISEASE KNOWLEDGE IN KOREAN AMERICANS

Michin Hong[1], and Sang Lee[2], *1. Indiana University, Indianapolis, Indiana, United States, 2. San Jose State University, San Jose, California, United States*

This study examined Alzheimer's disease (AD) knowledge and its predictors among Korean Americans (KAs). A total of 268 KAs in the Greater Washington metropolitan area participated in the study and completed a cross-sectional survey. Using the Alzheimer's Disease Knowledge Scale (ADKS), overall and domain knowledge was assessed. Multiple regression analyses were conducted with predictors including exposure to AD, social engagement, sources and frequency of health-related information, stigmatic beliefs (pity, antipathy, and social distance), English proficiency, and education. KAs reported 59% accuracy in overall AD knowledge. They were most knowledgeable about assessment and diagnosis domain and least knowledgeable about caregiving domain. Regression analyses showed that having more education is associated with greater overall and certain domain knowledge. Having more pity stigmatic beliefs is related to greater knowledge in both life impact and caregiving domains while having less pity stigmatic beliefs is associated with more risk factor knowledge; having less social distance stigmatic beliefs is associated with greater life impact knowledge; and having less antipathy stigmatic beliefs is related to better caregiving knowledge. Our findings revealed areas of misconceptions and knowledge gaps in KAs which need to be addressed in educational interventions. Different knowledge status across the domains demonstrates a multi-dimensional nature of AD knowledge. Multivariate findings confirmed the robust role of education in AD knowledge. Effect of different AD stigmatic beliefs on certain AD knowledge domains suggests ways of how stigma change can be efficient for the purpose of increasing AD domain knowledge in KAs.

TARGETING KNOWLEDGE, BARRIERS, AND FACILITATORS TO PARTICIPATION IN DEMENTIA RESEARCH (THE POWER PROJECT)

Martha Sajatovic[1], Lynn Herrmann[2], Clare Knebusch[3], Kaylee Sarna[4], Alan Lerner[1], Edna Fuentes-Casiano[5], and Christopher Burant[6], *1. Case Western Reserve University School of Medicine, Cleveland, Ohio, United States, 2. Northern Illinois University, DeKalb, Illinois, United States, 3. University Hospitals Cleveland Medical Center,* *Cleveland, Ohio, United States, 4. Case Western Reserve University, Cleveland, Ohio, United States, 5. Case Western Reserve University School of Medicine, Cleveland, Ohio, United States, 6. Case Western Reserve University, Parma, Ohio, United States*

Racial and ethnic minorities are under-represented in dementia research. We tested a conceptually-driven health communication approach targeting evidence-based barriers and facilitators to research participation vs. dementia awareness training. Input from the minority advisory board (MAB) of the Cleveland Alzheimer's Disease Research Center (CADRC) informed development of 2 brief health communication videos which differentially focused on research barriers and facilitators (POWER) versus an education control (EDU). A randomized controlled on-line survey compared POWER vs. EDU among 200 individuals ≥ 50 years. We examined pre/post video change in research motivation measured by the transtheoretical model, dementia knowledge and cumulative barriers and facilitators. Interim analysis included 129 individuals who completed the pre-video survey, mean age 58.8 (SD 14.9), 101 (78.3 %) women, 54 (41.9 %) non-white. 100 (77.5 %) completed the post-video survey. Whole sample dementia knowledge improved from pre (mean 4.6, SD 1.3) vs. post (5.8, SD 0.7) video (p <.01), as did facilitators to research from pre (22.4, SD 2.7) vs. post (22.8, SD 3.0) video (p=.02), while there was no significant change in barriers. Research motivation was increased pre (10.8, SD 2.0) vs. post (22.8, SD 3.0) video (p=.02). Overall, dementia knowledge improved more with EDU vs. POWER (p=.04). African-American participants trended towards greater improvement in dementia knowledge with EDU vs. POWER (p=.07), while non-African-Americans had greater facilitator improvement with POWER vs. EDU (p=.03). Targeted communication approaches that address knowledge gaps and both barriers and facilitators to participation may improve engagement of diverse groups in dementia research.

OLDER ADULTS' ONLINE INFORMATION SEEKING FOR ALZHEIMER'S DISEASE

Matthew Picchiello, Payton Rule, and Brian Carpenter, *Washington University in St. Louis, St. Louis, Missouri, United States*

Many older adults use the internet to gather health information. Yet past research shows that older adults display less understanding of internet concepts and score lower on information-retrieving tasks than younger adults, making them more vulnerable to internet misinformation. To address this, a variety of guidelines (e.g., HONCode) have been developed to help consumers identify credible sources. This is especially relevant for Alzheimer disease (AD), as research has shown that online AD information is mixed in its quality. The purpose of this study was to examine how older adults gather online AD information and evaluate their ability to find credible sources to improve knowledge. We recruited 83 older adults (Mage = 70.0, 60.2% female; 85.5% White) who completed the Alzheimer Disease Knowledge Scale (ADKS; Carpenter et al., 2009) before and after engaging in six AD-related search tasks (e.g., identify age of onset, risk factors, treatment, etc.). Older adults utilized a variety of search strategies, visiting both reputable (i.e., not-for-profit or university-based) and less scrutinized (i.e., commercially sponsored) websites, and a vast majority (95.0%) were unaware of HONCode guidelines for evaluating website quality. While most participants could locate some AD-related information (97.6% identified risk factors), other information was more elusive (29.3% could not identify age of onset). Despite this, participants showed improved ADKS scores, t(74) = 5.55, p < 0.001. Our research shows that many older adults can gather some accurate online information about AD but may benefit from additional resources on using effective search strategies and identifying credible sources.

SESSION 6170 (POSTER)

MENTAL HEALTH (POSTERS)

DEVELOPMENT AND VALIDATION OF THE LEISURE EUSTRESS-DISTRESS SCALE

Jaesung An[1], Laura Payne[2], and Toni Liechty[2], *1. California State University East Bay, Cupertino, California, United States, 2. University of Illinois Urbana-Champaign, Champaign, Illinois, United States*

Encountering stressors is a part of everyday life and can even occur when people engage in leisure activities. This is more prevalent among older adults due to the onset of chronic condition(s), lack of resources, and social isolation. Therefore, leisure related stressors could provoke complex emotions derived by positive and/or negative responses to stressors before, during, and after older adults engage in leisure activities. Different from the concept of leisure constraints, which emphasizes causes of stress that prevents leisure engagement in the first place, the concepts of leisure eustress and distress are associated with the emotional experience of stress in the context of leisure. Despite the presence of leisure-based eustress and/or distress among older adults, there is no measurement scale that assesses this phenomenon. Therefore, the purpose of this study was to develop and validate a leisure eustress-distress scale (LEDS). Phase one of this study included in-depth interviews, expert panelists review, and a pilot study to develop and refine items. In the second phase, a target study was conducted to examine the factor structure using exploratory and confirmatory factor analysis. For validity, LEDS showed partial support for construct and criterion validity. Strategies to strengthen the scale's validity will be discussed as well as future recommendations and practical implications of the LEDS.

BA FOR DEPRESSION AND DIABETES MANAGEMENT: EXAMINED VIA SINGLE-CASE DESIGN

Anna Robertson[1], and Leilani Feliciano[2], *1. University of Colorado, Colorado Springs, Colorado Springs, Colorado, United States, 2. University of Colorado Colorado Springs, Colorado Springs, Colorado, United States*

Type 2 Diabetes Mellitus (T2DM) is a pervasive, chronic disease whose prevalence increases with age. The most common treatment options for T2DM include medication, dietary changes, and engagement in physical activity, which require considerable lifestyle changes. Further, individuals with T2DM are highly likely to develop physical and mental health comorbidities that can complicate effective T2DM management. In fact, individuals with T2DM and other comorbidities are frequently excluded from behavioral and other interventions in randomized controlled trials due to their comorbidities. Individualized treatment is necessary to address these comorbid diseases and to effectively navigate lifestyle changes. As part of a larger study evaluating an at-home diabetes management program with patients at a Federally Qualified Health Care Facility, the current study utilized a single-case experimental design approach using changing criterion design to evaluate behavioral activation to treat depression and diabetes in a 68 year-old Hispanic woman with cognitive impairment. Across her intake, five treatment sessions, and two follow-up appointments, we collaborated with her to set and achieve behavioral goals while effectively managing her diabetes. By end of treatment, she reported significant improvements in depression and overall well-being, increased engagement in exercises, increased blood glucose tracking, and rated improvement in her overall efficacy in life that maintained through follow-up. Results revealed the effectiveness of behavioral activation in treating comorbidities in a low-income, diverse individual. Attendees will learn about a promising treatment avenue for older individuals with complex medical and psychiatric conditions and the utility of single case design.

UNDERSTANDING THE EXPERIENCE OF EUSTRESS AMONG OLDER ADULTS WITH CHRONIC CONDITIONS

Jaesung An[1], Laura Payne[2], Toni Liechty[2], and Yoshitaka Iwasaki[3], *1. California State University East Bay, Cupertino, California, United States, 2. University of Illinois Urbana-Champaign, Champaign, Illinois, United States, 3. San Jose State University, San Jose, California, United States*

In their longitudinal study of stress and health among adults, McGonigal and colleagues (2013; 2016) suggested that how person perceives stress is a key factor affecting their actual physiological health. This is related to the concept of eustress (i.e., positive response to a given stressor) which has received very little attention in the literature. Besides, older adults with chronic conditions deal with symptoms that are difficult to manage and can contribute to chronic stress, which can then affect their health status and quality of life. Thus, helping older adults to shift their perceptions and interpretations of stressors from distress to eustress, rather than trying to avoid stress seems to be a reasonable approach to help them experience healthy aging. The purpose of this study was to explore the experience of eustress among older adults with chronic conditions in the context of leisure. Sixteen participants were recruited from three settings in a Midwestern city: a retirement community, an assisted living center, and a community senior program. Findings showed that participants' health conditions were one of their greatest stressors, however, they modified their leisure engagement based on their conditions to enable their engagement in valued leisure activities. In the context of leisure, five themes emerged as facilitators that helped older adults to experience eustress: leisure satisfaction, sense of control, high levels of perseverance, positive attitude, and spiritual belief. Direct quotes and further discussion on how the themes are represented in the stress, leisure, and gerontology literature will be presented.

AGE AND COGNITIVE ABILITY AS PREDICTORS OF EMOTION REGULATION STRATEGY USE

Claire Growney, and Tammy English, *Washington University in St. Louis, St. Louis, Missouri, United States*

Emotion regulation (ER) is viewed as a cognitively demanding process and involves selecting and implementing specific strategies in support of one's emotional goals. Older adults are theorized to maintain emotional wellbeing by selecting ER strategies that are consistent with their available resources, which may involve engaging more with lower-arousal stimuli and less with higher-arousal stimuli, especially when cognitive resources are limited. The aim of this study was to examine relationships between age, cognitive ability, and use of different types of ER strategies. Participants (N = 287) aged 25-85 (M = 54.33, SD = 17.19) completed assessments of cognitive ability from the NIH Toolbox Cognitive Battery. In a laboratory task, participants viewed a series of film clips eliciting low-arousal emotions (sadness, contentment) and high-arousal emotions (disgust, amusement) under instructions to regulate pro-hedonically using any available strategy. They reported their use of disengagement (e.g., distraction, suppression), engagement (e.g., perspective-taking, awareness), and positive-focus strategies (e.g., savoring, positive reappraisal). Results from multilevel models revealed that with low-arousal stimuli, age was associated with higher engagement and lower disengagement, regardless of fluid cognitive ability. With high-arousal stimuli, a fluid cognition X age interaction indicated that there was an age-related increase in engagement among individuals with higher fluid cognitive ability, but not lower fluid cognitive ability. Findings support the idea that older adults tend to engage with emotional stimuli, which may aid with processing and support emotional memory for future regulation attempts. Fluid cognitive ability may be an important resource supporting older adults' engagement with high-arousal stimuli.

COMMUNITY MOBILITY PATTERNS OF OLDER ADULTS DURING THE COVID-19 PANDEMIC

Arne Stinchcombe[1], Nadia Mullen[2], John Timinski[1], Shawn Marshall[1], Gary Naglie[3], Mark Rapoport[4], and Michel Bédard[2], *1. University of Ottawa, Ottawa, Ontario, Canada, 2. Lakehead University, Thunder Bay, Ontario, Canada, 3. Baycrest Health Sciences, Toronto, Ontario, Canada, 4. University of Toronto, Toronto, Ontario, Canada*

The COVID-19 pandemic has had appreciative impacts on the lives of older adults. At various times during the pandemic, Canadian provinces put in place public health measures to prevent the spread of the virus, including closures of non-essential businesses and services. The Candrive Driving Cessation sub-study is a 12-year, mixed methods, longitudinal study. During the COVID-19 pandemic, participants from four sites (n=124, mean age=85.5 years) were asked to report how their community mobility patterns during the pandemic compared with before the pandemic. They also completed the COVID-19 Anxiety Syndrome Scale and the Assessment of Readiness for Mobility Transition (ARMT) tool. The results indicated that during the pandemic, participants were less likely to drive ($\chi2=7.11$, $p=.004$) or ride a public bus ($\chi2=20.05$, $p<.001$) when leaving their home. During the pandemic, they reported fewer trips to the supermarket (χ2=99.00, p<.001) and fewer visits with family (χ2=68.00, p=.001). We observed a statistically significant relationship between COVID-19 Anxiety Syndrome Scale scores and ARMT (Anticipatory Anxiety subscale; r= .810, p<.001), such that higher COVID-19-related anxiety was associated with greater anxiety related to anticipating changes in mobility. These results emphasize the impacts of the COVID-19 pandemic on the mobility patterns of older adults. Promoting community mobility for older adults alongside preventative public health measures is essential.

FACTOR ANALYSIS OF CORNELL SCALE FOR DEPRESSION IN DEMENTIA AMONG ASSISTED LIVING RESIDENTS

Rachel McPherson[1], and Barbara Resnick[2], *1. University of Maryland Baltimore and Baltimore County, Catonsvile, Maryland, United States, 2. University of Maryland, Baltimore, Maryland, United States*

The Cornell Scale for Depression in Dementia (CSDD) was developed to measure depressive symptoms among older adults with dementia. The psychometric qualities of the CSDD have been inconsistent regarding the factor structure, with some studies showing a four-factor model and others a five-factor model. The purpose of this study was to test the factor structure of the CSDD as a measure of depression among a sample of assisted living residents. It was hypothesized that a four-factor version of the CSDD would provide a better fit than a five-factor version of the CSDD. The present study used baseline data from the Function-Focused Care for Assisted Living Using the Evidence Integration Triangle (FFC-AL-EIT) intervention study. A total of 511 residents from 85 assisted living facilities were included in the analyses. Confirmatory factor analyses were conducted to examine the factor structure and a chi-square difference test was conducted to compare model fit. Three items were removed from both models due to small factor loadings. The chi-square difference test indicated that the five-factor model fit the data significantly better (χ2 = 796.08, Δχ2= 22.86, Δdf = 4, p < .001) than the four-factor model, although both the five-factor and four-factor models produced very poor model fits. These findings may be due to the fact that the CSDD relies on information from caregivers, and the measure might benefit from including observational signs of depression. Future work should examine other factors or items that belong in a depression measure among assisted living residents.

FEAR OF FALLING IS RELATED TO ANXIETY

Hyeon Jung Kim[1], Jennifer Yentes[2], Dawn Venema[3], and Julie Blaskewicz Boron[4], *1. University of Nebraska Omaha, Omaha, Nebraska, United States, 2. Texas A&M University, College Station, Texas, United States, 3. University of Nebraska Medical Center, Omaha, Nebraska, United States, 4. University of Nebraska, Omaha, Omaha, Nebraska, United States*

Fear of falling (FOF), defined as a psychological symptom, is related to increased fall risk, anxiety, and depressive symptoms. As physical function changes with age, FOF can appear beginning in midlife. FOF may result in avoiding physical activities, resulting in weakness of postural balance. Neuroticism is associated with anxiety and depression; thus, those high on neuroticism may have an increased FOF. This study aimed to address the relationships between FOF, neuroticism, and number of falls from external perturbations while standing. Participants included 45 participants (female: n=24; age range: 42-77yrs; age=62.44±9.25yrs). Five standing trials were completed on a force platform with perturbations. Hierarchical regression was used to investigate the impact of neuroticism (Big Five Inventory) and number of falls on FOF (The Falls Efficacy Scale International), accounting for age, anxiety (Geriatric Anxiety Scale), and depressive symptoms (Center for Epidemiological Studies Depression Scale). Anxiety was significantly associated with FOF (model 1; age, anxiety, depression), B=0.31, β=.55, t(41)=3.08, R2=.30, p=.004, 95% CI [0.11, 0.51]. Neuroticism was not significantly related to FOF (model 2; ΔR2=.05, ΔF=2.94, p=.094), nor was number of falls (model 3; ΔR2=.00, ΔF=0.01, p=.974). Results revealed that anxiety levels had the strongest relationship with FOF. This suggests that strategies to reduce daily anxiety may decrease FOF. Future research should examine how anxiety is related to history of falls, and how changes in physical functions (e.g., mobility, vision, proprioception) may impact FOF.

MARITAL DISSOLUTION AND DEPRESSIVE SYMPTOMS IN MIDDLE AND LATE LIFE: AN ANALYSIS OF THE HEALTH AND RETIREMENT STUDY

Julia Tucker[1], and Sae Hwang Han[2], *1. The University of Texas at Austin, New Braunfels, Texas, United States, 2. University of Texas at Austin, Austin, Texas, United States*

Literature to date has long indicated that marital relationships serve as one of the most important sources of health and well-being across adulthood. Despite the well-documented link between marital status and health, however, studies that have examined strict within-person linkages between martial transitions and subsequent health are limited . Drawing from the strength and vulnerability integration theory and the life course perspective, we investigated within-person mental health consequences of two forms of marital dissolution (i.e., divorce and widowhood), and whether the mental health consequences vary depending on the timing of marital dissolution (i.e., midlife vs late adulthood). Data for this study came from 11 waves of longitudinal data from the Health and Retirement Study (1998-2018). Study sample included 22,911 individuals 50 and older (11,429 women, 11,482 men) who were selected at the first wave at which they were identified as married during the observation period and subsequently followed up for up to 14 years (person-wave observations N=127,081). Approximately 4% and 17% of the study sample experienced a divorce and widowhood, respectively, during the observation. Mental health was assessed with an 8-item version of the Center for Epidemiologic Studies Depression scale. Study findings based on multilevel models indicated a robust within-person association between transition to widowhood and higher levels of depressive symptoms, but such association was not found regarding divorce. For women only, the mental health consequences of widowhood experienced during midlife were more detrimental compared to late-life widowhood. The findings are discussed in the context of intervention strategies.

SUICIDAL IDEATION AMONG OLDER ADULTS LIVING WITH CHRONIC ILLNESS

Abigail Poe, and Frank Puga, *The University of Alabama at Birmingham, Birmingham, Alabama, United States*

Older adults living with chronic illnesses, such as diabetes, cancer and heart disease, have an increased risk of poor mental health outcomes. While a link between living with chronic illness and depression have been examined in previous studies, relatively little is known about factors that increase and decrease the risk of suicidal ideation among older adults living with chronic illness. Using data from the third wave of the Midlife in the United States (MIDUS) database, we examined the relationship between living with a chronic illness were more likely to endorse thinking about death in the previous two weeks (OR=3.17, CI: 1.16 – 8.65, p=0.24). The analysis also revealed that the likelihood of suicidal ideation in the previous two weeks increased with the number of chronic conditions reported by participants (OR=1.128, CI: 1.04 – 1.23, p=0.005). The results of this study are consistent with previous studies suggesting a relationship between older adults living with a chronic condition are at a higher risk of suicidal ideation. Findings from this study can help inform intervention development to support mental health of older adults living with chronic illness. Future studies are needed to examine additional psychosocial factors that may mediate the relationship between living with a chronic illness and suicidal ideation among older adults.

THE IMPACT OF SLEEP ON MINDFULNESS, WELL-BEING, AND DEPRESSIVE SYMPTOMATOLOGY IN MIDDLE TO OLDER AFRICAN AMERICANS

Folasade Ilori[1], Sanaz Dabiri[1], Mara Ramirez-Ruiz[1], George Daniel[1], Robert Head[1], Regina Wright[2], and Denee Mwendwa[1], *1. Howard University, Washington, District of Columbia, United States, 2. University of Delaware, Newark, Delaware, United States*

The decline in physical and mental well-being is common with age. The negative impact of poor quality of sleep and depressive symptomatology contributes to the decline in well-being among middle to older adults. African Americans are more likely to report a decrease in well-being as they age. They are also disproportionately affected by poorer sleep quality and may be at greater risk for depressive symptomatology. Dispositional mindfulness is linked to improved well-being. Research has shown dispositional mindfulness is related to adaptive health behaviors, improved sleep quality, and reduced negative affect. Mindfulness allows engagement of early regulation of intense emotional responses because of nonjudgmental acceptance of thoughts and emotions. Therefore, this study aims to examine the impact of mindfulness on physical/mental well-being and depressive symptomatology through sleep. 131 African American participants were recruited for the study, with an average age of 58 years. The results showed a significant effect of mindfulness on well-being and depressive symptoms. Additionally, the impact of mindfulness on mental and physical well-being was mediated by sleep quality (B = .7920, CI [.1482, 1.6702]) and sleep disturbance (B = 2.874, CI [.1582, 6.335]). The results also showed an indirect effect of mindfulness on depressive symptoms through sleep quality (B = –6.139 CI [-12.871, -.5298]). This study demonstrates the positive impact of mindfulness on well-being and depressive symptomatology. Sleep quality also plays an important role in the relationship between dispositional mindfulness and physical/mental well-being and depressive symptomatology in middle to older African Americans.

GRANDPARENTING AND DEPRESSIVE SYMPTOMS IN URBAN CHINA: LIVING ARRANGEMENTS AND WORK STATUS AS MODERATING EFFECTS

Luyan Ma[1], and Zhaowen Cheng[2], *1. Peking University, Beijing, Beijing, China (People's Republic), 2. China Development Research Foundation, Beijing, Beijing, China (People's Republic)*

Scholars worldwide are divided as to whether grandparenting can benefit to older adults' well-being. Evidence from rural China supports that custodial grandparenting worsens grandparents' psychological well-being. However, given the great urban-rural gap, the situation in urban China might be different. To clarify this, we use CHARLS 2011-2013 (900 respondents) and examine the association between length and intensity of grandchild care and depressive symptoms among older adults living in urban China. We also explore the moderating effect of grandparents' living arrangements and work status. Multiple linear regression with interaction analysis is applied in our analysis. We find that moderate levels of grandchild care, without distinguishing between living arrangements and work status, are associated with reduced depressive symptoms ($\beta = -1.146$, $p < .05$). Grandparents are likely to have more depressive symptoms when working full-time and providing care at the same time. Comparing with not living with grandchildren, living with grandchildren is beneficial to grandparents' mental health. Findings suggest that psychological counseling services and economic support policies should be launched to relieve the work pressure of grandparents in financial difficulties.

CHANGE IN SOCIAL INTERACTION AND MENTAL HEALTH AMONG OLDER AMERICANS DURING COVID-19 PANDEMIC

Krystyna Keller[1], Jielu Lin[1], Melissa Zajdel[1], Fiona Gilpin Macfoy[1], Philip Shaw[1], Brenda Curtis[2], Lyle Ungar[3], and Laura Koehly[1], *1. National Institutes of Health, Bethesda, Maryland, United States, 2. National Institutes of Health, Baltimore, Maryland, United States, 3. University of Pennsylvania, Philadelphia, Pennsylvania, United States*

Recent research has shown the mental health consequence of social distancing during the COVID-19 pandemic, but longitudinal data are relatively scarce. It is unclear whether the pattern of isolation and elevated stress seen at the beginning of the pandemic persists over time. This study evaluates change in social interaction over six months and its mental health impact among older adults. We drew data from a panel study with six repeated assessments of social interaction and mental health conducted monthly May through October 2020. The sample included a total of 380 White, Black and Hispanic participants aged 50 and over, of whom 33% had low income, who residing in fourteen U.S. states with active stay-at-home orders in May 2020. The analysis examined how change in living arrangement, in-person interaction outside the household, quality of relationship with family and friends, and perceived social support affected trajectories of isolation stress, COVID worry and sadness. While their living arrangements and relationship quality remained stable, older adults experienced fluctuations in perceived social support and increases in in-person conversations outside the household. Living with a spouse/partner stabilized isolation stress and COVID worry over time. Individuals with better relationship quality with friends became happier over time. Changes in social support were associated with greater fluctuations in isolation stress and COVID worry. During the pandemic, social interactions are protective and lack of stability in feeling supported makes older adults vulnerable to stress. Efforts should focus on (re)building and maintaining companionship and support to mitigate the pandemic's negative impact.

AT THE INTERSECTION OF CULTURE AND MENTAL HEALTH

Daniel Jimenez, *University of Miami Miller School of Medicine, Miami, Florida, United States*

Although mental health disorders affect people across the lifespan, older adults face unique issues associated with accessing mental health treatment. These structural and psychosocial challenges are further exacerbated among older racial and ethnic minorities. Often compared to their white counterparts, racial and ethnic minority older adults face specific cultural factors and other systemic barriers that create stark disparities in diagnosis, treatment, and access to care. Increasing research on identifying barriers to treatment for older racial and ethnic minority adults has been recognized as an integral component in enhancing treatment access to improve behavioral health outcomes among these marginalized groups. Therefore, this review article aims to investigate the intersection of mental health and culture through the lens of three racial and ethnic minority groups in the United States – Blacks/African-Americans, Asian Americans, and Latinos. Authors provide unique insights on the differing needs of these under-researched communities by exploring psychiatric comorbidity, experiences with seeking, accessing, and engaging in treatment, and the unique cultural and psychosocial factors that affect treatment outcomes for these diverse groups. Future directions and recommendations to provide appropriate mental healthcare to Black/African-American, Asian American, and Latino communities are discussed with special attention placed on cultural adaptations, models of care, prevention, and practical strategies that can be implemented to reduce disparities and increase health equity.

EXPLORING THE PHYSICAL FUNCTION PROFILES OF OLDER ADULTS WITH SERIOUS MENTAL HEALTH CONDITIONS

Julia Browne[1], Miriam Morey[1], Eric Elbogen[1], Kim Mueser[2], and Katherine Hall[1], *1. Durham VA Health Care System, Durham, North Carolina, United States, 2. Boston University, Boston, Massachusetts, United States*

Older adults with serious mental health conditions experience high rates of comorbid chronic medical diseases, which affect the physical function and long-term aging trajectory of this population. Existing physical function research in this population has focused almost exclusively on endurance with little to no attention paid to other important domains such as balance, mobility, and strength, which are critical to promoting independence and improved quality of life. The primary aim of this study was to explore the multiple dimensions of function that are important to maintaining independence and health in older adults with serious mental health conditions. This study examined publicly available data from the 2014 and 2016 waves of the Health and Retirement Study, a national longitudinal panel study of older adults. Analyses were limited to participants that self-reported lifetime diagnoses of serious mental health conditions (schizophrenia, bipolar disorder, depression, posttraumatic stress disorder). The sample comprised 428 older adults over age 50 (M=67.1, SD=10.1; 68% female) who completed standardized assessments of grip strength, single-leg standing balance, and usual walking speed. Scores on these three measures were compared to established age-and/or gender-based norms for each assessment to characterize performance. Overall, 65% of the sample demonstrated deficits in strength and 31% of the sample performed below established norms for both balance and walking speed. These findings highlight that physical function in this population is compromised across multiple domains and suggest a need for multicomponent interventions.

DIFFERENT LEVELS OF LEISURE-TIME PHYSICAL ACTIVITY AND MENTAL HEALTH FOR OLDER ADULTS WITH DIABETES IN THE PANDEMIC

Jungjoo Lee[1], Junhyoung Kim[2], and Sua Han[2], *1. Indiana University, Blooimgton, Indiana, United States, 2. Indiana University, Bloomington, Indiana, United States*

This study is an initial investigation of the association of different levels of LTPA engagement with mental health (e.g., loneliness, happiness, and positive and negative affect) among older adults with diabetes during the COVID-19 pandemic. The COVID-19 has led public health researchers to improve mental health among older adults with diabetes. Leisure-time physical activity (LTPA) has been emerged to cope with mental health difficulties in the pandemic. Total 301 respondents were extracted from the Health and Retirement Study (HRS) based on the following two criteria: over 50 years old and the onset of diabetes. Multiple questionnaire items were used to assess mental health (i.e., loneliness, happiness, and positive and negative affect) for older adults with diabetes. Multivariate Analysis of Variance was utilized to investigate the relationships between the fixed variable (i.e., LTPA) and outcome variables (i.e., mental health). We categorized LTPA participation into three groups (i.e., low, mid, high) and examined mental health following a different level of LTPA participation. LTPA participation showed a significant group mean differences for loneliness, happiness, and positive affect, but not for negative affect. High-LTPA respondents presented lower loneliness) and higher happiness than Low-LTPA respondents. High-LTPA and Mid-LTPA respondents indicated higher positive affect than Low-LTPA respondents. This study provides evidence of the benefits of LTPA on mental health for older adults with diabetes. Our study supports the evidence that high-LPTA involvement can be effective in promoting mental health among older adults with diabetes in the COVID-19 era.

AGE DIFFERENCES IN EXPOSURE TO NOVEL SITUATIONS IN DAILY LIFE AND ASSOCIATED EMOTIONAL EXPERIENCE

Li Chu[1], Yochai Shavit[2], Nilam Ram[3], and Laura Carstensen[3], *1. Stanford University, Menlo Park, California, United States, 2. Stanford Center on Longevity, Stanford University, Stanford, California, United States, 3. Stanford University, Stanford, California, United States*

Exposures to novelties are cognitively beneficial in later adulthood, but their impact on emotional well-being is still unknown. Novel situations may bring excitement as well as anxiety, and this may be different across ages According to socioemotional selectivity theory, older adults prioritize familiar and positive experiences that likely contribute to better emotional well-being over novel and negative ones, suggesting that older adults may be motivated to avoid novel situations, especially if these experiences are associated with negative emotions. This study examined age differences in novelty experienced in daily life and the associated emotions. We utilized experience sampling data collected five times a day for one week from 375 participants (age range=18-94). Contrary to the hypothesis, older age exhibited a quadratic association with novel daily experiences such that situation novelty was lowest in middle adulthood. Results from multilevel models suggested that people with higher overall exposure to novel situations had higher overall levels of negative emotions, and that when in more novel situations the prototypical individual experienced more negative emotions in general. However, consistent with SST postulates, one of these associations were moderated by age; older adults experienced lower positive emotions during novel situations than younger individuals. In contrast, the association between situation novelty and negative emotions did not differ with age. Together, these findings suggest that older adults do often find themselves in novel situations but may experience them less positively than younger adults. Implications on learning-related programs and interventions designed to expose older adults to novelties will be discussed.

COMPASSIONATE LOVE AND LONELINESS: LATER LIFE MENTAL HEALTH IN THE UNITED STATES

Nirmala Lekhak[1], Tirth Bhatta[2], Eva Kahana[3], and Joel Synder[1], *1. University of Nevada, Las Vegas, Nevada, United States, 2. University of Nevada Las Vegas, Las Vegas, Nevada, United States, 3. Case Western Reserve University, Cleveland, Ohio, United States*

Loneliness is a serious public health problem that affects over 25% of older adults and is associated with an increased risk of depression, cognitive decline, and premature death. Previous research on social support mechanisms that contribute to loneliness has consistently illustrated the role of emotional support in reducing loneliness. However, the importance of compassionate love in reducing loneliness and, as a consequence, improving psychological well-being in later life has received little attention. Neurobiology indicates that the brain regions associated with loneliness and compassion overlap, suggesting that increasing compassion-related emotions may help alleviate loneliness. Using data from a nationwide web-based survey (n=1,861), we examined the influence of compassionate love on loneliness and assessed whether loneliness mediates the relationship between compassionate love and mental health outcomes. Even after controlling for emotional support, estimates from an ordinary least squares regression (OLS) model suggest that older adults who felt loved had significantly lower levels of loneliness (b=-0.84, p< 0.001). Feeling of love also contributed to significantly fewer depressive symptoms (b=-2.03, p< 0.001) and anxiety (b=-1.07, p< 0.001). Loneliness completely mediated the effect of compassionate love on anxiety (b=-0.82, p< 0.001) and significantly mediated its influence on depressive symptoms (b=-1.18, p< 0.001). Our findings underscore the need to design interventions that increase compassionate love to reduce loneliness and improve psychological wellbeing among older adults.

DAILY STRESS, ANTICIPATORY ANXIETY, RUMINATION, AND NEGATIVE AFFECT IN LATE LIFE

Zexi Zhou, and Karen Fingerman, *The University of Texas at Austin, Austin, Texas, United States*

Chronic and daily stress are risk factors to older adults' health and well-being. However, most studies of stress have focused on the reactivity and recovery process following the onset of stress. Relatively little research has investigated the worries that precede stress (e.g., anticipatory anxiety) and how such worries may contribute to older adults' subsequent emotional experiences and rumination, especially in daily settings. This study investigated the joint associations of daily stress and anticipatory anxiety on rumination and negative affect in older adults' everyday life. We leveraged the ecological momentary assessment (EMA) data over 5 to 6 days from the Daily Experiences and Well-being Study (N = 267, Mage = 73.72). Anticipatory anxiety was moderately correlated with stresses experienced that day, r = .23, p < .001. We found significant joint associations between daily stress and anticipatory anxiety with rumination and negative affect. Higher daily anticipatory anxiety (M+1SD) combined with higher stress generated the highest rumination and negative affect, whereas lower daily anticipatory anxiety (M-1SD) paired with lower stress generated the lowest rumination and negative affect. Higher daily anticipatory anxiety paired with lower stress, or lower anticipatory anxiety paired with higher stress, led to a moderate level of rumination and negative affect. These results suggest that anticipatory anxiety toward potential stress has distinct negative effects on older adults' daily experiences, and these effects may contribute to stressors and to heightened rumination. The findings highlight the role that proactive emotional expectations may play in older adults' everyday life.

GENERATIVITY AND OLDER ADULTS' COVID-19 ADJUSTMENT AND MENTAL HEALTH

Christine So[1], Katherine Fiori[1], Amy Rauer[2], and Christina Marini[1], *1. Adelphi University, Garden City, New York, United States, 2. University of Tennessee Knoxville, Knoxville, Tennessee, United States*

Generativity, the capacity to be productive, caring, and concerned with the well-being of the next generation, has been linked to positive mental health outcomes and posttraumatic growth (Bellizzi, 2004). Generativity may be particularly important nowadays as older adults adjust to the pandemic and its aftermath. For example, after months of social distancing, the availability of vaccines has enabled many older adults to begin resuming social activities. Considering the meaning-making function of generativity, generativity may be associated with more positive outcomes, including better mental health and views on quality of life and family relationships during this post-pandemic adjustment period. The current study used a community sample of 136 older adults (M age = 67.77, range 50-91; 69.3% females; 93% White) to explore whether generativity predicted older adults' anxiety and depressive symptoms, and attitudes about how the pandemic affected their quality of life and family relationships. Using hierarchical linear regressions controlling for age and gender, we found that generativity was negatively linked to anxiety and depressive symptoms. Furthermore, those with greater generativity were more likely to report that their family relationships improved because of the pandemic. In contrast, generativity was not associated with positive growth in the personal domain or with perceptions that the pandemic had harmed either personal or family domains. Our findings are consistent with Erikson's theory on the important role that generativity plays in shaping well-being and psychological health in older adults, and our findings suggest these effects may be especially pronounced during this post-pandemic adjustment period.

THE ASSOCIATION OF INCREASING RESILIENCE WITH POSITIVE HEALTH OUTCOMES AND QUALITY OF LIFE AMONG OLDER ADULTS

Shirley Musich[1], Shaohung Wang[2], James Schaeffer[2], Sandra Kraemer[3], Ellen Wicker[4], and Charlotte Yeh[4], *1. Optum Labs, Bloomfield Hills, Michigan, United States, 2. Optum Labs, Minnetonka, Minnesota, United States, 3. UnitedHealthcare, Minnetonka, Minnesota, United States, 4. ASI, Inc., Washington, District of Columbia, United States*

Background: Resilience has been recognized as a concept central to successful aging. Higher resilience has been associated with positive mental health while a direct impact on physical health outcomes has been less consistent. Objective: To investigate three levels of resilience (low, medium, and high), identify characteristics associated with medium and high resilience and measure the impact of increasing resilience on selected health outcomes: quality-of-life (QOL), and healthcare utilization and expenditures.

Methods: The study sample was identified from adults age ≥65, covered by an AARP® Medicare Supplement Insurance Plan from UnitedHealthcare, who had completed a health survey during May-June 2019 (N=3,573). Resilience was categorized to three levels: low, medium, and high. Other positive resources, including purpose-in-life, locus of control, social connections, and optimism, were dichotomized as high/low and counted with equal weighting as a continuous variable. Quality of life was measured from the health survey; healthcare utilization and expenditures from administrative databases.

Results: Among weighted survey respondents, the prevalence of low, medium, and high resilience levels were 27%, 29%, and 43%, respectively. The strongest predictors of medium and high resilience included increasing number of other positive resources, lower stress, and no depression. Individuals with medium and high resilience had significantly higher QOL, lower healthcare utilization and reduced healthcare expenditures.

Conclusions: Interventions promoting the maintenance and/or increase of resilience should include a focus on other positive resources and stress/depression management. Resilience strategies integrated into healthy aging programming could be associated with improved health outcomes.

POSITIVE AND NEGATIVE RELATIONSHIPS, OUTLOOK, AND DEPRESSION PREDICT LONELINESS IN OLDER ADULTS DURING COVID-19

Benjamin Hougaard[1], Vennisia Mo[2], Anahita Eskandari[2], and Rowena Gomez[2], *1. Palo Alto University, Mountain View, California, United States, 2. Palo Alto University, Palo Alto, California, United States*

The COVID-19 pandemic has changed the way many older adults live and function in the United States. Because of the isolation from stay-at-home mandates and higher risk of death from infection, many older adults are experiencing depressive symptoms, anxiety, and increased loneliness (National Council on Aging [NCOA], 2021; Center for Disease Control [CDC], 2021). One factor might be whether one has a spouse, children, or friends and if those relationships are positive or negative (Vanderhorst & McLaren, 2005). Besides the quality and nature of the relationship, another factor might be the amount of virtual contact while in isolation during COVID-19 (Regis College Online, 2020.In this study, we examined the relationships between outlook (optimism, pessimism, hopelessness), depression, loneliness, and social relationships in older adults during the COVID-19 pandemic in a sample of 808 adults 60 years of age or older. The data was gathered from self-reported questionnaires from the psychosocial and lifestyle questionnaire and health questionnaire from the Health and Retirement Study (HRS) 2020 version (HRS, 2021).We found that loneliness scores were significantly predicted by self-reported measures of positive and negative relationships, along with optimism, pessimism, hopelessness, depressive symptom scores, and COVID-19 life changes (Adjusted R2 = .447, F(12, 795) = 55.26, p < .001). COVID-19 has changed the way many older adults live and function. Finding ways to increase the level of communication older adults are able to have with their close relationships is crucial to combating this epidemic of loneliness.

SESSION 6180 (POSTER)

MINORITY AND DIVERSITY POPULATIONS

HEALTHCARE DISPARITY IN THE ASSESSMENT OF DEMENTIA IN THE PRIMARY CARE SETTING

Regina Gibson, Maneetha Kodali, Priya Priyambada, Priya Mendiratta, Danish Hasan, Melodee Harris, Jeanne Wei, and Gohar Azhar, *University of Arkansas for Medical Sciences, Little Rock, Arkansas, United States*

Literature suggests racial implicit bias can significantly affect quality of care. Data demonstrates that older adult Blacks are twice as likely to have dementia as their White counterpart. Inappropriate cognitive screening by providers or diagnosing dementia just based on clinical impression could easily result in an over or under-estimation of the dementia. We reviewed the rate and method of cognitive screening in randomly selected patient records (n=75) at a primary care university clinic. Our results indicated that the cognitive screening rate for Black patients was lower compared to their White counterpart (43.4% Blacks vs 68.5% Whites, $p < 0.05$). We designed a quality improvement project to identify any contributory causes and challenges involved in screening for dementia with the goal to reduce racial disparity in dementia diagnosis. We identified knowledge deficits in providers in their approach towards patients with dementia and a lack of experience in their use of appropriate instruments for cognitive screening. A multipronged educational program, with videos, case conferences, presentations and one-to-one training by dementia experts and a neuropsychologist was employed to reduce the bias and train the providers in appropriate screening methods. Post-educational intervention, screening rates greatly improved in n=75 randomly selected patients from both races. In Whites, the screening rate increased by 20.9% to 89.4% and in Blacks by 38.9% to 82.3% ($p < 0.05$). Overall, the quality improvement driven educational intervention improved the self-efficacy of providers and improved the standardized dementia screening rates in Black patients to levels comparable to those of White patients.

RACIAL DIFFERENCES IN THE ASSOCIATION BETWEEN LONELINESS AND COGNITIVE STATUS AMONG BLACK AND WHITE MEN

Marino Bruce[1], Bettina Beech[2], Gillian Marshall[3], and Roland J. Thorpe, Jr.[4], *1. University of Houston Tilman J. Fertitta Family College of Medicine, Houston, Texas, United States, 2. University of Houston, Houston, Texas, United States, 3. University of Washington, Seattle, Washington, United States, 4. Johns Hopkins University, Baltimore, Maryland, United States*

Background: Loneliness is a stressor that has been found to increase the likelihood of poor health and dementia. Few studies have focused on this association among men and even fewer studies have examined racial disparities in loneliness and cognitive functioning among this group. The purpose of this study was to examine racial differences in the association between loneliness and cognitive functioning among national sample of men aged 50 years and older.

Methods: Data were drawn from Black and White men in the 2016 Health and Retirement Study who completed the Leave Behind Questionnaire (n=2226). Cognitive function was the primary outcome and was measured by a dichotomous variable derived from a modified version of the Telephone Interview for Cognitive Status. Loneliness was the primary independent variable and was derived from the 3-item UCLA Loneliness Scale.

Results: Black men made up 18.5% of the study sample; however, the proportion of this group with scores indicating cognitive impairment or dementia (35.9%) doubled the corresponding percent of white men (17.6%). Findings from race-stratified modified Poisson regression models indicated that loneliness was associated with a higher prevalence of cognitive impairment or dementia for White men (PR=1.24, CI:1.05-1.47), but Black men (PR=0.92, CI:0.73-1.16).

Conclusions: Results from this study raise important questions about the salience of pooled analyses and suggest a need for tailored approaches to mitigate cognitive decline. Additional studies focusing on Black men are needed to develop effective interventions preserving cognitive functioning among this population.

ADJUSTMENT TO AGING AMONG LBGT+ OLDER ADULTS

Sofia von Humboldt, Francis Carneiro, and Isabel Leal, *ISPA - Instituto Universitário, Lisbon, Lisboa, Portugal*

Intervention programs that highlight predictors of adjustment to aging (AtA)(1) for minority older lesbian, gay and bisexual (LGB) populations are scarce(2).The aim of this preliminary study is to build a structural model to explore whether socio-demographic, health and lifestyle-related variables, are correlates of AtA in a group of LGB older adults(3).The sample comprised 287 LGB older adults aged 75 years old and older.Convenience sampling was used to gather questionnaire data.Measures encompassed the Adjustment to Aging Scale, the Satisfaction with Life Scale, demographics and lifestyle and health-related characteristics.Structural equation modeling was used to explore a structural model of the self-reported AtA, comprising all the above variables.The structural model indicated the following significant correlates: perceived health($\beta=0.456$; $p< 0.001$), leisure($\beta=0.378$; $p< 0.001$), income($\beta=0.302$; $p< 0.001$), education($\beta=0.299$; $p=0.009$), spirituality($\beta=0.189$; $p< 0.001$), sex($\beta=0.156$; $p< 0.001$), physical activity($\beta=0.142$; $p< 0 .001$), satisfaction with life($\beta=0.126$; $p< 0.001$), and marital status($\beta=0.114$; $p=0.008$).The variables explain respectively 76.4% of the variability of AtA. These outcomes suggest that policy making and community interventions with LGB older adults may benefit of including variables, such as, perceived health, leisure and income, as these were pointed out as significant for this group of older adults for promoting adjustment to aging in late adulthood. 1.von Humboldt S et al. How do older adults experience intergenerational relationships? Different cultures, ambivalent feelings. Educ. Gerontol.2018;44(8):501-513. 2.von Humboldt S et al. Analyzing adjustment to aging and subjective age from Angolan and Portuguese community-dwelling older adults' perspectives. Int.J.Gerontol.2013;7(4):209-215. 3.von Humboldt S et al. What influences the subjective wellbeing of older adults?: A systematic review of the literature. Rev. Argent.Clín.Psicol.2014;23(3):219-230.

PHYSICAL ACTIVITY AND EPISODIC MEMORY IN AFRICAN AMERICAN OLDER ADULTS

Rio Tate, and Brent Small, *University of South Florida, Tampa, Florida, United States*

African Americans are more likely to have Alzheimer's Disease (AD) yet less likely to be included in AD research. Additionally, memory complaints may signal the clinical genesis of AD. Interventions such as physical activity that can help individuals maintain their cognitive functioning as they age have merit in research. The objective of this study is to examine the influence of physical activity of various intensities on episodic memory in African American older adults at the interindividual and intraindividual levels over time. We used data from the Health and Retirement Study over 12 years. Our analyses included an indicator of episodic memory and we examined physical activity of three intensities as predictors while controlling for relevant demographic and health variables. Preliminary data indicates that African American older adults who engaged in more frequent physical activity (regardless of intensity) had better episodic memory. Individuals who engaged more frequently in physical activity had a slightly greater rate of decline than those who engaged less frequently in physical activity. Physical activity may act as a buffer against cognitive decline for older adults. Intensity need not be vigorous to observe changes.

UNDERSTANDING THE NEEDS AND FUTURE OF OLDER BLACK AND HISPANIC WORKERS IMPACTED BY COVID-19

Kendra Jason, *University of North Carolina at Charlotte, Charlotte, North Carolina, United States*

COVID-19 infection and associated deaths are unequally distributed, as 78.5% of decedents are adults over 65 years of age; and Hispanics accounted for 24.2% of deaths. Black people account for 30% of infections and 18.7% of deaths, although they represent only 12.5% of the population. Older Black and Hispanic adults are in “Double Jeopardy” with their experiences shaped by racism and ageism, thus, putting them at higher risk for exposure to SARS-CoV-2, the virus that causes COVID-19, and poor health outcomes. Centering the intersections of race, age, and socioeconomic status and utilizing a scoping review (N=55), this study identifies the four primary risks faced by Black and Hispanic adults that help explain disparate COVID-19 work outcomes: (1) being an essential worker, (2) type of work performed, (3) workplace risks; and (4) community and geographic risk factors. This study also (1) explores the impacts of COVID-19 influence work participation, and (2) identifies processes linking ageism, racism, health, and employment situations in shaping the health and work-ability of older working adults. This research centers populations in which COVID-19 has had the most devastating financial impact: Black and Hispanic workers, Black women, and low-wage workers. This study increases our understanding of older Black and Hispanic adults lived experiences of managing COVID-19 – information that is critical for planning intervention and support services to ameliorate impact of the disease on Older Black and Hispanic adults; and informs policy and practice for economic recovery from the pandemic for other marginalized populations.

ADVERSE CHILDHOOD EXPERIENCES AND DEPRESSIVE SYMPTOMS AMONG RACIALLY/ETHNICALLY DIVERSE OLDER ADULTS IN THE US

David Camacho[1], Julia Vazquez[2], Laura Vargas[3], Charles Henderson[4], and Brenda J Jones-Harden[2], *1. University of Maryland, Baltimore, Norwalk, California, United States, 2. University of Maryland, Baltimore, Baltimore, Maryland, United States, 3. University of Colorado School of Medicine, Department of Psychiatry, Aurora, Colorado, United States, 4. Cornell University, Ithaca, New York, United States*

Adverse childhood experiences (ACEs) and depression are major public health concerns. However, few studies have examined the relationship between ACEs and mid- and late-life depression among racially/ethnically diverse groups. We explore this relationship among U.S. racially/ethnically diverse community-dwelling midlife and older adults (≥50 years of age). Guided by ACEs and Minority Stress Frameworks, we used general linear models to examine this relationship with data from Wave 3 of the National Social Life, Health, and Aging Project. We created an ACEs composite ranging from 0 to 7 (e.g., violence, health, poverty) and assessed the role of individual ACEs on depressive symptoms (CES-D). Final adjusted models (n:1424) included key demographic, health (e.g., chronic disease), social (living alone, social isolation, loneliness), and minority stress factors (e.g., limited access to healthcare and treatment, perceived discrimination). Results indicated that higher composite score ACEs (particularly childhood violence and poor health) were positively associated with higher levels of depressive symptoms. We found no interactions between race/ethnicity and ACEs. Our results suggest that ACEs contribute to the presence and severity of depressive symptoms into mid- and late-life adulthood. Consistent with Minority Stress Framework, common life-course stressors for minoritized groups may explain a lack of significant interactions in our models. Future research should explore the association of ACEs and other important health outcomes in diverse midlife and older adults. Finally, research is needed to examine if and how culturally appropriate depression interventions can be adapted to address the role of ACEs in later life health.

BLACK GREEK LETTER ORGANIZATIONS: FACILITATING HEALTH PROMOTION FOR AFRICAN AMERICANS ACROSS THE LIFECOURSE

Chivon Mingo, *Georgia State University, Atlanta, Georgia, United States*

African Americans remain underrepresented in accessing and utilizing evidenced-based health promotion interventions (EBIs). Challenges with dissemination and implementation of EBIs further corroborate existing racial/ethnic health/healthcare disparities. Therefore, there is a need to identify effective ways to increase the widespread adoption of health promotion behaviors among African Americans across the life course. It is plausible that engaging in non-traditional partnerships (i.e., community groups or organizations valued in the community with the capacity and infrastructure) could result in greater adoption and improved utilization of EBIs among African Americans. Although frequently overlooked as a study variable in empirically sound public health research, Black Greek Letter Organizations (BGLO) could be an innovative and practical approach to advancing health in the African American community. It is necessary to gain preliminary evidence of feasibility (e.g., motivation, target population reach, acceptability,). Therefore, the purpose of this study was to conduct a content analysis to identify the intentions and communication trends of BGLOs as it pertains to public health and the African American community and assess population reach and perceptions by evaluating responses to communication specific to health promotion.

We assessed health promotion patterns of four BGLOs in a ten-county metropolitan area. Coded content included communication via the organization's webpage, Facebook, Twitter, YouTube, Instagram, and LinkedIn from a five-year time period. Findings confirm that BLGOs are invested in the health and well-being of the community, place emphasis on mitigating health inequities, and are uniquely positioned to serve as stakeholders for the translation of EBIs to end-users.

EXPLORING AGE AND RACE DIFFERENCES IN THE REPORT OF ADVERSE CHILDHOOD EXPERIENCES AMONG WOMEN AGING IN CUSTODY

Alex Bishop, and Claire Stolfa, *Oklahoma State University, Stillwater, Oklahoma, United States*

Survey data for this study was collected from N = 544 women, aged 18 and older (M = 39.03; SD = 10.32), under correctional custody in Oklahoma. Participants reported an average of M = 4.94; SD = 2.94 childhood adversities. Chi-square analyses revealed that age was associated with the proportion of women who experienced parental divorce (χ(2, N = 525) = 8.03, p < .05., lived with a substance abuser (χ(1, N = 528) = 7.14, p < .05), lived with a mentally ill household member (χ(2, N = 524) = 15.04, p < .05) and lived with household member who went to prison (χ = (2, N = 528) = 18.99, p < .001). Race was also associated with the proportion of participants who reported experiencing a household member go to prison (χ(1, N = 538, = 15.92, p < .001). Furthermore, race was associated with the proportion of women who reported not feeling loved by family (χ(1, N = 525), = 4.87, p < .05), being physical hurt or injured by a parent (χ(2, 525) = 8.01 p < .05), and being verbally insulted or humiliated (χ = 7.38 (1, N = 537, p < .01). Results suggest that age and race are associated with the self-disclosure of past childhood adversities among women in custody. This has implications relative to how clinicians such as social workers, counselors, and psychiatrists provide rehabilitative services and programs to women-of-color aging under correctional control.

ACCULTURATION ON PSYCHOLOGICAL DISTRESS AMONG OLDER KOREAN AMERICANS: DOES ETHNIC COMMUNITY SOCIAL CAPITAL MATTER?

Juyoung Park, Maria Aranda, Yeon Jin Choi, and
Yuri Jang, *University of Southern California, Los Angeles, California, United States*

Responding to the rapid growth of the older immigrant population and building upon the literature on the critical role of acculturation in older immigrants' health and well-being, we focused on the role of ethnic community social capital (social cohesion, social engagement, safety, and negative interactions in ethnic communities) in older Korean Americans. Guided by social capital and stress-buffering theories, we examined the direct effect of acculturation and ethnic community social capital on psychological distress, as well as their interactions. We hypothesized that the negative impact of low acculturation on mental health would be lowered by positive perceptions of and experiences in ethnic communities. Using data from 2,150 participants in the Study of Older Korean Americans (Age range = 60-99, M [SD] = 73.4 [7.97]), the direct and interactive effect models were examined. Results showed that low acculturation posed a significant risk to mental health and all four types of ethnic community social capital had a significant direct effect. Furthermore, significance was observed in the interaction of acculturation with social cohesion (B [SE] = .01 [.01]. p < .05) and with negative interaction (B [SE] = -.01 [.01]. p < .01). The negative impact of low acculturation was attenuated among those with a high sense of ethnic community social cohesion but intensified among those with frequent experiences of negative interactions with ethnic community members. Our findings highlight the importance of social capital that forms within ethnic communities and provide implications for programs and services to promote older immigrants' mental well-being.

CULTURAL AND SOCIAL ACTIVITIES AND MENTAL HEALTH AMONG INDIGENOUS OLDER ADULTS IN THE UNITED STATES

Yeonjung Lee[1], Kathryn Braun[2], Yanyan Wu[3],
Collette Adamsen[4], and Shelly Davis[5], *1. University of Hawai'i at Mānoa, Honolulu, Hawaii, United States, 2. University of Hawai'i at Mānoa, Thompson School of Social Work & Public Health, Honolulu, Hawaii, United States, 3. University of Hawai'i at Mānoa, Honolulu, Hawaii, United States, 4. University of North Dakota, Grand Forks, North Dakota, United States, 5. University of North Dakota School of Medicine & Health Sciences, Grand Forks, North Dakota, United States*

Although the number and percentage of indigenous older adults are growing, little is known about the risk and protective factors associated with mental health among this population. We estimated regression models for mental health using data from the 2017-2020 needs assessment of indigenous elders (aged 55+) administered by the University of North Dakota, which included 19,143 indigenous elders, including 17,184 American Indians, 1,521 Alaska Natives, and 438 Native Hawaiians. The Mental Health Index (MHI) was used, with five questions: during the past month, how much of the time (1) were you a happy person, (2) have you felt calm and peaceful, (3) have you been a very nervous person, (4) have you felt downhearted and blue, and (5) have you felt so down in the dumps that nothing could cheer you up? The answers for MHI-5 were standardized on a 0-100 scale, where higher scores indicate optimal mental health. Having ADL and/or IADL difficulties was associated with worse mental health. Frequent engagement in social activities was positively associated with mental health. Data also suggest that those engaged in cultural practice all the time compared to people who engaged in cultural practice less frequently had higher levels of MHI-5, controlling for other variables. These findings underscore the importance of cultural activities, as well as social activities and physical health, in the management of mental health.

RACIAL DIFFERENCES IN COPING STRATEGIES AND MENTAL HEALTH OUTCOMES

Jordan McWilliams[1], Meghan Custis[2], Natasha Peterson[3], and Jeong Eun Lee[3], *1. Iowa State University, Ankeny, Iowa, United States, 2. Iowa State University, Muscatine, Iowa, United States, 3. Iowa State University, Ames, Iowa, United States*

Previous literature has examined the consequences of loneliness coping methods; however, scarce research has examined racial/ethnic disparities and the differential association between coping activities and psychological outcomes. This study aimed to fill this gap in the literature by examining racial/ethnic differences in loneliness coping strategies and their impact on anxiety and depression among middle-aged and older adults. Data were from the 2018 Loneliness and Social Connections survey (N=3,233) conducted by AARP. Findings revealed minorities reported higher levels of loneliness and coped with loneliness by socializing with friends in person, socializing with friends using technology, and individualized activity significantly more compared to white counterparts. Logistic regressions revealed that minorities who engage in risky behaviors are 1.66 times more likely to be depressed (95% CI [1.07, 2.58]) and 1.98 times more likely to be anxious (95% CI [1.51, 2.59]). Moreover, the odds of being anxious increased by 58% if minorities coped with loneliness by socializing with friends via technology (95% CI [1.12, 2.21]). However, minorities who socialize with friends in person are 48% less likely to be anxious (95% CI [.35,.79]). In general, socializing methods have more implications for mental health among minorities. Findings suggest that differential coping strategies may have differential outcomes for minorities. The results of this study point to the need for further longitudinal research examining factors contributing to coping strategies and the direction of causality between coping strategies and psychological outcomes.

PREPARING THE GROUND: DEVELOPING COMMUNITY-BASED STRATEGIES TO ENGAGE OLDER BLACK MEN IN HEALTH RESEARCH

Jamie Mitchell[1], Kent Key[2], Elena Flores[1], Sean Knurek[3], Tam Perry[4], Vanessa Rorai[4], Joan Ilardo[5], and Alexandra Sass[1], *1. University of Michigan, Ann Arbor, Michigan, United States, 2. Michigan State University, Flint, Michigan, United States, 3. Michigan State University, Corunna, Michigan, United States, 4. Wayne State University, Detroit, Michigan, United States, 5. Michigan State University, East Lansing, Michigan, United States*

Black men across the lifespan are overburdened by poor health and underrepresented as participants in health research. The Flint Healthier Black Elders program seeks to engage more older Black men in research that could contribute to health discoveries by developing and testing strategies to recruit Black men into a community participant research pool (PRP). The PRP recruitment strategies account for the influence of gender role norms, mistrust derived from current and historical research and medical abuses, and other factors that affect older Black men's willingness to participate in safe and ethical research. This initiative also focuses on building trust in research engagement by foregrounding the voices of local older men as community stakeholders and research gatekeepers, and tailoring multimedia recruitment materials to represent older Black men more fully and positively. Videos and print materials developed as recruitment tools specifically tailored to older Black men were pilot tested for messaging and impact, and the results of this community-driven process can serve as an innovative model for equitable and trustworthy research recruitment in Black communities. We would like to acknowledge the contributions of the Flint Healthier Black Elders Community Advisory Board: Yaushica Aubert, Rev. Dr. Sarah Bailey, E. Hill DeLoney, Luther Evans, Ella Greene-Moton, Cynthia Howell, Bishop Bernadel Jefferson, Beverly Lewis, Geraldine Redmond, Sharon Saddler, Arlene Sparks, Erica Thrash-Sall.

PSYCHOSOCIAL AND BEHAVIORAL INDICATORS OF CHRONIC PAIN AMONG MIDDLE-AGED AND OLDER BLACK MEN

Anna Wakita[1], Melicia Whitt-Glover[2], Amber Brooks[3], Jaylyn Clark[4], Katrice Perry[5], Knashawn Morales[6], and Tamara Baker[7], *1. Gillings School of Global Public Health, Durham, North Carolina, United States, 2. Gramercy Research Group, Winston Salem, North Carolina, United States, 3. Wake Forest School of Medicine, Winston-Salem, North Carolina, United States, 4. Atrium Health Wake Forest Baptist, Winston-Salem, North Carolina, United States, 5. Cecil G. Sheps Center For Health Services Research, Chapel Hill, North Carolina, United States, 6. Perelman School of Medicine at the University of Pennsylvania, Philadelphia, Pennsylvania, United States, 7. University of North Carolina, Chapel Hill, Cary, North Carolina, United States*

There is a lack of data describing the pain experience of Black men. This may be the result of social messaging that men are to project strength and avoid any expression of emotion or vulnerability. This avoidant behavior(s) however, often comes too late when illness/symptoms are more aggressive and/or diagnosed at a later stage. This begins to address two larger issues – the willingness to acknowledge pain and to seek medical attention when experiencing pain. To address this lack of data, this study aimed to determine the influence psychosocial indicators have in the pain experience of Black men 40+ years old. Participants from the Active & Healthy Brotherhood study were categorized based on the pain question from the Health-Related Quality of Life Questionnaire. Demographics, general health, and psychosocial measures were compared across pain groups. A multivariable logistic regression model was used to determine predictors of pain, while adjusting for other factors. Results showed that the men (n=303) were mostly married (54%) and employed (53%). Those reporting arthritis (OR=4.5; 95% CI 2.0, 10.0), good health (2.8; 1.2, 6.6), higher somatization (3.2; 1.2, 8.8) compared to excellent/very good self-rated health, were more likely to self-report pain in the past 30 days. Findings from this study show that continued efforts are needed to identify the unique pain experiences of Black men, while recognizing the impact it has on their identity as a man, a person of color, and as a person living with pain.

IS ETHNIC HERITAGE MEANINGFUL IN ADULTHOOD? ETHNIC IDENTITY AND WELL-BEING IN MEXICAN-ORIGIN FEMALE ADULTS

Hin Wing (Florence) Tse[1], Jiaxiu Song[2], Elizabeth Muñoz[2], and Su Yeong Kim[2], *1. Department of Human Development and Family Sciences, The University of Texas at Austin, Austin, Texas, United States, 2. The University of Texas at Austin, Austin, Texas, United States*

Being the largest immigrant group in the U.S., the process of exploring, forming, and retaining ethnic identity is a critical component to Mexican immigrants' successful adaptation and wellbeing. Despite recognizing the dynamic nature of ethnic identity development, extant research has predominantly focused on adolescence, overlooking the development and impact of ethnic identity in adulthood, when individuals' experiences are continuously shaped by critical life events (e.g., moving to a new country). Additionally, there is a lack of longitudinal research on mid-late adulthood. Filling these gaps, this study utilized a three-wave longitudinal dataset of 595 Mexican-origin female adults (Mage.wave1 = 38.39) to examine their initial levels and trajectories of ethnic identity development (i.e., exploration, centrality, and resolution) and understand how these individuals' initial levels and trajectories of ethnic identity are associated with their wellbeing (i.e., life meaning, resilience, and depressive symptoms) at Wave 3. Using latent growth curve modeling, unconditional models revealed that initial levels of ethnic identity in Mexican-origin female adults were moderately high, and that their centrality and resolution of ethnic identity remained stable while their exploration of heritage identity increased over time. The conditional model also showed that Mexican-origin female adults' higher initial levels of centrality and resolution were associated with a greater sense of life meaning (and resiliency, only true for resolution levels) but not with depressive symptoms. These findings suggest that ethnic heritage is associated with more positive perception in life and may inform interventions on developing a positive ethnic identity that is related to better wellbeing.

LIMITED ENGLISH PROFICIENCY AND HEALTH LITERACY IN KOREAN OLDER ADULTS: MEDIATING EFFECT OF ACCULTURATION

Hae Sagong, and Pao-Feng Tsai, *Auburn University, Auburn, Alabama, United States*

Language proficiency and comprehension in the culture and health systems of the host country are imperative factors enabling appropriate health literacy (HL) for non-English speaking immigrants. Older immigrants with limited English proficiency have fewer opportunities and limited abilities to improve their English skills. Increasing individuals' acculturation levels can be an effective strategy for older immigrants than solely educating English language skills. The purpose of this study is to investigate the mediating effect of acculturation between English proficiency and HL in older Korean immigrants. From June to October of 2020, a total of 244 older Korean immigrants aged 50 years or older residing in the Southern US were recruited. English proficiency was categorized into limited (very limited to fair) and fluent (fluent to very fluent). HL and acculturation were measured using the Health Literacy Survey-12 Questionnaires (HLS-Q12), and the East Asian Acculturation Measure (EAAM), respectively. Covariates were gender, age, monthly income, education, and length of residency in the U.S. The statistically significant differences were shown in age, gender, education, perceived health, and length of residency in the US by the level of English proficiency The limited English proficiency was negatively associated with HL (β= -.192, p=.002) and acculturation had a mediating effect between English proficiency and HL (β= -.133, p=.001). To alleviate the language barrier that causes low HL in older Korean immigrants, enhancing their understanding of the host country's culture as well as improving organizational HL should be considered.

CORRELATES OF HEALTH LITERACY IN THE BLACK BELT AREAS OF ALABAMA: IMPORTANCE OF INTERNET ACCESS

Avani Shah[1], Yan Luo[2], LeAnna Roberts[1], and Hee Lee[3], *1. University of Alabama, Tuscaloosa, Alabama, United States, 2. The University of Alabama, Tuscaloosa, Alabama, United States, 3. University of Alabama, Birmingham, Alabama, United States*

Health literacy, which is defined as being able to understand and utilize information related to one's health, is an essential part of the health care process as it is related to health outcomes. However, little is known about health literacy in Black Belt communities in Alabama although this rural area has shown very high rates of health concerns such as diabetes, cardiovascular disease, stroke, and cancer (CDC Interactive Atlas, 2022). Study participants were recruited from the Black Belt areas of Alabama. A total of 180 African-American participants with a mean age of 57.5 completed a survey. A regression analysis was conducted to understand if sociodemographic and other relevant factors would predict health literacy. Lower education, gender, age, perceived racism, and perception that race impacts health care quality predicted health literacy. Interestingly, those with less internet access had significantly lower health literacy. Access to internet and smart phones was a reported concern for over a third of the participants. Only a quarter of participants reported use of the internet to assist with lifestyle modifications while almost half reported internet use to obtain health information; suggesting this as a potential means to improve health literacy and even potential lifestyle modification in health behaviors. Recommendations are made for interventions to improve health literacy in minority populations of this underserved region.

HOW IS MENTAL HEALTH IN LATE LIFE SHAPED BY STRUCTURAL RACISM?

Reed DeAngelis[1], Patricia Homan[2], and Tyson Brown[3], *1. University of North Carolina at Chapel Hill, Chapel Hill, North Carolina, United States, 2. Florida State University, Tallahassee, Florida, United States, 3. Duke University, Durham, North Carolina, United States*

Less than one percent of studies on the link between race and health have focused on structural racism. Empirical research on how structural racism affects health in later life is especially rare. Moreover, the conceptualization of structural racism in the race theory literature has often differed from the measurement strategies used in aging and health research. This study advances the field by 1) utilizing a novel, theory-informed latent measure of structural racism in states across multiple domains, including political participation, education, economics, housing, and the judicial system, 2) mapping structural racism across states, and 3) quantifying the association between structural racism and mental health outcomes (depressive symptoms and frequency of poor mental health days) among Black and White older adults. We use administrative data measuring state-level racial stratification linked to geocoded individual-level demographic and health data from the HRS (N=9,126) and the

BRFSS (N=308,029). Results show that, whereas structural racism is consistently associated with worse mental health for Black people, it is either unrelated to health or predictive of better health among Whites. Findings highlight the utility of rigorously conceptualizing and measuring structural racism and its impact on health among older adults.

PROMOTING POSITIVE AGING IN COMMUNITY-DWELLING SOUTH ASIAN AMERICANS: AN EXPLORATORY QUALITATIVE STUDY

Mushira Khan[1], Sheetal Shah[2], and Ajla Basic[1], *1. Mather Institute, Evanston, Illinois, United States, 2. University of California (Davis), Sacramento, California, United States*

Between 2010 and 2017, South Asians were the fastest-growing major ethnic minority group in the US, growing at a rate of 40% over the previous decade (SAALT, 2019). This exponential growth, along with a rapidly aging US population, implies that a significant proportion of the South Asian American population will be 65 years or older in the coming years; yet research on the lived experiences/needs of older South Asian Americans is limited. To address this gap, this qualitative study explored barriers and facilitators to healthy or positive aging in a sample of community-dwelling South Asian Americans 50 years and older. In-depth, semi-structured interviews were conducted with 32 South Asian American older adults (18 women and 14 men). Thematic analysis of the interview data showed that level of acculturation, proficiency in English, cultural beliefs/practices, awareness about available health and social services, degree of religiosity, and the density of social networks were key determinants of healthy aging. Compared to those who were US-born or had immigrated earlier in life, participants who had immigrated later in life (post-retirement) appeared more financially and/or emotionally dependent on their adult children and expressed ambivalence vis-à-vis future caregiving arrangements and intergenerational co-residence. Nearly all participants shared that helping their adult children with childcare, cooking, or other household chores gave them a sense of purpose and made them feel valued. Study findings suggest that along with culturally appropriate programs and policies to support healthy aging, increased volunteering opportunities may enhance subjective well-being in South Asian American older adults.

SESSION 6190 (POSTER)

SEXUAL HEALTH IN LATER LIFE

HETERONORMATIVE DEFINITIONS OF SEX: IMPLICATIONS FOR LGBT+ WOMEN'S PREVENTIVE HEALTHCARE

Jessica Noblitt, and Anne Barrett, *Florida State University, Tallahassee, Florida, United States*

The dominant cultural definitions of sex, which is heteronormative, has implications for preventive health screening among LGB+ women. Medical recommendations for women's screening exclude some same-sex behaviors from this definition, and they center on reproduction – both of which can discourage LGB+ women's preventive health screening. Qualitative studies have found that sexual minority women, as well as their doctors, are less likely to see sexual health exams as important for sexual minority women's healthcare because many are not engaging in penile-vaginal intercourse. However, we are aware of no study that has used a large, nationally representative dataset to examine potential differences in health screening by sexual identity. We used data from the National Health Interview Survey (2018; n=1394) to examine differences by sexual identity in having Pap tests and mammograms. We found that sexual minority women were about 40% less likely than heterosexual women to have ever had a Pap test. Moreover, among sexual minority women, lesbian women were about 50% less likely than bisexual women to have ever had one. Sexual minority women also were 22% less likely than heterosexual women to have had a Pap test in the last 12 months. Differences by sexual identity in receiving mammograms were less striking. We found, however, that bisexuals were 25% less likely than lesbians to have ever had a mammogram. In addition, these differences in health screening were more pronounced in younger than older women.

SEXUAL ACTIVITY OF OLDER ADULTS: WE'RE ASKING THE WRONG QUESTIONS

Janie Steckenrider, *Loyola Marymount University, Los Angeles, California, United States*

Sexual activity of older adults is an under researched area as most surveys on sexual behavior end at age 60 reflecting the myth that older adults are not sexually active. Only recently has survey data asked specifically about sexual activity of those ages 60 to 95. Their consensus is over half of males and a third of females over 70 are sexually active. Most striking is the current body of research almost exclusively defines sexual activity measured as partnered sexual behaviors of intercourse, fondling, kissing, touching. Given the reality for many older adults lacking an active sex partner due to death, sexual dysfunction, or serious illness, the aim of this study was to determine if the right survey questions are being asked for older adults. Seven major surveys, underlying most current research, were analyzed regarding solitary sex (masturbation) compared to partnered sex. Results of this study found extensive questioning about aspects of partnered sex including pleasure, satisfaction, pain, relationship status, sexual functioning, anxiety, individual sexual acts, etc. compared to only two questions about masturbation, both only about frequency. The psychological and physiological benefits of sexual activity, both partnered and solo sex, are well documented and correlate with higher life satisfaction for older adults. Sexual activity needs to be redefined to also include solitary sex and this begins by asking the right questions. This study has implications for the need to bring a broader perspective in promoting a healthy sex life among older adults, defined both as partnered and solitary sex.

CONTEXT-DEPENDENT SEXUAL CHANGES DURING WOMEN'S MIDLIFE TRANSITIONS

Amber Watts, and Sarah Jen, *University of Kansas, Lawrence, Kansas, United States*

For women, midlife represents an important stage of transition, including shifts in physiological, social, and sexual experiences. Prior research demonstrates that women's sexuality is more dynamic and context-dependent than men's. Most research focused on women's sexuality in mid- to later-life emphasizes physiological changes, while largely ignoring changes stemming from social, psychological, and relational contexts. The present study examined midlife women's diverse sexual experiences within the context of their lives. We conducted semi-structured interviews with 27 women, ages 39-57 and used interpretive phenomenological analysis to investigate perceptions and interpretations of midlife sexual experiences and changes. Themes included changes in sexual engagement, unwanted sexual experiences, body image, and sexual healthcare. Participants reported changes in frequency of sex and sexual desire within the context of their diverse social roles and identities, prior intimate relationships, and sexual health. Women contrasted perceptions of their own bodies with societal perceptions of sexiness. Frequently reported negative experiences with sexual healthcare informed a distrust of healthcare systems. The diverse and changing nature of participants' experiences supports prior evidence of sexual fluidity and context-dependence. By questioning societal expectations around sexuality and body image, participants illustrated the potential of counternarratives to combat dominant beliefs and stereotypes about midlife women's sexuality. To improve sexual health and education, psychoeducational interventions and improved training for healthcare professionals are needed.

SEXUAL MOTIVES, SEXUAL FREQUENCY, AND SEXUAL SATISFACTION AMONG MIDDLE-AGED DIFFERENT-SEX AND SAME-SEX COUPLES

Hye Won Chai, Sara Mernitz, and Debra Umberson, *The University of Texas at Austin, Austin, Texas, United States*

Reasons for having sex and frequency of sex are significant correlates of sexual satisfaction. However, the possible interplay between sexual motives and sexual frequency remains unexplored. Also, prior studies on sexual satisfaction largely focused on heterosexual couples and less is known about the experiences of same-sex couples. Using dyadic survey data collected from 838 middle-aged spouses in 419 gay, lesbian, and heterosexual marriages, this study examined whether the associations between sexual motives and sexual satisfaction differed by sexual frequency and whether these dynamics varied across gay, lesbian, and heterosexual couples. Results showed that intrinsic sexual motives (e.g., for enjoyment and pleasure) were associated with higher sexual satisfaction only in the context of more frequent sex, and this association did not differ for same- and different-sex couples. On the other hand, extrinsic sexual motives (e.g., to please spouse) were associated with lower levels of sexual satisfaction in the context of high-frequency sex only among men married to men and women married to men, wherein the association was stronger for heterosexual couples compared to same-sex couples. These associations were not significant with less frequent sex. Results suggest that while frequent engagement in sex with intrinsic sexual motives benefits middle-aged adults' sexual satisfaction regardless of relationship type, the sexual satisfaction of individuals married to men is vulnerable to the negative consequences of engaging in sex due to external pressure. These findings highlight the importance of considering how sexual experiences of men and women in midlife same-sex marriages compare to those of different-sex marriages.

SESSION 6200 (POSTER)

SOCIAL DETERMINANTS OF HEALTH (POSTERS)

CAN SOCIAL ENVIRONMENT OFFSET THE GENETIC RISK OF MYOCARDIAL INFARCTION AMONG OLDER ADULTS?

Chenkai Wu[1], and Chen Sheng[2], *1. Duke Kunshan University, Kunshan, Jiangsu, China (People's Republic), 2. Fudan University, Shanghai, Shanghai, China (People's Republic)*

The interrelatedness between social determinants of health impedes researchers to identify important social factors for cardiovascular health. Additionally, it remains largely unknown whether a derivable social environment could offset the genetic risk for cardiovascular events. We developed a polysocial score approach to quantify the aggregate effect of social factors on myocardial infarction (MI). We also examined the association of polysocial score and polygenic risk scores (PGS), and their interaction, on MI. Data are from the Health and Retirement Study, a longitudinal cohort of a nationally representative sample of Black and White Americans with pre-calculated PGS for MI (N=6,036). We included 24 social factors from five categories (economic stability, neighborhood environment, education, community, and social context, and healthcare system) and used forward stepwise regression to screen for important ones. Polysocial score was created using 14 social factors and was classified as low (< 28), intermediate (29-39), and high (40+). The incidence of MI was 4.5, 8.5, 10.5 per 1000 person-years among Whites with a low, intermediate, and high PGS, respectively; no graded association was found among Blacks. Polysocial score stratified the rate of MI in each tertile of PGS among Whites. We found a significant additive interaction between PGS and polysocial score. The difference in MI rate was 10.3 per 1000 person-years among individuals with a high genetic risk, while the difference significantly reduced to 3.5 per 1000 person-years among those with a low genetic risk. Desirable social environment could possibly offset the increased risk of MI associated with genetics among Whites.

ASSOCIATION BETWEEN VIOLENT CRIME INCIDENT PROXIMITY AND COGNITIVE FUNCTION IN OLDER AFRICAN AMERICANS

Genesis Tan[1], Alejandro Gimenez-Santana[1], Zuzanna Osiecka[1], Darlingtina Esiaka[2], Bernadette Fausto[1], and Mark Gluck[1], *1. Rutgers University - Newark, Newark, New Jersey, United States, 2. Robert Wood Johnson Medical School, Rutgers University, Newark, New Jersey, United States*

Research on Area Deprivation Index (ADI) suggests that the built environment and neighborhood stressors (e.g., violent crime incidents) play a role in later-life cognitive function. However, most of the research linking ADI and cognitive function was conducted on majority White American samples. Further, while ADI is useful in facilitating efficient integration of social determinants of health (SDOH) into models of cognitive aging, it does not account for the impact of micro-level measures of neighborhood stressors on cognitive function. Therefore, the purpose of the current study was to determine whether violent crime incident proximity (VCIP) contributes to later-life cognitive function above and beyond ADI in older African Americans. Participants (N=147; M= 68.34) from an ongoing study, Pathways to Healthy Aging in African Americans—a Rutgers University-Newark community partnership fostered over 16 years of community engagement, health education, and public service—responded to measures of cognitive ability, SDOH, and demographic details. The results show that VCIP is a trending predictor of cognitive performance, when adjusting for age, gender, education, depression, and ADI. The result aligns with our hypothesis that individuals living in areas with greater VCIP will have poorer performance on cognitive tasks. Our findings suggest that for African Americans in an urban setting, hyper-local VCIP appears to be more useful at capturing the impact of neighborhood disadvantage on cognitive decline and Alzheimer's disease risk. Therefore, for later-life cognitive health in African Americans, it is important to consider micro-level measures of neighborhood stressors such as VCIP.

CHILDHOOD PHYSICAL ABUSE INCREASES THE RISK OF SUBJECTIVE MEMORY IMPAIRMENT

Lauren Roach[1], Tyler Bell[2], and Caitlin Pope[3], *1. University of Kentucky, Holland, Michigan, United States, 2. University of California, San Diego, La Jolla, California, United States, 3. University of Kentucky, Lexington, Kentucky, United States*

Subjective memory impairment, defined as self-reported difficulties in recall and learning, doubles the risk of Alzheimer's Disease and related dementia, despite being weakly related to objective memory decline. Because of its strong stability over time, it may be possible that subjective memory impairment reflects earlier life risk factors for dementia such as adverse childhood experiences. It is reported that over a fifth of older adults worldwide experienced physical abuse during childhood. Previous cross-sectional studies suggest physical abuse is associated with later cognitive impairment. Still unclear, are the longitudinal associations between childhood abuse and subjective memory impairment in later life. Using a sample of adults drawn from the Health and Retirement Study (n = 19,185, Mage = 67.05, SD = 11.33) we assessed associations between reported physical abuse by a parent before the age of 18 and subjective memory impairment (current memory problems and perceived memory decline) over periods of up to 18 years. Generalized linear mixed models examined longitudinal associations between childhood physical abuse and subjective memory impairment while controlling for depressive symptoms and other empirically relevant covariates. Experiencing childhood physical abuse was associated with increased likelihood of reporting more current memory problems (OR = 1.17, 95% CI 1.04, 1.33) and perceived memory decline in later life (OR = 1.27, 95% CI 1.13, 1.43). Findings suggest childhood physical abuse is associated with subjective memory impairment, a strong predictor of dementia. Understanding early life conditions, including adverse childhood experiences may help explain associations between subjective memory impairment and dementia risk.

IS THE HEALTH OF OLDER AMERICANS WITH A GED EQUIVALENT TO THEIR PEERS WITH A HIGH SCHOOL DIPLOMA?

Esme Fuller-Thomson, Robin Grossman, and Andie MacNeil, *University of Toronto, Toronto, Ontario, Canada*

Previous research has found higher levels of educational attainment to be strongly associated with better health outcomes in later life, such as better cognitive functioning and fewer functional and sensory impairments. However, most studies have grouped General Educational Development (GED) recipients with high school graduates, neglecting potential differences in socioeconomic status, health behaviours, and health outcomes among these two groups. The aim of the current study is to identify differences in the age-sex-race-poverty adjusted prevalence and odds of cognitive impairment, hearing impairment, vision impairment, limitations in activities of daily living (ADLs), and ambulation limitations among three groups of older American adults: high school dropouts, GED recipients, and high school graduates with no post-secondary education. The present study uses secondary analysis of the 2017 American Community Survey, a nationally representative survey of community-dwelling and institutionalized older adults aged 65 years and older, of whom 20,489 were GED recipients, 154,892 had a high school diploma and 49,912 had finished grade 8 but had not completed high school. Our findings indicate that there is a gradient in health outcomes among Americans aged 65-84, with the highest prevalence and odds of cognitive impairment, hearing impairment, vision impairment, ADL limitations, and ambulation limitations occurring among high school dropouts, followed by GED recipients, and the lowest prevalence among high school graduates. These findings suggestion that although GED recipients have better health outcomes than high school dropouts, there is still a significant disparity in health status between GED recipients and high school graduates.

HISTORY OF JOB STRAIN AND RISK OF LATE-LIFE DEPENDENCY: A NATIONWIDE SWEDISH REGISTER-BASED STUDY

Ingemar Kåreholt[1], Charlotta Nilsen[1], Janne Agerholm[2], Susanne Kelfve[3], Jonas Wastesson[2], Kirsten Nabe-Nielsen[4], and Bettina Meinow[5], *1. Jönköping University, Jönköping, Jonkopings Lan, Sweden, 2. Karolinska Institutet, Stockholm, Stockholms Lan, Sweden, 3. Linköping University, Linköping, Ostergotlands Lan, Sweden, 4. University of Copenhagen, Copenhagen, Hovedstaden, Denmark, 5. Stockholm Gerontology Research Center, Stockholm, Stockholms Lan, Sweden*

There is substantial evidence that work plays a significant role in post-retirement health. Yet little is known about its role in when late-life dependency may occur. We examined associations between job strain and the risk of entering late-life dependency. Individually linked nationwide Swedish registers were used to identify people 70+ alive in January 2014, and who did not experience the outcome (late-life dependency) during two months prior to the start of the follow-up. Late-life dependency was operationalized as use of long-term care. Information about job strain was obtained via a job exposure matrice and matched with job titles. Cox regression models with age as time-scale (adjusted for living situation, educational attainment, country of birth, and sex) were conducted to estimate hazard ratios (HR) for entering late-life dependency during the 24 months of follow-up (n=993,595). Having an initial high starting point of job strain followed by an increasing trajectory throughout working life implied a 23% higher risk of entering late-life dependency at a younger age, compared with the reference group (low starting point with a decreasing trajectory). High initial starting point followed by a stable trajectory implied a 12% higher risk of entering late-life dependency at a younger age. High initial starting point followed by a decreasing trajectory implied a 10% risk reduction, and a low starting point with a stable trajectory implied a 22% risk reduction, of entering late-life dependency at a younger age. Reducing stressful jobs across working life may contribute to postponing late-life dependency.

SEQUENCING OF PLANNED AND UNPLANNED BIRTHS AND IMPLICATIONS FOR MID- AND LATER-LIFE HEALTH AMONG NLSY79 WOMEN

Mieke Thomeer[1], Clifford Ross[1], Rin Reczek[2], and Christina Bijou[2], *1. University of Alabama at Birmingham, Birmingham, Alabama, United States, 2. Ohio State University, Columbus, Ohio, United States*

Existing studies demonstrate that unplanned births (e.g., unwanted, mistimed) are associated with worse health for mothers in the short-term and—according to some preliminary evidence—in mid- and later-life. Yet as life course and reproductive career frameworks highlight, childbearing experiences often unfold over a number of years, with a considerable amount of diversity in pregnancy and birth experiences even for the same individual. For example, a person may have an unplanned birth in late adolescence followed by only planned births in early adulthood. In order to provide a more holistic understanding of how birthing experiences births are associated with midlife health, we use Sequence Analysis (SA) on the 1979 National Longitudinal Survey of Youth (NLSY79; N=3,992) to examine how patterning of planned and unplanned births is associated with physical and mental health at ages 50 and 60 (SF-12). Preliminary analysis indicates that compared to respondents with only planned births, respondents with unplanned birth(s) followed by planned birth(s) have worse physical and mental health at midlife, but there is no difference in health for respondents with only planned births, only unplanned births, and planned birth(s) followed by unplanned birth(s). Future analysis with SA will consider how more detailed sequences (e.g., timing, number and type, ordering, spacing) are associated with these mid- and later-life health outcomes, taking into account selection factors such as childhood SES and educational attainment. This project demonstrates the need for life course perspectives on the long-term health implications of unplanned births, recognizing diversity within and between individuals.

COGNITIVE AGING IN THE SHADOW OF THE CLOSET: THE EFFECTS OF IDENTITY CONCEALMENT AND DISCRIMINATION

Douglas Hanes, and Sean Clousten, *Stony Brook University, Stony Brook, New York, United States*

Lesbian, gay, and bisexual (LGB) people tend to experience poorer cognitive health as they age; discrimination and identity concealment are common LGB experiences that carry emotional, health, and cognitive tolls. Previous research utilized data on research participants in same-sex relationships (SSR) to successfully identify a subset of LGB people and analyze their aging experiences. The present study relied on one situation in which identity concealment was legally mandated: military service. Until 2011, LGB people were banned from participating in military service in the U.S., leading to either concealment or institutionalized discrimination (i.e., discharge) for most LGB servicepeople. Using Health and Retirement Study (HRS; 1998–2016) data, this project analyzed the combined effects of veteran status and SSR on cognitive performance. Using multilevel longitudinal modelling, we found that while non-SSR veterans had higher mean scores than non-SSR civilian participants (the reference group), SSR civilians and veterans both had mean scores lower than the reference (SSR: β=-0.514, p=0.031; SSR+veteran (β=-1.065 p=0.081). These results may be limited due to the low number of SSR+veteran participants (n = 28). Nevertheless, these results suggest the potential for using veteran status among LGB people to study the health effects of identity concealment and discrimination on aging.

EARLY-LIFE EXPOSURE TO THE CHINESE FAMINE OF 1959–1961 AND LATER-LIFE HEALTH: EARLY LIFE AS A CRITICAL PERIOD

Mengling Cheng, Nicolas Sommet, Daniela Jopp, and Dario Spini, *University of Lausanne, Lausanne, Vaud, Switzerland*

Barker's fetal origins hypothesis and the critical period theory suggest that early life events have long-term health effects. However, evidence of the famine exposure in early life and its effects on health in later life is scarce and inconsistent. To explore the effects of early-life exposure to the Chinese famine of 1959-1961 on later-life multimorbidity, we performed Poisson growth curve models using CHARLS Life History 2014 and CHARLS 2011-2018 (42,775 observations from 12,060 respondents). Our analyses revealed two findings. First, there was an overall detrimental effect of the early-life famine exposure on multimorbidity, although there was no effect of severity of famine exposure. Second, there was no overall interaction between famine exposure and life stages, although a more parsimonious model suggested that the detrimental effect of famine exposure was more pronounced in earlier life stages than in later life stages. Findings suggest that early life is a critical period in the life course and provides developmental origins of health and disease in later life.

LIFE-COURSE SOCIOECONOMIC STATUS AND MORBIDITY AND MORTALITY IN THE MIDUS NATIONAL SAMPLE

Yanping Jiang[1], Li Chen[2], and Samuele Zilioli[3], *1. Rutgers, The State University of New Jersey, New Brunswick, New Jersey, United States, 2. Augusta University, Augusta, Georgia, United States, 3. Wayne State University, Detroit, Michigan, United States*

Socioeconomic status (SES) is a well-established social determinant of health shaping the distribution of the burden of morbidity and mortality. In this area, a less understood topic is how life-course SES affects physical health. This study aimed to examine the effects of childhood and adulthood SES and social mobility on morbidity and all-cause mortality. Data were drawn from the Midlife in the United States study (MIDUS, N = 7,108, ages 25-74 years, 88.4% of White, 51.6% of female). Childhood and adulthood SES were assessed at baseline (i.e., 1995-1996). Mortality was tracked through June of 2018 (N = 1,425 deceased). The number of comorbidities was assessed at baseline and the third wave of MIDUS in 2013-2014 (N = 2,786). Results showed that lower childhood SES was associated with a larger increase in the number of comorbidities at the third wave of MIDUS and higher mortality risk (ps < .05). However, when including adulthood SES in the model, adulthood SES, but not childhood SES, was associated with morbidity and mortality (ps < .01). Childhood SES was indirectly associated with morbidity and mortality through adulthood SES (ps < .01). Participants achieving upward mobility (i.e., low childhood SES, high adulthood SES) had a smaller increase in the number of comorbidities and lower mortality risk (ps < .01) than those reporting persistent low SES in childhood and adulthood. These findings indicate the unique effect of adulthood SES on physical health and highlight the potential health benefits of upward mobility in middle-aged and older US adults.

LONGING FOR LOVE: FINANCIAL STRAIN AND LATER LIFE MENTAL HEALTH IN THE US

Tirth Bhatta[1], Jeffrey Albert[2], Stacy Torres[3], Eva Kahana[2], Nirmala Lekhak[4], and Timothy Goler[5], *1. University of Nevada Las Vegas, Las Vegas, Nevada, United States, 2. Case Western Reserve University, Cleveland, Ohio, United States, 3. University of California, San Francisco, San Francisco, California, United States, 4. University of Nevada, Las Vegas, Nevada, United States, 5. Norfolk State University, Norfolk, Virginia, United States*

Objectives: Emotional support has been consistently identified as a mechanism through which socioeconomic resources influence mental health outcomes. Despite emerging evidence that compassionate love has a beneficial effect on mental health, its distribution across levels of financial strain and subsequent role in mediating the effect of financial strain on later life mental health have yet to be examined.

Methods: Based on our nationwide web-based survey of adults aged 50 years and older (n=1751), we conducted a mediation analysis to estimate the direct and indirect effects (via two mediators, feeling loved and emotional support) of financial strain on depressive symptoms and anxiety.

Results: We documented a statistically significant overall effect of financial strain on depressive symptoms (b=0.14, p-value< 0.001) and anxiety (b=0.196, p-value< 0.001). We found a statistically significant path-specific effect (from financial hardship) through compassionate love alone on depressive symptoms (b=0.018, p-value=0.003) and anxiety (b=0.016, p-value=0.005), but did not find effects for paths through emotional support. There was also a significant direct effect of financial strain on both depressive symptoms and anxiety. Discussion: Our study advances a new line of research by looking at the role of compassionate love in transmitting the effects of financial strain on mental health in later life. Findings suggest that the detrimental effect of financial hardship on mental health operates through its negative effect on the receipt of compassionate love, rather than by its impact on emotional support.

SUBJECTIVE SOCIAL STATUS MODERATES BACK PAIN AND MENTAL HEALTH: A LONGITUDINAL ANALYSIS OF OLDER MEN

Christina Mu[1], Dylan Jester[2], Peggy Cawthon[3], Katie Stone[4], Nancy Lane[5], and Soomi Lee[1], *1. University of South Florida, Tampa, Florida, United States, 2. University of California San Diego, La Jolla, California, United States, 3. California Pacific Medical Center Research Institute, San Francisco, California, United States, 4. University of California, San Francisco, Castro Valley, California, United States, 5. University of California, Davis Health, Davis, California, United States*

Objectives. This study tested the longitudinal relationship between back pain and mental health and examined the moderating role of subjective social status (SSS). Method. Community-dwelling older men from the MrOS Study provided four study visits of data collected between 2000-2016 (15,975 observations nested within 5,979 participants). Back pain frequency and severity were assessed at visits 1-4. General mental health was measured at each visit by the 12-item Short Form Survey Mental Component Score (SF-12 MCS; higher scores representing better mental health). National and community SSS were assessed at visits 1 and 3 with the MacArthur Scale. Growth curve models tested longitudinal within-person change associations after accounting for the repeated measures within each person. Age was used as the primary time variable. Results. At baseline, those with higher back pain-frequency/severity reported lower SF-12 MCS. After accounting for this between-person difference, there were bidirectional within-person associations between back pain frequency/severity and SF-12 MCS. On follow-up visits when back pain frequency/severity increased from baseline, participants reported lower SF-12 MCS (p<.001). On follow-up visits when SF-12 MCS decreased from baseline, participants also reported higher back pain frequency/severity (p<.001). Higher national and community SSS at baseline and having increases or consistently higher SSS over time attenuated the negative relationships between back pain frequency/severity and SF-12 MCS. Results were consistent after controlling for an extensive list of baseline health covariates and pain medications. Discussion. These findings highlight how self-perceived social status may buffer the relationship between greater back pain frequency/severity and lower mental health.

MULTIMORBIDITY AND ITS ASSOCIATION OF WIDOWHOOD, RACE, AND ETHNICITY IN OLDER ADULTS

Maki Karakida[1], Qian Song[2], Jeffrey Stokes[3], Suzanne Leveille[3], and Beth Dugan[3], *1. UMass Boston, Boston, Massachusetts, United States, 2. Universiy of Massachusetts Boston, Boston, Massachusetts, United States, 3. University of Massachusetts Boston, Boston, Massachusetts, United States*

Living with chronic disease is common in later life and over 60% of adults 65+ have two or more conditions. Spousal loss, also common in late adulthood, is linked to chronic diseases, like heart attacks, cardiovascular disease, and strokes. This study examines the associations between widowhood, race/ethnicity, and onset of multiple chronic conditions (i.e., cancer, diabetes, heart disease, stroke) among 4,187 Americans aged 60+. Using the RAND HRS Longitudinal File 2018, we analyzed how married/partnered adults without major chronic conditions in 2010 experienced widowhood and developed cancer, diabetes, and/or cardiovascular disease during the subsequent eight years. We used ordinal logistic regressions to examine the associations between marital status, race/ethnicity, and multimorbidity onset, controlling for age, gender, birthplace, living conditions, income, education, smoking habits, physical activities, self-reported BMI, and Medicaid enrollment. Among participants, 69.41% were non-Hispanic White, 13.04% were non-Hispanic Black, 14.19% were Hispanic (any race), and 3.37% were non-Hispanic other. The mean age was 70.33 years, more than half (54.79%) were female, and 83.85% were married or partnered in 2018. Older widowed group were more likely to be non-Hispanic White women without smoking habits nor multimorbidity. The onset of multimorbidity at follow-up was elevated among divorced or separated non-White/Hispanic participants (OR = 1.83, 95%, CI 0.896, 3.744) unlike widowed non-White individuals (OR = 0.71, 95%, CI 0.433, 1.152). Age, previous smoking behavior, BMI, and birth in the South were all significantly associated with increased multimorbidity risk ($p<0.017$). The association of widowhood and health outcomes may vary by race and ethnicity.

RACIAL/ETHNIC DISPARITIES IN THE RISK OF DEMENTIA: THE ROLE OF STRESS EXPOSURE IN LATE LIFE

Wen-Hua Lai, *Michigan State University, East Lansing, Michigan, United States*

The number of individuals with Alzheimer's disease and related dementias is expected to triple from 5 million to 13.7 million by 2050 in the US. Current studies suggest that older Black and Latinx adults experience poorer cognitive health; their dementia prevalence is 1.5 to 2 times higher than their white counterparts. Excessive stress exposure (e.g., traumatic experiences and discrimination) may serve as contributors to the cognitive health inequalities faced by racial/ethnic minorities. However, extant studies on cognitive health in diverse aging populations remained limited. In particular, little is known about how the level and effect of stress exposure account for cognitive health disparities across racial/ethnic groups. This study examines whether racial/ethnic differences in stress exposure (traumatic events, stressful life events, perceived everyday discrimination, lifetime discrimination, and financial strain) shape cognitive health disparities by race/ethnicity. Data from the 2006-2012 Health and Retirement Study are used to address the research question (N=9,251). Preliminary results based on ordinal logit regression models and moderation analyses suggest that all racial/ethnic minority older adults, especially Blacks, were more exposed to stressors and experienced poorer cognitive health than their White peers. However, even though some stressors are associated with adverse cognitive health, greater stress exposure among minority older adults explains little cognitive disparities faced by them. Moreover, the magnitude of the stressor effects on cognitive health is smaller for Blacks and Latinxs than for Whites. This study will discuss the implication of these unexpected findings and areas of promising future research.

THE NEIGHBORHOOD CONTEXT AND ALL-CAUSE MORTALITY AMONG OLDER ADULTS IN PUERTO RICO

Catherine Garcia[1], Mary McEniry[2], and Michael Crowe[3], *1. Syracuse University, Syracuse, New York, United States, 2. University of Wisconsin-Madison, Madison, Wisconsin, United States, 3. University of Alabama-Birmingham, Birmingham, Alabama, United States*

The neighborhood contexts in which older adults live are increasingly being recognized for their role in influencing disease processes and risk of death among the U.S. population. However, few studies have focused on neighborhood impacts among older populations residing in Puerto Rico– a U.S. territory –who are especially vulnerable to the effects of the environment as they “age in place” in the context of a budget crisis, the great recession, the debt crisis, and Hurricanes Irma and María. The combination of these events can obstruct access to neighborhood resources, services, and contexts considered necessary for promoting healthy aging. Thus, it is warranted to understand the effects of place on mortality in Puerto Rico, whose social and economic contexts differ from the U.S. and are more similar to that of other Latin American and Hispanic-Caribbean countries. We used 2000 U.S. Census data at the block-group level linked to the 2002 Puerto Rican Elderly Health Conditions Project with mortality follow-up to 2021 to examine neighborhood characteristics that are conceptualized as influencing mortality (e.g., residents without a high school degree; households receiving public assistance income; residents living below the poverty level; unemployed residents; residential stability; age structure). Multilevel mixed-effects parametric survival models with a Weibull distribution were estimated. Overall, results show that neighborhood socioeconomic disadvantage is associated with an increased risk of mortality among older Puerto Ricans. This suggests that older Puerto Ricans clustered in disadvantaged communities are more likely to experience a cumulative burden of social disadvantages that adversely impacts their longevity.

ARE PERCEIVED NEIGHBORHOOD CHARACTERISTICS ASSOCIATED WITH CHRONIC PAIN IN MIDDLE-AGED AND OLDER ADULTS?

Yulin Yang, *University of California, San Francisco, San Francisco, California, United States*

Neighborhoods predict many health outcomes including functional limitations and disability; however, how neighborhoods are associated with chronic pain remains poorly understood. This study uses examined the association between four perceived neighborhood characteristics (social cohesion, physical disorder, safety, and social ties) and chronic pain in a nationally representative sample of adults aged 51+ in the US. Among 14,069 participants (58.65% women; mean age 68.81) in the Health and Retirement Study (2006-2008), we investigate whether neighborhood social cohesion, neighborhood physical disorder, neighborhood safety, and neighborhood social ties were associated with odds of having moderate-severe and limiting pain using adjusted logistic regression. After adjusting socio-demographic factors (age, gender, race/ethnicity, education, wealth, marital status), residence in neighborhoods with high perceived social cohesion, safety, and more social ties were associated with lower odds of having moderate-severe and limiting pain. Perceived neighborhood physical disorder did not predict whether respondents have moderate-severe and limiting pain or not.

RURAL ADULTS' BEHAVIOR CHANGES DURING COVID-19: A LATENT CLASS ANALYSIS

Tim Killian, and Betsy Garrison, *University of Arkansas, Fayetteville, Arkansas, United States*

The advent of the SARS-CoV-2 virus necessitated behavior changes for most older adults. Changes were largely associated with voluntary or enforced compliance with social distancing policies. Whereas the value of social distancing for mitigating the spread of the dangerous SARS-CoV-2 virus is not the subject of serious debate among public health advocates, policies that encouraged or enforced social distancing have been met with skepticism in the general public. Understanding patterns in behavior changes may be helpful to public health professionals and policymakers who develop health communication and revised guidelines in the efforts to contain the spread of the SARS-CoV-2 and future public health infections. Our study examined patterns in behavior changes. This study had two aims. First, using survey responses from 661 adults living in rural areas about changes they made to 20 different behaviors, we identified four classes of behavior changes: (1) non-social distancers (10.7%), (2) social distancers (54.0%), (3) social distancers making civic exceptions (24.0%), and (4) social distancers making religious exceptions (11.3%). Second, polytomous logistic regression was used to predict the probability of membership in those latent patterns of behavior change. Predictor variables included demographic variables (i.e., age, sex, and race) and variables theoretically predicted to covary with patterns of behavior change (i.e., social trust, self-assessment of health, experience of pain, and depressive symptoms). This study provides insight into behavior changes during the outbreak of the SARS-CoV-2 virus that may be used by practitioners to understand variations in how people responded to the outbreak.

SOCIAL DETERMINANTS OF HEALTH AND QUALITY OF LIFE AMONG OLDER ADULTS NEW TO LONG-TERM SERVICES AND SUPPORT

Onome Osokpo[1], Karen Hirschman[1], Liming Huang[1], and Mary Naylor[2], *1. University of Pennsylvania, Philadelphia, Pennsylvania, United States, 2. University of Pennsylvania - School of Nursing, Philadelphia, Pennsylvania, United States*

The number of older adults requiring long-term services and support (LTSS) is increasing. Social determinants of health (SDoH)—underlying economic, social, and structural factors—fundamentally shape people's health including quality of life (QoL). However, the influences of SDoH factors on QoL are relatively unexplored among older adults new to LTSS. The purpose of this study was to examine the relationship between SDoH factors and overall QoL ratings among older adults new to LTSS using data from a prospective NIA funded longitudinal study of change in health related QoL in this population. QoL was measured using a single item: "How would you rate your overall quality of life at the present time?" (1- Poor to 5- Excellent). SDoH variables included years of education, marital status, food security, spirituality, social isolation, financial resources, and social support measures. A full multivariable regression analysis was performed adjusting for age, sex, cognitive status, functional status, physical and emotional health, and LTSS type. Among the 470 participants, 71% were female, 51% were white, 20% were married, and the average age was 81 years (+/- 8 years). Having adequate financial resources to pay for health care needs (p <.0001) was positively associated with QoL. No other SDoH factors were significant. Access to resources to meet health care needs is critically important in promoting the quality of life of older adults especially at the start of LTSS. Implications for future research and policy will be discussed.

SOCIAL DETERMINANTS OF HEALTH UNDERLIE RACIAL/ETHNIC DISPARITIES IN PSYCHOLOGICAL HEALTH AND WELL-BEING

Dylan Jester[1], Jordan Kohn[1], Lize Tibirica[2], Michael Thomas[3], Lauren Brown[4], James Murphy[1], and Dilip Jeste[1], *1. University of California San Diego, La Jolla, California, United States, 2. University of California, San Diego, San Diego, California, United States, 3. Colorado State University, Fort Collins, Colorado, United States, 4. San Diego State University School of Public Health, San Diego, California, United States*

This study sought to determine the impact of selected social determinants of health on psychological health and well-being (defined as depression, cognition, self-rated health) among Black and Hispanic/Latinx adults relative to White adults aged 51 to 89. We measured disparities in depression, cognition, and self-rated health among 2,306 Non-Hispanic/Latinx Black, 1,593 Hispanic/Latinx, and 7,244 Non-Hispanic/Latinx White adults from the Health and Retirement Study (n=11,143). Blinder-Oaxaca decomposition was used to examine whether differences in selected social determinants of health explained a larger share of the disparities than age, sex, measures of health, health behaviors, and healthcare utilization. Selected social determinants included education, parents' education, number of years worked, marital status, veteran status, geographic residence, nativity status, income, and insurance coverage. Black and Hispanic/Latinx adults reported worse depression, cognition, and self-rated health compared to White adults. Selected social determinants of health explained a larger proportion of the Black-White disparities in depression (51%), cognition (39%), and self-rated health (37%) than did age, sex, measures of health, health behaviors, and healthcare utilization. Social determinants of health explained a larger proportion of the Hispanic/Latinx-White disparity in cognition (76%) and self-rated health (75%), but age and functional status primarily drove the disparity in depression (28%). Education, parents' education, years worked, income, and insurance parity were social determinants associated with the disparities.In conclusion, differences in social determinants of health underlie racial/ethnic disparities in depression, cognition, and self-rated health among older adults. Education, income, number of years worked, and insurance parity are key social determinants of health.

SOCIOECONOMIC CHARACTERISTICS AND HEALTH OF OLDER ADULTS IN RURAL CAMBODIA: ROLES OF SOCIAL AND WELFARE SUPPORT

Kakada Kuy, *WASHINGTON UNIVERSITY ST LOUIS, UNIVERSITY CY, Missouri, United States*

Considering differences in support systems and socioeconomic characteristics, findings from studies of high-income nations could be biased if generalized to population of low- and middle-income countries. Insights into roles of social support in socioeconomic characteristics and health relationships are valuable for health interventions targeting older adults in low-resource communities, such as rural Cambodia, but such knowledge remains unexplored. This study examined mediating roles of social and welfare support in associations between socioeconomic characteristics and health among older Cambodians. Data came from a 2019 survey of older Cambodians age 60 and older (N=220) living in three rural provinces. Dependent variables included health complaints and psychological well-being index. Independent variables were wealth index derived from household items and living conditions, and subjective socioeconomic characteristic derived from three self-perceived economic circumstances. Social support and welfare support were operationalized using Social Support and Social Network scale and status of welfare assistance, respectively. Mediation analysis using Structural Equation Modeling substantiated a full mediation effect of social support on the relationship between subjective socioeconomic characteristic and psychological health. A partial mediation of social support was also found in the subjective characteristic and physical health relationship. However, no mediation was found in relationships between wealth index and health. Welfare support did not mediate any relationship between socioeconomic characteristics and both health outcomes. Healthy aging interventions in low-resource settings could benefit from improving existing support system of family and friends, which may buffer the impact of economically negative self-image on one's health and well-being in the community.

SOCIAL DETERMINANTS OF COGNITIVE HEALTH

Amber Rusch, Janella Camp, and Julie Hicks Patrick, *West Virginia University, Morgantown, West Virginia, United States*

Social determinants of health (SDOH), such as age, race, sex/gender, socioeconomic status, and access to healthcare, influence wellbeing, and shape day-to-day life. To what degree SDOH influence cognitive decline is less well understood. Thus, we applied frameworks of SDOH to understand cognitive health better. We used data from the CDC's 2020 Behavioral Risk Factor Surveillance System, in which 61,770 adults (mean age = 64.7, SD = 10.4, range 24-80+ yrs.) supplied demographic information and answered questions about cognitive decline. We conducted a logistic regression and interpreted the Odds Ratios (ORs). A significant equation emerged, X2 (DF = 8) = 438.214, p < 0.001. Each indicator of age, sex, race, and education uniquely contributed to the equation. Older adults, those with less education, and those identified as American Indian (OR = 1.25) were more likely to express cognitive decline. Using this equation, we correctly classified 0%, so we added a second step that included SDOH beyond demographic predictors: number of health conditions, access to health care, urban/rural status, and depression. The model retained its significance (X2 (DF=12) = 3400, p < .001. The OR showed adults with depression were 3.8 times more likely to report cognitive decline. Thus, examining a range of SDOH beyond demographics increases our understanding of the context in which cognitive decline occurs.

SESSION 6210 (POSTER)

SOCIAL DIMENSIONS OF COVID-19: HEALTH AND CAREGIVING DURING THE PANDEMIC

"MISERY LOVES COMPANY": THE OTHER SIDE OF COVID-19 FOR SPOUSAL CAREGIVERS

Jing Geng[1], Toni Calasanti[2], and Sadie Giles[2], *1. Virginia Tech, BLACKSBURG, Virginia, United States, 2. Virginia Tech, Blacksburg, Virginia, United States*

Gerontologists have voiced much concern about the potential for the pandemic to create social isolation risks for older people, especially older caregivers, for whom the lockdown cut off many sources of support. This presentation is based on a national study of older same-sex and heterosexual people who care for their spouses with Alzheimer's disease and related dementias. The qualitative, interview-based research began before the pandemic, and we were able to ask caregivers about their experiences during this public health crisis. Drawing on a total of 48 interviews, this presentation documents the surprising finding that, although caregivers discussed some challenges, they found much to say about the positive aspects of the lockdown and continued restrictions, including not having to rush for appointments or social engagements and being less frustrated with their care receivers as a result. They also described instances of greater social connection rather than less through the use of technology. In addition, some caregivers found that being with their care receiver all day gave them greater insights into disease progression and how to manage it, as well as greater intimacy. Finally, the phrase "misery loves company" was used to convey that the pandemic provided a situation wherein other people also were restricted in ways that some caregivers had been prior to the pandemic; as a result they felt others had more of an appreciation of what their lives had been like.

PROTEIN CONSUMPTION SINCE COVID-19 PANDEMIC AMONG DIFFERENT RACES

Lillie Monroe-Lord[1], Azam Ardakani[2], and Lily Spechler[1], *1. University of the District of Columbia, Washington, District of Columbia, United States, 2. Howard University, Beltsville, Maryland, United States*

Covid-19 has changed individuals eating behavior. This study examines how protein consumption changed since Covid-19 pandemic. This is a cross-sectional study design with a total of 10,035 adults aged 40-100 years old surveyed through Qualtrics by dietary screening tool. The protein consumption was questioned by "How often do you eat chicken or turkey?" and "How often do you eat not-fried fish or seafood?". Pre and since pandemic responses were compared by Wilcoxon signed-rank tests. Participants were 57% female, 43% male, 75% White, 14% African American, %7 Asian, and 4% Hispanic. According to the analysis, chicken, or turkey (p <.001) and fish or seafood (p <.001) consumption significantly reduced since Covid-19 pandemic. Chicken or turkey consumption reduced significantly among African American (p < .01), White (p < .01), and Hispanic (p < .05) participants while this reduction was not significant among Asians. Moreover, Fish or seafood consumption also significantly reduced among African American (p < .05) and White participants (p < .01), while did not change among Asians and Hispanics. In conclusion, since Covid-19 pandemic, protein consumption significantly reduced among some races (i.e., African American and White) while changed at a lower grade (i.e., Hispanic), or remained unchanged (i.e., Asian) among other races. It could be justified by considering that foods with high amount of protein and especially fish or seafood is part of the eating culture of some races. Reduction in protein consumption resulted from changes in the daily routine of people and financial instability resulting from the Covid-19 pandemic.

TRAJECTORIES OF ANXIETY SYMPTOMS DURING THE COVID-19 PANDEMIC AMONG OLDER ADULTS

Soyoung Choun[1], Dylan Lee[2], Maria Kurth[1], Hye Soo Lee[1], Heidi Igarashi[1], and Carolyn Aldwin[1], *1. Oregon State University, Corvallis, Oregon, United States, 2. Touro University Nevada, Henderson, Nevada, United States*

Older adults face particular challenges during the COVID-19 pandemic, including increased risk for morbidity and mortality (CDC, 2021). Social distancing and lockdown to prevent contagion may create social isolation and loneliness, adversely affecting mental and physical health. We examined anxiety symptom trajectories of older adults and identified risk and protective factors during the early months of the COVID-19 pandemic. We also examined how anxiety symptoms were associated with both between- and within-person variations in loneliness, social contacts, and physical problems. We sampled 247 older adults (Mage = 71.1, SD = 7.3, range = 51 - 95), who participated in eight weekly longitudinal online surveys from April 28 to June 23, 2020. Multilevel modeling analysis controlling for age, gender, marital status, and education showed that anxiety symptoms significantly decreased in the first few weeks, but then increased around week 6 of the study period. At the between-person level, individuals with higher levels of both loneliness and physical problems were at risk for experiencing higher levels of anxiety, but social contacts were not significant. Middle-aged participants reported higher anxiety symptoms than older participants. Women experienced higher anxiety symptoms than men. As a protective factor, individuals who were high in resilience had significantly lower anxiety symptoms over time, compared to those with low in resilience. In the within-person level, anxiety symptoms were positively coupled with both loneliness and physical symptoms over time. We conclude that lonely individuals and those in poor health were at greater risk of poor mental health during the pandemic.

EFFECTS OF CHANGES IN THE FREQUENCY OF SOCIAL OUTINGS ON DEPRESSION AND WELL-BEING DURING THE COVID-19 PANDEMIC

Koji Abe, *Kagoshima University, Kagoshima, Kagoshima, Japan*

In Japan, in order to reduce the risk of infection with COVID-19, a state of emergency was declared in areas the infection had spread to, and priority measures were issued in equivalent areas. As a result, many senior citizens who were not good at using the Internet lost the opportunity to communicate with others through interpersonal interaction. Previous studies have shown that reduced interpersonal interaction negatively affects the mental health of senior citizens. However, little research has been done on the effects of socially created restrictions on interpersonal interaction. The purpose of this study was to focus on the changes in the frequency of going out among senior citizens and to examine the effect on mental health. An internet survey of a nationwide sample of individuals was conducted in October 2021. In total, there were 1600 respondents (males, 47.8%; females, 52.2%; mean age, 70.39(SD=4.67) years). During the pandemic, 47.1% participants had decreased the frequency of going out, and 52.9% had either no change or a slight increase in the frequency of going out compared to the period before the pandemic. Multiple regression analysis showed that social capital and decreasing frequency of going out had a significant effect on depression. However, a decrease in the frequency of going out had no effect on subjective well-being, and only social capital had a significant effect. The results showed that a decrease in frequency of going out increased the depressive mood, but social capital had an even greater impact on depression and subjective well-being.

CAREGIVING FOR PEOPLE WITH DEMENTIA DURING THE PANDEMIC: A SCOPING REVIEW

Phillip Cantu[1], Joanna Chyu[2], Neil Mehta[2], and Markides Kyriakos[2], *1. The University of Texas Medical Branch, Galveston, Texas, United States, 2. UTMB, Galveston, Texas, United States*

Background: The COVID-19 pandemic has had a large impact on the roles and responsibilities of caregivers for older adults with dementia. An increasing number of studies have examined the unique challenges faced by caregivers during this time, including extended work hours, anxiety around contracting COVID-19, and adhering to public health guidelines. Informal caregivers may also face greater strain on their personal lives during lockdown. Objective: To conduct a scoping review to examine factors impacting well-being of caregivers of older adults with dementia during the first year of the COVID-19 pandemic. Method: We conducted a PubMed search using the terms "COVID-19," "older adults," and "caregiving" or "caregiver." Sixty-seven papers were identified published between June 2020 and December 2021.

Results: All papers identified were cross-sectional and conducted after the pandemic began and prior to the availability of COVID-19 vaccines. Articles highlighted increasing burdens such as financial and physical stress, as well as worsened psychological wellbeing through increased anxiety and depression among caregivers during the pandemic. Additionally, themes of protective factors on wellbeing in the form of social connection and telehealth interventions emerged. Discussion: Limitations to our review include lack of longitudinal information on caregiver experience to better identify broad impacts on caregiver well-being. Studies not only identified new, pandemic-related risk factors for caregiver burden, but also a heightened effect of pre-existing risk factors (e.g. income, living situation, gender) on burden. Caregiver psychiatric outcomes reflect the overall population's increase in mental illness since the start of the pandemic.

MAKING "NONESSENTIAL" FAMILY/VOLUNTEER CAREGIVING ESSENTIAL IN LONG-TERM CARE HOMES

Annie Robitaille, Linda Garcia, and Michaela Adams, *University of Ottawa, Ottawa, Ontario, Canada*

For individuals living in long-term care (LTC), loneliness is often a concern. With the COVID-19 pandemic, this is only exacerbated as strict restrictions are put in place on visits between residents and their loved ones and on volunteer presence. Understanding how these changes affect residents, family caregivers, and volunteers is paramount to best implement changes with regards to how family/volunteer caregiving presence is managed during pandemics. The objective of this study was to gain a better understanding of the response to COVID-19 that pertains to the family caregiver and volunteer presence in LTC and increase the evidence about the impact of reduced levels of family caregivers and volunteers on residents, caregivers, and volunteers. A total of 64 semi-structured interviews were conducted with caregivers and volunteers. Of these interviews, 49 were one-time interviews and 15 were weekly interviews over a 5-month period to examine the impact of the ever-changing pandemic restrictions on caregivers, volunteers, and residents. Thematic analysis was used to analyze the interviews and two independent researchers coded each interview. Results highlight the importance of connections in LTC, the feeling that human rights were neglected, the importance of flexibility amongst staff, the role of caregivers as advocates for residents, increased caregiver guilt, and resident decline in physical and emotional well-being. The role of family caregivers and volunteers as essential in LTC homes will be discussed and recommendations to revisit policies on the family caregiver and volunteer presence to improve the preparedness for future pandemics and outbreaks will be presented.

OPTIMAL AGING AND SATISFACTION WITH SOCIAL SUPPORT DURING THE COVID-19 PANDEMIC

Hye Soo Lee[1], Soyoung Choun[1], Maria Kurth[1], Heidi Igarashi[1], Dylan Lee[2], and Carolyn Aldwin[1], *1. Oregon State University, Corvallis, Oregon, United States, 2. Touro University Nevada, Henderson, Nevada, United States*

Social support is important for optimal aging, especially during the COVID-19 pandemic when older adults are at risk of social isolation and its attendant health problems. Providing support may be especially protective of health outcomes. We examined whether actual received, provided, and satisfaction with support were related to optimal aging early in the pandemic (April-May, 2020). Survey participants (N=238) were on average 71.2 years old (SD=7.3), 73% female, 92.6% White, and highly educated (48% with post-graduate degrees). Optimal aging (Aldwin & Igarashi, 2016) was indicated by a latent variable of health outcomes, including depressive symptoms, cognitive lapses, and physical symptoms. Nearly all older adults (90+%) reported receiving or providing actual support from or to at least one family member or friend. We investigated the associations between age, summed social support, satisfaction with support, and health outcomes, controlling for chronic illnesses. Two SEM models were estimated for received support and provided support, respectively. After trimming non-significant paths, both models had acceptable fits (CFI > .90, RMSEA < .08, SRMR < .08). Age and chronic illnesses had negative associations with health outcomes, but neither received nor provided social support was significant. However, satisfaction with both received and provided support were significant and independently associated with optimal aging in both models. Thus, isolation levels in this sample were surprisingly low, as indicated by high levels of social support received and provided. However, only the quality of (or satisfaction with) support was important for optimal aging during this unique and shared stressful experience.

HEALTHCARE ACCESSIBILITY AND UTILIZATION AMONG LGBTQ+ OLDER ADULTS

Jessika Dayrit[1], Ana Maria Pasatiempo[2], Shirley Salom-Bail[3], and Cesz Islaya[3], *1. Washington University in St. Louis, Menlo Park, California, United States, 2. U.S. Department of Veterans Affairs, Anchorage, Alaska, United States, 3. US Department of Veterans Affairs, Menlo Park, California, United States*

Background: Studies show disparities in healthcare have exacerbated during the COVID-19 pandemic, especially among Lesbian, Gay, Bisexual, Transgender, and Queer + (LGBTQ+) older adults. The aim of this paper is to understand health care utilization and accessibility among LGBTQ+ older adults and to examine if social assets, such as income, education, and employment are associated with health care utilization and accessibility.

Methods: Data from BRFSS 2020 was used. Study focused on LGBTQ+ and non-LGBTQ+, age 65 and older, comparing health care utilization and accessibility. Data was weighted for complex sampling design. Logistic regression was used to examine the odds of health care accessibility and health care utilization while controlling for socioeconomic status.

Results: Total sample size of study was 14,453. 6.14% of participants identified as LGBTQ+, which 11% of them were unemployed (CI=0.08-0.17), 21% earned less than $15,000 annually (CI=0.15-0.28), and 35% did not graduate from high school (CI=0.27-0.44). Our analyses indicated LGBTQ+ are less likely to have primary health care provider than non-LGBTQ+ (OR=0.64; CI=0.48-0.84); they are less likely to have health care insurance than non-LGBTQ+ (OR=0.60; CI=0.39-0.93). We did not find association if LGBTQ+ are less likely to seek medical help, when needed, due to cost (OR=0.72; CI=0.53-1.02). Our findings suggest disparities in socioeconomic status, such as income, employment, and education have significant association with health care accessibility and health care utilization. Limitation of study includes recall bias due to self-report. Longitudinal and qualitative research regarding healthcare utilization and accessibility among older LGBTQ+ population need to be explored.

AGE DIFFERENCES IN SELF-CONTINUITY REMAIN ROBUST IN RESPONSE TO THE COVID-19 PANDEMIC

Yi Lu, and Corinna Löckenhoff, *Cornell University, Ithaca, New York, United States*

Self-continuity, the perceived connectedness to one's past and future selves, predicts well-being and tends to be higher among older adults (Rutt & Löckenhoff, 2016). Self-continuity is also susceptible to major life changes (Sani, 2008). The pandemic brought dramatic changes in multiple life domains, especially for older adults who experienced higher rates of COVID-19 morbidity and mortality and may have been more likely to restrict their behavior as a result. This study examined whether age differences in self-continuity remained robust in response to the pandemic using representative U.S. survey data. Pre-pandemic data (Fall 2016, N = 230, aged 18 – 87, M = 50.85, SD = 16.40, 47.83% female, 67.83% white) and mid-pandemic data (Summer 2020, N = 230, aged 18 – 88, M = 50.20, SD = 19.49, 48.27% female, 64.78% white) were demographically matched using propensity scores. Participants rated their self-continuity one, five, and ten years into the past and future. Multi-level modeling examined the effects of age, temporal distance (in years), temporal direction (past vs. future), and assessment time (pre- vs. mid-pandemic) on self-continuity. Consistent with prior research, self-continuity was lower for more distant intervals, especially for the past. An interaction between temporal direction and assessment time indicated that future self-continuity was lower mid-pandemic than pre-pandemic. Across samples, however, advanced age was associated with higher self-continuity and the size of this effect did not vary by assessment time. Overall, findings suggest that even though future self-continuity decreased during the pandemic, existing age effects remained robust to this disruption.

COPING AND UNCERTAINTY IN THE CONTEXT OF COVID-19: DIFFERENCES BETWEEN PARTNERED AND UNPARTNERED OLDER ADULTS

Ashley Tate[1], Christina Marini[2], Suyoung Nah[3], and Lynn Martire[1], *1. Pennsylvania State University, University Park, Pennsylvania, United States, 2. Adelphi University, Garden City, New York, United States, 3. Pennsylvania State University, State College, Pennsylvania, United States*

The initial conditions of the COVID-19 pandemic made it such that individuals—especially older adults—experienced uncertainty about their own health/well-being, as well as that of their loved ones and communities. The current study examined how older adults' social context shaped their well-being (i.e., anxiety, depressive symptoms, and sleep quality) early in the pandemic. Specifically, we tested whether there were differences in uncertainty, communal coping, and well-being among partnered individuals who indicated that their partner was their primary source of emotional support during the pandemic versus un-partnered individuals who indicated another social tie as their primary source of emotional support. Data were collected between May and August 2020 from 101 older adults (Mage = 80.63, SD = 8.96). Correlational analyses showed that uncertainty about one's own health/well-being was positively associated with anxiety ($p < .05$) and communal coping (i.e., viewing the pandemic as a stressful period that will be worked through together) was negatively associated with depressive symptoms ($p = .001$) and anxiety ($p < .01$). Results from independent samples t-tests showed that, on average, partnered older adults reported fewer depressive symptoms ($p < .05$), less uncertainty about their own health/well-being ($p < .05$), and higher communal coping ($p < .001$) compared to un-partnered older adults. Unexpectedly, no group differences were found for anxiety or sleep quality. Results suggest the unique benefit of having a partner as an emotional support confidant in the context of the pandemic, perhaps because older adults were largely confined to their homes during lockdown.

HOW COVID-19 NEWS AFFECTS OLDER ADULTS' MENTAL HEALTH

Grace Li[1], Zoe Ziyi Ng[2], and W. Quin Yow[3], *1. Palo Alto High School, Palo Alto, California, United States, 2. Raffles Institution, Singapore, Singapore, 3. Singapore University of Technology & Design, Singapore, Singapore*

Media affects the trajectory of many individuals' mental health. With the rise of COVID-19 cases, the media not only provides informative updates on the pandemic, it also fuels the hysteria and paranoia of citizens across the world. Studies show that older adults (OA) who consume media frequently were at a higher risk for declining mental health (Negarestani et al., 2021) and that individuals experience negative bias more than positive bias (Vaish et al., 2013). However, no studies have directly investigated how much positive and negative COVID-19 news affect OA's mental health and emotions. Sixty-nine OA (aged 55-95) answered questions about their weekly media consumption, how closely they followed COVID-19 news, and the General Health Questionnaire. They were then randomly assigned to read either positive or negative COVID-19 news (n=35 and 34 respectively), and asked if the news made them feel happy/fearful and if they wanted to read more about/ignore the news. Analysis revealed that the more OA consumed media and closely followed COVID-19 news, the more they felt unhappy and depressed, rs>.25, ps<.05. There was a significant condition effect, where OA who read positive news reported more positive emotions than those who read negative news, $t(67)=5.21$, $p<.001$. Chance analyses revealed that positive news evoked positive emotions significantly above chance, $t(34)=8.99$, $p<.001$, but negative news evoked negative emotions only marginally above chance, $t(33)=1.92$, $p=.064$. These findings suggest that media consumption of COVID-19 news does negatively impact OA's mental wellbeing, and OA appear to have a strong positivity bias for COVID-19 news.

OLDER ADULTS DURING THE COVID-19 PANDEMIC: ROLE OF HEALTH CONDITIONS IN RESILIENCY AND PERCEIVED STRESS

Allyson Sloan, *Johns Hopkins University School of Medicine, Baltimore, Maryland, United States*

The COVID-19 pandemic has necessitated protracted lockdowns, exacerbating the challenges associated with social isolation. Older adults, who often suffer from social isolation, may have a harder time coping with the added isolation imposed by COVID-19. In this study, we investigated the resiliency and coping skills of older adults amidst the COVID-19 pandemic, and whether they were associated with different co-morbidities. We conducted a 45-minute telephone survey of 107 participants to assess their experiences during the COVID-19 pandemic. Participants were recruited from existing Johns Hopkins studies. The survey included the Brief Resilient Coping Scale, the Perceived Stress Scale, and questions about current health conditions (arthritis, osteoporosis, high blood pressure, heart disease, and depression/anxiety) and whether these conditions worsened, improved, or remained unchanged since the beginning of the pandemic. We regressed scores for resiliency and coping scores on a series of indicators of whether co-morbidities had worsened during the pandemic. On average, participants were 76 years old and 63% were female. There was no association between resiliency scores and any of the co-morbidities (r2=2.8%). With respect to perceived stress, participants who reported their depression/anxiety worsened during the pandemic also reported greater levels of perceived stress (B=0.83, 95% confidence interval: 0.30, 1.36). We were surprised that additional co-morbidities did not affect resiliency or stress. In order to better serve geriatric populations, health professionals should closely monitor those patients who have depression and anxiety during times of social distancing, epidemics, or pandemics.

OLDER AGE IS (STILL) ASSOCIATED WITH MENTAL HEALTH BENEFITS IN JUNE–JULY 2021 OF THE COVID-19 PANDEMIC

Amanda Chappell[1], Kelly Smith[2], and JoNell Strough[2],
1. West Virginia University, Morgantown, West Virginia, United States, 2. WVU, Morgantown, West Virginia, United States

In the early months of the COVID-19 pandemic, older age was associated with less anxiety and depression (Bruin de Bruin, 2021). Similar results were found for data collected during the June-July 2020 spike in cases (Smith et al., 2021). Theorists have suggested that benefits of age for well-being may be reduced when stressors are prolonged and unavoidable (Charles, 2010). Here, we investigated whether older age continued to be protective in June-July 2021, when vaccines had become widely available, but the pandemic persisted. Secondary data analysis was conducted from the Understanding America Study, based on n=5,535 (M=52.69 yrs., SD=16.04) participants who responded to online self-report surveys. Participants reported symptoms of anxiety and depression (assessed by the Patient Health Questionnaire, PHQ-4), engagement in protective behaviors (e.g., wearing a mask), and coping strategies (e.g., getting extra exercise). Multiple regression analyses predicted anxiety and depression from age, coping strategies, and protective behaviors, controlling for marital status, gender, and income. Coping through exercise and calling family/friends were significantly associated with less anxiety and depression, whereas coping by using social media and engaging in protective behaviors was significantly associated with more anxiety and depression. The harmful effects of protective behaviors may reflect the people engaging in these strategies most often are also those most worried about COVID-19. Even after accounting for coping strategies and protective behaviors, older age was still associated with fewer symptoms of anxiety and depression. Implications of older adults' resilience in the face of a prolonged stressor for promoting mental health are discussed.

"ADAPTING TO A NEW REALITY": OLDER ADULTS' EXPERIENCES DURING THE COVID-19 PANDEMIC

Jodie Oshana[1], Mariana Guzzardo[2], and Irina Todorova[3],
1. University of Connecticut, Storrs, Connecticut, United States, 2. California State University, Hayward, California, United States, 3. Northeastern University, Boston, Massachusetts, United States

Older adults were uniquely affected during the COVID-19 pandemic, given that they were most at risk of serious complications and death if infected. Numerous preventative measures were abruptly mandated, including stay at home orders and social distancing that led to social isolation. Given this context, the aim of this qualitative study is to explore the lived experiences, perceived challenges, and mechanisms for resilience of older adults during the first wave of the pandemic. Our sample (n=50), derived from a larger international study with data from 15 countries, includes individuals 60 or older in Puerto Rico and mainland United States. Following thematic analysis of responses from an online survey, three themes were identified: resilience through reflection and adaptation, resilience through critique of systemic problems and injustices, and resilience through reaffirmation of values. Findings support various recommendations for improving support to older adults in future crises.

ARE OLDER ADULTS ABLE TO DRAW UPON PRIOR EXPERIENCES WHEN COPING WITH THE NOVEL COVID-19 STRESSOR?

Maria Kurth, Heidi Igarashi, Hye Soo Lee,
Soyoung Choun, and Carolyn Aldwin, *Oregon State University, Corvallis, Oregon, United States*

Despite higher physiological vulnerability to stress, older adults may accumulate resources through prior experiences that can promote resilience (Aldwin & Igarashi, 2016). During the COVID-19 pandemic, older adults drew on prior experiences and resources to cope (McKinlay et al., 2021; Herron et al., 2021), although these events were typically not specified. Some found vulnerability due to prior trauma (Galica et al., 2021). We examined whether older adults drew upon specific experiences or more general resilience resources in coping with this novel stressor. Data were collected using an online survey from April 28-May 4, 2020 from 235 older adults in Oregon (Mage = 71.35, SD = 7.39; 74% female; 92% White). We examined open-ended responses from a question that asked whether prior experiences influenced how they were dealing with the COVID-19 situation. Nearly 2/3 provided valid responses (n=144). After inductive open coding, preliminary consolidation resulted in three broad categories: past experiences (74%), resources (19%), and both (8%). The most common prior experiences were illness (n = 20) and work (n = 19). Some (n=10) reported specific coping strategies learned during prior stressful experiences. Resources include personal characteristics (e.g., being "introverted" or "resilient"), financial ("financially secure") and social resources ("loving spouse"). Five reported experiences that made COVID-19 more difficult ("PTSD/anxiety prior to COVID-19 makes this even worse"). Although 1/3 of the sample could not draw upon a prior experience in coping with this novel stressor, many older participants could utilize their lived experience when coping with problems during the COVID-19 pandemic.

CHANGES IN LIFE SATISFACTION DURING THE FIRST YEAR OF THE COVID-19 PANDEMIC: A LONGITUDINAL STUDY OF JAPANESE ADULTS

Takeshi Nakagawa, Taiji Noguchi, Ayane Komatsu, Sayaka Okahashi, and Tami Saito, *National Center for Geriatrics and Gerontology, Obu, Aichi, Japan*

The outbreak of the novel coronavirus (COVID-19) has exerted a major impact on daily life. Despite older adults being at a higher risk of severe illness from COVID-19, research has indicated that older adults experienced the same or even higher levels of well-being during the early phase of the pandemic than younger adults. To investigate adverse long-term effects, we examined how individuals' well-being changed during the first year of the pandemic. A total of 5,281 Japanese adults aged 15—89 years participated in an online survey in February 2020 (before the first state of emergency) and were followed up in March 2021 (during the second state of emergency; follow-up rate 54.7%). Well-being was assessed as a one-item indicator of life satisfaction, with a range of 0 - 10. Counterintuitively, results of a latent change score model demonstrated that life satisfaction increased over time (unstandardized coefficient of 1.17, SE = 0.16, standardized coefficient of 0.58). Individuals aged 64 years and below, with low levels of education, living alone, and perceiving worse health and economic status showed less increase in life satisfaction. In an additional analysis, those more concerned about the pandemic at follow-up displayed less increase. The findings suggest that most people did not exhibit a decrease in life satisfaction during the first year of the COVID-19 pandemic. However, certain individuals could be vulnerable to the outbreak due to the lack of resources. Researchers should better understand the factors that drive the resilience of older adults in the face of adversity.

COGNITIVE COPING AND PERSPECTIVE-TAKING AMONG OLDER ADULTS DURING THE COVID-19 PANDEMIC: AN ECOLOGICAL INVESTIGATION

Kristin Heideman[1], Eric Griffith[2], Daniel O'Connor[3], Irina Orlovsky[3], Elizabeth Alwan[3], and Bruna Martins-Klein[4], *1. Yale Child Study Center, New Haven, Connecticut, United States, 2. Duke University, Durham, North Carolina, United States, 3. University of Massachusetts Amherst, Amherst, Massachusetts, United States, 4. University of Southern California, Los Angeles, California, United States*

In response to the COVID-19 pandemic, older adults report engaging in coping to manage sources of pandemic stress (e.g., loneliness, reduced healthcare access, ageism). Variability in cognitive coping strategies, however, has not been explored through an ecological model lens. In this study, we interviewed older adults online in the northeastern US (N=33, age 63-92) regarding stress and coping strategies during the pandemic, using the taxonomy of cognitive strategies from the Cognitive Emotion Regulation Questionnaire. Consistent with Bronfenbrenner's ecological model, stress and cognitive coping were qualitatively coded using NVivo in reference to individual, immediate environment (microsystem), connections between environments (mesosystem), and societal (macrosystem) factors. Microsystem-level stressors were prevalent and endorsed in all interviews, but stress was reported at multiple ecological levels. Common microsystem stressors included changes to work/personal life, travel restrictions, and loss of face-to-face socialization. Many participants reported engaging in adaptive cognitive coping (87%), with perspective-taking being one of the most common strategies (78%). Perspective-taking was endorsed across all levels of the ecological model (e.g., comparing the pandemic to other personal experiences, considering family-level resilience, and reflecting on impact to community). The multi-level structure of pandemic stress and coping highlights that older adults subjectively experience stress simultaneously at multiple ecological levels. In turn, they confront stressors using individualized patterns of cognitive coping that extend beyond intrapersonal experience/insight to help fully contextualize the COVID-19 experience. Future studies should explore the use of perspective-taking at intra- and interpersonal levels as integrated coping approaches for managing naturalistic stressors in daily life.

FUTURE TIME PERSPECTIVE MODULATES AFFECTIVE REACTIVITY TO SOCIAL PROBLEMS DURING THE PANDEMIC

Elizabeth Zambrano Garza[1], Yoonseok Choi[1], Theresa Pauly[2], Denis Gerstorf[3], and Christiane Hoppmann[1], *1. University of British Columbia, Vancouver, British Columbia, Canada, 2. University of Zurich, Zurich, Zurich, Switzerland, 3. Humboldt Universität zu Berlin, Berlin, Berlin, Germany*

Socioemotional Selectivity Theory posits that individuals with a limited future time perspective (FTP), prioritize emotionally meaningful, positive social interactions. Due to the high value placed on positive social interactions, individuals with a limited FTP might be particularly vulnerable to experiencing elevated negative affect when problems that involve other people do occur as compared to an experience of non-social problems. This project examined the role of FTP in modulating social problem–negative affect links during the pandemic, a time when people were particularly aware of their mortality, and thus their remaining time in life. This study used data from 150 Canadian adults (Mage =43 years, SD= 19, range 18-83, 78% women) who participated in two measurement bursts (one in 2020 and one in 2021). Participants provided FTP information at baseline and then repeatedly reported their negative affect and everyday problem characteristics in 10 consecutive daily diaries across both bursts. Results from multi-level models reveal a differentiated picture. The within-person association between social problem occurrence and elevated negative affect was significant among individuals with a more limited FTP. In contrast, at the between-person level, experiencing more social problems was associated with higher overall negative affect among those with a more extended FTP. To better understand these differential associations, follow-up analyses will explore if type of person involved in the problem and how the problem was handled matter for how they respond to social problems. Findings will be discussed in the context of the Strength and Vulnerability Integration model.

LONG-TERM POSITIVE AND NEGATIVE CONSEQUENCES OF THE COVID-19 PANDEMIC AMONG OLDER ADULTS

Carolyn Aldwin[1], Soyoung Choun[1], Maria Kurth[1], Hye Soo Lee[1], Dylan Lee[2], and Heidi Igarashi[1], *1. Oregon*

State University, Corvallis, Oregon, United States, 2. Touro University Nevada, Henderson, Nevada, United States

Despite their greater physiological vulnerability, community-residing older adults have shown surprising psychological resilience, at least at the beginning of the COVID-19 pandemic. However, a handful of reports suggest that older adults' well-being has decreased after a few months, although others have suggested a recovery after a year (Schlomann et al., 2021). The purpose of this study was to examine change in change from baseline (April-May, 2020) to a 13- month follow-up (June, 2021). We analyzed data from 162 older adults with complete data at both time points. Mean age at baseline was 72, SD = 7.6, range = 51-96; 71% were female, 13% were minorities; 74% were married, 71% retired, and most (85%) had at least a BA. Linear modelling showed that there were only marginal increases in the number of problems across time (B = .25, p = .08), but their severity did not increase. There were no significant changes in depression, anxiety, loneliness or physical symptoms over this time period. The modest increase in problems may have been offset by an end to being in lockdown and an increase in social contacts which doubled over this time period, B = 1.65, p <.001). More troubling was that self-reported resilience decreased, B = -.92, p < .01), as did the ability to perceive positives in this situation, B = -2.46, p < .01), and self-reported cognitive problems increased, B=.67, p < .01). Thus, the results showed decidedly mixed effects, suggesting individual differences in long-term adaptation to COVID.

SOCIAL CONNECTION IN OLDER ARKANSANS DURING COVID-19: CHANGES AND SATISFACTION

Robin McAtee[1], Jennifer Peszka[2], Anne Goldberg[2], Laura Spradley[1], Noura Musallam[2], Lauren Allen[2], Sophie Vogle[2], and Luke Simpson[2], *1. University of Arkansas for Medical Sciences, Little Rock, Arkansas, United States, 2. Hendrix College, Conway, Arkansas, United States*

Social support is important to the health and well-being of older adults. Changes in social support (both frequency and satisfaction with) and barriers to social support during the pandemic remain unknown. During Spring 2021 an automated phone survey of adults 65 and older in Arkansas was completed. Calls were placed to 27,296 households where 8,745 individuals answered, and 867 (N=723 White, non-Hispanic) older Arkansans completed the 18 question self-report survey. Results indicated that: 41% had curtailed their in-person interactions significantly; 61% continued to engage in in-person social interactions outside of their home once a week or more; and social group activities decreased from 52% to 41%. Additionally, it was reported that 88% used technology for social interactions once a week or more and 60% reported technology interactions made them feel socially connected. Despite this, only 67% reported being satisfied with their social connection during the pandemic compared to 93% prior to the pandemic. While many participants continued in-person social interactions, social activity and satisfaction decreased during the pandemic. Social technology alternatives were used by many and for some, social connection was reported to be satisfactory. The value of what was learned from this survey has application outside pandemic times. Understanding and acknowledging that social isolation exists for older adults in normal times and improving technological access to social activities has great value. This knowledge can be used to substantiate the expansion and improvement of older adult friendly virtual platforms therefore contributing to reducing social isolation.

HOW CAREGIVERS AND OLDER US VETERANS MANAGED SOCIAL ISOLATION DURING THE COVID-19 PANDEMIC

Leah Haverhals[1], Roman Ayele[2], and Hillary Lum[3], *1. VA Eastern Colorado Health Care System, Rocky Mountain Regional VA Medical Center, Denver, Colorado, United States, 2. VA Eastern Colorado Health Care System, Aurora, Colorado, United States, 3. University of Colorado Anschutz Medical Campus, Aurora, Colorado, United States*

To protect themselves from contracting the SARS-CoV-2 virus, many older adults managing multiple medical conditions experienced increased social isolation. The objective of our qualitative research study was to describe how older Veterans receiving care from the United States (US) Department of Veterans Affairs (VA) healthcare system, and their caregivers, managed increased social isolation during the pandemic. We recruited Veterans and their caregivers residing in rural and urban areas who received care from either a tele-palliative care or a tele-geriatrics clinic connected to one VA Medical Center, inviting them to participate in phone interviews. From May-September 2021, we interviewed N=23 participants (n=9 Veterans and n=14) caregivers. We applied a deductive and inductive approach to thematic analysis to analyze interview data. Findings revealed that while caregivers experienced increased anxiety, which they attributed to pandemic-related changes, they also expressed solidarity in that others were experiencing similar stressors. Many caregivers and Veterans shared experiences of increased loneliness, which some found difficult to manage as communication with their social networks was sparse. At the same time, the pandemic made them value relationships with others more than before. Some Veterans noted they kept busy with hobbies and did not feel much loneliness despite increased isolation. Caregivers caring for Veterans with dementia stated they experienced confusion about their narrower social networks because they could not remember reasons why they were not regularly spending time with them. Findings demonstrate the need to identify strategies and policies to better support caregivers and older Veterans during times of crisis.

FACTORS ASSOCIATED WITH NURSING HOME DIRECT CARE PROFESSIONALS' TURNOVER INTENT DURING COVID-19

Verena Cimarolli[1], Natasha Bryant[1], Francesca Falzarano[2], and Robyn Stone[1], *1. LeadingAge, Washington, District of Columbia, United States, 2. Weill Cornell Medicine, Douglaston, New York, United States*

The negative effects of the COVID-19 pandemic on the well-being of direct care professionals (DCPs; nursing assistants and aides) in nursing homes (NHs) has led to high rates of DCPs' turnover and staff shortages - both issues that were already prevalent before the pandemic. More optimal staffing levels and less turnover are essential for optimal NH quality of care, but little is known about factors associated with turnover in DCPs in NHs during the pandemic. Hence, the purpose of this study was to examine the mediating roles of 1) quality of employer communication related to COVID-19; 2) DCPs' perceived preparedness to care for residents with COVID-19; and 3) DCPs' job satisfaction in the relationship between overall COVID-19-related work stress and intent to remain in one's job (an indicator of turnover). Path analyses (N=809) demonstrate a significant, indirect effect between COVID-19-related stress and intent to remain in one's position through the variables of communication, preparedness, and job satisfaction. Higher levels of COVID-19 related stress were associated with poorer communication quality, lower levels of preparedness, and lower job satisfaction, which was subsequently associated with a reduced likelihood of intent to remain in one's job. However, direct effects show that better communication quality was associated with better preparedness correlating with higher job satisfaction which increased the likelihood of intent to remain in one's job. Findings underscore the importance of employer supports in DCPs' job satisfaction and turnover in NHs and, thus have implications for how to improve quality of care in NHs.

SESSION 6220 (POSTER)

AGHE POSTER SESSION II

Explore how education, evaluation, and related efforts in gerontology can inform community connections and practices.

COLLABORATIVE PARTNERSHIP BETWEEN STATE AGENCIES AND ACADEMIA ADDRESSING LONG-TERM CARE WORKFORCE NEEDS

Katie Ehlman, Karla Diekemper, and Kevin Valadares,
University of Southern Indiana, Evansville, Indiana, United States

The rural areas of southwestern Indiana are challenged with insufficient healthcare workers in the long-term care industry. The University of Southern Indiana (USI) Geriatric Workforce Enhancement Program (GWEP) is collaborating with state agencies to address shortages in licensed administrators, activity professionals and social service designees. These roles, vital in the nursing facility, hold educational requirements through the Indiana State Department of Health (ISDH) and the Indiana Professional Licensing Agency (IPLA). USI gerontology faculty addressed workforce challenges in five phases: 1) Evaluation of state educational requirement and comparison to current USI gerontology courses; 2) Development of new coursework to support state requirements; 3) Expansion of preceptor pool; 4) Proposal to state agencies; 5) USI curriculum modifications. Faculty evaluated the educational and training requirements for these roles and compared the requirements with current courses. Preceptors were needed for students' field experiences; a preceptor pool was developed through funded training. The requirements and course alignment were included in the program proposal to the state agencies. Upon ISDH, IPLA and University New Program Development Committee approval, additional instructors were recruited. Results of this initiative include a: 1) Fully approved and launched Administrator-in-Training (AIT) residency embedded in curriculum at undergraduate and graduate level; 2) Fully approved Activity Professional Certificate Program; 3) Pool of 10 certified preceptors; and 4) Onset of the social service designee certificate program. This collaborative partnership developed between USI, ISDH and IPLA ensure state agency requirements are met academically for students entering the long-term care workforce.

DEMENTIA CARE COORDINATION FOR CAREGIVERS OF VETERANS DIAGNOSED WITH DEMENTIA: AN INNOVATIVE VA INITIATIVE

Judith Howe[1], Eve Gottesman[2], and Nicholas Koufacos[2],
1. Ichan School of Medicine at Mount Sinai, Bronx, New York, United States, 2. James J. Peters VA Medical Center, Bronx, New York, United States

There are expected to be 335,425 Veterans with dementia by 2033. Dementia has a significant impact on families, especially caregivers. Caregivers often report high levels of stress and burden, which can cause them to develop physical and mental illness, impacting the care they provide to family members with dementia. In 2021, under a Veterans Health Administration (VHA) directive, the Bronx VA Geriatric Research, Education and Clinical Center developed a Dementia Care Coordination program, funded by the VHA Office of Rural Health sponsored Geriatric Scholars Program. Led by a Dementia Care Coordinator (DCC), who is also a clinical social worker, the program identified caregivers of Veterans with dementia who reported experiencing stress and burnout while caring for Veterans with dementia. The DCC provided support via telephone and VVC and also shared resources focused on stress reduction, relaxation techniques, and coping with grief. During 2021, 23 caregivers of diverse racial and ethnic backgrounds were enrolled in the program and 17 were found to have significant caregiver burden. Over 100 support calls were made on the topics of stress reduction, problem solving and community resources. Common problems reported by caregivers included sundowning, sleep problems, grief, and increased social isolation due to the COVID-19 pandemic. Caregivers showed a willingness to participate in the program, indicating that the information, resources and support provided by the DCC helped reduce their stress levels and allowed them to provide ongoing care. Recent program developments, findings from an IRB approved survey of participants, and expansion plans will be reported.

TRAINING PHYSICIAN-SCIENTISTS IN SOCIAL AND BEHAVIORAL SCIENCE: INDIANA ADRD MEDICAL SCIENTIST TRAINING PROGRAM

Nicole Fowler[1], Brittney-Shea Herbert[1],
Christopher Callahan[2], Siyun Peng[3], Brea Perry[3],
Karmen Yoder[1], Gary Landreth[1], and William Truitt[1],
1. Indiana University School of Medicine, Indianapolis, Indiana, United States, 2. Indiana University School of Medicine, IU Center for Aging Research, Indianapolis, Indiana, United States, 3. Indiana University, Bloomington, Indiana, United States

There is a critical need to grow and strengthen the pipeline of physician scientists who have expertise in sociomedical and behavioral research and are dedicated to addressing the nation's challenges posed by Alzheimer's disease and related dementias (ADRD). In 2021 The Indiana ADRD Medical Scientist Training Program (IADRD MSTP) was designed to meet this need and is built on the infrastructure of a robust portfolio of ADRD research, graduate training programs in medical neurosciences and sociology, and our existing MD-PhD program at Indiana University School of Medicine. The Aims of the IADRD MSTP are: 1) To recruit and train a competitive pool of diverse students who have an interest and commitment to social and behavioral research and patient care focused on ADRD; 2) To engage MD-PhD students early in mentored sociomedical and behavioral research that integrates IUs systems-based medical training curriculum with our cutting edge ADRD research that reinforces commitment and minimizes attrition of physician-scientists ADRD; and 3) To graduate students with dual MD-PhD degrees with strong methodological training in social and behavioral science and experts in ADRD who will be successful independent investigators at the best academic medical centers nationwide. The program includes rigorous didactic training in social, behavioral, and clinical research methods, with flexibility to allow students to focus their effort on one methodological area of interest; early initiation of ADRD research experiences with multidisciplinary teams of mentors and advisors; and the provision of educational experiences that enhance students' abilities to become independent researchers.

ASSOCIATION BETWEEN EDUCATION LEVEL AND DEPRESSIVE SYMPTOMS AMONG COMMUNITY-DWELLING OLDER ADULTS IN ICELAND

Milan Chang Gudjonsson[1], Chiharu Nishizuka[2], and Sigurveig Sigurdardottir[2], *1. Norwegian Institute of Public Health, Oslo, Norway, 2. University of Iceland, Reykjavik, Iceland*

Objectives. Previous research studies have suggested that a higher education level has a positive impact on one's health throughout life. The aim of this study was to examine the association between education level and depressive symptoms among community-dwelling older adults aged 65 years and older in Iceland. Method. This is a cross-sectional study using data from the Age, Gene/Environment Susceptibility–Reykjavik Study (AGES–RS) cohort (n = 3,989, mean age = 76.2, 56.3% women). Education was classified into four levels: primary (n = 895), secondary (n = 1,980), college (n = 630), and university (n = 484). For the analysis, education was categorized into two groups: primary education versus higher than primary education (secondary, college, and university). Depressive symptoms were assessed by using the 15-item Geriatric Depression Scale. High depressive symptoms (HDEPS) were defined if the GDS score was 6 or higher. Results. Education was highly significantly associated with the 15-GDS score ($p < .001$). Compared to people with primary education, those with higher than primary education level were significantly less likely to have HDEPS after adjusting for confounders including age, gender, body mass index, physical activity, coronary diseases, and smoking status. Discussion. Older adults with higher than primary education were less likely to have HDEPS compared to those with primary education in the current cross-sectional analysis. The findings indicate that level of education is highly associated with depressive symptoms of community-dwelling older adults in Iceland.

UTILIZING COMMUNITY ANALYSIS TO INCREASE AWARENESS OF HEALTH DISPARITIES IN OLDER OKLAHOMANS

Donna Sylvester, *Langston University, Drumright, Oklahoma, United States*

Where we live affects us. The state of Oklahoma consistently ranks in the bottom ten percent for health outcomes, health policies, and health behaviors of older adults. Physical therapy students in Oklahoma must recognize the impact that social determinants of health have on older adults in order to fully meet the needs of their future patients. Prior to final clinical experiences, third-year Doctor of Physical Therapy students explore these concepts through individual community analysis projects in urban and rural communities across the state. The students visit their chosen community to assess access to transportation services, food, housing, and healthcare-specific to older adults. Additionally, students explore opportunities for exercise classes targeted toward older adults and the walkability of the community. Students come away with a better understanding of the wide array of social determinants of health experienced by older adults in Oklahoma and learn of opportunities to advocate for future patients in their communities.

AGING AGENCIES' AND PROVIDERS' REASONS FOR HOSTING OR NOT HOSTING GERONTOLOGY INTERNS

Rona Karasik[1], Phyllis Greenberg[2], Maria Kroeber[1], Jessica VanderWerf[1], and Claudia Burgos Zuniga[1], *1. St. Cloud State University, St. Cloud, Minnesota, United States, 2. St. Cloud State University, St Cloud, Minnesota, United States*

Hands-on experience is essential to gerontological education and associated with numerous student benefits. Much less is known about the community agency perspective, including why they do/don't host gerontology interns. In this national study (n=281), non-profit, for-profit, and government aging-service providers (e.g., Social Services, Health Care, Housing) were surveyed regarding their perceptions of internship benefits, challenges, and areas to improve. Unique to this study is the inclusion of both hosting (n=129) and non-hosting (n=142) agencies. Hosts' reasons for accepting interns included: share experience/knowledge (n=81, 87%); future university relationships (n=71, 76%); intergenerational interaction for students (n=69, 74%) and clients (n=60, 65%); attract future employees (n=68, 73%); and fills unmet need at agency (n=47, 50%). Non-host reasons for abstaining included: lack of applicants (n=58, 41%); never considered it (n=40, 28%); insufficient staffing (n= 37, 26%); unsure where to start (n=34, 24%) or find/attract interns (n=34, 24%), and too time-consuming (n=25,18%). Additional reasons for nonparticipation included: lack of space; insufficient intern-suitable work; risk/liability; and agency policy. Both hosting and non-hosting agencies anticipated/realized student-related challenges (e.g., limited motivation, inconsistent availability, inadequate preparation) and agency-based factors (e.g., insufficient time, staffing). Given the ongoing need for suitable gerontology internship sites and the finding that almost half of the non-hosting agencies indicated possible future interest in accepting gerontology interns (n=80, 49%), attention to agency recommendations (e.g., increased faculty communication/feedback, stronger student commitment/preparation, recognition of agency contributions) is warranted. Strategies for addressing identified challenges and implementing requested changes to enhance the community agency experience with gerontology interns are discussed.

CRAFTING AN UNDERGRADUATE CONCENTRATION IN AGING ACROSS THE UNIVERSITY AND ASSESSING COMPETENCIES

Kristine Mulhorn, *Drexel University, Wallingford, Pennsylvania, United States*

In the last few years, our Health Administration Department has grown its undergraduate offerings in aging and now is promoting those courses as a concentration available for any major. A recent collaborative effort between our college and the honors college, our university has created a university-wide set of courses across all majors related to topics in aging. In our university, students can pursue a concentration with as few as three courses that are relevant to their majors. Usually, the courses in a concentration are taught by those in the major. However, the global issue of aging can be taught as a specialty area for many majors. To ensure students meet the learning objectives, the following assessment plan was developed for three key courses offered by the Health Administration Department—Healthy Aging, Aging and the Law and either Aging in a Global Context or Aging Services Management. First, a curricular map of the areas of competency within our program are outlined and then the content and areas of assessment are considered based on whether the competencies are “Introduced”, “Reinforced,” and “Mastered.” Next, the key assignments in each course within the concentration were aligned with the Program Objectives for the Health Administration bachelor’s program to assess student achievement of key competencies. In the process of offering the concentration in Aging across multiple majors, it is important for various departments to understand how courses in aging add valuable competencies regardless of their major.

FLINT INTERGENERATIONAL LIVING EXPERIENCE

Jennifer Blackwood, and Elizabeth Yost, *University of Michigan-Flint, Flint, Michigan, United States*

Previous studies indicate that students who have a formative experience with an older adult, in a personal or professional setting, are more likely to choose to work in geriatrics. With a growing population of older adults, the need for empathetic health professionals who desire to work in geriatrics is needed. In Fall, 2021 four graduate students (2 physical therapy, 2 occupational therapy) moved into a senior housing community in Flint, Michigan. From that moment, the Flint Intergenerational Living Experience (FILE) began. The purpose of FILE is to mold these students into empathetic future health professionals who choose to work in geriatrics within their careers. These four twenty-something year-olds live, learn, study, eat, and share life with their senior neighbors with the hope of gaining a better understanding of aging issues of older adults who chose to remain in Flint. In exchange for completing service hours, the FILE students live in an apartment complex rent-free. This presentation will describe the activities performed, outcomes achieved, and perceptions of the FILE program after one-year of being in the program. Based on data gathered within the first year of the program, activities that impacted the personal growth of the students to understand the impact of aging in an urban setting will be described. The influence of loss (e.g. death, physical abilities) and the framework of rehabilitation needs of the urban dwelling older adults will be discussed. Lastly, strengths and weaknesses of this lived experience will be presented.

LONGITUDINAL ASSOCIATION BETWEEN HOSPITALIZATION AND TRANSFER TO RESIDENTIAL CARE FACILITIES AMONG OLDER ADULTS

Reza Amini[1], and Amat Sidhu[2], *1. University of Michigan-Flint, Ann Arbor, Michigan, United States, 2. University of Michigan-Flint, Flint, Michigan, United States*

Dementia increases the risk of post-hospitalization transfer to residential care facilities (RCF), increasing mortality risk. The risk of falling is significantly higher among people with dementia, leading to more hospital admissions (HA). This study examines the association between HA and transferring to RCF controlling for dementia and falling. This secondary data analysis used nine years of data from the National Health and Aging Trends Study (2011-2019) with 2,548 participants (each wave). Transfer to RCF was measured based on the residency status, HA and history of falling by survey questions, and dementia (probable, possible, no dementia) by combining Clock Drawing Test, word recall test, and previous dementia diagnosis. Falling increased the risk of transition to RCF by 31%; however, this association was not statistically significant. Dementia was a significant predictor for transition to RCF (Odds Ratio (OR)=3.889). Transferring to RCF was significantly associated with HA (OR=1.835); after including falling, OR increased to 2.067, showing falling moderates this association. Including dementia into the model dropped HA’s OR to 1.620. The interaction between falling and dementia showed that frequent HA could increase the risk of transition to RCF by 61%. Probable dementia plus a history of falling can increase the risk of transition to RCF by 22 times and 14 times for those cases of probable dementia without a history of falling. These results may reflect the necessity of screening for the risk of falling and dementia among community-dwelling older adults to prevent falling, hence, frequent HA and ultimately transition to RCF.

ADDRESSING COVID-19 HEALTH DISPARITIES THROUGH VIRTUAL EDUCATION AND COLLABORATION

Kelly Boyd, Jacob Walker, Jenil Benett, Jeffrey Graupner, and Katherine Thompson, *University of Chicago, Chicago, Illinois, United States*

The South Side of Chicago, made up of predominantly Black and Latinx neighborhoods, has higher rates of COVID-19 infection and death rates and lower COVID-19 vaccination rates than other areas of Chicago. People aged 65 and older comprise nearly 15% of the region's population. The SHARE Network at the University of Chicago has a long history of providing healthy aging education to organizations serving older adults on Chicago's South Side. Using this pre-existing curricular structure, investigators created a monthly virtual workshop for community members to address COVID-19 related health disparities for older adults. Topics address aging concerns (i.e. dementia, mobility) and pandemic concerns (i.e. health disparities, vaccine hesitancy). At the end of the sessions, participants can ask questions to experts and share resources. Attendance has ranged from 15-20 participants, predominantly formal and informal caregivers. In post-attendance surveys, 80% of respondents identified as Black or African-American. Of the 20 respondents, 95% felt more knowledgeable about the topics discussed and all felt more knowledgeable about local health resources. Three-quarters felt more confident in the caregiving role, and 95% planned to make healthy lifestyle changes to benefit themselves or a loved one (i.e. more exercise, seeking respite care). These results demonstrate the positive impact of a timely community-informed virtual workshop. Providing virtual education on COVID-19 and healthy aging directly to older adult-focused community organizations and their clients is an early step health systems can take to address health disparities.

DEVELOPMENT OF PODCAST IN SERVICE OF THE NEXT GENERATION OF GEROPSYCHOLOGISTS

Branden Schaff[1], Rachel Weiskittle[1], and Lindsey Jacobs Dodson[2], *1. University of Colorado Colorado Springs, Colorado Springs, Colorado, United States, 2. University of Alabama Tuscaloosa, Tuscaloosa, Alabama, United States*

The current geropsychology workforce falls woefully short of meeting the mental healthcare needs of older adults, with only 3% of licensed psychologists identifying Geropsychology as their primary or secondary specialty. Formal training in geriatric mental health is extremely limited. Out of the over 400 APA-accredited doctorate-level psychology programs in the U.S., only five provide specialty training in Geropsychology. Consequently, the vast majority of psychologists who treat older adults have never received formal education or training in geriatrics. It is imperative that evidence-based geropsychology education is disseminated to a wide audience of mental health providers across all levels of training and career development. The Geropsychology Podcast was developed to address this gap as a novel pedagogical resource commensurate with educational competencies established by the 'Pikes Peak Model for Professional Geropsychology.' Topics include geriatric assessment methods, intervention, consultation, and foundational knowledge on adult development and aging. The feasibility and acceptability of the podcast was evaluated with a two-year pilot study from 2019 to 2021. During this time, eleven episodes were published across multiple podcast platforms. Preliminary results found the episodes were downloaded by over 1,500 unique listeners across 34 countries. These results indicate that The Geropsychology Podcast is scalable, acceptable, and potentially fulfilling an educational need that people are actively seeking. This poster describes the podcast's model of curriculum development and ongoing quality metrics and impact analysis. Future work holds that this podcast will continue to be a vital resource for the field.

DOES THE NUMBER OF DISEASES OR DISEASE SEVERITY AFFECT THE AGING ATTITUDES IN HEALTH RETIREMENT STUDY?

Da Jung Chang, *Miami University, Oxford, Ohio, United States*

The number of older adults is increasing worldwide, coupled with an increase in chronic disease. Evidence has shown a relationship between health conditions and changes in attitudes toward own aging (ATOA) and thus may contribute to a negative ATOA among older adults with more health conditions. Additionally, studies also show that ATOA can affect the health of older people and become a vicious circle. To promote a healthier life for older adults, it is important to assist them to maintain a more positive ATOA. Therefore, the purpose of this study wants to determine the relationship between the diseases number and ATOA for older adults ($N = 6303$). Although the relationship between the number of the diseases has been discussed in previous studies, this study will use 2012 and 2016 waves Health and Retirement Study data to update the relationship by using generalized estimating equation. To understand whether it is the disease severity that affects ATOA, this study uses Charlson Comorbidities Index to measure the burden of diseases and use structural equation models to understand the relationship between variables and do the model pathway analysis. The initial results show that an individual with a greater number of diseases ($p < .01$, $r=-.039$), and a higher score of CCI have more negative ATOA ($p < .01$, $r=-.04$). These findings suggest both the number and severity of diseases contribute to ATOA in older adults. Furthermore, the CCI provides a method to identify the disease severity and can be used in the national databases.

OPTIMIZING OLDER ADULT BLOOD PRESSURE SCREENING IN A COMMUNITY SETTING BY INTERPROFESSIONAL STUDENTS

Erin Miller[1], Rima Charara[2], Ali Turfah[3], and Jennifer Mendez[4], *1. Wayne State University School of Medicine, Detroit, Michigan, United States, 2. Wayne State University Eugene Applebaum College of Pharmacy and Health Sciences, Dearborn, Michigan, United States, 3. University of Michigan School of Public Health, Ann Arbor, Michigan, United States, 4. Wayne State University, Toronto, Ontario, Canada*

A novel program was implemented in an effort to optimize the blood pressure taking skills of medical and pharmacy students, in collaboration with older individuals in Detroit. Under the supervision of Interprofessional faculty, pharmacy and medical students provided blood pressure screenings at the popular Riverwalkers program, a community exercise program designed for older Detroiters. Prior to volunteering at the program, students were required to complete the AMA blood pressure modules to develop proficiency in blood measurement best practices. Over the course of two months, 72 students provided blood pressure screenings for 79 older individuals during 266 distinct encounters. We believe this program can serve as a model for other professional schools, as it efficiently accomplishes several distinct

PAEAN: PAIN IN AGING, EDUCATIONAL ASSESSMENT OF NEED: OPIOID DIAGNOSES AND IMPACTS ON PAIN DIAGNOSIS IN OLDER ADULTS

Beth Hogans[1], Bernadette Siaton[2], Julie Witter[2], Leslie Katzel[3], Lana Brown[4], Laura Frey-Law[5], and John Sorkin[6], *1. VAMHCS/Johns Hopkins School of Medicine, Baltimore, Maryland, United States, 2. UMB, Baltimore, Maryland, United States, 3. VAMHCS/UMB, Baltimore, Maryland, United States, 4. Central Arkansas Veterans Healthcare System, North Little Rock, Arkansas, United States, 5. Carver School of Medicine, University of Iowa, Iowa City, Iowa, United States, 6. UMB/VAMHCS, Baltimore, Maryland, United States*

Pain is prevalent in older adults of both genders but more so in women. The extent to which this is impacted by opioids is not well established. We sought to evaluate common pain diagnoses among older adults noting whether the pattern of female preponderance holds across all conditions and whether opioids might impact this. Utilizing the 2017 Medicare 5% standard analytical claim sample we examined the rate of pain condition diagnoses in older females and males with or without opioid-related diagnoses. We have previously reported that low back pain and opioid diagnosis coding rates interact in older adults, we here expand this finding. We established a condition definition file for opioid use, not including overdose-related codes. We segmented the older adult Medicare part B claims file into those with and those without opioid diagnoses, separated by CMS-coded gender. Diagnostic rates of the 100 most common pain diagnoses in each of the subpopulations showed low back pain was the most prevalent pain diagnosis regardless of gender or opioid diagnosis status. Chest pain unspecified, neck pain, and abdominal pain unspecified, were also highly prevalent. All pain conditions were diagnosed at higher rates in the opioid subpopulation. Few diagnoses were more common in males, these included sex-specific conditions, diabetic neuropathy, and vascular claudication. Although pain conditions are common in older adults, diagnosis rates are elevated in those with opioid diagnoses. This impacts the educational needs of geriatricians, and other healthcare providers, and may indicate needs for more research in pain and aging.

IMPLEMENTING A HEALTHY BRAIN INITIATIVE IN THE NATION'S LARGEST COUNTY JURISDICTION

Tony Kuo[1], Noel Barragan[2], Mariana Reyes[2], and Ariane Thomas[2], *1. University of California, Los Angeles, Los Angeles, California, United States, 2. Los Angeles County Department of Public Health, Los Angeles, California, United States*

In 2019, there were an estimated 166,857 Los Angeles County (LAC) residents living with Alzheimer's disease. By 2040, this number is expected to rise by 150% to 405,382, with 152,980 and 35,341 of them, respectively, being Black and Latinx. Locally, there is special interest in reducing dementia risk among the two communities, as modifiable risk factors such as untreated hypertension, diabetes, and smoking are disproportionately higher in these groups (e.g., hypertension – Black, 35.9% vs. White, 27.3%; diabetes – Black and Latinx, 14.4% and 13.6%, respectively, vs. White, 8.8%). In LAC, considerable investments have been made to help create and implement the local arm of the California Healthy Brain Initiative (Healthy Brain Initiative: Los Angeles or HBI-LA). Launched in 2019, HBI-LA utilized a multi-level, multi-sector approach to expand the breadth and quality of tools available to the Black and Latinx communities and key stakeholders who work with these communities. The initiative set out to complete the following State-approved objectives: (i) educate the public and health professionals about dementia care and prevention; (ii) develop policies that improve access to health, aging, and prevention services for those with cognitive decline; and (iii) disseminate reliable, culturally sensitive information and tools to promote best practices on brain health. The present investigation examines the stepwise process that LAC took to achieve these objectives, including the development of two culturally tailored educational workshops (one for community members, one for healthcare and social services professionals) and how a U.S. Congressperson and County Supervisor supported dissemination efforts.

ADAPTING PRIMARY CARE WORKFLOWS TO PROMOTE ADVANCE CARE PLANNING WITH AN EMPHASIS ON A DEDICATED ACP FACILITATOR

Kevin Valadares[1], Suzanne Leahy[1], Katie Ehlman[1], and Robin Arnold[2], *1. University of Southern Indiana, Evansville, Indiana, United States, 2. Deaconess Clinic, Evansville, Indiana, United States*

The COVID-19 pandemic has sharpened attention regarding the need to proactively plan for a future medical crisis. Advance Care Planning (ACP) has emerged in the last 30 years as a potential way to improve individuals' end-of-life care by ensuring that patients explore and communicate personal values, goals, and preferences regarding future medical care to surrogate decision makers and medical providers. Elevating ACP as a core function of direct patient care, the University of Southern Indiana's (USI) Geriatric Workforce Enhancement Program (GWEP) embedded a multi-modal ACP initiative in a primary care clinic, anchored by the Medicare Annual Wellness Visit (AWV). Within this initiative, the role of a dedicated ACP Facilitator embedded in the practice is highlighted to promote and bill (Medicare CPT codes 99494, 99498) for ACP conversations. The addition of an ACP Facilitator (who is a licensed clinical social worker) as part of the primary care team complements the efforts of the providers to focus on What Matters most to patients. This is particularly important to patients with serious illness. This presentation will summarize the re-alignment efforts of the primary care clinic to prioritize ACP conversations for older adults, amounting to 10,000 visits per year.

ADVANCING LATE-LIFE TRAUMA-INFORMED CARE EDUCATION: DEVELOPMENT AND EVALUATION OF AN EDUCATIONAL PODCAST

Rachel Weiskittle[1], Lola Baird[2], Hannah Bashian[3], Anica Pless Kaiser[4], Kelly O'Malley[5], Anna Etchin[4], and Jennifer Moye[5], *1. University of Colorado Colorado Springs, Colorado Springs, Colorado, United States, 2.*

Boston VA Medical Center, Jamaica Plain, Massachusetts, United States, 3. VA Boston HCS, Boston, Massachusetts, United States, 4. VA Boston Medical Center, Jamaica Plain, Massachusetts, United States, 5. VA Boston Healthcare System, Boston, Massachusetts, United States

Posttraumatic stress disorder (PTSD) may emerge or reemerge in the context of life-threatening illness, retirement, and life review, leading to complications in disease management and end-of-life care. Symptoms of PTSD in later life can be misattributed or overlooked by healthcare professionals, caregivers, and the older adults experiencing PTSD themselves. The "Talking Later" podcast was developed as an accessible educational product to improve recognition and trauma-informed responses to late-life PTSD. Each of the ten episodes had distinct goals and content objectives, which were identified through problem identification and needs assessment by a multidisciplinary team of geriatric clinicians. In the first three months of its publication in November 2021, the podcast has been downloaded by 1,473 unique listeners across 19 countries. The podcast was evaluated via feedback survey (N=39). Approximately 97% of respondents reported the episodes as engaging and informational. 87% stated that no more than general knowledge of PTSD was required to enjoy the podcast. Qualitative analysis of open-ended feedback items found that participants were interested in learning about additional comorbidities and diversity issues related to late-life trauma reengagement. The present poster will additionally describe ongoing efforts to address these and other feedback responses with the ongoing development of a second season of the podcast.

ASSESSING TELEHEALTH USE AMONG OLDER ADULTS WITH LIMITED RESOURCES DURING THE COVID-19 PANDEMIC

Marie Dezine[1], Naushira Pandya[2], Sashah Damier[2], and Sweta Tewary[2], *1. Nova Southeastern University - - Ft Lauderdale, FL, North Miami, Florida, United States, 2. Nova Southeastern University - - Ft Lauderdale, FL, Fort Lauderdale, Florida, United States*

The COVID-19 pandemic created new barriers to accessing primary care services, particularly among older adults who has faced barriers related to access to care, transportation, health literacy, and social isolation. Nova Southeastern University South Florida Geriatric Workforce Enhancement Program (NSU SFGWEP) partnered with primary care clinics and a local community partner to conduct wellness calls to older adult patients identified through clinic EHR. This project aimed to provide educational and telehealth support to vulnerable adults with limited resources in the Tri-County region of Florida. Wellness calls were made to determine educational and technical support needs of the older adults designated as underprivileged. We identified 44 participants to receive telehealth devices. Samsung tablets were mailed with educational resources, developed by NSU SFGWEP related to COVID-19 pandemic. The information included health, vaccine education, and instructions to access telehealth services. They had the tablets for six months. We conducted bi-weekly calls to offer peer training to access the educational materials. The participants were asked a series of questions to assess the effectiveness of the peer training support. Among participants, 36% (n=16) found the education materials impactful. Most participants, 89% (n=39), used the tablet, and 23% (n=10) reported using it daily. 11% (n=5) used it for telehealth, 7% (n=3) to connect with friends and family, and 7% (n=3) to connect with faith. This pilot project suggests that tablets were beneficial in assisting the participants in accessing education materials and resources encouraging the use of telehealth appointments and eliminating some of the social isolation.

SESSION 6230 (POSTER)

AGING IN PLACE

MOTIVATIONS TO VOLUNTEER: SURVEY OF A SERVICE AGENCY IN RURAL MICHIGAN

Rita Hu[1], Ruth Dunkle[1], and Julie Tarr[2], *1. University of Michigan, Ann Arbor, Michigan, United States, 2. ShareCare of Leelanau, Leland, Michigan, United States*

While volunteers are the foundation of service agencies in rural communities, they are difficult to recruit. This study aims to understand the characteristics of volunteers in a rural community that could aid in recruitment. All volunteers (N=127) for an organization providing services to keep older adults in their homes in rural Michigan were approached to participate in the study. Data were gathered via telephone-interview survey (N=76) and in-person focus groups (N=14) in the summer of 2021 to understand demographic factors as well as benefits and community factors contributing to volunteer participation. Most volunteers were female (61%), married (71%), over age 70 (M=71), and lived with others (72%). In the past year, 49% volunteered 1-5 hours per week and with multiple organizations (70%). They identified the primary benefits from volunteering as getting to know new people (66%). Volunteers agreed that they feel they contribute to the community (97%), have a strong attachment to the community (91%), and have the ability to make a difference in the community (95%). Volunteers were less aware of what could be done to meet the needs in the community (54%) and understand the needs and problems facing the community (59%). Focus group data suggest that volunteers desire information about community needs and aging in place. Due to the lack of centralized locations, social and educational hot spots such as coffee shops could attract new volunteers. Having a sense of community is an important component of volunteering and should be fostered when recruiting new volunteers.

SELF-RATED ORAL HEALTH SATISFACTION AMONG OLDER ADULTS RECEIVING ONE HOME AND COMMUNITY-BASED SERVICE

Steffany Chamut[1], and Shahdokht Boroumand[2], *1. Harvard School od Dental Medicine, Boston, Massachusetts, United States, 2. National Institutes of Health (NIH), Bethesda, Maryland, United States*

Objective: To assess self-rated oral health (OH) satisfaction among recipients of the home and community-based services (HCBS) administered by the Administration on Aging.

Methods: This cross-sectional study is representative of the national population of the 2014 National Survey of Older

Americans Act Participants (NSOAAP), and analyzed baseline OH data from community-dwelling adults (n= 3,995) age 60 and older covering case-management, congregate-meals, home-delivered-meals, homemaker-services, and transportation.

Results: Among the 3,995 participants, 35% received only one HCBS, the majority being age 75-84 (42%), females (67%), Non-Hispanic Whites (72%), and living in urban areas (53%). About 54% reported having a dental visit in the last twelve months, 30% were not satisfied with their OH, and 45% reported having 4-6 medical conditions. Congregate-meals (67%), home-delivered-meals (23%), and transportation (6%) were the most services provided (n=1,130). Being not satisfied with general health (OR=4.44, CI95=2.81-7.00) p<.0001, experiencing difficulties with three or more activities of daily living (ADLs) (OR=2.06, CI95=1.15-3.70) p= 0.0149, and not having a dental visit in the last twelve months (OR=1.66, CI95=1.06-2.59) p= 0.0248 were the strongest indicators negatively associated for not being satisfied with OH among HCBS participants.

Conclusion: Oral diseases and oral microbiota are known to be precursors of dementia, Alzheimer's, multiple systemic diseases (i.e. diabetes), and mortality. Understanding OH issues among HCBS recipients could refine policies that focus on improving functional status with person-centered services, and help identify opportunities to revamp older adults' oral and systemic health, promote healthy aging and longevity allowing them to continue living independently at home.

UPDATING ESTIMATES OF DRIVING LIFE EXPECTANCY

Jonathon Vivoda, *Miami University, Oxford, Ohio, United States*

Information is limited about driving life expectancy, and the amount of time between loss of driving ability and death. The most often cited study (by Foley and colleagues, 2002) analyzed data collected in the mid-1990s and used life expectancy estimates to determine survival probabilities. Although that study was well designed, longitudinal data from the Health and Retirement Study (HRS) are now available to use participants' actual date of death to assess issues related to driving life expectancy. HRS data from 1996-2018 were assessed; only participants who had answered the driving ability question for at least one wave, and had a reported death date were included. The percentages of participants were determined who never reported the ability to drive, always reported the ability to drive, and those who transitioned from driving to non-driving. Time between loss of driving ability and death was calculated among former drivers by subtracting the interview date when respondents reported an inability to drive (after having previously reported being able to drive) from the participants' date of death. Only about 3% reported never driving, with a nearly even split between those who stopped driving (49%) and those who always drove (48%). Women were more likely to report being a never/former driver (65%) compared to men (36%). Among former drivers, the average time between inability to drive and death was 1312 days (3.59 years), and was significantly longer for women (437 days). Among former drivers, the average age for reporting inability to drive was about 83 years old.

PRIORITIZING FUTURE RESEARCH ON NONDRUG DEMENTIA CARE INTERVENTIONS

Eric Jutkowitz[1], Peter Shewmaker[1], and
Fernando Alarid-Escudero[2], *1. Brown University, Providence, Rhode Island, United States, 2. Center for Research and Teaching in Economics (CIDE), Mexico City, Aguascalientes, Mexico*

We previously used an evidence-based mathematical model to evaluate the cost-effectiveness of psychosocial interventions that reduce the risk of a nursing home admission for people with dementia from a healthcare payer perspective. We found the incremental cost-effectiveness of MIND, an in-home intervention for people with mild-moderate dementia, compared to usual care was $271,456 per quality-adjusted life-year (QALY). The incremental cost-effectiveness of NYU Caregiver Intervention (NYUCI), which is for people with moderate dementia, compared to usual care was $3,964/QALY. Here we quantify the uncertainty around our cost-effectiveness estimates. First, we calculated the expected value of partial perfect information (EVPPI), which is the value of eliminating uncertainty around the treatment effect (i.e., risk of entering a nursing home) of MIND and NYUCI, and represents the maximum willingness-to-pay for a study to inform these estimates. Given a willingness-to-pay of $110,000/QALY, population EVPPI for MIND and the NYUCI were $81,000,000 and $395,000,000, respectively. Second, we calculated the expected value of sample information (EVSI), the expected net benefit of sampling (ENBS) and the optimal sample size (OSS). EVSI is the amount of uncertainty reduced from a pragmatic trial evaluating the risk of entering a nursing home for people in the intervention compared to usual care. ENBS is the return of a pragmatic trial with a fixed ($1,050,000) and per person ($2,000) cost to conduct the study. The OSS is the sample size that maximizes ENBS and was 3,571 for MIND and 5,357 for NYUCI. There is value in conducting pragmatic trials on MIND and NYUCI.

RACIAL AND ETHNIC DISPARITIES IN COGNITIVE DIFFICULTY AMONG OLDER ADULTS: EVIDENCE FROM NEW YORK CITY

Ethan Siu Leung Cheung[1], and Jinyu Liu[2], *1. Columbia University, New York, New York, United States, 2. Columbia University, New York City, New York, United States*

This study examined racial and ethnic disparities in cognitive difficulty among older adults in New York City (NYC). Also, we tested whether physical health, family structure, individual socioeconomic status (SES), and neighborhood SES explained the disparities. Based on community districts, individual-level data from the 2019 American Community Survey were merged with neighborhood data from NYC Community District Profile. A sample of 5,622 NYC residents aged 60 or older was included across 55 community districts. The outcome variable, cognitive difficulty, was measured by a binary variable in which respondents' self-reported challenges with cognitive health (1=having challenge, 0=no). Racial and ethnic groups included Whites, Blacks, Latinos/Hispanics, and Asians. We used multilevel logistic regressions for analysis. Results show that Latinos/Hispanics had the highest odds of reporting cognitive difficulty across groups.

Physical health, marital status, individual SES, and access to parks were significantly associated with cognitive difficulty. Physical health, family structure, and multilevel SES partially explained or influenced the racial and ethnic disparity in cognitive difficulty. However, such influence varied by race and ethnicity. Physical health and individual SES contributed to the disparities for Latinos/Hispanics and Blacks, compared to Whites. Neighborhood SES attenuated the disparity in cognitive difficulty between Latinos/Hispanics and Whites. Also, family structure uniquely explained the disparity for Blacks. No significant disparity was identified between Asians and Whites. This study shed light on the important roles of multilevel factors in predicting racial and ethnic disparities in cognitive difficulty. Findings provide direction for interventions to reduce racial and ethnic disparities in cognitive difficulty.

AGING IN COMMUNITY: LESSONS LEARNED IN THE FIRST YEAR OF DEVELOPING A GRASSROOTS, RURAL PROGRAM

Emily Kinkade, Melisa Hajdar, and Heather Fuller, *North Dakota State University, Fargo, North Dakota, United States*

The North Dakota Aging in Community project has an overarching goal of creating programs that improve the quality of life of rural older adults by increasing community-level support to help them age in place in two rural communities. The progress of program development and implementation was assessed across the project's first year through program data and steering committee surveys. Program data, including steering committee meeting minutes and monthly activity reports completed by program staff, were qualitatively analyzed for successes, challenges, and lessons learned by finding common themes within these data. Successes included the use of an apprenticeship/mentorship model utilizing consultants from similar grassroots, rural organizations, recruitment of an optimistic, enthusiastic, and collaborative steering committee, and employing patience to develop community-led efforts based on unique community needs. Challenges included hiring qualified staff in rural communities, limitations in infrastructure opportunities, and need for creative marketing strategies. Survey results aligned with these conclusions, yet demonstrated the strengths and challenges related to incorporating the ideas and needs of diverse stakeholders. These findings highlight the unique challenges in developing programs to support rural aging-in-place, yet also highlight unique strategies that leverage rural strengths. Based on the findings of this first-year evaluation, future directions include conducting needs assessments to identify new avenues for program development, ensuring local program ownership through continued development of local steering committees, and continuing the mentorship/apprenticeship model while creating strategies to successfully foster independence. By sharing lessons learned, this program may serve as a replicable model to foster rural aging-in-place.

FOOD INSECURITY AMONG OLDER ADULTS IN NEW YORK CITY: DOES LOCATION MATTER?

Ethan Siu Leung Cheung, *Columbia University, New York, New York, United States*

Having access to adequate and appropriate food sources is essential to addressing food insecurity among older adults. However, the role of locational characteristics in explaining food insecurity remains unclear, especially in urban areas. This study investigated the association of distance to grocery stores, neighborhood disadvantage, and social cohesion with food insecurity among older adults in New York City. Individual-level data were drawn from a 2-year Poverty Tracker Study. The sample included New York City residents aged 65 or older (baseline N = 710). Based on the respondents' residential address and neighborhood ZIP codes, the individual-level data were merged with two spatial datasets: American Community Survey and ReferenceUSA. ArcGIS 10 (near analysis) was used to manage spatial data and calculate the distance to grocery stores. Hierarchical logistic regression models were employed for analyses. Descriptive results show that more older adults in neighborhoods with economic disadvantage and lower level of social cohesion reported more food insecurity. Logistic regressions suggested that after controlling for individual-level characteristics (e.g., age, gender, race and ethnicity, and education), living farther (0.26–0.50 miles and 0.51–0.70 miles) from the nearest grocery store was positively associated with food insecurity. Residing in economically disadvantaged neighborhoods also increased the odds of food insecurity. Community social cohesion was a marginally significant protective factor against food insecurity. Findings suggest that locational characteristics play a significant role in predicting food insecurity in New York City, suggesting that community outreach and grocery delivery programs are needed to mitigate the risk.

CONNECTING RURAL OLDER ADULTS WITH DISABILITIES TO HOME MODIFICATIONS WITH A REMOTE HOME ASSESSMENT

Emily Nabors[1], Catia Garell[2], and Jon Pynoos[1], *1. University of Southern California, Los Angeles, California, United States, 2. Thrive for Life LLC, Honolulu, Hawaii, United States*

Older adults living in rural areas have particular challenges to accessing critical supportive services such as home modifications to promote functioning and safety. Conducting remote home assessments through telehealth has the potential to reduce time spent and overall cost that occur in conducting in-person assessments. During the pandemic, providers turned to telehealth to preserve continuity of assessment services with few research-based practices to guide them. With support from a NIDLRR SBIR grant, Thrive for Life LLC in partnership with the USC Leonard Davis School of Gerontology conducted research to develop a remote home assessment that aims to connect health and home modification providers with rural older adults (65+) with disabilities, a population that may not receive home modifications otherwise. Research included a literature review, key informant interviews with five experts in the field, and individual phone interviews with 30 rural older adults who have disabilities. The literature was analyzed and used to inform the interview questions. Key informant interview responses were analyzed for models, potential challenges, lessons learned, and opportunities to impact priority needs. Consumer interview responses were analyzed for needs, preferences, concerns, and challenges related to technology use. Findings demonstrate common barriers such as lack of access to broadband and smart technology; circumstances in which remote assessments are, and are not, likely to be successful; and the potential value of conducting remote home assessments in rural areas to ensure equity of access to home modifications for older adults with disabilities during the pandemic and beyond.

OPENING THE DOOR TO AGING IN PLACE: FINDINGS FROM THE INTERGENERATIONAL TORONTO HOMESHARE PROGRAM

Jessica Hsieh[1], Raza Mirza[2], Jackie Tanner[3], Amanda Bull[2], Andrea Gardiola[4], Carley Moore[2], Deirdre Kelly-Adams[2], and Christopher Klinger[1], *1. University of Toronto, Toronto, Ontario, Canada, 2. National Initiative for the Care of the Elderly, Toronto, Ontario, Canada, 3. Natioinal Initiative for the Care of the Elderly, Toronto, Ontario, Canada, 4. National Initative for the Care of the Elderly, Toronto, Ontario, Canada*

Older adults prefer to live in their own homes for as long as possible — to 'age in place' — but for myriad reasons, may be unable to do so. To address this, a number of housing alternatives have been explored, including homesharing, or homeshare, an exchange-based shared housing approach with the potential to empower older adults to age in place by enabling them to obtain additional income, companionship, and assistance with completing household tasks in exchange for renting out a room in their home.An intergenerational homesharing pilot program in Toronto matched older adults (55+) with postsecondary students. With limited research in the area, a mixed methods research study was embedded within the pilot project with the goals of: 1) conducting a scoping review to map and synthesize the literature related to outcomes of homeshare participation for this population, 2) conducting in-depth interviews with homeshare participants (N=22) to learn about their experiences, and 3) conduct a full evaluation and exit survey to better understand the implications of the project. Results were organized around the following themes: (1) benefits and challenges of participating in homeshare for older adults; (2) intergenerational engagement as social exchange; and (3) the key role of agency facilitation as a determinant of the experience of homesharing for older adults. Results spoke to the unique benefits and challenges of participating in homeshare for this population. Findings were used to derive implications for policy and practice, as well as highlight areas for future research.

INTEGRATED CARE POLICY AND PRACTICE IN THE US: THE SCENARIO OF AGING IN CHINATOWN

Yuanyuan Hu, and Qingwen Xu, *New York University, New York, New York, United States*

Background: Older Chinese adults, the fastest-growing population among older immigrants, experience multiple barriers to access quality physical and behavioral health care, including low English proficiency, low health literacy, and segregation between health care and social care sectors (Tsoh et al., 2016). While integrated care attempts to address these issues, there is still a lack of culturally sensitive integrated care practices to address the needs of older Chinese immigrants.

Methods: This article reviews the definition and history of integrated care policies in the U.S., and compares four integrated care models on the service user and community levels, including the Chronic Care Model (CCM), Program of All-Inclusive Care for the Elderly (PACE), Patient Navigation Model, and Delivery System Reform Incentive Payment (DSRIP) Program.

Results: Taking the community-dwelling older Chinese immigrants as the context, this article discusses factors that are essential to this group of older adults and proposes a framework to integrate social determinants of health in the development of integrated care practice with the infusion of cultural values and norms.

Conclusion: Integrated care for older immigrants asks for a complicated mass reconstruction of current care systems. We propose an innovative framework that fully takes advantage of CBO's capacity in providing culturally appropriate services is proactive and preventive in nature by addressing social determinants of health directly, recognizes the role of family and community in older immigrants' life and aging process, and provide equal attention to the older adults' needs in health, mental health, and elderly care.

SESSION 6240 (POSTER)

AGING IN PLACE: SOCIAL DETERMINANTS OF HEALTH

AGING IN PLACE: TURNING TO THE VOICES OF EXTENSION EDUCATORS

Susan Koerner[1], Brianna Anderson[2], and Sehyun Ju[1], *1. University of Illinois - Urbana-Champaign, Urbana, Illinois, United States, 2. Saint Louis University, St. Louis, Missouri, United States*

Most adults report a preference for aging-in-place (AIP) – remaining safely in their own home and community as they age, even as they become more dependent on others. When attempting to determine options and feasibility for AIP, older adults and/or their families – especially those living in non-metropolitan rural areas and small towns, may turn to Extension educators for information and guidance. For the current study we interviewed seven family-focused Extension educators responsible for 25 counties throughout a Midwestern state to explore the challenges, supports, patterns of experience, and service/policy recommendations that these professionals find relevant to AIP in their regions. The principal investigator (PI) conducted each semi-structured interview by phone; each audio-recorded interview lasted approximately 60 minutes. Two trained research assistants and the PI applied combined deductive-inductive thematic analyses to the transcribed interview data following Braun and Clarke (2012), utilizing MAXQDA, and ensuring trustworthiness during the coding process. Five major categories with sub-themes emerged: Challenges to AIP (e.g., transportation), Supports to AIP (e.g., churches), Most-Challenged Populations (e.g., middle-income families who neither can afford in-home assistance nor are eligible for government aid), Attitudes Toward AIP (e.g., caution against social isolation), and Recommendations for Services/Policies to Facilitate AIP (e.g., government funding, in-home technology assistance). Some variation across counties was apparent with, for example, one county making concerted efforts to retain young adults in its communities (i.e., reducing out-migration), thus enhancing family presence making AIP more feasible, non-isolating. Our findings will be especially noteworthy to social service providers and aging-focused public policymakers.

SPIRITUAL RESILIENCE? THE ROLE OF RELIGIOSITY IN BUFFERING THE EFFECT OF NEIGHBORHOOD DISORDER ON COGNITIVE DECLINE

Haena Lee[1], Yeon Jin Choi[2], and Jong Hyun Jung[3], *1. USC, Los Angeles, California, United States, 2. University of Southern California, Los Angeles, California, United States, 3. Sungkyunkwan University, Seoul, Seoul-t'ukpyolsi, Republic of Korea*

Living in neighborhoods with high levels of disorder and danger can induce psychological distress and compromise cognitive function. However, not all individuals who live in difficult life circumstances have poor health outcomes. Research on resilience shows that some older adults maintain healthy profiles despite adversity, but this has not been tested with respect to cognitive aging. In this paper, we focus on religiosity–religious belief and attendance–as a source of resilience and how it can reverse or reduce cognitive risks in later life that result from long-term exposure to neighborhood disorder. We used 2006-2016 Health and Retirement Study (HRS) to investigate how religiosity moderates the relationship between neighborhood disorder and cognitive decline. We assessed trajectories of cognitive functioning using the Telephone Inventory for Cognitive Status. We measured neighborhood disorder and neighborhood unsafety using the 2006/2008 HRS interviewer observation data and Housing data. We found that individuals living with higher levels of neighborhood disorder had lower cognitive functioning at baseline. The disorder effect was mitigated by religious belief—for instance, poor neighborhood conditions were negatively associated with cognitive function only for those with lower religious belief. The protective effect of religious belief was more pronounced among older Black women. This is consistent with prior literature that spirituality serves as a protective factor in the African American community, especially among women, for triumphing over adversity and lack of secular resources over the life course.

GEOGRAPHIC PROXIMITY TO NEIGHBORHOOD RESOURCES AND DEPRESSIVE SYMPTOMS AMONG KOREAN OLDER ADULTS

JuHyeong Lee, Donghee Shin, Yeoju Kim, and Giyeon Kim, *Chung-Ang University, Seoul, Seoul-t'ukpyolsi, Republic of Korea*

Given the importance of geographic proximity to neighborhood resources especially during the COVID-19 pandemic, this study examine whether the relationship between geographic proximity to neighborhood resources (e.g. hospitals, public transportation, etc.) and depressive symptoms varied by geographic location (i.e., rural vs. urban areas) among older adults in South Korea and whether this relationship was mediated by participation in social activities (e.g. education, club, community, etc.). The nationally representative samples, Korean older adults aged 65 or older, were drawn from the 2020 Survey of Living Conditions and Welfare Needs of Korean Older Persons (N=9,732, Urban=6,975, Rural=2,757). Hierarchical regression models, Baron and Kenny's steps, and Sobel Test for the mediation effect were conducted. Results showed that geographic proximity was negatively associated with depressive symptoms in urban areas (B=-.041, p<.001), while positively associated in rural areas (B=.034, p<.01). Participation in social activities partially mediated the relationship in urban areas (Z=-2.162, p<.05), while there was no significant mediation effect in rural areas. Additionally, geographic proximity to hospitals or public transportation was significantly associated with depressive symptoms in rural areas. The findings suggest that geographic proximity to neighborhood resources helps older adults reduce social isolation, which may improve mental health of older adults living in urban areas during the pandemic. However, geographic proximity to neighborhood resources could make older adults living in rural areas become depressed, emphasizing that the characteristics of the urban and rural areas need to be considered to create an aged-friendly environment.

NEIGHBORHOOD PREDICTORS OF MENTAL HEALTH OF OLDER AMERICANS: EVIDENCE FROM A 5-YEAR LONGITUDINAL STUDY

AFOLABI OREKOYA[1], Henry Egbuchiem[2], Olawale Olanisa[3], Abimbola Arisoyin[4], Ujunwa Ebili[5], Adeleye Adaralegbe[6], and Khuzeman Abbasi7, *1. Wellspring Medical Center, Riverdale, Georgia, United States, 2. The Everest Foundation, Los Angeles, California, United States, 3. IQVIA Biotech, Morrisville, North Carolina, United States, 4. TCA health, Lagos, Lagos, Nigeria, 5. Emel Specialists and Pediatric Center, Festac Town, Lagos, Nigeria, 6. University of Connecticut, Storrs, Connecticut, United States, 7 Vanderbilt University Medical Center, Glen Burnie, Maryland, United States*

With increasing dependence on other people in old age, environmental resources become an important asset for older adults to experience healthy aging. Data on the longitudinal relationship between neighborhood and mental health in late life is scanty. This study utilized hierarchical multiple regression model analysis to investigate whether and which neighborhood factors predicted depression and anxiety among older Americans followed up for over five years within the same neighborhood. Two waves of data containing a cohort of 1,731 older adults from the NSHAP project were used. Outcome measures were depression and anxiety. Predictors were four neighborhood factors: Social cohesion (NSC), social ties (NSC), neighborhood problems (NP), and perceived neighborhood danger (PND). We adjusted for demographic and physical health characteristics. The mean age of the respondents was 71.4 ± 6.5 years and were mostly females (55.5%). Lower NSC and a higher PND significantly predicted depression. However, the model only explained 2.8% of the variance in depression. In the covariate-adjusted model, none of the neighborhood factors predicted depression, but the model significantly improved to 32.5%. NP was the only significant predictor of anxiety in the final model and explained 27.8% of the variance in anxiety. Covariates, which are primary determinants of mental health disparity, have a much larger role to play. This study sheds some light on the complexity of the relationship between neighborhood and mental health in older adults. Future policy development and interventions should target improving both physical and social environments to enhancing the mental wellbeing of older adults.

CHARACTERISTICS OF LONG-TERM HOME CARE PATIENTS WITH DEMENTIA

Takashi Yamanaka[1], Maiko Mizuki[1], Kiwami Kidana[1], Ryonosuke Yamaga[2], and Masahiro Akishita[1], *1. Graduate School of Medicine, The University of Tokyo, Bunkyo-ku, Tokyo, Japan, 2. Tsubasa Home Care Clinic, Funabashi-city, Chiba, Japan*

This study aimed to clarify the characteristics of older adults with dementia receiving physician home visits. We prospectively registered 179 patients aged ≥65 years, estimated to receive physician home visits for over 6 months, in a clinic in Chiba, Japan, in 2020–2021. The patients' mean (±SD) age was 85.1±7.4 years and ranged from 68 to 102 years. Out of the total patients, 57.5% were men. We collected clinical information; employed the Dementia Assessment Sheet in Community-based Integrated Care System 21 items (DASC-21) and EuroQOL five dimensions 5-level (EQ-5D-5L) every 6 months; and calculated the incidence of death. Eighty-two patients (45.8%) were diagnosed with dementia at the commencement of physician home visits. The characteristics of older adults diagnosed with dementia (D+ group) were compared with the characteristics of those who were not (D- group). The D+ group was older than the D- group (86.4±6.6 years vs. 84.1±8.0 years, p=0.04118). Total cholesterol levels and DASC-21 scores were higher in the D+ group compared to the D- group (180.2±41.7 vs. 163.7±51.2, p=0.04091; 62.3±14.5 vs. 50.2±16.2, p=0.00004, respectively). The EQ-5D-5L was not significantly different between the groups (0.439±0.255 vs. 0.397±0.267, p=0.32409). The proportion of those living in assisted living facilities or fee-based homes for the elderly was higher in the D+ group ($\chi2$=8.5177, df=2, p=0.01414, V=0.2258). The mortality rate after 6 months was 20.7% in the D+ group and 16.5% in the D- group ($\chi2$=0.5305, df=1, p=0.46641). In conclusion, the characteristics of patients with dementia should be further elucidated to provide better care.

PARTICIPATORY RESEARCH APPROACH FOR EVALUATING HOME ENVIRONMENT FOR OLDER ADULTS WITH DISABILITIES

Juliana Tissot[1], Widya Ramadhani[2], Lizandra Vergara[1], and Wendy Rogers[3], *1. Federal University of Santa Catarina, Florianópolis, Santa Catarina, Brazil, 2. University of Illinois Urbana-Champaign, Urbana, Illinois, United States, 3. University of Illinois Urbana Champaign, Champaign, Illinois, United States*

Regardless of where they live, older adults' ability to retain their independence depends on their health and capacity. Considering that older adults are more likely to experience disabilities, there are opportunities for built environmental intervention to help them conduct everyday activities to achieve successful aging in place. We conducted participatory research with designers, architects, and aging specialists to identify aspects and characteristics of the physical space that can support or limit older adults' ability to do everyday activities. The research was conducted at the McKechnie Family LIFE Home, a home simulation facility. Participants were asked to walk through the home spaces and identify potential challenges and solutions for older adults with different disabilities (i.e., mobility, cognitive, sensory, socio-emotional), followed by a group discussion. Preliminary findings showed that the bathroom and kitchen had the most barriers. Recommendations to improve bathroom safety include installing high friction flooring, grab bars on both toilet sides, adequate wheelchair maneuvering space, and color contrast. Cooking was mentioned as a difficult activity and solutions included appliances at waist level, layout in "C" or a "U", lights under cabinets, and in the foot space. Also, the cabinets doors should be translucent to allow them to check what is inside. The house floor plan should be designed with considerations of users' everyday activities and the relationship between these activities, such as having the bathroom nearby bedroom, laundry nearby the kitchen to improve users 'mobility. We have developed a protocol for designers to follow when evaluating home spaces.

SENIOR HOUSINGS' ROLE FOR AGING IN PLACE: FOCUSING ON THE NATIONAL PROFILE OF INDEPENDENT LIVING FACILITIES IN KOREA

Sojung Park[1], and ByeongJu Ryu[2], *1. Washington University in St. Louis, St. Louis, Missouri, United States, 2. Chuncheon Hyoja Social Welfare Center, Chuncheon-si, Kangwon-do, Republic of Korea*

Understanding the changing preference for alternative housing arrangements is important due to the confluence of a global population aging, increasing cost concern for long-term care, and the desire of older people for aging in place (AIP). To date, little is known about to what extent the current housing models meets the needs of AIP for older people. Guided by the Person-Environment fit perspective, we examined the South Korean case using the first national data on independent living facilities (ILF) for older adults. Employing a convergent mixed-method design, we conducted a quantitative analysis of 277 ILFs and qualitative interviews with executive directors and managers from 10 facilities. We found the majority of the housings serve the low-income, and the residents' health status varies widely (i.e., ranging from fully independent to those homebound). However, the characteristics and nature of services available and staff composition are not adequate to meet the needs of the residents. Notably, privacy issues (i.e., a shared restroom and bedroom) in congregate settings stood out, decreasing the occupancy rate. Our findings suggest that the housing model needs to be diversified corresponding to the resident's needs for health and social care and economic affordability and should respect their privacy needs. We discussed ways to reform the current policy governing the ILFs, including strengthening service coordination programs to alleviate gaps between the residents' needs and the service availability. Our findings provide implications for improving and reforming the existing housing model to age in place in Korea and potentially other aging societies.

SOCIAL INTERACTIONS OF COMMUNITY SPACE ATTENDEES AND ANTICIPATED FUNCTION OF THE SPACE AMID THE COVID-19 PANDEMIC

Mai Takase[1], Ryogo Ogino[2], Ryoichi Nitanai[1], Riko Nakayama[1], Hongjik Kim[1], Neo Kazembe[1], Jun Goto[3], and Katsuya Iijima[1], *1. The University of Tokyo, Tokyo, Tokyo, Japan, 2. Saga University, Saga, Saga, Japan, 3. Tokai University, Hiratsuka, Tokyo, Japan,*

Introduction: A regional community space in Japan, Chiiki-Katsudokan, was founded to facilitate the social interactions of older adults through activities. Meanwhile, the COVID-19 pandemic occasionally forced this space to close or limited the volume of its participants. In this research, the operation of the space was reviewed by monitoring the changes in the social interactions of the attendees, and by investigating the anticipated function from the attendees' needs. Method: A semi-structured interview targeting the attendees of Chiiki-Katsudokan was conducted in December 2021 (N=19, main age:80s). The level of social interaction before and during the pandemic and the newly anticipated function of the space were examined.

Results: First, deep and light interactions were observed. Those with deep interactions initially had wide social connections and used Chiiki-Katsudokan to interact with friends. Meanwhile, those with light interactions only talked to other attendees while attending the space. During the quarantine, those with deep interactions stayed connected with others and met privately, while those with light interactions faced a higher risk of social isolation. Second, the most popular newly anticipated functions of the space were "Place to gather with friends (n=14)" and "Interaction with younger generation (n=14)." "Opportunity to learn about the new pandemic-lifestyle (n=11)" was also rated high, while need for "online events" was rated the lowest (n=7).

Conclusion: The pandemic re-emphasized older adults' need for direct interaction. Low interest in technology-based countermeasures suggested that community spaces should expand their operation method while considering offline methods (e.g., pen-pal system) that could enhance social interaction.

TYPES OF ATTENDEES IN COMMUNITY SPACE IN JAPAN: TOWARD DESIGNING AN ENVIRONMENT FOR SOCIAL PARTICIPATION

Mai Takase[1], Ryogo Ogino[2], Ryoichi Nitanai[1], Riko Nakayama[1], Hongjik Kim[1], Neo Kazembe[1], Jun Goto[3], and Katsuya Iijima[1], *1. The University of Tokyo, Tokyo, Tokyo, Japan, 2. Saga University, Saga, Saga, Japan, 3. Tokai University, Hiratsuka, Tokyo, Japan*

Introduction: Designing community space for social participation of older adults is essential for healthy aging. The behavioral characteristics of the attendees have much to offer as they relate to social settings designed in the space. This study aims to elucidate the basic typology of the attendees considering their motivation for attendance and state of social connection.

Methods: Semi-structured interviews targeting attendees of Chiiki-Katsudokan, a space designed for social participation in a larger aging estate in Japan, were conducted in December 2021 (N=16, 16% male). Attendees were asked about their reasons for attending events at Chiiki-Katsudokan, interaction levels with other attendees, and levels of social participation during the COVID-19 pandemic.

Results: Based on the interviews, attendees were classified into three types: Seeker, Hobbyist, and Socializer. First, Seekers (n=3) used Chiiki-Katsudokan as the primary means of preventing social isolation. Amongst the three types, the social interaction level of Seekers was the lightest, and the opportunity decreased when Chiiki-Katsudokan closed during the quarantine. Second, the main motivation for Hobbyists (n=5) was the event contents which matched their interests. Hobbyists were also likely to engage in hobby networks, which continued privately during the pandemic. Finally, Socializers (n=8) attended Chiiki-Katsudokan to communicate with friends. Many were initially socially active and engaged in social interaction outside Chiiki-Katsudokan, e.g., teatime with friends, during the quarantine.

Conclusion: This study suggested that designing community space for social participation requires defining the varying levels of engagement and expecting relationships outside the space based on the behavioral characteristics of the attendees.

MEANINGFUL ACTIVITY ENGAGEMENT AND WELL-BEING AMONG DISABLED OLDER ADULTS: THE MODERATED ROLE OF ENVIRONMENT

Yi-Hsuan Tung[1], Iris Chi[1], Shinyi Wu[1], and Shiau-Fang Chao[2], *1. University of Southern California, Los Angeles, California, United States, 2. National Taiwan University, Taipei, Taipei, Taiwan (Republic of China)*

Engaging in meaningful activities has been seen as an important way to sustain the well-being of older adults with disabilities and to achieve person-centered care. Yet, it is still unclear whether and to what extent meaningful activity engagement promotes well-being for community-dwelling older adults with disabilities, and how the environmental factors could affect these relationships. This study aims to investigate the relationship between meaningful activity engagement and psychological well-being, and to explore the moderated role of environmental factors (physical, attitudinal, service/support, policy). Survey data conducted in Taiwan between April and July of 2018 were analyzed by using multiple regression (N=1,244). Three types of meaningful activities (instrumental, social, and leisure) were identified based on a self-rated activity meaningfulness measure. Findings showed that higher levels of engagement in three types of meaningful activities were associated with better quality of life (QOL), but only engaging in meaningful leisure was associated with less depressive symptoms while adjusting functional status. Perceived better policy-related environment (e.g., long-term care services) could reinforce the positive effects of three types of meaningful activity engagement on QOL and depressive symptoms. Findings also indicated perceived attitudinal environment moderated the association between meaningful leisure activity engagement and QOL. These results established the influences of meaningful activity engagement on the well-being of community-dwelling older adults with disabilities and highlight the importance of age-friendly environment in supporting meaningful activity engagement and older adults' well-being.

SESSION 6250 (POSTER)

ATTITUDES ABOUT AGING (POSTERS)

OLDER ADULTS' INDIVIDUAL TRAJECTORIES IN SOCIAL STATUS AND AGING ANXIETY

Tim Kuball, and Georg Jahn, *Chemnitz University of Technology, Chemnitz, Sachsen, Germany*

A high social standing in comparison to others is associated with positive psychological and health outcomes. Highest social standing is assigned to the group of middle-aged adults, hence, on average, older adults face a loss in status relative to younger age groups and relative to their former selves. Experienced and expected age-related changes in subjective social status and their association with aging anxiety have not yet received much attention in aging research. Using a new methodological approach, respondents indicated their perceived and expected social status for five points in time: 10 years ago, 5 years ago, now, in 5 years, in 10 years, which allowed for inter- and intrapersonal comparisons. They did the same for the average status of members of their age group. Early and later in old age (N = 191; range 65 – 88; MW = 73.5 years), participants expected higher losses in status than they have experienced in the past. However, low personal status in relation to others showed higher associations with aging anxiety ($R2 = .16$) than disadvantageous age-related intrapersonal changes ($R2 = .14$). Perception of a stable subjective status trajectory as well as distancing oneself from the group older adults, as in perceiving one's personal status above the groups' status, was related to reduced anxiety of aging. Taken together, analysis of individual status trajectories can help to gain new insights on attitudes toward aging. Implications for creating a more positive perception of aging are discussed.

QUALITY OF LIFE AND ATTITUDES TOWARD AGING IN OLDER ADULTS DURING THE COVID-19 PANDEMIC

Morgan Inman[1], Maria MacLean[1], Olive Bryanton[2], William Montelpare[1], and Jessica Strong[1], *1. University of Prince Edward Island, Charlottetown, Prince Edward Island, Canada, 2. Prince Edward Island, Charlottetown, Prince Edward Island, Canada*

Research has shown that positive or negative views of aging are associated with quality of life. Prior research has found that community dwelling older adults aged 65 and older with more negative views of aging have lower scores on quality of life scales, whereas those with higher views of aging have higher scores on quality of life scales. A group of 264 community dwelling older adults (Mean age = 72.4 years, 62-92 years old) living in Prince Edward Island, Canada, completed a survey measuring attitudes towards aging and quality of life during the COVID-19 pandemic. The sample consisted of a majority of retired (n=206) older adults, living in an urban area (n=151), and approximately 55% receiving a household income of $26,000 to $75,000 per year. Regression analysis found that attitudes towards aging significantly predicted quality of life ($F(1,127)=24.9, p< 0.01$), with positive attitudes predicting higher quality of life scores and negative attitudes predicting lower quality of life scores. The model showed that the predictor, attitudes towards aging, explained 16.5% of the variance in quality of life ($B=-2.7, t=-4.9, p< 0.01$). This suggests that attitudes towards aging play a role in predicting quality of life in older adults during the COVID-19 pandemic.

INTERACTIONS WITH PEOPLE WITH DEMENTIA, LEARNING EXPERIENCES, AND PUBLIC STIGMA AGAINST DEMENTIA

Taiji Noguchi[1], Takeshi Nakagawa[1], Ayane Komatsu[1], Erhua Shang[2], Chiyoe Murata[3], and Tami Saito[1], *1. National Center for Geriatrics and Gerontology, Obu, Aichi, Japan, 2. Aichi Toho University, Nagoya, Aichi, Japan, 3. Tokai Gakuen University, Nagoya, Aichi, Japan*

Overcoming stigma around dementia is a global challenge. This cross-sectional study examined the association of experiences of interacting with people with dementia (PwD) and learning about dementia, with the public-stigma against dementia. We recruited—via an internet survey—710 Japanese adults (mean age = 46.3 years; 49.3% females) without any medical or welfare license, or dementia-related work experience. Public-stigma against dementia was assessed using the Japanese version of Phillipson et al.'s scale (2012) exploring dementia-related attitudes in the context of "personal avoidance," "person centeredness," "fear of labeling," and "fear of discrimination." Multivariable linear regression analysis was employed to examine the association of interacting with PwD and learning regarding dementia as explanatory variables with dementia stigma score, adjusting for sociodemographic variables. Regarding interactions with PwD, talking or activities with PwD were associated with low "personal avoidance" ($\beta = -1.47, p = 0.002$), "fear of labeling" ($\beta = -0.96, p = 0.020$), and "fear of discrimination" ($\beta = -0.396, p = 0.043$). Experiences of living with PwD were associated with low "personal avoidance" ($\beta = -2.35, p = 0.002$) and "fear of discrimination" ($\beta = -0.789, p = 0.013$). Learning experiences at school regarding dementia were associated with low "personal avoidance" ($\beta = -4.01, p < 0.001$), and self-learning experiences were associated with low "personal avoidance" ($\beta = -1.73, p = 0.049$) and high "person centeredness" ($\beta = 1.27, p = 0.037$). However, workplace learning was not associated with any area. Interacting with PwD and learning about dementia might reduce associated public-stigma.

AWARENESS OF AGE-RELATED GAINS AND LOSSES AND THEIR ASSOCIATIONS WITH PHYSICAL AND COGNITIVE FUNCTION

Sarah Barber[1], Vanessa Martinez Lenis[1], and Kate Hamel[2], *1. Georgia State University, Atlanta, Georgia, United States, 2. San Francisco State University, San Francisco, California, United States*

Awareness of age-related change (AARC) refers to people's recognition of how aging has affected their performance, behavior, and ways of experiencing life. Sometimes these age-related changes are perceived as losses (AARC-Losses), such as when people notice declines in their health. However, other times these age-related changes are perceived as gains (AARC-Gains), such as when people notice they have developed a better sense of what is important to them. Past research has shown that higher AARC-Losses (and to a lesser extent lower AARC-Gains) are associated with poorer self-rated health. However, no research has yet examined whether AARC also relates to an objective performance-based measure of health. To address this, we examined the cross-sectional relationships between AARC-Losses and AARC-Gains with gait speed (i.e., a measure of physical function) in 164 community-dwelling older adults. Participants in this study also completed health-related questionnaires and the NIH Toolbox Cognition Battery. Results showed that AARC-Losses were most strongly predicted by depression levels, but higher AARC-Losses were also predicted by slower gait speeds. A different pattern emerged for AARC-Gains. After controlling for demographic factors, depression, and other self-reported measures of health, we found that higher AARC-Gains were predicted by poorer cognition and slower gait speed. The counterintuitive relationship between AARC-Gains and objective cognition has previously been reported in the literature. However, this study is the first to document that AARC-Gains are also associated with poorer performance on an objective measure of physical function. We discuss features of the AARC questionnaire that may lead to these paradoxical effects.

FUTURE SELF, PERCEIVED CONTROL, AND AGING PREPARATION BEFORE AND AFTER THE PANDEMIC: MODERATED MEDIATION EFFECT

Yue Hu, Zhixuan Lin, and Helene Fung, *The Chinese University of Hong Kong, Hong Kong, Hong Kong*

Aging preparation, which can be seen as an adaptation to age-related challenges, is always oriented toward the future. The present study aims to explore how thinking about the future self and aging preparation are related. Domain-specific aging preparation was assessed in a longitudinal sample including 359 Hong Kong adults aged from 20 to 98 yrs. In both the pre- (2018) and during pandemic (2020) waves, perceived control fully mediated the positive relationship between thinking clarity on the near future self and aging preparation in the financial domain. However, the mediation effect of perceived control on aging preparation was moderated by age in the pre-pandemic wave, with a higher effect for older adults than for younger adults. Yet, these age differences were no longer significant during the pandemic. The present findings suggested the critical role of perceived control in preparation for the age-related changes and the age-equating effect of COVID-19 pandemic outbreak.

PHYSICAL FUNCTION, SELF-PERCEPTIONS OF AGING, AND DEPRESSIVE SYMPTOMS AMONG OLDER ADULTS

Suyoung Nah[1], Lynn Martire[2], and Ashley Tate[2], *1. Pennsylvania State University, State College, Pennsylvania, United States, 2. Pennsylvania State University, University Park, Pennsylvania, United States*

Poor physical function has been linked to greater depressive symptoms among older adults. On the other hand, older adults' perceptions of positive and negative age-related changes provide personal strength and vulnerability to stressful events, respectively. We therefore expected that positive self-perceptions of aging (SPA) would be associated with fewer depressive symptoms, while negative SPA would be related to greater depressive symptoms, beyond the effect of physical function. We further tested the hypotheses that positive SPA would buffer the association between physical function and greater depressive symptoms, whereas negative SPA would exacerbate this association. This study used data from 108 older adults (mean age = 81.09) in independent-living or retirement communities. Results from a linear regression revealed that more positive SPA ($B = -0.21$, $p = .02$) and less negative SPA ($B = 0.21$, $p = .06$) were associated with fewer depressive symptoms, even after controlling for physical function, both types of SPA, and other covariates. In contrast, physical function was no longer significantly associated with depressive symptoms ($B = -0.15$, $p = .19$), after controlling for both types of SPA. There were no significant moderating effects of positive and negative SPA. Findings suggest that how positively and negatively older adults perceive their own aging may be important for their mental health while experiencing less physical function in late life.

ADVANCE DIRECTIVES: SOLO AGERS RISK OF BECOMING "UNBEFRIENDED"

Rupal Parekh[1], Kathryn Betts Adams[1], and Donna Schuman[2], *1. University of Connecticut, West Hartford, Connecticut, United States, 2. University of Texas at Arlington, Arlington, Texas, United States*

Solo agers are an at-risk population of almost 14 million older U.S. adults currently living alone (Administration for Community Living, 2018). Having been independent for most of their lives they often enter older age unprepared for declining health. Even though the numbers of solo agers are rapidly increasing with the aging of the Baby Boomer generation, research remains scant on this population (Colby & Ortman, 2014). A mounting concern facing solo agers is finding themselves "unbefriended" (i.e., having no one to act as health care proxy in the event of incapacitation due to a medical crisis). The risk of unbefriended status emphasizes the critical importance of advance care planning; however, many solo agers have no advance directives and factors influencing advance care planning in this group are unclear. In this mixed-methods study, we examined factors influencing advance care planning among solo agers. Survey data were collected from 467 members of a Facebook group for self-identified "elder orphans," six of whom subsequently participated in qualitative interviews. Among these solo agers, 55% indicated they had advance directives. Hierarchical logistic regression results indicated financial and overall wellbeing predicted having advance directives; however, perceived health risk did not. An interpretive phenomenological analysis of data from six in-depth interviews revealed emergent themes of fears of the future and reluctance to plan for end of life despite acknowledging health risks. Findings can inform policies to meet the growing needs of solo agers who may be at elevated risk of becoming unbefriended.

ATTITUDES TOWARD AGING AND WELLNESS ENGAGEMENT IN LIFE PLAN COMMUNITIES

Jennifer Smith[1], Matthew Fullen[2], and Philip Clarke[3], *1. Mather Institute, Evanston, Illinois, United States, 2. Virginia Tech, Blacksburg, Virginia, United States, 3. Wake Forest University, Winston-Salem, North Carolina, United States*

Life Plan Communities, also known as Continuing Care Retirement Communities, typically offer a wide range of wellness programs and services, including fitness classes, educational lectures, volunteer opportunities, and social events. Despite the convenience of onsite wellness resources, some residents choose not to participate in wellness offerings available at the community. One factor that may influence engagement in wellness behaviors is older adults' attitudes toward aging, which has been associated with differences in health and well-being over time. The purpose of this research was to examine the relationship between attitudes toward aging and wellness engagement among residents of Life Plan Communities. A total of 447 residents (ages 59 to 97; M = 81.82, SD = 6.55; 65% female) of 10 communities completed surveys that measured their attitudes toward aging, self-reported wellness, interest in improving wellness, participation in wellness programs, and barriers to wellness participation. Multiple regression analyses revealed that more positive attitudes toward aging were associated with better wellness, higher interest, more frequent participation, and fewer barriers, controlling for age, gender health, education, and marital status. Follow-up analyses revealed that these effects could be accounted for by specific types of aging attitudes (i.e., psychological growth, psychosocial loss, and physical change). For example, greater psychological growth was associated with greater wellness, interest in improving wellness, and wellness participation, whereas greater psychosocial losses was associated with greater perceived barriers and lower wellness. These findings have implications for the development, implementation, and promotion of wellness programs for older adults.

WHO PLANS FOR LATER LIFE? AN EXAMINATION OF MIDDLE-AGED AND OLDER FLORIDIANS

Anne Barrett, Hope Mimbs, Cherish Michael, and Jessica Noblitt, *Florida State University, Tallahassee, Florida, United States*

The extension of life expectancy highlights the importance of understanding how people conceptualize – and plan for – their later years. We address this issue using data from an online survey of over 3,400 Floridians aged 50 and older that was conducted between December 2020 and March 2021 and funded by the Florida Department of Transportation. We examine five types of planning: for health care needs, financial well-being, living arrangements, driving retirement, and end-of-life care. We find that the likelihood of planning varies considerably across these types. Only 23 percent of respondents reported planning "some" or "a lot" for driving retirement, compared with 74 percent for health care needs, 76 percent for end-of-life care, 77 percent for living arrangements, and 83 percent for financial well-being. Likelihood of planning varied by age, gender, socioeconomic status, health, and race or ethnicity. Across all types of planning, older adults and those with at least a college degree and higher income were more likely to have planned. Women were more likely than men to plan for their financial future, living arrangements, driving retirement, and end-of-life care. Those in better health were more likely to plan for their financial future and end-of-life care. The effects of race or ethnicity were less consistent across the types of planning. White respondents were more likely than other race or ethnic groups to report planning for their living arrangements and end-of-life care, while Hispanic respondents were more likely than other groups to plan for driving retirement.

SESSION 6260 (POSTER)

BRAIN HEALTH, HEALTH BEHAVIORS, AND SOCIAL RELATIONSHIPS

AGITATION IN ALZHEIMER'S DISEASE: A DECISION TREE FOR HEALTHCARE PROVIDERS

George Grossberg[1], Angela Sanford[2], Susan Scanland[3], Karen Tracy[4], and Richard G Stefanacci[5], *1. St Louis University School of Medicine, St Louis, Missouri, United States, 2. St Louis University, St Louis, Missouri, United States, 3. U of Pittsburgh, Pittsburgh, Pennsylvania, United States, 4. GSA, Washington, District of Columbia, United States, 5. Thomas Jefferson University, Philadelphia, Pennsylvania, United States*

Agitation in Alzheimer's Disease (AAD) impacts nearly 80% of persons with Alzheimer's Disease and is a cause of significant distress for patients and family/professional caregivers.Clinicians need guidance relative to assessment as well as non-pharmacologic and pharmacologic treatment approaches to AAD. To this end, the Gerontological Society of America (GSA) convened a group of experts representing Geriatric Psychiatry, Gerontological Nursing, Geriatric Medicine, and Long-Term Care to develop a "Decision Tree for Healthcare Providers" in the evaluation and management of AAD. The "Decision Tree" is a practical, user-friendly template for clinicians which provides a step-by-step approach to differential diagnosis of AAD, including conditions such as delirium, pain/discomfort, environmental and psycho-social stressors. The "Decision Tree" also walks the clinician through a range of non-pharmacologic treatment options such as music therapy; activities therapy, environmental modification and de-prescribing. The "Decision Tree" highlights rational use of pharmacotherapies as well as their hazards in this vulnerable population.

ASSOCIATIONS BETWEEN DAILY DRINKING AND DAILY MEMORY LAPSES AMONG MIDDLE-AGED AND OLDER ADULTS IN THE MIDUS STUDY

Sara Miller[1], Jacqueline Mogle[2], Ashley Linden-Carmichael[3], and David Almeida[2], *1. Pennsylvania State University, University Park, Pennsylvania, United States, 2. The Pennsylvania State University, University Park, Pennsylvania, United States, 3. Pennsylvania State University, Pennsylvania State University, Pennsylvania, United States*

Alcohol use predicts short- and long-term memory impairment. However, it is unclear how alcohol influences subjective memory, which refers to perceptions of one's own memory functioning. This study examined associations between daily alcohol use and memory lapses (i.e., subjective memory) and evaluated perceived impact of memory lapses on daily life. Participants (n=953; Mage=55.2) were non-abstaining adults from the Midlife in the United States (MIDUS) study who participated in the 8-day daily diary project. Survey items included number of drinks and 9 memory lapse items (1=yes). After each reported memory lapse, participants indicated memory lapse irritation (range=1-10) and interference (range=1-10). Covariates included age, gender, race, education, and cognitive functioning. Multilevel logistic regression analysis revealed that within-person alcohol use (OR=1.07; p< 0.01), but not between-person alcohol use (p>0.05), was associated with greater odds of reporting any memory lapses. When assessing retrospective and prospective lapses separately, only the prediction of prospective lapses from between-person alcohol use was significant (OR=1.11; p=0.01). Finally, multilevel linear regression analysis indicated that neither within-person nor between-person alcohol use was predictive of reported irritation or interference from memory lapses (p>0.05). Study findings revealed between- and within-person associations between alcohol use and subjective memory. At the daily-level, individuals were more likely to notice memory lapses on days they drank more than usual. At the person-level, people who drank more relative to others were more likely to report prospective memory lapses. Future studies should assess how associations between alcohol use and subjective memory relate to objective cognitive functioning outcomes.

INVESTIGATION INTO THE PREDICTORS OF HELP-SEEKING BEHAVIOR IN OLDER ADULTS

Michael Kann[1], Silvia Chapman[2], Martina Azar[3], Jillian Joyce[4], Leah Waltrip[5], Shaina Shagalow[4], Sandra Rizer[5], and Stephanie Cosentino[5], *1. Columbia University, Pittsburgh, Pennsylvania, United States, 2. Columbia University Irving Medical Center, New York City, New York, United States, 3. VA Boston Healthcare System, Boston, Massachusetts, United States, 4. Columbia University, New York City, New York, United States, 5. Columbia University Medical Center, New York, New York, United States*

Early help seeking (HS) among patients with emerging Alzheimer's disease and related dementias (AD/ADRD) can have considerable implications for treatment course, access to clinical trials, lifestyle, and future quality of life. Previous studies in older adults suggest cognitive impairment itself does not lead people to seek help; rather, HS appears to be driven by Subjective Cognitive Decline (SCD), personality, and mood. It is possible, however, that tests used to measure objective cognition were not sensitive to detect subtle cognitive impairments that may influence HS behavior. In this study of 142 cognitively healthy older adults, we examined if utilizing cognitive tasks sensitive to preclinical AD (i.e., short term memory binding, associative memory, and susceptibility to semantic interference) revealed an independent association between objective cognition and HS, or if SCD continued to be a primary driver. Participants were assessed for HS, SCD severity, personality traits (conscientiousness and neuroticism), depressive symptoms, and demographics (age, gender, education). Partially and fully adjusted regression models were conducted to examine the association between cognitive tests and HS whilst adjusting for demographics, personality, depressive symptoms, and SCD. Associative memory was the only cognitive marker significantly worse in those who help seek (B=- 0.07, SE=0.03, p=.031); however, it did not withstand adjustment for SCD. Only increased SCD (B=0.06, SE=0.02, p=.005) and educational attainment (B=0.42, SE=0.15, p=.005) had independent associations with HS. Ongoing work is establishing possible moderators of these associations to unravel the multifaceted influences on HS and to guide strategies to increase HS in older adults with SCD.

PATTERNS OF HEAVY ALCOHOL USE AMONG OLDER MARRIED AND COHABITING COUPLES

Angela Curl, Jennifer Bulanda, and Amy Roberts, *Miami University, Oxford, Ohio, United States*

Heavy drinking has increased among older adults in recent years. Research suggests romantic partners influence each other's alcohol use, but this influence may vary by partnership type and relationship quality. Heavy drinkers are more likely to form cohabiting versus marital unions and, relative to marriage, cohabitation is linked with a higher risk of heavy episodic drinking. Although some studies have explored older married couples' alcohol consumption, we lack research on older cohabitors despite the substantial growth in this form of partnership during later life. We use data from the 2014-2018 waves of the Health and Retirement Study to examine drinking behavior among a sample of older married and cohabiting couples (n=1,876) using Actor-Partner Interdependence Models (APIM). Heavy drinking is measured as consuming more than 3 drinks on a given day or 7 drinks per week for women, or 4 drinks on a given day or 14 per week for men (NIAAA, 2021). Compared to first marriages, being in a cohabiting union is associated with significantly higher odds of one (OR=5.22) or both (OR=3.82) partners becoming heavy drinkers over the observation period, but there are no significant differences between those in first marriages and remarriages. Relationship quality is also a significant correlate of heavy drinking risk, with male partners' negative relationship quality and female partners' positive relationship quality associated with a higher risk of heavy drinking over time. Results suggest the importance of accounting for partnership type and relationship quality in understanding partners' drinking behavior.

DEVELOPMENT OF A BEHAVIORAL FRAMEWORK FOR DEMENTIA CARE PARTNERS' FALL RISK MANAGEMENT

Yuanjin Zhou[1], Clara Berridge[2], Nancy Hooyman[2], Tatiana Sadak[2], Tracy Mroz[2], and Elizabeth Phelan[2], *1. University of Texas at Austin, Austin, Texas, United States, 2. University of Washington, Seattle, Washington, United States*

Although older adults living with dementia (OLWD) are at high risk for falls, few strategies that effectively reduce falls among OLWD have been identified. Dementia care partners may have a critical role in fall risk management (FRM). However, little is known in what ways care partners behave that may be relevant to FRM and how to effectively engage them in FRM. Semi-structured, in-depth interviews were conducted with 14 primary care partners (Age: 48-87; 79% women; 50% spouses/partners; 64% college-educated; 21% people of color) of community-dwelling OLWD to ascertain their own behaviors and those of care partners who were secondary in the caring role. The analysis of interview data suggested a novel behavioral framework consisting of eight domains of FRM behaviors adopted across four stages. The domains were 1. functional mobility assistance, 2. assessing and addressing health conditions, 3. health promotion support, 4. safety supervision, 5. modification of the physical environment, 6. receiving, seeking, and coordinating care, 7. learning, and 8. self-adjustment. Four stages of FRM included 1. supporting before dementia onset, 2. preventing falls, 3. preparing to respond to falls, and 4. responding to falls. FRM behaviors varied by the care partners' caring role. Primary care partners engaged in behaviors from all eight domains. Secondary care partners were reported to assist in health promotion support, safety supervision, modification of the physical environment, and receiving, seeking, and coordinating care. This multi-domain and multi-stage framework will inform intervention development to engage care partners in managing fall risk for community-dwelling OLWD.

LONGITUDINAL ASSOCIATIONS OF SOCIAL CONNECTEDNESS, SOCIAL CONTRIBUTION, SOCIAL ENGAGEMENT, AND LATE-LIFE DRUG USE

Atami De Main[1], Daniel Powers[2], and Bo Xie[2], *1. Weill Cornell University, New York City, New York, United States, 2. The University of Texas at Austin, Austin, Texas, United States*

Substance misuse among older adults is a growing and complex problem with implications for society, aging adults, and their families. It is understudied in research and clinical practice. Limited and mixed evidence exists that suggests relationships between changes in older adults' social environment and their drug use over time. This study addressed this gap by examining potential associations between social environment and drug use among community-dwelling older adults. Data were drawn from 3-waves of the national longitudinal survey of Midlife Development in the United States (MIDUS) (N= 2,020; age range=55-94 years; Mean=63.10, SD=5.66 at Wave 1). We estimated multilevel logistic growth models to assess the relationships between social environment indicators (social connectedness, social contribution, social engagement) and drug use, controlling for age, marital status, race/ethnicity, education level, household income, employment status, and number of chronic conditions. Our findings showed significant odds of drug use over the 20-year period of study, which were increased among older adults with multiple chronic conditions with a 59.5% risk of drug-related problems. Social contribution (feelings of being valued by society) negatively predicted older adults' drug use whereas social connectedness and social engagement were not significant predictors over time. The models also indicated a moderating effect of social contribution on drug use, showing low changes in drug use over time with low social contribution. Our findings illuminate the differential roles of social environment indicators in drug use. Future research, policy, and practice may particularly focus on the role of social contribution in late-life drug use.

DEMENTIA CAREGIVERS: THE IMPACT OF SOCIAL DISTANCING ON RELIGIOUS AND SPIRITUAL PRACTICE AND BEHAVIORAL SYMPTOMS

Katherine Britt[1], Kavita Radhakrishnan[2], Liam Fry[2], and Kathy Richards[2], *1. University of Pennsylvania, Austin, Texas, United States, 2. University of Texas at Austin, The, Austin, Texas, United States*

Prevalent among older adults with Alzheimer's disease related dementia (ADRD), behavioral symptoms can cause adverse consequences for those with ADRD and their caregivers. Prompting earlier institutionalization and increased rapid cognitive decline, behavioral disturbances are difficult to manage. Social isolation prompted by the COVID-19 pandemic limited social and religious activities utilized by caregivers and older adults with ADRD for coping and may have affected behavioral symptoms and overall well-being. This qualitative study aimed to explore the impact of the pandemic on behavioral symptoms, religious and spiritual (R/S) utilization for coping, and well-being in caregivers and older adults with ADRD. A purposive sample of 7 home family caregivers and 7 nursing home caregivers (4 indirect family caregivers, 3 nurse practitioners) actively caring for an older adult with ADRD participated in semi-structured telephone interviews. Directed content analysis was used to analyze data. While behavioral symptoms increased overall for older adults with ADRD and social R/S practice abruptly declined, they still utilized individual R/S resources for coping such as prayers, reading religious texts, and holding a prayer book which provided a calming effect, decreased their anxiety, and prompted memories. Caregivers participated in R/S virtual groups which calmed them, connected them with others, helped them transition to sleep, and prompted mindfulness. Resources and interventions utilizing social and individual R/S for coping are warranted as they have the potential to promote cognitive stimulation, connection with others, decrease neuropsychiatric symptoms, and decrease stress.

SESSION 6270 (POSTER)

CARE INTERVENTIONS AND INNOVATIONS

TOILETING AND MOBILITY ASSISTANCE PREFERENCES OF PATIENTS ON AN ACUTE CARE FOR ELDERS (ACE) UNIT

Lucy Wilson[1], Emily Hollingsworth[1], Avantika Shah[2], and Sandra Simmons[1], *1. Vanderbilt University Medical Center, Nashville, Tennessee, United States, 2. Johns Hopkins University, Baltimore, Maryland, United States*

While the Agency for Healthcare Research and Quality (AHRQ) fall prevention guidelines include recommendations for providing consistent toileting and mobility assistance during hospitalization, little is known about hospitalized older adults' preferences for receiving such assistance. The aim of this study was to identify older adults' perceived need and preferences for toileting and mobility assistance during their hospital stay. We interviewed 150 patients aged 50 or older and asked about their perceived need for toileting and mobility assistance and how frequently hospital staff provided it. A total of 75 patients (50%) reported a need for toileting assistance; and, of those who reported a need for assistance, 95% reported that staff provided assistance at a frequency that met their needs. A total of 72 patients (48%) reported a need for mobility assistance; however, an additional 41 patients (27%) had not yet attempted to ambulate at the time of the interview. Across all patients, 100 (67%) reported either no attempt or having ambulated only once during their hospital stay. Most patients who required toileting or mobility assistance stated it was "very" or "extremely important" to receive assistance (82% and 76%, respectively). In summary, approximately one-half of older patients on an ACE unit require toileting and/or mobility assistance. Efforts to provide consistent toileting and mobility assistance during hospitalization could require significant staff time based on the number of patients who need it. Further research is needed to determine how to comprehensively implement AHRQ fall prevention guidelines in the hospital setting for older patients.

4MS AGE-FRIENDLY HEALTHCARE INITIATIVE IMPLEMENTATION ON AN ACUTE CARE FOR ELDERS UNIT

Lucy Wilson, Chelsea Rick, Sarah Welch, Sarah Nelson, Olivia Lawson, Hannah Boren, and Mariu Duggan, *Vanderbilt University Medical Center, Nashville, Tennessee, United States*

Although evidence supports 4Ms [Medication, Mentation, What Matters Most (WMM), Mobility] care for older adults, successful implementation at an academic hospital is not well described. The aim of this study was to describe the implementation methods and process measures for 4Ms delivery on the Acute Care for Elders (ACE) unit at an academic hospital. We used the Institute for Healthcare Improvement's Model for Improvement to guide efforts. We set SMART goals for each M: best possible medication reconciliation, identification of potentially inappropriate medications, and recommendations to deprescribe (medication), delirium screen documented 2x/day and delirium nonpharmacologic protocol in place (mentation), documentation of WMM and care alignment (WMM), Johns Hopkins-Highest Level of Mobility screen assessed during the patient's hospitalization, mobilization of patient 3x/day offered and documented, and restraints avoided (mobility). We mapped current and ideal workflows. We sought community grant funding to expand the implementation team, supporting a nurse educator to train the unit and data analyst to extract real-time data from the electronic medical record to inform improvement processes. Multiple Plan-Do-Study-Act cycles were run iteratively and discussed at weekly team meetings. We included patients >65 years old, admitted for >48 hours, and excluded patients admitted on hospice. Of 519 eligible patients admitted from 04/2021-01/2022, goals were met by 454 (87%) for medication, 187 (36%) for mentation, 130 (25%) for WMM, and 6 (1%) for mobility. We found implementing 4M care processes at an academic hospital to be feasible. Further exploration of barriers to meeting the mobility target is warranted.

ADDRESSING GAPS IN PRIMARY CARE DIAGNOSIS OF COGNITIVE IMPAIRMENT VIA A NURSE CONSULTATION

So Young Shin[1], Nhat Minh Bui[2], Rachel Kiekhofer[2], Collette Goode[2], Sarah Dulaney[2], and Katherine Possin[2], *1. Inje University, Busan, Pusan-jikhalsi, Republic of Korea, 2. Memory and Aging Center University of California, San Francisco, San Francisco, California, United States*

Purpose: This study aimed to identify the concerns and unmet needs of patients and care partners after incident primary care diagnosis of cognitive impairment.

Methods: Primary care providers referred older adults who had newly diagnosed with cognitive impairment for a telephone encounter, the 'Brain Health Consultation' (BHC), with a dementia expert nurse. The nurse assessed for questions or concerns regarding immediate needs, cognitive, neuropsychiatric, functional, or other symptoms; cognitive assessment results and the diagnosis; care planning including safety, prognosis, treatments, advance care planning, and community services.

Results: Patients (N=37) and care partners (N=30) completed the BHC. The patients were racially/ethnically diverse; 51% Asian, 18% Non-Hispanic White, 10% Hispanic, 10% Black, 11% other). Most patients (70%) and caregivers (70%) endorsed cognitive concerns, and many patients endorsed mood (65%), sleep or fatigue (49%), and pain (10%) concerns. All patients and care partners had questions about the assessment results and diagnosis, and some patients (11%) and caregivers (13%) expressed concerns about disease progression. Few patients and caregivers expressed care planning needs.

Conclusion: Following incident cognitive impairment diagnosis in primary care, patients and families have unmet needs around understanding their assessment and diagnosis. Care planning may be reserved for a follow-up consultation after the patient and family have had time to understand and accept the diagnosis. While we used a dementia expert nurse to perform the BHC, given the types of concerns identified, a supervised, trained, unlicensed health professional (e.g., a care team navigator) may be appropriate to perform the BHC.

A VIRTUAL STAFF TRAINING TO IMPROVE COMMUNICATION FOR OLDER ADULTS DURING MASK WEARING

Sara Mamo, Katherine Garrity, and Kara Wheeler, *University of Massachusetts Amherst, Amherst, Massachusetts, United States*

The need for masking protocols in care centers for older adults exacerbated communication challenges in an already difficult environment. The purpose of this study was to alleviate the burden of communicating while wearing masks by providing a virtual staff training that introduced a headset amplifier and communication tips. The training was delivered via Zoom to small groups of staff at three Programs for All-inclusive Care for the Elderly (PACE®) organizations. The training included education about the impact of age-related hearing loss, instructions for using a headset amplifier, and communication tips. Staff were encouraged to use the amplifier with as many participants as possible to ease communication while wearing masks—rather than targeting participants based on hearing status. A pre/post quasi-experimental approach was undertaken. Fifty-one staff members completed the training and immediate pre/post questionnaires to measure knowledge gain. Follow-up questionnaires (including open-ended responses) were collected at 2- (n = 29), 4- (n = 23), and 6-months (n = 23) post-training. In addition, we completed one focus group (n = 5) and one in-depth interview regarding the feasibility of participation in the research project and brainstorming to increase use of the amplifiers. By integrating quantitative and qualitative findings, we highlight communication improvements when using the amplifiers and tips for integrating amplifiers into group care programs. The findings from this study will contribute to the development of a large-scale intervention to address hearing loss and support communication for older adults in group care settings.

SIGNIFICANCE OF SECOND YEAR MEDICAL STUDENTS PARTICIPATING IN THE 48-HOUR HOSPICE HOME IMMERSION PROJECT, 2017–2018

Samuel Hanlon, Benjamin Packard, and Marilyn Gugliucci, *University of New England College of Osteopathic Medicine, Biddeford, Maine, United States*

Medical education on palliative medicine and end-of-life care is generally lacking in the medical curricula. The University of New England College of Osteopathic Medicine (UNECOM) Learning by Living: 48 Hour Hospice Home Immersion Project is an immersion-based learning model whereby UNECOM 2nd year students live in an18-bed acute care hospice house to care for dying patients, provide family support, and conduct post-mortem care. This project determined if and in what ways immersion experiences were valuable in augmenting student medical end-of-life care education during AY 2017-2018.Retrospective ethnographic/

autobiographic data were analyzed from the eight randomly selected student hospice immersion journals (approx. 200 pages) who participated during academic year 2017-18. Pre-fieldwork, fieldwork, post-fieldwork journals were reviewed and analyzed using manual content analysis followed by NVivo 12+ analysis. Thematic coding resulted in representative quotes, key words, and native concepts. Inter-rater reliability was established with the use of a codebook and agreed upon thematic definitions. Four key themes included: Subversion of End of life (EOL) Expectations; Character Development/Introspection; Exposure to Diverse Cultural/Spiritual Perspectives; and Skills to Bring into Future Practice. Proximity to death/dying resulted in reflections on values and priorities, and a renewed sense for compassionate patient care. Students developed skills for future practice, including competency in EOL and post-mortem care, navigating difficult, emotionally laden family dynamics, and contributing to an interprofessional staff team even in uncomfortable situations. This immersion positively affected student perspectives about death and end-of-life care; creating life-altering experiences in patient-centered-care. Students stated significant impacts to employ as a physician.

AN INNOVATIVE APPROACH TO ENHANCING COPD CARE AND MANAGEMENT IN A RURAL NORTHERN COMMUNITY

Shannon Freeman[1], Anthon Meyer[2], Kelly Skinner[3], and Laura Peach[3], *1. University of Northern British Columbia, Prince George, British Columbia, Canada, 2. Northern Health Authority, Prince George, British Columbia, Canada, 3. University of Waterloo, Waterloo, Ontario, Canada*

Background: COPD is the third leading cause of death worldwide. Rural communities often face challenges to provide high quality chronic disease care for aging populations. Despite these longstanding challenges, there was an intention to improve the care setting by developing and fostering a shared vision for quality care, as evidenced by enhancing COPD screening and care. To ensure consistent and longitudinal patient access to high quality of care as well and ongoing physician recruitment and retention a new rural program was developed. Objective-In this presentation we will describe a new rural community based COPD program from conceptualization and development through to current functioning highlighting areas of innovation. Methods-A process evaluation guided by Moore et al.'s framework to assess program implementation, mechanisms of impact, and context was conducted. Qualitative thematic analysis was undertaken of stakeholder interviews conducted in 2021 (n=11) and document review (n=60;~500 pages) of key clinic documents dated back to pre-program development.

Results: We describe five phases of program development: Survive; Reorganize and Stabilize; Assess and Respond; Build and Refine; and Sustain and Share. Outreach and localizing resources improved access to the program. Acquiring secured physician compensation, capturing quality data, and improving patient and provider self-efficacy built the capacity of the system and stakeholders within it. Finally, relationships were forged through building an integrated facility, collaborative networking, and patient engagement. The key elements of program implementation were the resources required to ensure its operation, categorized as hardware, software, organizational, and human.

EVALUATING IMPLEMENTATION FIDELITY TO A NURSE-LED CARE MODEL IN NURSING HOMES: A MIXED-METHODS STUDY

Raphaelle Ashley Guerbaai[1], Sabina De Geest[2], Michael Simon[1], Lori Popejoy[3], Nathalie Wellens[4], Kris Denhaerynck[1], and Franziska Zúñiga[5], *1. The Institute of Nursing Science, Basel, Basel-Stadt, Switzerland, 2. Institute of Nursing Science, Basel, Basel-Stadt, Switzerland, 3. University of Missouri, Columbia, Missouri, United States, 4. Haute Ecole La Source, Lausanne, Vaud, Switzerland, 5. University of Basel, Basel, Basel-Stadt, Switzerland*

Implementation fidelity assesses the degree to which an intervention is delivered as intended. Little is known about how it acts as a moderator between an intervention and its intended outcome(s) and which factors affect the fidelity trajectory over time. We exemplify implementation fidelity in INTERCARE, a nurse-led care model implemented in eleven Swiss nursing homes (NH) successfully decreasing unplanned hospital transfers. A mixed-methods design was used, guided by the Conceptual Framework for Implementation Fidelity. Fidelity to INTERCARE's core components was measured with 44 self-developed items at 4-time points (baseline, 6, 12 months after intervention start, 9 months post-intervention; fidelity scores were calculated for each component and overall. Structured notes from NH meetings were used to identify moderators affecting the fidelity trajectory over time. Generalized linear mixed models were computed to analyze the quantitative data. Deductive thematic analysis was used for the qualitative analysis. The quantitative and qualitative findings were integrated using triangulation. A higher overall fidelity score showed a decreasing rate of unplanned hospital transfers (OR: 0.65 (CI=0.43-0.99), $p=0.047$). Higher fidelity score to advance care planning was associated with lower unplanned transfers (OR= 0.24 (CI 0.13-0.44), $p= < 0.001$) and a lower fidelity score for communication tools (e.g., ISBAR) to higher rates in unplanned transfers (OR= 1.69 (CI 1.30-2.19), $p= < 0.003$). High implementation fidelity to INTERCARE was necessary to achieve a reduction in unplanned transfers. In-house physicians with a collaborative approach and staff's perceived need for nurses working in extended roles were important factors for high fidelity.

AN INTERPROFESSIONAL APPROACH TO DEPRESCRIBING: A CURRICULAR FRAMEWORK

Winnie Sun[1], Cheryl Sadowski[2], and Barb Farrell[3], *1. Ontario Tech University, Lindsay, Ontario, Canada, 2. University of Alberta, Edmonton, Alberta, Canada, 3. Bruyere Continuing Care, Ottawa, Ontario, Canada*

Deprescribing is an important approach for managing polypharmacy and reducing harm from potentially inappropriate medications. Healthcare professionals identify barriers to deprescribing, including lack of knowledge and skill. This is not surprising as pre-licensure education does not consistently incorporate components of deprescribing into curricula. As such, there is a clear need to consider how to promote deprescribing competencies, teach related knowledge and skills and assess learning outcomes. The Canadian Deprescribing Network (CaDeN) Health Care Professional Committee undertook a consensus process to develop a proposed competency framework that describes essential knowledge, teaching strategies, and assessment protocols to promote deprescribing skills and advocate for consistent education about deprescribing principles and practices. The framework is informed by the deprescribing process, which includes gathering and interpreting patients' medication history and clinical information within their context, using tools that help identify potentially inappropriate medications, weighing potential benefit and harm of continuing or deprescribing medications, using shared decision-making to make decisions about deprescribing, communicating deprescribing and monitoring plans, and monitoring progress and outcomes. The competency framework considers interprofessional learning and how to involve patients and care partners in deprescribing decisions. Integrating deprescribing competencies in healthcare curricula requires an intentional and structured approach across all years of the program, focusing on interprofessional collaboration. Learning activities should be active and practical, progressing from early to advanced learner skills and include integration of deprescribing during experiential education. This framework includes a review of the competencies, learning outcomes, and assessment strategies, with a discussion of strategies to incorporate interprofessional learning activities.

CONSIDERATIONS OF AGE-FRIENDLY 4M PRINCIPLES IN DEPRESCRIBING INTERVENTIONS: A SCOPING REVIEW

Jinjiao Wang[1], Jenny Shen[2], Yeates Conwell[2], Kobi Nathan[3], Fang Yu[4], Erika Ramsdale[2], Donna Fick[5], and Sandra Simmons[6], *1. University of Rochester School of Nursing, Rochester, New York, United States, 2. University of Rochester Medical Center, Rochester, New York, United States, 3. St. John Fisher College, Rochester, New York, United States, 4. Arizona State University, Phoenix, Arizona, United States, 5. Penn State University, University Park, Pennsylvania, United States, 6. Vanderbilt University Medical Center, Nashville, Tennessee, United States*

The 4Ms – Medication, Mentation, Mobility, and What Matters - represent the key components in the Age-Friendly Health Systems initiative and provide a conceptual framework for research in the older adult population. Over 40% of older adults experience polypharmacy, which can be addressed by deprescribing unnecessary medications. This review aimed to assess the degree to which the 4Ms were considered in intervention design, sample selection, and outcome assessment in deprescribing trials by keyword search in six databases and snowballing. Thirty-seven of the 564 trials identified met the review eligibility criteria. Imbalanced consideration of 4Ms in the deprescribing trials was observed. Intervention design: "Medication" was considered in all trials; "Mentation" was considered in 8 trials; "Mobility" (n=2) and "What Matters" (n=6) was less often considered. By targeting providers, most of the trials lacked consideration of patient-centeredness - aligning what matters most to older adults and their families with deprescribing decision making and implementation. Sample selection: "Medication" was considered in 15 trials (e.g., samples including patients taking ≥ 5 medications or specific types of medications), whereas "Mentation" (n=6), "Mobility" (n=6) and "What Matters" (n=0) were less often considered. Outcome assessment: "Medication" was the most commonly assessed outcomes (n=33), followed by "Mobility" (n=13) and "Mentation" (n=10) outcomes, with no study examining "What Matters" outcomes. 4Ms were not purposefully considered in the intervention design, sample selection, and outcome measurement of existing deprescribing trials. Future deprescribing trials need a more balanced and complete consideration of the 4Ms in the trial design and implementation.

HIGH-RISK ELDERLY SCREENING IN MEDICAL INTENSIVE CARE UNIT

Gowrishankar Gnanasekaran[1], and Narendrakumar Alappan[2], *1. Cleveland Clinic Foundation, Cleveland, Ohio, United States, 2. Fairview Hospital, Cleveland Clinic, Cleveland, Ohio, United States*

Geriatrics care in medical intensive care units (MICU) establishes a unique opportunity in early screening of High Risk Elderly (HRE) patients admitted for critical care. Many MICUs do not have a standard protocol to screen for HRE patients as part of their daily huddle. Our program is a quality improvement initiative to improve early identification of HRE patients in the MICU. HRE patients were identified based on nursing specific screening triggers at one of the Regional Hospitals of a large teaching hospital in Northeast Ohio.The program was designed as a part of geriatrics care expansion at regional hospital sites. Identified patients were discussed in daily huddles to determine unique geriatric needs in caring for these patients. A geriatrics co-management team was engaged in comprehensive geriatric assessments and care transition when it was needed. Geriatrics care in MICU demonstrates a unique opportunity in early identification of HRE patients. This helps to support a patient -centered approach in caring for critically ill elderly patients. The program would lay foundations in early screening for risk factors and optimizing elderly care in MICU.

RESULTS OF A PILOT IMPLEMENTATION OF AN ADL GUIDELINE FOR NURSING PROFESSIONALS IN THE NETHERLANDS

Svenja Cremer[1], Michel Bleijlevens[1], Silke Metzelthin[1], Janneke de Man-van Ginkel[2], and Sandra Zwakhalen[1], *1. Maastricht University, Maastricht, Limburg, Netherlands, 2. Julius Center for Health Sciences and Primary Care, Utrecht, Utrecht, Netherlands*

Nursing care in activities of daily living (ADL), such as washing, dressing, or eating is frequently provided while being poorly informed by scientific evidence. To address nursing professionals' need for guidance we developed a practice guideline on ADL-care. This guideline comprises eleven core recommendations on involving care receivers and informal caregivers in ADL-care, identifying ADL-care needs, and effective ADL-interventions. Since the success of this guideline hinges on its actual use by nursing professionals, we assessed the use and determined influencing factors to guide targeted strategies for future implementation in different nursing care settings. In a mixed-method study, nursing professionals documented the number of core recommendations applied over three weeks using recording forms and a self-administered questionnaire to identify barriers and facilitators. In addition, we conducted focus groups to capture team experiences in applying the 11 core recommendations and clarifying survey results. Seven nursing care teams participated from various settings: hospital (n=1), rehabilitation (n=2), home-care (n=1), and long-term care (n=3). Preliminary results reveal that participants consider the core recommendations compatible with and adaptable to current practices, and their care settings. Participants experienced advantages over existing practices. However, core-recommendation usage and perception of influencing factors appeared to be highly context-dependent, especially regarding the involvement of informal caregivers in ADL-care. Limited knowledge on the application of interventions to improve ADL limited the use of some recommendations. Our results underline the necessity of careful selection of targeted strategies for each setting tailoring the core recommendations to the different qualifications and roles of nursing professionals.

DEVELOPMENT OF A HOPE-BASED HEALTH PROMOTION PROGRAM TO IMPROVE HEALTH BEHAVIORS AMONG DIVERSE OLDER ADULTS

Britteny Howell[1], Amber Worthington[2], and Leslie Redmond[3], *1. University of Alaska Anchorage, Anchorage, Alaska, United States, 2. UNIVERSITY OF ALASKA ANCHORAGE, Anchorage, Alaska, United States, 3. University of Manitoba, Anchorage, Alaska, United States*

Studies have shown that health education can improve dietary intake, exercise, and energy balance, which improves health outcomes and quality of life. However, diverse low-income older adults may have low self-efficacy coupled with potentially negative opinions regarding the aging process. Emerging research suggests that asset-based approaches utilizing persuasive and hopeful messages may be particularly effective with diverse populations of older adults who may be struggling with negative perceptions of self-efficacy. Research also shows that health behavior change interventions are most likely to be successful among diverse populations when they incorporate messages of resilience and facilitate information sharing and diffusion among participants. This presentation outlines the program curriculum development process of a student-led health promotion program by an interdisciplinary team of university researchers. Public health, dietetics, and communication faculty utilized Persuasive Hope Theory (PHT) and Self-Efficacy Theory to create a 15-week program to improve fruit and vegetable intake and physical activity among low-income adults aged 55+ living in Anchorage, Alaska. We will also detail the curricular components for this NIA-funded program which will be delivered in Fall 2022.

A DEDICATED APPROACH TO PALLIATIVE DEMENTIA CARE

Judith Meijers[1], Sascha Bolt[2], Sandra Zwakhalen[1], Chandni Khemai[1], Jos Schols[1], Daisy Janssen[1], Jenny van der Steen[3], and Jesper Biesmans[4], *1. Maastricht University, Maastricht, Limburg, Netherlands, 2. Tilburg University, Tilburg, Noord-Brabant, Netherlands, 3. Leiden University Medical Center, Leiden, Zuid-Holland, Netherlands, 4. Zuyderland, Zuyderland, Limburg, Netherlands*

Nursing staff play a central role in the palliative care for people with dementia. Development of their palliative care competences may support timely recognition and addressing of individual needs of persons with dementia and their family caregivers in long term care. In the DEDICATED (Desired Dementia Care Towards End of Life) project, we aim to develop materials to support nursing staff in providing palliative dementia care. The first step of the project concerned a needs assessment, mapping the perspectives of nursing staff, family caregivers and people with dementia (scoping review, surveys and semi-structured interviews). Using these studies' results as a starting point, an intervention (the DEDICATED approach) was built, using an iterative co-creation approach involving nursing staff and educators (N=12). These 'ambassadors' were also trained to disseminate the approach within their care teams and nursing curricula. First reactions from the pilot study regarding the DEDICATED-materials are positive and nurses and nurse educators are eager to use the materials (www.dedicatedwerkwijze.nl). Currently the DEDICATED-approach is being evaluated using a mixed methods pretest-posttest controlled design comparing three groups: a design group (12 wards), a test group (28 wards, 28 new-trained ambassadors) and a control group (12 wards). The main outcomes of study are e.g. self-efficacy, empowerment and engagement in providing palliative care for people with dementia. A secondary outcome involves longitudinal trends of the quality of dying of persons with dementia within the group.

ASSESSING INTERPROFESSIONAL ORAL HEALTH EDUCATION AND PRACTICE FACILITATION OUTCOMES WITHIN LONG-TERM CARE

Jennifer Crittenden[1], Rachel Coleman[2], David Wihry[3], Labrini Nelligan[4], and Denise O'Connell[4], *1. UMaine Center on Aging, Bangor, Maine, United States, 2. University of Maine, Bangor, Maine, United States, 3. University of Maine, Orono, Maine, United States, 4. Lunder-Dineen Health Education Alliance of Maine, Bangor, Maine, United States*

Older adults residing in long-term care (LTC) settings are at an increased risk of poor oral health due to comorbidities and limited ability to provide self-care. Routine oral care is essential for maintaining overall health. Coupled with resident vulnerability is a traditional lack of training and focus on oral health care in LTC. MOTIVATE (Maine's Oral Team-Based Initiative: Vital Access to Education) is a pilot (N = 8 sites) interprofessional education program focused on daily oral health care within LTC, providing education and technical assistance to advance staff knowledge, skills, and attitudes about oral health. An evaluation was carried out using a pre/post survey design with instruments administered immediately before and after learning module completion along with a survey administered one month after implementation. Knowledge, attitudes, and oral health practices were assessed. A statistical comparison between baseline (N = 491) and post-launch (N = 215) scores revealed a statistically significant improvement ($p < 0.001$) across all knowledge and attitudes measures including the perceived importance of oral health, understanding of interprofessional roles among the care team, the role of oral health in supporting resident dignity and quality of life, and confidence in providing oral health care. Factors facilitating the transfer of knowledge to practice (N = 478) included personal interest in the topic (46.4%), knowing where to obtain information when needed (47.6%), and knowing how to apply learning to LTC daily care responsibilities (62.4%). Findings underscore the importance of oral health training and implications for practice transformation in an interprofessional context.

EFFECTS OF SPECIAL NURSING UNITS IN NURSING HOMES: FOCUSING ON HEALTH OUTCOMES AND SATISFACTION

Eunhee Cho, YeaSeul Yoon, Seonhwa Choi, and Eunkyo Kim, *Yonsei University, Seoul, Seoul-t'ukpyolsi, Republic of Korea*

This quasi-experimental study aimed to evaluate the effectiveness of special nursing units in nursing homes by comparing health outcomes and satisfaction between the general nursing units and special nursing units across nursing homes in South Korea. Surveys—paper, phone, and online—were conducted five times (March, August, and November 2019; June and October 2020) for health outcomes (health pattern changes and the number of residents with new health problems) and four times (March and August–November 2019; June and October 2020) for satisfaction. Descriptive analysis, χ^2-test, paired t-test, and McNemar test were performed using the SPSS 25.0 program. The results showed an improvement in the health outcomes of residents in the special nursing units. Regarding health pattern changes, there was a decrease in the number of residents facing problems related to consciousness, cardiovascular function, urination, defecation, and pain and of those with new health problems such as aches, falls, pressure sores, and urinary incontinence. Furthermore, caregivers' satisfaction in the special nursing units was higher than that of their counterparts in the general nursing units. The results of this study will be used as evidence to expand this special nursing unit's services in the future.

HEALTHCARE AIDE-FOCUSED INTERVENTIONS TO IMPROVE PAIN MANAGEMENT IN LONG-TERM CARE

Jennifer Knopp-Sihota[1], Megan Nuspl[2], Tara MacGregor[2], Jennifer Reeves[2], and Ahsan Saleem[2], *1. Athabasca University, Edmonton, Alberta, Canada, 2. University of Alberta, Edmonton, Alberta, Canada*

Pain is endemic for residents of long-term care homes, with many residents experiencing pain daily. Given that healthcare aides provide most daily care for residents, they are ideally situated to deliver timely assessment and non-drug interventions for managing resident pain. In this Cochrane-style systematic review, we searched 7 databases to identify intervention studies that included long-term care residents aged ≥60 years who received interventions to reduce chronic pain. Interventions were either delivered by healthcare aides at the resident level or were directed at healthcare aides to improve their pain management practices. We screened 400 titles/abstracts and 152 full-text articles. Nine studies met inclusion criteria and were included in a narrative review. Due to the limited number of studies and variety of study designs, data were insufficient to perform meta-analyses or thematic analysis. Three studies described pain interventions delivered by healthcare aides at the resident level reporting significant improvement of pain. Six studies described pain interventions delivered to healthcare aides. Results of these interventions were inconsistent; 2 reported significant improvements in pain-related outcomes (e.g., resident pain, monitoring of pain), 3 reported insignificant changes, and 1 reported a positive correlation between measured pain and pain medication use. We concluded that despite the paucity of research in this area, this systematic review provides preliminary support for pain interventions by healthcare aides for long-term care residents. Future research exploring interventions for healthcare aides to take greater roles in pain management could unlock further improvements in resident care.

DELIVERING FOOD RESOURCES AND KITCHEN SKILLS TO OLDER ADULTS WITH FOOD INSECURITY AND HYPERTENSION

Rebecca Rivera[1], Richard Holden[2], Mariah Adams[3], Emily Dawkins[3], Wanzhu Tu[1], and Daniel Clark[1], *1. Indiana University School of Medicine, Indianapolis, Indiana, United States, 2. Indiana University School of Public Health, Indianapolis, Indiana, United States, 3. Eskenazi Health, Indianapolis, Indiana, United States*

Non-Hispanic Black adults experience higher rates of food insecurity, poor diet quality, and hypertension compared with their non-Hispanic White counterparts. Delivering Food Resources and Kitchen Skills (FoRKS) is an integrated intervention that concurrently addresses food insecurity, nutrition literacy, and chronic disease self-management among older patients at a Federally Qualified Health Center. Two clinical dietitians led virtual hypertension self-management, cooking skills, and nutrition education classes twice per week for 16 weeks. Participants registered for classes, ordered free meal ingredients, and received encouragement from the dietitians through the FoRKS mobile technology application. This study presents diet quality descriptive results from the FoRKS pilot intervention conducted at Eskenazi Health from September 2021 to January 2022 in Indianapolis, Indiana. Participants (n=13) with hypertension (systolic blood pressure ≥120 mm Hg) and who identified as food insecure per the 18-item US Household Food Security Survey Module completed the 2018-version of the National Cancer Institute's Automated Self-Administered 24-hour (ASA24) Dietary Assessment Tool at baseline and post-intervention assessments. Healthy Eating Index (HEI)-2015 scores range from 0-100 and were calculated from ASA24 data. Participants were non-Hispanic Black (n=12) or non-Hispanic White (n=1) with mean age 58 years (range 53-65 years). Mean±SD HEI-2015 scores improved from 51.5±11.9 at baseline to 55.2±12.5 after the intervention. This preliminary data supports further investigation into the efficacy of integrated lifestyle interventions, i.e., FoRKS, using a randomized controlled study design. Addressing food and culinary skills can lead to improvements in diet quality that may translate to improved disease management among diverse older adults.

PATIENTS' SPIRITUAL CONCERNS AND NEEDS DURING GOALS OF CARE CONVERSATIONS: HEALTHCARE CHAPLAINS' PERSPECTIVES

Jung Kwak[1], Shilpa Rajagopal[2], Neha Dronamraju[1], George Handzo[3], and Brian Hughes[3], *1. The University of Texas at Austin, Austin, Texas, United States, 2. Project*

Horseshoe Farm, Pomona, California, United States, 3. HealthCare Chaplaincy Network, New York, New York, United States

Healthcare chaplains are critical members of interdisciplinary healthcare teams and routinely facilitate advance care planning (ACP) and goals of care conversations with patients with serious illnesses. These conversations involve discussion of one's deeply held personal values and beliefs as well as uncertainty, fears, and hopes for current and future health care needs. However, there is limited empirical data on how patients' spiritual concerns and needs are addressed during these conversations. An online survey of 563 board-certified chaplains was conducted from March to July 2020 to identify chaplains' roles in facilitating goals of care conversations and included three open-ended questions about patients' hopes and fears and how chaplains addressed them. Quantitative data and written qualitative responses from 244 chaplains were analyzed using descriptive analysis and content analysis, respectively. Majority of participants were white (83.6%), female (59%), Protestant (63.1%), employed full-time (82%), and worked in community hospital settings (45.5%) or academic medical centers (32.8%). Six major themes emerged from chaplains' qualitative responses: (1) the utility of ACP; (2) focus on the present moment; (3) achieving a personally defined "good death"; (4) spiritual and religious matters and beliefs; (5) caring for and connection with family; and (6) how to address hopes and fears during ACP. ACP and goals of care conversations reflect profound human desires and needs; they require deeper listening and engagement by interdisciplinary team members to provide adequate spiritual and psychosocial support in addition to providing medical information to fulfill the intended meaning and purpose of ACP.

HEALTH SYSTEM IMPLEMENTATION, SCALING, AND IMPACT OF THE 4MS FRAMEWORK TO ADVANCE AGE-FRIENDLY CARE

Julia Adler-Milstein, Courtney Lyles, and Stephanie Rogers, *University of California, San Francisco, San Francisco, California, United State*

There is a critical need to redesign the healthcare system to provide more effective and tailored care to older adults. The 4Ms Framework (What Matters, Medication, Mentation and Mobility) offers a blueprint to guide health system efforts to deliver more age-friendly care. We sought to characterize and assess real-world implementation experiences with the 4Ms in three health systems (University of California, San Francisco, University of Utah, & Anne Arundel Medical Center). Specifically, we conducted semi-structured interviews (N=29) with diverse stakeholders from each site to characterize the approach to operationalize the framework and assess the implementation experience. Via cross-site content analysis of interview transcripts, we identified four themes. First, the 4Ms offer a compelling conceptual framework around which to organize health system efforts to advance age-friendly care, but each "M" required distinct, complex implementation work that resulted in a fragmented implementation experience. Second and relatedly, inpatient and ambulatory efforts to implement the 4Ms became disconnected, with missed opportunities for synergies and gave little attention to the 4Ms during care transitions. Third, non-physician leadership was key to initiating 4Ms implementation efforts, but obtaining physician buy-in, which often came later, was essential to full implementation. Fourth, sustained 4Ms implementation efforts required both top-down vision and communication from leadership as well as bottom-up culture change that engaged and motivated frontline workers. As efforts to spread the 4Ms Framework advance, these results offer important implementation guidance and also suggest domains in which the Framework may need to be adapted to accommodate real-world implementation experiences.

NURSE PRACTITIONER–LED IMPLEMENTATION OF HUDDLES TO SUPPORT STAFF IN LONG-TERM CARE HOMES

Katherine McGilton[1], Alexandra Krassikova[2], Aria Wills[3], Margaret Keatings[3], Jennifer Bethell[3], Veronique Boscart[4], and Souraya Sidani[5], *1. KITE Research Institute: Toronto Rehabilitation Institute-UHN, Toronto, Ontario, Canada, 2. Toronto Rehabilitation Institute, University Health Network, Thornhill, Ontario, Canada, 3. Toronto Rehabilitation Institute, Toronto, Ontario, Canada, 4. Conestoga, Kitchener, Ontario, Canada, 5. Ryerson University, Toronto, Ontario, Canada*

Staff working in long-term care (LTC) homes frequently report experiencing moral distress related to lack of autonomy and not being able to provide quality care. Huddles have been used as a communication tool for many years in acute care settings to improve collaboration and safety culture. In LTC homes, huddles are implemented less often, despite evidence of their benefits in improving support and teamwork. In this pre-test post-test implementation study, huddles led by a nurse practitioner (NP) were introduced in a privately-owned not-for-profit LTC home with < 150 beds, located in a medium urban centre in Ontario, Canada. Objectives of the study were to 1) examine fidelity of huddle implementation; 2) examine the extent to which the huddles improved staff' outcomes of moral distress, job satisfaction, and support provided by the NP estimated with Bayesian proportional odds model. A total of 48 huddles were carried out by the NP over 15 weeks. Huddles were most commonly attended by personal support workers (98%) and registered practical nurses (96%), with an average of 7 individuals per huddle. Topics most often addressed at huddles were related to resident care (46%) and staff concerns (34%). Strong statistical evidence of a reduction in overall moral distress was evident for staff attending the huddles, when compared to staff who did not (posterior probability =.9933). No changes in job satisfaction and support provided by the NP were observed. Introducing huddles in LTC homes may be effective at reducing moral distress experienced by staff.

SESSION 6280 (POSTER)

CAREGIVING AND SOCIAL SUPPORTS

WHAT MATTERS TO OLDER SURGICAL PATIENTS AND THEIR CARERS DURING THEIR HOSPITALIZATION?

Janani Thillainadesan[1], Helen Box[2], Leanne Kearney[2], Vasi Naganathan[2], Michelle Cunich[3], Sarah Aitken[2], and Sue Monaro[2], *1. Department of Geriatric Medicine and*

Centre for Education and Research on Ageing (CERA), Concord Hospital, Concord, New South Wales, Australia, 2. Concord Hospital, Concord, New South Wales, Australia, 3. University of Sydney, Sydney, New South Wales, Australia

Older adults account for a growing proportion of the surgical population. We investigated patient- and carer-reported experiences of hospitalization in this group. A mixed-methods study using telephone and postal surveys of recently hospitalized vascular surgical patients aged ≥ 65 years at an acute care academic hospital. Qualitative data were thematically analyzed using a framework approach. In total 46 patients (mean age 77 years, 78% male) and nine carers were surveyed. Nine (20%) patients were frail (Clinical Frailty Scale score >4). The majority of patients reported overall they felt their views were listened to (n=42, 89%), were kept informed (n=39, 83%) and were asked about their pain level (n=37, 79%). Among the nine carers, seven reported overall they felt their views were listened to (n=42, 89%) and were kept informed (n=39, 83%). Thematic analysis of responses to open-ended survey questions about their experience of hospitalization revealed four key themes: receiving fundamental care including hygiene and nutrition, importance of the hospital environment such as sleep and meals, being informed and involved in health care decision-making, and treating pain and deconditioning to help recovery. Findings from this study identified that older adults admitted to hospital for surgical care, and their carers, highly value care that meets fundamental needs and involves them in decision-making and recovery. These priorities can be addressed through Age-Friendly Health System initiatives such as the implementation of the "4Ms" of geriatrics care: what matters, medication, mobility and mentation.

A SUCCESSFUL EDUCATIONAL INTERVENTION LINKING DEMENTIA PATIENTS AND FAMILIES WITH COMMUNITY RESOURCES

Stacy Barnes[1], Edmund Duthie[2], Kathryn Denson[2], Jennifer McAlister[3], Wendy Betley[3], Amanda Szymkowski[2], Michael Malone[4], and Deborah Simpson[4], *1. Marquette University, Milwaukee, Wisconsin, United States, 2. Medical College of Wisconsin, Milwaukee, Wisconsin, United States, 3. Alzheimer's Association Wisconsin, Milwaukee, Wisconsin, United States, 4. Advocate Aurora Health, Milwaukee, Wisconsin, United States*

Unpaid caregivers provided approximately 83% of the care for the 6.2 million Americans aged 65+ who were living with Alzheimer's dementia in 2021. Physicians and other health professionals are not well informed about dementia-related community resources and rarely refer patients/families despite strong evidence which supports incorporating community services as part of an ongoing treatment plan. To bridge this gap, partnership with community agencies is essential. The Alzheimer's Association's "Direct Connect" referral program is provider-initiated and connects patients/families with disease information, care consultations, support groups, a 24/7 Helpline, and other resources. As part of the Wisconsin Geriatric Workforce Enhancement Program award from HRSA (U1QHP28712) 1,023 health professionals working in Wisconsin hospitals and primary care clinics were trained to use Direct Connect. Our educational intervention re-framed dementia from a hopeless disease to a chronic condition requiring supportive services as a necessary component of the disease management plan. Results of a paired-samples t-test (n=675) indicated our educational intervention had a significant impact on trainees' self-reported pre/post-test knowledge in both hospitals [t(444) = -34.67, p < 0.001, d = 1.64] and primary care [t(229) = -24.63, p < 0.001, d = 1.62]. By the end of the 5-year project period, Direct Connect referrals totaled 1,352 and the program grew from less than 50 referrals to 290 annually. While these results are promising, Direct Connect remains underutilized and initiatives to further increase referrals from providers must be expanded.

STRONGER MEMORY: EXPERIENCES OF OLDER ADULTS AND CAREGIVERS IN AN INTERVENTION PROGRAM FOR COGNITIVE PERFORMANCE

Hyun Kang[1], Catherine Tompkins[1], Kendall Barrett[1], Francesca Keesee[1], Catherine Magee[1], Mckenzie Lauber[1], Emily Ihara[1], and Jessica Fredericksen[2], *1. George Mason University, Fairfax, Virginia, United States, 2. Goodwin House Incorporated, Alexandria, Virginia, United States*

Subjective cognitive decline (SCD), defined as self-reported memory issues that have worsened over the past year, can be one of the first indications of Alzheimer's disease and related dementias. SCD affects nearly 9% of Virginians aged 45 or older, and 31% of these individuals live alone. A practice-based intervention is essential to addressing the challenges associated with cognitive impairment. This study examined the effect of StrongerMemory program, which involves a series of cognitive exercises. The StrongerMemory program provides a 12-week curriculum designed to stimulate the brain's prefrontal cortex, which governs the ability to retrieve memories. Participants are encouraged to spend 20 to 30 minutes a day reading aloud, writing or journaling and completing simple math problems. The Mason Gerontology Research Team investigated the pre- and post-cognitive outcomes among 43 participants who participated in the StrongerMemory program to determine the effectiveness of the program. The cognitive outcomes were evaluated using the Mini Montreal Cognitive Assessment 2.1 (Mini MoCA). The mean (SD) scores in Mini MoCA evaluated in the participants were 12.60 ± 2.1 (pre-test) and 13.53 ± 1.9 (post-test). The mean difference was statistically significant. Our results indicate that the StrongerMemory program is beneficial for cognition. The premise around the StrongerMemory program is that prior to a diagnosis or even with a diagnosis of mild cognitive impairment, a decline can be slowed and possibly prevented by participating in a program like StrongerMemory. The Mason Gerontology Research Team continues to evaluate the StrongerMemory program to examine its impact on SCD.

PSYCHONEUROLOGICAL SYMPTOMS IN CANCER SURVIVORS AND THEIR CAREGIVERS: A LONGITUDINAL PILOT STUDY

Kristin Litzelman, Jen Stevens, Ashley Berghoff, Afnan Balubaid, and Kristine Kwekkeboom, *University of Wisconsin-Madison, Madison, Wisconsin, United States*

In cancer patients, stress is associated with a psychoneurologic symptom cluster of depressed mood, anxiety, pain, fatigue, and sleep disturbance. The stress of caregiving may trigger similar symptoms among caregivers and warrants investigation. The purpose of this analysis was to characterize correlates of psychoneurologic symptoms in cancer caregivers. Cancer survivor-caregiver dyads (n=29) provided eight weekly symptom reports using a web-based assessment system. Symptom burden was calculated as the sum of symptom severity (mean=7.5, SD=8.1, range=0-41). Primary and secondary stressors of caregiving were also assessed. Mixed modeling was used, accounting for repeated measures. Models controlled for person-mean of time varying covariates, as well as sociodemographic, clinical, and care-related covariates. A secondary analysis assessed interdependence in survivor and caregiver symptoms using Actor-Partner Interdependence Models. In descriptive analyses, caregivers most frequently reported feeling anxious (44% on average across timepoints), sleep problems (31%), fatigue (25%), depressed mood (24%), and feeling irritable/angry (24%). Within caregivers, greater hours of care (beta=0.11, p<.01) and more patient symptoms (beta=0.10, p<.01) were associated with greater symptom burden. Between caregivers, higher baseline perceived stress was associated with greater symptom burden (beta=0.38, p=.04) and coresidence with the survivor was associated with lower symptom burden (beta=-12.8, p<.01). Caregivers experienced higher symptoms when patients specifically reported anxiety, lack of appetite, or pain (beta=1.4, 2,4, and 3.0, p<.05). Cross-lagged Actor-Partner Interdependence Models indicated interdependence among survivor and caregiver symptom burden. The findings provide preliminary evidence of the interrelationship of psychoneurologic symptoms in survivors and patients, with implications for symptom management and supportive care practice.

DEVELOPMENT OF A BRIEF MEASURE OF COMMUNICATION QUALITY: THE 5- AND 10-ITEM FAMILY INPATIENT COMMUNICATION SURVEYS

Emily Burke[1], James Slaven[2], Tracy Taylor[3],
Patrick Monahan[2], Greg Sachs[1], and Alexia Torke[1],
1. Indiana University (IU) Center for Aging Research, Regenstrief Institute, Inc., Indianapolis, Indiana, United States, 2. Indiana University, Indianapolis, Indiana, United States, 3. Regenstrief Institute, Inc., North Vernon, Indiana, United States

Communication quality between clinical care teams and families impacts important outcomes like satisfaction, depression, and anxiety. Assessment tools must be efficient and reliable to be useful in the clinical environment. We report the development of 5 and 10-item versions of the validated 30-item Family Inpatient Communication Survey (FICS). Data were from 364 surrogate decision makers (SDMs) for incapacitated older adults in the ICU. Most SDMs were adult children (66.8%). SDMs were 70.9% female, 68.9% white, with a mean age of 58.3. Exploratory factor analysis revealed high internal reliability for the single-factor FICS5 (α= .88) and two-factor FICS10 (α= .93). The FICS10 reliably measures two subscales: information (α= .91) and emotional support (α=.81). Good discriminant and predictive validity were demonstrated when comparing total scores to outcomes at 6-8 weeks after hospital discharge, including anxiety (correlation coefficient (ρ)= -.13; p=.0234), depression (ρ =-.15; p=.0076), decision regret (ρ =--.15; p=.0066), and satisfaction (ρ =-..48; p<.0001). Repeating analysis with a new sample (n=188) revealed similar results with Cronbach's alpha ranging from .81 to .93. The FICS5 revealed significant associations (p<.05) at 6-8 weeks after discharge with distress (-.22), while the FICS10 demonstrated significant associations with distress (-.28), anxiety (-.20), depression (-.19) and decision regret (-.27). Confirmatory factor analysis indicated adequate fit (CFI: FICS5= .994, FICS10= .994; RMSEA: FICS5= .093, FICS10= .103). The FICS provides clinicians and interventionists with a reliable, low burden tool to evaluate communication quality and respond quickly, which could impact satisfaction and other important outcomes for patients and families.

THE VALIDITY AND RELIABILITY OF THE DISTRESS THERMOMETER IN FAMILY SURROGATES OF ICU PATIENTS

Emma O'Brien[1], Emily Burke[2], James Slaven[3],
Tracy Taylor[4], and Alexia Torke[2], *1. Regenstrief Institute, Inc., Indianapolis, Indiana, United States, 2. Indiana University (IU) Center for Aging Research, Regenstrief Institute, Inc., Indianapolis, Indiana, United States, 3. Indiana University, Indianapolis, Indiana, United States, 4. Regenstrief Institute, Inc., North Vernon, Indiana, United States*

Brief, reliable assessment tools are highly valued in both research and clinical settings. The single-item Distress Thermometer (DT) asks participants to rank their overall level of distress from zero to ten. Similar measures of distress perform well in oncology populations, but the validity of the DT has not been well tested with other populations. To determine its validity and reliability, we analyzed data from family surrogates (n=188) of critically ill ICU patients. Surrogates were asked to rate their distress during the first four days of the patient's ICU stay and 6-8 weeks after discharge (n=127). Data were analyzed using Spearman non-parametric correlation due to the distributions of the data. DT scores at both baseline and follow-up were significantly correlated with anxiety (GAD-7: correlation coefficient (ρ)=.527, p<.0001; ρ=.543, p<.0001, respectively), depression (PHQ-9: ρ=.480, p<.0001; ρ=.399, p=.0002), distress (Kessler-6: ρ=.477, p<.0001; ρ=.528, p<.0001), and negative religious coping (ρ=.149, p=.0426; ρ=.238, p=.0074). Results also indicated that spiritual well-being at baseline and follow-up (FACIT: ρ=-.391, p<.0001, ρ=-.443, p<.0001) and positive religious coping at baseline (RCOPE: ρ=-.164, p=.0253) have an inverse relationship with overall distress. At baseline, surrogates with better positive religious coping and/or more involvement in organizational religious activity (ρ=-.189, p=.0106) were more likely to report lower distress. The DT could be an efficient, single item predictor of outcomes that impact patient and family care. Future research could confirm its validity as a measure of distress, in a variety of clinical populations and environments that could inform clinical care for patients and families.

CHARACTERIZING GENERATIONAL CAREGIVING USING DATA FROM THE BRFSS

Benjamin Olivari[1], Nia Reed[1], Erin Bouldin[2],
Eva Jackson[3], John Omura[1], Lisa McGuire[1], and
Janet Croft[1], *1. CDC, Atlanta, Georgia, United States, 2.*

University of Utah, Salt Lake City, Utah, United States, 3. Alzheimer's Association, Chicago, Illinois, United States

As the proportion of family and friends in the U.S. providing informal care increases, it is important to understand how this may impact certain demographic groups. Millennials and older adults are two generational segments of caregivers of interest given the complexities associated with these groups. Millennials can be sandwiched between a growing older population of parents or grandparents while also raising young children, often providing care for both. Similarly, older adults frequently balance caring for spouses, themselves, and grandchildren. We characterized these two groups of caregivers using 2015-2019 Behavioral Risk Factor Surveillance System (BRFSS) data from the Caregiver Optional Module administered in 44 states, D.C., and Puerto Rico. Among 246,223 Module respondents, 21.3% reported providing care for a family member or friend. Among caregivers, 12.4% were identified as Millennials (aged 18-38 years), and 19.7% were older adults (aged≥65 years). About one-in-three Millennial caregivers reported providing care to a parent and half to another relative, such as a child or grandparent. While less than 4% of Millennial caregivers reported providing care for a spouse, nearly one-in-five older adult caregivers did. Although their care recipients may differ, both groups reported high intensity of care, with 30% of caregivers in each group providing 20 hours of care or more weekly. Caregiving among older adults can be further complicated by their own health difficulties, with over half of older adult caregivers reporting having two or more chronic conditions and one-third reporting a disability. BRFSS data may inform planning efforts pertaining to these caregiving groups.

PERCEIVED NEEDS, FELT CONCERNS, AND QUALITY OF LIFE OF OLDER ADULTS IN MISSISSIPPI: AN INTERGENERATIONAL APPROACH

Muhammad Riaz[1], Laura Downey[2], Carolyn Adams-Price[3], Donna Peterson[2], Lori Staton[2], and Alisha Hardman[2], *1. Mississippi State University, Starkville, Mississippi, United States, 2. Mississippi State University, Mississippi State, Mississippi, United States, 3. Mississippi State University, STARKVILLE, Mississippi, United States*

The purpose of the study was to identify felt needs and concerns of older adults living in their own homes in Mississippi using intergenerational perspectives. This mixed-methods study used snowball sampling to collect data through semi-structured interviews and structured questionnaires that asked about the quality of life and current and future problems among aging adults. Three generations of Mississippians participated in the study, including grandparents (N = 22), adult children (N = 23), and grandchildren (N = 19). Quantitative data were analyzed using SPSS, while qualitative data were managed with MaxQDA. Respondents identified concerns with physical health, difficulty living independently, and mental health problems affecting life satisfaction and quality of life. Incongruently with the intergenerational stake hypothesis, adult children were more invested in their children than their parents. Older adults who live closer to significant others and family were more resilient despite having physical and mental issues. Physical issues related to mobility, access to daily need services, and help with basic tasks like food preparation and mowing lawns, and issues related to mental health seemed less pronounced. Consistent with other research studies, older adults showed a positive sense of self. Similarly, parents showed resilience without being intrusive and overbearing while considering themselves as support for their children. Results could inform the development of programs or initiatives for grandparents, adult children, grandchildren, and others involved in caregiving activities and planning for older adults in Mississippi.

ASSOCIATION OF CARDIOVASCULAR DISEASE WITH RACE/ETHNICITY IN FAMILY CAREGIVERS OF PERSONS LIVING WITH DEMENTIA

Dawon Baik[1], Bryan McNair[2], and Sophia Centi[3], *1. University of Colorado, Aurora, Colorado, United States, 2. Colorado School of Public Health, University of Colorado Anschutz Medical Campus, Aurora, Colorado, United States, 3. CU Anschutz Medical Campus College of Nursing, Aurora, Colorado, United States*

Family caregivers of persons with dementia (dementia FCGs) experience high caregiving burden, and caregiving-related stressors have been linked to cardiovascular disease (CVD). Racially and ethnically diverse FCGs face additional challenges in managing their own health; however, racial/ethnic disparities in caregiving-associated cardiovascular health are understudied and poorly understood. To fill the gap, we evaluated racial/ethnic differences in CVD risk and CVD conditions among dementia FCGs in the U.S. Using 2015-2020 Behavioral Risk Factor Surveillance System data (N = 6,132), we compared CVD risk and CVD conditions in racial/ethnic dementia FCG minorities to non-Hispanic White dementia FCGs. Logistic regression models were used to estimate unadjusted (OR) and adjusted odds ratios (AOR) with 95% confidence intervals (CI) for association of race/ethnicity with CVD risk and CVD conditions, adjusting for potential confounders. Compared to non-Hispanic White FCGs, non-Hispanic Black FCGs (AOR 0.33, 95% CI 0.2-0.53) and non-Hispanic Asian FCGs (AOR 0.16, 95% CI 0.05-0.51) were less likely to have depressive symptoms. Hispanic FCGs (OR 0.69, 95% CI 0.5-0.95), non-Hispanic Black FCGs (AOR 0.6, 95% CI 0.41-0.86), and non-Hispanic Asian FCGs (AOR 0.51, 95% CI 0.28-0.94) were less likely to smoke. Non-Hispanic Black FCGs were less likely to exercise (OR 0.69, 95% CI 0.52-0.91) and more likely to be obese (AOR 1.64, 95% CI 1.14-2.36). The findings confirm racial/ethnic disparities in psychological, behavioral, and metabolic risk factors for CVD among dementia FCGs. Future studies should investigate how dementia FCGs' caregiving-related conditions affect CVD and how racial/ethnic considerations can inform culturally appropriate prevention-care strategies.

CARING FOR INDIVIDUALS WITH DEMENTIA AND COGNITIVE IMPAIRMENT IN LOS ANGELES: A CAREGIVER PROFILE

Ariane Thomas[1], Noel Barragan[1], Mariana Reyes[1], and Tony Kuo[2], *1. Los Angeles County Department of Public Health, Los Angeles, California, United States, 2. University of California, Los Angeles, Los Angeles, California, United States*

In 2020, the Los Angeles County Department of Public Health launched Healthy Brain LA (HBLA). HBLA is a multi-pronged project designed to promote cognitive health, reduce the risk of dementia, and help develop a dementia-focused strategic plan for Los Angeles County (LAC) that prioritizes the needs of those impacted by dementia and cognitive impairment and their caregivers. To support this effort, the HBLA team analyzed weighted data from the 2019 and 2020 California Health Interview Survey (CHIS) to better understand the profile of adult caregivers of individuals with dementia and cognitive impairment. CHIS is a publicly available, population-based, web and telephone survey that asks California residents about a wide range of health topics, yielding representative data on all 58 counties in the state. In 2019-2020, an estimated 1.6 million adults provided care to individuals aged 18 years or older in LAC. About 322,880 of those caregivers provided care for individuals with dementia and cognitive impairment, representing 2% of LAC's adult population. Many of these caregivers were female (59%), Latino/Hispanic (44%), and between 50-64 years of age (32%). Most of them experienced challenges, such as financial stress (61%), physical/mental health problems (18%), or a change in job status (27%), due to caregiving. These data provide the first local estimate of dementia and cognitive impairment caregiving in nearly 15 years. Results offer critical information about this population that will be used by the HBLA team and its partners to guide efforts to effectively meet the needs of caregivers in LAC.

HEALTH COACHING FOR DEMENTIA CAREGIVERS: LESSONS LEARNED FROM THE ICARE4ME STUDY

Lauren Fisher, Lauren Massimo, and Karen Hirschman, *University of Pennsylvania, Philadelphia, Pennsylvania, United States*

Frontotemporal dementia (FTD) is a common cause of young-onset neurodegenerative disease that causes progressive changes in behavior and personality. FTD is often diagnosed around age 60, creating complex care needs that result in caregivers of persons with FTD experiencing high rates of depression, burden, and poor self-care. The iCare4Me for FTD study (NCT04686266) randomized 15 caregivers to receive a virtual health coaching intervention over 6 months (10 sessions) and 15 caregivers to the control group. To better understand the caregivers' experience with the health coach intervention, two focus groups with intervention group caregivers (n=5) were held. Focus groups were recorded, transcribed and coded using content analysis. Caregivers reported the most valuable aspect was the relationship that was developed with their health coach. Caregivers particularly valued having someone to talk to who was outside their immediate social and support networks. It was noted the structured self-care curriculum served as a good backbone for discussions, but more specific coping conversations related to loss of patient empathy, prognostic uncertainty, and anticipatory grief are needed. One caregiver described being, "… awash in grief and it's affected my memory" while another described "grief is a big issue and I don't really find too many people understand it, because my husband is alive, but so many parts of him are gone". These findings will be used to inform future studies utilizing health coaches for caregivers of persons with FTD. Implications for evidence-based virtual health coaching interventions with caregivers of persons living with FTD will be described.

QUALITY OF LIFE AND SOCIAL DETERMINANTS PREDICT HOSPICE IN DEMENTIA CAREGIVING DYADS: A MACHINE LEARNING APPROACH

Suzanne Sullivan, Wei Bo, Chin-Shang Li, Wenyao Xu, and Yu-Ping Chang, *University at Buffalo, Buffalo, New York, United States*

Hospice care is available to assist people with serious illness and their caregivers who wish to age in place, avoid unnecessary hospitalizations, and remain at home through the end-of-life. However, hospice care is under-utilized nationally despite the disproportionate prevalence of end-of-life dementia caregiving burdens among disadvantaged groups. The reasons are unclear, but emerging research suggests that systemic barriers may contribute to underutilization. Commonly used quality-of-life frameworks have long included social determinant of health (SDH) factors such as social, environmental, financial, and healthcare access needs. Investigating the link between quality-of-life and SDH concerns of persons with dementia (PWD) and their caregivers may help identify when a PWD might benefit from hospice care. This study uses machine learning techniques to longitudinally analyze caregiver/care-recipient dyads in the National Health and Aging and Trends Study (NHATS) linked to the National Study of Caregiving (NSOC) (2015-2018) to identify quality-of-life and SDH predictors of hospice use among 117 PWD and their primary caregivers. Results indicate that distinguishing features selected by Information Gain Ratio [IGR] predict that memory rating, receiving food stamps, whether health prevents enjoying life, having trouble chewing or swallowing, diabetes, a regular doctor, and nobody to talk to can predict hospice use well (accuracy=0.6848; sensitivity=0.8244; specificity=0.5371; AUC=0.7425). Quality-of-life/SDH factors are important longitudinal predictors of hospice that can be detected up to three years prior to death. Our study uses inductive, machine learning approaches to provide testable hypotheses for future research to improve the quality of end-of-life care through hospice for PWD and their caregivers.

SELF-CARE AND QUALITY OF LIFE IN PEOPLE WITH PARKINSON'S DISEASE AND THEIR CAREGIVERS

EUNYOUNG KIM[1], JuHee Lee[1], Misook Chung[2], and Subin Yoo[1], *1. Yonsei University, Seoul, Seoul-t'ukpyolsi, Republic of Korea, 2. University of Kentucky, Lexington, Kentucky, United States*

Objective: To examine associations of self-care and the quality of life (QOL) in patients with Parkinson's disease (PD) and their caregivers dyads.

Background: Patients with PD engage in self-care with motor and non-motor symptom experiences. There is insufficient knowledge about associations of self-care and QOL in patients with PD and their caregivers though PD patients and family caregivers are interdependent. Method: A total of 73 PD patients and primary family caregivers from the Korean Parkinson's Disease Association or who visited outpatient clinics of the tertiary hospitals in Korea participated in this study. Dyad members completed the survey of the self-care (the Self-Care of Chronic Illness Inventory and Caregiver Contribution to Self-Care of Chronic Illness Inventory) and QOL (Parkinson's Disease Quality of Life Questionnaire and The Parkinson's Disease Questionnaire-Care). The comparisons of self-care and quality of life within two dyad members were conducted via paired t-test and Pearson's correlation using SPSS 26.0 Result: PD patients reported significantly higher levels of self-care maintenance (78.34 vs. 70.21, patients vs. caregiver respectively, p<.001) and management (65.9 vs. 60.49, p=.029) than caregivers. Patients' self-efficacy was significantly correlated with their QOL (r=.270, p=.021). Caregiver contribution to self-care management was significantly correlated with their own QOL (r=.365, p=.001) and patients' QOL (r=.234, p=.047).

Conclusion: The self-care efficacy of patients and the contribution of caregivers to self-care management can affect the QOL of both patients and caregivers. A dyadic approach for the intervention of self-care management is crucial to improve the QOL of patients with PD and caregivers.

UNDERSTANDING THE CHARACTERISTICS AND WELL-BEING OF AMERICAN INDIAN AND ALASKA NATIVE GRANDPARENT CAREGIVERS

Ramona Danielson[1], Shelly Davis[2], and Collette Adamsen[3], *1. North Dakota State University, Fargo, North Dakota, United States, 2. University of North Dakota School of Medicine & Health Sciences, Grand Forks, North Dakota, United States, 3. University of North Dakota, Grand Forks, North Dakota, United States*

Background: American Indian/Alaska Native (AI/AN) grandparents have always had an important role in their grandchildren's lives. Grandparents being the primary caregiver of their grandchildren has become a more pronounced occurrence in AI/AN populations in recent years and warrants review.

Methods: Data come from the National Resource Center on Native American Aging's 2017-2020 needs assessment of AI/AN adults ages 55+. Analysis explored demographic and well-being indicators by caregiving status (N=19,855): not a caregiver of a grandchild (non-CG; 71%); part-time caregiver (PT-CG; 18%); and primary caregiver (PR-CG; 11%).

Results: Caregivers were more likely to be younger, be married, have higher education and incomes, and live with family in a single-family residence than non-CG. PR-CG were more likely to be female, employed full-time, and live with family on reservation/trust land than PT-CG and non-CG. Regarding indicators of well-being, caregivers were more likely to participate in cultural practices than non-CG. PT-CG were more likely to socialize and have recently participated in vigorous exercise, were less likely to have fair/poor health, and had fewer daily self-care restrictions than PR-CG and non-CG. PR-CG were more likely to be obese and daily smokers and had a higher measure of mental health concern, but were less likely to have recently binge drank or mainly eat alone than PT-CG and non-CG.

Conclusions: The demographics reviewed were all significantly different. PT-CG had better outcomes, pointing to a potential protective benefit, while PR-CG had more mental health strain. Further research is needed to better understand the interconnectedness of the indicators analyzed.

CAREGIVER SINGING VERSUS MUSIC ACTIVITIES IN DEMENTIA CARE: DIFFERENT BENEFITS IN DIFFERENT OCCASIONS

Lena Hammar[1], Annica Lövenmark[1], and Anna Swall[2], *1. Mälardalen University, Västerås, Vastmanlands Lan, Sweden, 2. Dalarna University, Falun, Dalarnas Lan, Sweden*

Music has been used in the care of persons with dementia (PWDs) in decades, and research show that music activities such as background music, music listening, sing-along activities and playing instruments have positive effects on mood, emotions and interaction. However, Caregiver Singing (CS)-when caregivers are singing for or together with PWDs during care activities, are commonly in literature mixed up with other music activities. CS is a care intervention aiming to facilitate care situations and has shown to be useful to increase interaction and cooperation in care activities. This study aimed to describe caregivers' experiences of the differences between using CS compared to music in the care of persons with dementia.Data was three focus group interviews with 12 professional caregivers and residential facilities for PWDs. Data was analyzed with qualitative content analysis. Results revealed that CS are a successful tool to communicate, cooperate and bring out the PWDs hidden resources during care activities. The PWDs were told to be more adequate even thou the caregivers sings instead of speaking. Music activities were described to increase moods and socialization and are important part to increase a nice atmosphere. However, it does not increase cooperation in the way CS does. As interventions to facilitate caring situations with PWDs are needed, and CS has shown to be effective and should therefore be seen as an intervention not mixed up with traditional music activities. It is an important contribution in the education for staff in dementia care to include training in CS.

FORMAL CAREGIVER BURDEN IN NURSING ASSISTANTS IN NURSING HOMES: A FEASIBILITY STUDY

Rachel Kunkle[1], Claudia Chaperon[2], and Ann Berger[2], *1. University of Nebraska Medical Center, Elkhorn, Nebraska, United States, 2. University of Nebraska Medical Center, Omaha, Nebraska, United States*

Formal caregivers are the direct care workforce that aid residents in nursing homes. Providing care to residents is hazardous and physically demanding. Formal caregiver burden encompasses five attributes – perceived stress, caring for another, dependency of the older adult, responsibility, and competence. Exploring the five attributes of formal caregiver burden using a mixed-methods approach will determine if the attributes are present and how the nursing home setting contributes to formal caregiver burden. The purpose of this feasibility study is to describe formal caregiver burden of nursing assistants who provide direct care to residents in a nursing home setting in the Midwest United States. Study site one was only able to enroll three participants; therefore, results were limited. However, study site two was able to recruit and enroll the desired sample size (N=9). Interviews and self-report measures (Background/COVID-19 Questionnaire, Perceived Stress Scale, Caring Behaviors Inventory, and Nursing Home Staff Competency Assessment) were completed, and the PI compared integrated mixed methods results. Results suggest all the attributes of formal caregiver burden were present, and no additional attributes were identified. The feasibility of virtual recruitment, enrollment, and data collection procedures were confirmed. Multiple challenges played a role in the unsuccessful recruitment of this feasibility study at site one; however, virtual recruitment was successful at site two. Further exploration will inform identification and measurement of formal caregiver burden to ensure support for nursing assistants, continue the vitality of the nursing assistant workforce in nursing homes/long-term care, and improve the lives of nursing assistants.

ASSOCIATION BETWEEN INCREASED CAREGIVER BURDEN AND MENTAL HEALTH DURING THE COVID-19 PANDEMIC IN JAPAN

Isuzu Nakamoto[1], Hiroshi Murayama[2], Mai Takase[3], Yoko Muto[2], Tami Saito[4], and Takahiro Tabuchi[5], *1. Tohoku University, Tokyo, Tokyo, Japan, 2. Tokyo Metropolitan Institute of Gerontology, Tokyo, Tokyo, Japan, 3. The University of Tokyo, Tokyo, Tokyo, Japan, 4. National Center for Geriatrics and Gerontology, Obu, Aichi, Japan, 5. Osaka International Cancer Institute, Osaka, Osaka, Japan*

During the COVID-19 pandemic, informal caregivers' mental health was more deteriorated than non-caregivers. The objective of this study was to examine the association between increased caregiver burden and severe psychological distress (SPD) during the pandemic. We used cross-sectional data from a nationwide internet survey conducted between August and September 2020 in Japan. Of 25,482 participants aged 15–79 years, 1,920 informal caregivers were analyzed (mean age, 52.3 ± 15.9 years; men, 48.8%). SPD was defined as the Kessler 6 Scale (K6) ≥ 13. The self-rated change in caregiver burden was measured with the single question item. A binary logistic regression analysis was used to examine the association between SPD and increased caregiver burden, adjusted for demographic, socioeconomic, health, and caregiving variables. To examine the differential association between increased caregiver burden and SPD, interaction terms were added and binary logistic regression was separately conducted in all variables. Of total caregivers, 56.7% reported the increased caregiver burden and 19.3% were SPD. Increased caregiver burden was significantly associated with SPD, with an adjusted odds ratio 1.90 (95% confidence interval 1.37–2.66). The association between increased caregiver burden and SPD was stronger among married caregivers, with disease treatment, and with their care-receiver's care need level 1–2 (Japanese long term care service levels). This study demonstrated that increased caregiver burden was associated with SPD during the pandemic. Therefore, measures against mental health for the caregivers with increased caregiver burden need to be implemented immediately.

POSITIVE CAREGIVING AND CAREGIVING RELATIONSHIP ASSOCIATION WITH MENTAL HEALTH AND PERCEIVED GENERAL HEALTH

Cristina de Rosa, Ashleigh Holmes, Weijun Wang, and Yu-Ping Chang, *University at Buffalo, Buffalo, New York, United States*

Caregiver burden is well understood as an important contributor to caregiver health. However, little is known about how positive aspects of caregiving (i.e., personal growth, gratitude, finding meaning) and the quality of caregivers' relationships with care recipients might play a role in caregiver health. The study aimed to examine whether positive caregiving and caregivers' relationship with care recipients were associated with caregiver mental health (depression and anxiety) and perceived general health. The sample consisted of 2,652 family caregivers in the National Study of Caregiving (NSOC) III (2017) providing care to older adults. A series of multiple regression models with covariate adjustments (i.e., caregiver's age, sex, and race/ethnicity) were performed to examine the associations. Results indicated that positive aspects of caregiving predicted caregiver mental health but did not predict perceived general health. Caregivers' relationship with care recipients and caregiver burden significantly predicted caregiver mental health ($b = 0.285$ [S.E. = 0.045], $p < .001$) and perceived general health ($b = 0.096$ [0.016], $p < .001$). After controlling for caregiver burden, only caregivers' relationship with care recipients remained a significant predictor of caregiver mental health ($b = 0.182$ [0.041], $p < .001$) and perceived general health ($b = 0.077$ [0.018], $p < .001$). Our results suggest that positive caregiving perceptions and quality of relationships between caregivers and care recipients are linked to better caregiver mental health. Interventions to reduce caregiver burden, including strategies to help caregivers maintain positive attitudes and positive relationships with care recipients, might be beneficial to improving caregiver health.

ENGAGING AFRICAN AMERICAN FAMILY CAREGIVERS THROUGH ART AND CREATIVE ACTIVITIES: A CASE STUDY

Afeez Hazzan[1], Luvon Sheppard[2], and Joyce Hazzan[3], *1. State University of New York at Brockport, Hilton, New York, United States, 2. Rochester Institute of Technology, Rochester, New York, United States, 3. Liberty University, Lynchburg, Virginia, United States*

Studies have shown that engaging family caregivers of people with dementia in creative activities can provide therapeutic benefits by relieving stress and promoting well-being. However, there is a dearth of studies focusing on the involvement of racial minority family caregivers of people with dementia in research involving art and creative activities. The purpose of this study is to present the results of a case study interview with an artist-educator-community collaborator who acted as a key facilitator for the ACTION ARTS study. The purpose of the ACTION ARTS study was to utilize mobile technology applications for facilitating creative activities to enhance health and well-being of African-American family caregivers and their loved ones in the middle-to-late stages of dementia. The study included activities such as memory stimulation, art viewing, art making, and other forms of creative expressions. The research question for the current case study was: What are the best practices for engaging African-American family caregivers of older adults in the middle-to-late stages of dementia in research involving art and creative activities? Thematic analysis of the qualitative data from the case study interview yielded the following recommendations/results: (1) Design the program of art and/or creative activities in an easy way to facilitate interaction among participants; (2) Make the program as accessible and relevant as possible so everyone is able to relate to it; (3) Emphasize areas of commonality that could help in giving both the facilitators and participants food for thought.

IMPACTS OF SOCIAL RELATIONSHIPS ON CO-OCCURRING SYMPTOMS AND FUNCTIONING IN OLDER ADULTS WITH COGNITIVE IMPAIRMENT

Bada Kang1, Sijia Wei[2], Eleanor McConnell[2], and Kirsten Corazzini[3], *1 Yonsei University, Seoul, Seoul-t'ukpyolsi, Republic of Korea, 2. Duke University, Durham, North Carolina, United States, 3. University of New Hampshire, Durham, New Hampshire, United States*

Social relationships are crucial for well-being of older adults with cognitive impairment (CI), however, evidence is lacking on how social relationships may influence symptom experience and functioning among those living with CI. This study aimed to identify subgroups of older adults with CI with distinct symptom and functioning profiles and to examine the association between latent class membership and social relationships. The sample included 927 older adults who were screened as having moderate or severe CI from wave 2 of the National Social Life, Health and Aging Project. Symptom (i.e., pain, fatigue, sleep disturbance, depression, anxiety, and stress) and functioning (i.e., instrumental activities of daily living, activities of daily living, and urinary incontinence) variables were used to identify subgroups. Latent profile analyses identified five distinct groups: most (51.7%) belonged to the low-symptom-high-functioning; few (7%) belonged to the high-symptom-low-functioning; while two groups had average symptom burden, one group (25%) had frequent urinary incontinence and normal daily functioning (poor-urinary-functioning), and the other group (5%) had normal urinary functioning and the worst daily functioning (worst-daily-functioning); interestingly, 13% belonged to high-symptom-normal-functioning group. Multinomial logistic regression modeling showed that, among social networks, support, strain, and engagement, members in groups with worse symptom burden and daily functioning were significantly more likely to have social strain, after adjusting for covariates (p-values < 0.01). Only severe CI was associated with worst-daily-functioning (OR = 3.24, p-value = 0.002). Interventions that ameliorate social strain may benefit symptom management and promote independent daily living among older adults with CI.

SESSION 6290 (POSTER)

COGNITION, AGING, AND THE SOCIAL ENVIRONMENT

OBJECTIVE HEARING, SUBJECTIVE HEARING, AND PHONE-BASED MEMORY TESTING

Taylor Atkinson, and Ross Andel, *University of South Florida, Tampa, Florida, United States*

Hearing impairment may make responding to phone-based memory tests difficult. Words with fricative consonants may pose particular difficulty, as telephones exclude high-frequency sounds necessary for their intelligibility. We hypothesized that recall would be impacted by hearing ability and word type (fricative vs. non-fricative) in a phone-based word list task.Participants (N=1,352, mean age=69.1) in the 2016 and 2018 waves of the Health and Retirement Study completed a phone-based word list recall task evenly split (5 each) between fricative and nonfricative words. Hearing was measured objectively (OH) and subjectively (SH), and each were dichotomized into 'good' and 'poor' hearing. Covariates included age, sex, race, education, depression, a subjective health rating, and functional limitations. Separate mixed-design ANCOVAs were used for OH and SH, where word type recall was within-subject, and hearing ability was between-subject. For OH, there was a main effect of word type (F(1,1341)=5.67, p=.02) and hearing ability (F(1, 1341)=87.76, p<.001) but no interaction (p>.05). Participants recalled 0.35 fewer fricative words than nonfricative words, and participants with poor OH recalled 0.12 fewer words on average (ps<.001). For SH, there was still a main effect of word type (F(1,1341)=5.39, p =.02), but no effect of hearing ability (p>.05). OH and SH classifications had low agreement (Kappa=.22, p<.001). Hearing ability and word acoustic properties can affect word recall in phone-based tests. Objective hearing tests are important, as subjective ratings do not necessarily agree. Researchers should be careful when constructing telephone-based cognitive tests in order to avoid memory impairment misestimation.

SHORT-TERM COUPLED ASSOCIATION BETWEEN BLOOD PRESSURE AND COGNITIVE FUNCTIONING

Tomiko Yoneda[1], Andrea Piccinin[2], Jonathan Rush[2], Nathan Lewis[2], Jamie Knight[2], Rebecca Vendittelli[2], and Scott Hofer[2], *1. Northwestern University, Evanston, Illinois, United States, 2. University of Victoria, Victoria, British Columbia, Canada*

An extensive body of research has investigated the association between cognition and blood pressure (BP). Limited research, however, has examined the association at the daily within-person level. No study has yet applied an intensive measurement design utilizing the convenience and objectivity of mobile devices for cognitive assessments and automated BP monitors. To address this gap in the literature, we recruited community-residing healthy adults (N=64; Mage=70.6, SD=3.5; 76.6% female), who recorded their BP and completed a battery of brief cognitive tasks twice daily for 14 days. Multi-level models estimated associations between systolic/diastolic BP (sBP/dBP) and cognitive functioning, adjusting for time-varying self-reported effort, stressors, and physical activity, as well as time-invariant variables (age, sex, education, and anti-hypertensive medication). At the interindividual level, results suggest that individuals with higher overall sBP and dBP relative to others performed worse on delayed-reproduction and visual short-term memory tasks. At the intraindividual level, on occasions when individuals had higher sBP compared to their personal average, they performed relatively worse on delayed-reproduction tasks. Mean sBP was also significant within these models, suggesting that this coupled relationship is stronger for individuals with higher sBP on average. Analyses did not indicate significant associations for working memory, reaction time, or cognitive interference assessments, which may have been due to relatively limited power for between-person analyses. Use of such digital health technology is critical for detecting the complex nature of and interplay between physiological and cognitive processes. Further, research based on intraindividual associations may contribute to strategies aiming to promote lifestyle modifications.

CROSS-VALIDATION OF THE LICHTENBERG FINANCIAL DECISION RATING SCALE

Emily Flores, and Peter Lichtenberg, *Wayne State University, Detroit, Michigan, United States*

This study examines the cross-validation of the long form of the Lichtenberg Financial Decision Rating Scale in relation to decision making abilities and suspected financial exploitation.Ninety-five older adult community participants underwent an assessment session which included the LFDRS, cognitive tests and the Independent Living Scale financial management subtest. The LFDRS has four subscales including an intellectual factor that measures choice, understanding, appreciation, and the rationale of decisions. Demographic information was also collected.The concurrent validity of the subscales and LFDRS were examined by Pearson correlations in order to be able to examine the relationship between cognitive test scores, ILS money management scores and LFDRS risk scores. Hierarchical regression analysis was conducted to determine whether cognitive and financial management tests were contributed to the prediction or risk scores greater than demographic variables. LFDRS total was significantly related to executive functioning and female gender. The Financial Situational Awareness subscale showed significant correlations with Trailmaking B but was unrelated to demographics. The relationship of executive functioning to vulnerability to exploitation was largely driven by the Financial Situational Awareness subscale. This finding is consistent with previous studies of the LFDRS and adds to the evidence supporting the concurrent validity of the LFDRS with cognitive functioning.

THE INTERPLAY BETWEEN MEMORY SPECIFICITY AND COGNITIVE INHIBITION

Jessie Chien, and Teal Eich, *University of Southern California, Los Angeles, California, United States*

Pattern separation studies suggest age-related declines in discriminating between a newly and a previously encountered overlapping mental representations. However, when similar experiences occur contemporaneously, shared features may serve as intrinsic factors that interfere with the ability to encode and retrieve events as distinct memories. If so, successful inhibition of competitors might also be necessary to maintain memory specificity. Here, we investigated the interplay between memory specificity and inhibitory control in younger (20-35;n=34) and older (65+;n=37) adults by testing whether and how presenting a target item with a lure item (varied in its similarity to the target) influenced recognition accuracy, probed using a 3-item (target, lure, and a non-presented control) forced-choice recognition test. Surprisingly, we found no age-related differences, including in target accuracy, which was high in both groups (young=80.25%; older=77.86%). While not age-specific, we did find that the pattern of errors varied as a function of the level of similarity between the items at encoding. When target and lure were highly similar, a greater proportion of control items were falsely-recognized relative to lure items. It is possible that inhibition of the lure spread to the target, leaving both inaccessible at retrieval (e.g., a retrieval-induced forgetting effect). When the target and lure were less similar, participants false alarmed more to lure than control, potentially because the lure provided less competition and thus did not necessitate inhibitory control. These results shed light on how inhibitory processes might be differentially involved, but age-invariant, depending on the similarity of encoded items.

THE ROLE OF CAREGIVING IN COGNITIVE FUNCTION AND CHANGE: A REGARDS STUDY

Joanne Elayoubi, *USF, Land o' Lakes, Florida, United States*

Caregiving is often associated with elevated levels of stress and depressed mood. There is some evidence that higher caregiving strain is associated with worse cognitive functioning, however, findings are mixed. The current study examined the relationship between caregiving and cognitive functioning, and the potential mediating effects of depressive symptoms and high-sensitivity C-reactive protein (hsCRP). We identified participants in the Reasons for Geographic And Racial Differences in Stroke (REGARDS) study who were family caregivers at baseline assessment (n=3,118), and then used propensity matching on 14 sociodemographic and health variables to identify 3,118 non-caregivers. Participants completed repeated assessments of global cognitive functioning, learning and memory, and executive functioning and processing speed. Our results showed caregivers and non-caregivers did not differ on cognitive functioning at baseline or in rate of change in cognition over time. Caregivers had higher baseline depressive symptoms than non-caregivers but depressive symptoms and hsCRP did not mediate the relationship between caregiving strain and cognition. The present study, using several methodological advances not found in most previous papers on caregiving and cognition (large sample size, propensity matching of caregivers and non-caregivers, longitudinal methods) found no evidence that caregiving or caregiving strain significantly influenced cognitive performance. Results are consistent with recent research demonstrating that, while caregiving can be highly stressful, many caregivers are resilient and do not show marked declines in cognition and health, or higher mortality. A more balanced narrative of caregiving, emphasizing resilience and both the problems and benefits of caregiving, is indicated.

AGE-RELATED CHANGES IN CUED TASK SWITCHING

Elizabeth Lydon[1], and Raksha Mudar[2], *1. University of Illinois Urbana-Champaign, Champaign, Illinois, United States, 2. University of Illinois Urbana Champaign, Champaign, Illinois, United States*

The task switching paradigm is widely used to examine cognitive switching, a critical subcomponent of cognitive control. Studies on aging suggest that switching is particularly vulnerable to age-related changes in cognition. However, the effects of manipulating the stimulus dimension on task switching performance is relatively understudied. In this study, 13 younger adults (YA; 11F; Mean Age= 22.31) and 13 older adults (OA; 8F; Mean Age= 65.85) completed a novel cued task-switching paradigm requiring speeded same-different judgments based on a perceptual (color) or conceptual (animal) dimension of the stimuli. Task switching performance was measured using switch cost, which is the difference in accuracy between switch and repeat trials. Overall both YA and OA exhibited switch costs, indicating increased cognitive demand when switching between judgments compared to repetition of the same judgement. In regard to group differences, YA and OA performed similarly when performance was collapsed across the stimulus dimensions; however, when examined separately, OA exhibited worse performance than YA when making conceptual judgements. These results highlight the importance of examining carefully manipulated stimulus-related factors in task switching paradigms to advance our understanding of cognitive control and aging.

EXPLORING LINGUISTIC PATTERNS ON A STORY RECALL TASK IN PEOPLE WITH MILD COGNITIVE IMPAIRMENT

Angela Boland, Adelaide Jensen, Patrick Davidson, and Vanessa Taler, *University of Ottawa, Ottawa, Ontario, Canada*

Mild cognitive impairment (MCI) involves declines in language and episodic memory. Episodic memory is often assessed using language tasks. To prevent linguistic factors from confounding recall scores, memory and language should be jointly examined. We explored linguistic patterns on a story recall task among cognitively healthy adults aged 65+ (n=18) and people with amnestic MCI (n=18). Participants completed immediate and delayed (20-30min) recall on a set of novel story recall materials (6 pairs, i.e., 12 stories total). Stories were coded using a propositional coding scheme (where a proposition refers to the smallest unit of meaning), as well as a unit scoring scheme (i.e., individual words). Responses were coded as veridical (word-for-word), gist (general idea), and distortion (error). Linguistic features of the output were coded using the Linguistic Inquiry and Word Count (LIWC) program. Overall, people with MCI produced more verbs, fewer time-related words, and fewer total words than control participants. In the MCI group, delayed unit- and proposition-based veridical and gist recall scores were positively correlated with certainty and causation words, indicating that higher certainty about events and their causal links is associated with better memory. Total words were positively correlated with all immediate and delayed recall scores, indicating that amount of linguistic output is strongly linked to memory in MCI. Time-related words were positively correlated with immediate unit-based veridical recall, suggesting that, in MCI, more words denoting time signal better immediate recall of story details. Examining linguistic features of verbal output in memory tasks could improve detection of MCI.

FACTORS ASSOCIATED WITH COGNITIVE FUNCTION AMONG OLDER ADULTS IN VIETNAM

Yasuhiko Saito[1], Choy Lye Chei[1], Nguyen Vu[2], and Linh Dong[3], *1. Nihon University, Chiyoda-ku, Tokyo, Japan, 2. Institute of Population, Health and Development, Hanoi, Ha Noi, Vietnam, 3. Institute of Population, Health and Development, Ha Noi, Ha Noi, Vietnam*

While Viet Nam is aging rapidly, there are few studies on cognitive function of older adults. We aimed to study status of cognitive function among older adults in Viet Nam and examine factors associated with cognitive function. The baseline data of the Longitudinal study of Ageing and Health in Viet Nam conducted in 2018/2019 was used for the study. LSAHV was a nationally representative survey of those aged 60 and above and computer-assisted personal interview (CAPI) using a tablet was conducted for data collection. The number of older person included in the study was 5,530. Cognitive function was measured by Short Portable Mental Status Questionnaire (SPMSQ). Factors such as demographic, socioeconomic, health behavior and daily activities such as reading newspaper were examined for their association with cognitive function by linear regression analyses. We found that better cognitive function was associated with engaging in physical activity in both male and female, listening to radio and receiving material support from children in male, and reading in female. Poorer cognitive function was associated with IADL limitation and financial support in both male and female, obesity in male, and hypertension and hearing loss in female. Our study provides an understanding of the associated factors with cognitive function of older people in Viet Nam. Some of the factors examined are modifiable and can be improved to prevent cognitive decline. It is also important to consider sex differences in planning and implementation of interventions and programs to prevent cognitive decline in Viet Nam.

PSYCHOLOGICAL WELL-BEING AND PHYSICAL HEALTH ON SUBJECTIVE AND OBJECTIVE MEMORY IN OLDER ADULTS

Zhong-xu Liu[1], Brenda Whitehead[2], and Anda Botoseneanu[1], *1. University of Michigan Dearborn, Dearborn, Michigan, United States, 2. Grace College, Winona Lake, Indiana, United States*

Self-report measures of memory, often used in survey studies of older adults, are heavily influenced by stress, depression, and life satisfaction; this makes it difficult to tease memory performance apart from psychological well-being, and highlights the value of shifting to remotely-administered objective memory tasks when feasible. This study investigates how indicators of psychological well-being, psychological distress, and physical health differentially influence the subjective and objective memory measures in order to compare the extent to which they are explained by participants' psychological and physical health profile. 404 adults aged 55 and older without diagnosed cognitive impairment participated in an online survey which involved measures of physical health (PHY; multimorbidity, BMI), psychological well-being (PWB; life satisfaction, positive and negative affect), psychological distress (PDS; perceived stress, anxiety, depression) and subjective memory complaints (SM), along with remotely-administered objective memory tasks (OM). Regression analyses found all three health/well-being composite variables (PHY, PWB, PDS) maintained significant effects on SM ($p < .01$); PWB and PDS had no significant effects on OM, whereas PHY maintained significance on OM throughout ($p = .02$).So, SM measures are highly influenced by the psychological profile of the participant, highlighting the importance of controlling for these factors when relying on subjective memory measures. That physical health was the only significant predictor of the OM tasks in this study not only reveals remotely-administered OM tasks to be more immune to participants' psychological profile, but also supports previously-established links between physical health and brain function.

METACOGNITION AND EMOTIONS IN OLDER AFRICAN AMERICAN ADULTS

Katherine Kero[1], Colt M. Halter[1], John L. Woodard[1], Bruno Giordani[2], Ana Daugherty[1], and Voyko Kavcic[1], *1. Wayne State University, Detroit, Michigan, United States, 2. University of Michigan, Ann Arbor, Michigan, United States*

Older adults in the earliest stages of cognitive decline often present with subjective cognitive complaints which may not be fully reflected in objective measures of cognition. Previous research suggests that a relationship exists between negative emotions, stress and metacognition, but these relationships have not yet been examined in the context of COVID-19. The purpose of this study was to examine the role of stress and emotions in perceived cognition in the context of the COVID-19 pandemic. Telephone screenings were administered to 206 older African Americans (aged 64–94 years). Objective cognition (Telephone Interview for Cognitive Status [TICS]), subjective cognition (Cognitive Change Questionnaire [CCQ]), perceived stress scale 4 (PSS-4), and survey questions about affective responses to COVID-19 experiences were measured. Objective TICS scores predicted subjective CCQ executive function scores (F(1, 197)=4.37, p=.038, R2=.022). Discrepancy scores were calculated as the standardized residual variance between objective and subjective measures. Survey items describing emotional states were summarized with emodiversity scores following Quoidbach and colleagues' (2014) formula. Discrepancy scores were correlated with perceived stress, as well as global and negative emodiversity (Spearman r=.294, .279, .318, p<.001). In conclusion, we have shown that objective and subjective measures of cognition are related, but discrepancies exist between objectively-measured and self-perceived cognition. Increased stress and greater negative emotions are associated with greater overestimation of cognitive difficulties relative to one's objective level of cognition. As stress and negative emotions have increased for many during the pandemic, individuals may also have depreciated their self-appraisal of cognitive abilities in the present climate.

WHO NEEDS THEIR NEIGHBORS? EXPLORING NEIGHBORHOOD DISPARITIES IN COGNITIVE FUNCTION THROUGH PATH ANALYSIS

Daniel Rong Yao Gan, and John Best, *Simon Fraser University, Vancouver, British Columbia, Canada*

Neighborhoods are diverse and may or may not present opportunities for stress reduction or social engagement depending on their qualities. Based on the stress connectome (Dum et al., 2019), psychosocial stress may accelerate cognitive aging, which explains place-based disparities in cognitive function. This study examines two attributes of the neighbourhood environment, and their potential to influence cognitive function through semantic fluency.Using aggregated baseline (cross-sectional) data from N=1,010 neighborhoods with 5 or more respondents in the Canadian Longitudinal Study on Aging, we examined the effects of neighborhood greenness and cohesion on aggregates of age-, sex-, and education-adjusted cognitive test scores. Participants were community-dwelling adults aged 44 and above. Semantic fluency was assessed using the Animal Fluency Test (AFT). Delayed recall was assessed using Rey's Auditory Verbal Learning Test (RAVLT), whereas executive function was assessed using Mental Alternation Test (MAT). Neighborhood qualities were found to affect delayed recall (B=.34, p<.001) and executive function (B=.42, p<.001) through semantic fluency (B=.08, .10, p<.01). Semantic fluency fully mediated the effects of neighborhood attributes on cognitive function. Further stratifying these neighborhoods by socioeconomic status showed that cohesion has stronger effects in poorer neighborhoods (B indirect=.104) than richer neighborhoods (B indirect=.066). The effect of greenness was no longer significant upon stratification. Neighborhoods offer an important social arena for adults in mid- and late-life to practice conversing, especially in poorer neighborhoods, which improves cognitive function. Creating opportunities for socialization by improving cohesion and neighborhood parks may reduce place-based disparities in cognitive health. Causality remains to be ascertained.

COGNITIVE PROFILES OF SPOUSAL AND PARENTAL CAREGIVERS: AN HRS STUDY

Katelyn Singer[1], and Benjamin Katz[2], *1. Virginia Tech Graduate School, Blacksburg, Virginia, United States, 2. Virginia Tech, Blacksburg, Virginia, United States*

Previous work analyzing the health and wellbeing correlates of caregiving has found increased rates of depression (Caputo, Pavalko, & Hardy, 2016), anxiety (Joling et al., 2015), and elevated risks of health problems, specifically cardiovascular-related incidents like hypertension (Capistrant, Moon, & Glymour, 2012), cardiovascular disease (Capistrant et al., 2012), and strokes (Haley et al., 2010). Research on specific cognitive effects that this responsibility may elicit has been less of an area of focus, especially when examining domains related to executive functioning. The present research investigated whether executive functioning mechanisms (such as processing speed, recall, and attention) are impacted in caregivers and if their function is mediated by interpersonal factors like birth year, gender, education, and depressive symptomology. Using the Health and Retirement Study, we compared spousal and parental caregivers of persons with medical conditions (n = 143) and non-caregivers (n = 975) who completed the 2015 Consumer and Activities Mail Survey (CAMS). Additional demographic and cognitive performance information was paired from the corresponding RAND 2016 data and the 2016 Harmonized Cognitive Assessment Protocol (HCAP) data. Preliminary ANCOVA results indicated, surprisingly, that spousal/parental caregivers were more likely to exhibit better executive function performance (p < .05) compared to non-caregivers, while delayed recall measures were not linked to caregiving status. These results indicate that intact executive function might be linked to one's ability to provide caregiving for parents and/or spouses; while the HCAP was only administered at a single time point, future research should examine the longitudinal effects of caregiving on cognitive function.

THE EFFECT OF MOOD ON SELF-REPORTED COGNITION FOR INDIVIDUALS WITH HIV

Emilee Ertle[1], Darby Simon[2], Jax-Patrick Vogt[1], Benjamin Mast[1], and Shirish Barve[1], *1. University of Louisville, Louisville, Kentucky, United States, 2. University of louisville, Louisville, Kentucky, United States*

Older adults with HIV may experience cognitive changes. The Patient Assessment of Own Functioning Inventory (PAOFI) is a self-report measure of cognitive abilities with memory, language, and cognitive/intellectual functions domains. Self-reported cognition can be influenced by many factors. This study examined the relationship between demographics, performance-based cognitive tests, mood, and self-reported cognition in a sample of 23 HIV-positive individuals (mean age=56.7). The PAOFI memory domain positively correlated with depression (PHQ-9; r=.64, p=.001) and anxiety (GAD-7; r=.48, p=.019), but not tests of cognition. The PAOFI cognitive/intellectual functions domain also positively correlated with the PHQ-9 (r=.65, p=.001) and the GAD-7 (r=.66, p=.001), but not cognitive tests. Regression analysis found similar models for both domains. Both models included education, race, anxiety, and delayed recall. Depression was the only unique variable in the memory model, F(5, 17)=4.09, p=.013, R2=.55, and word reading was unique to the cognitive/intellectual functions model, F(5, 15) = 6.91, p = .002, R2 = .70. In contrast, the language domain correlated negatively with four cognitive measures: word reading (r=-.46, p=.038), learning of a word list (r=-.47, p=-.024), delayed recall of a word list (r=-.51, p=.012), and verbal fluency (r=-.49, p=.045). Regression analysis found age, gender, depression, word reading, and delayed recall predict PAOFI language scores, F(5, 15)=6.27, p=.002, R2=.68. These findings suggest mood, demographics, and performance on cognitive tests are related to self-reported cognition. Mood is likely a better predictor of self-reported memory and higher-level cognitive abilities, and cognitive tests may better predict self-reported language abilities.

EVERYDAY PROSPECTIVE MEMORY LAPSES AND INFLAMMATION IN OLDER ADULTS

Erin Harrington[1], Jennifer Graham-Engeland[2], Martin Sliwinski[3], Mindy Katz[4], Karina Van Bogart[2], Jacqueline Mogle[3], Richard Lipton[4], and Christopher Engeland[1], *1. Pennsylvania State University, University Park, Pennsylvania, United States, 2. Pennsylvania State University, Pennsylvania State University, Pennsylvania, United States, 3. The Pennsylvania State University, University Park, Pennsylvania, United States, 4. Albert Einstein College of Medicine, New York, New York, United States*

Prospective memory (PM) refers to our memory for future intentions, such as attending an appointment or taking medication. Research suggests that PM deficits can distinguish healthy older adults from those in early stages of dementia. However, limited work has examined PM and biological markers associated with pathological memory decline. The current study examined older adults' everyday PM lapses and inflammation. Older dementia-free adults (n =237, Mage=76.86 years), enrolled in the ongoing Einstein Aging Study, completed a two-week ecological momentary assessment (EMA) as part of the first wave of data collection. Participants provided two blood samples (pre/post EMA) and self-reported daily PM lapses during nightly surveys. Inflammatory levels quantified from blood were averaged and included in regression analyses predicting total number of PM lapses (covarying for: age, education, race, health, BMI, depressive symptoms). Reporting more PM lapses was associated with higher circulating levels of interleukin [IL]-8 (p=.007); no significant associations emerged with C-reactive protein or other circulating or stimulated (ex-vivo) cytokines (IL-1β, IL-4, IL-6, IL-8, IL-10, TNF-a). Gender moderated the observed link between IL-8 and PM lapses (p=.015); specifically, higher levels of IL-8 were associated with more PM lapses among men (95%CI=[0.54, 4.72]) but not women (95%CI=[-1.56, 1.25]). Other researchers that found poor cognitive performance in association with elevated IL-8 have suggested that this relation may be indicative of neurodegeneration and future pathology. Future studies should continue to examine daily PM lapses and inflammation across genders to identify mechanisms through which these constructs may relate to neurodegeneration and dementia risk.

DAILY STRESS, DYADIC COPING, AND COGNITIVE FUNCTIONS IN MIDLIFE SAME- AND DIFFERENT-SEX MARRIAGES

Yiwen Wang, *University of Texas at Austin, Austin, Texas, United States*

Little is known about same-sex couples' stress experience and cognitive performance at older ages as compared to different-sex couples. Sexual minority older adults may be at greater risk of cognitive impairment and dementia than their non-LGB counterparts due to life-long exposure to the discrimination and stigma associated with sexual minority status. In this study, I use daily dyadic longitudinal data from the Health and Relationships Project (HARP) to explore the patterns of daily cognitive functioning (memory failures and unconstructive repetitive thinking) among spouses in same-sex and different-sex marriages within the United States (N = 836 individuals, 419 couples). The primary focus of this study is to assess how daily stress—as reported by each spouse—is associated with cognitive function, and how these associations vary for women and men in same- and different-sex marriages. To examine how dyadic coping (the process through which couples manage stress together) matters, I also test whether collaborative dyadic coping buffers the health impact of daily stressors on cognitive function. Results suggest that same-sex couples experience more daily stress and have worse cognition compared to different-sex couples. While both respondent- and spouse-reported daily stress are negatively associated with cognitive function, the association between spouse-reported stress and cognition is stronger for women in same-sex marriages compared to men in different-sex marriages. Both men and women in same-sex marriages are more likely to cope with stress collaboratively than their counterparts in different-sex marriages, which helps buffer the negative consequences of daily stress on cognition.

ASSOCIATIONS BETWEEN NEIGHBORHOOD CHARACTERISTICS AND COGNITIVE FUNCTIONING TRAJECTORIES BY RACE/ETHNICITY

Amy Thierry[1], and Heather Farmer[2], *1. Xavier University of Louisiana, New Orleans, Louisiana, United States, 2. University of Delaware, Newark, Delaware, United States*

Older adults living in neighborhoods with high physical disorder and low social cohesion may be especially vulnerable to experiencing declining health. However, less is known about how neighborhoods may influence age-related patterns of cognitive functioning for different racial/ethnic groups. Therefore, we examine whether perceived neighborhood characteristics (safety, cleanliness, and social cohesion) are associated with trajectories of cognitive functioning across race/ethnicity. Using data from the 2006-2016 waves of the Health and Retirement Study, our study includes 11,870 non-Hispanic White, non-Hispanic Black, and Mexican adults 65 and older. We conducted linear mixed models stratified by race/ethnicity using an age-accelerated design to understand how neighborhood characteristics are related to trajectories of cognitive functioning (measured by the Telephone Interview for Cognitive Status; range: 0-35). We also explore if sociodemographic, behavioral, and health characteristics account for this association. Analyses revealed that cognitive functioning showed a quadratic change with age. Negative neighborhood perceptions were associated with declines in cognitive functioning with increasing age for each racial/ethnic group. Among White adults, all neighborhood characteristics were negatively associated with cognitive functioning in fully adjusted models. For Black adults, perceived uncleanliness was significantly associated with trajectories of cognitive functioning. In Mexican adults, perceptions of uncleanliness and lower cohesion were significantly associated with worse cognitive functioning, but not in fully adjusted models. These findings suggest that the perceived neighborhood context is an important social determinant of cognitive health for older adults, and distinct aspects of the neighborhood may be more correlated with cognitive functioning for certain racial/ethnic groups than others.

THE INTERACTIVE EFFECTS OF EDUCATION AND SOCIAL SUPPORT ON COGNITION IN AFRICAN AMERICANS

DeAnnah Byrd[1], Yanping Jiang[2], Samuele Zilioli[3], Peter Lichtenberg[3], Roland J. Thorpe, Jr.[4], and Keith Whitfield[5], *1. Arizona State University, Phoenix, Arizona, United States, 2. Rutgers, The State University of New Jersey, New Brunswick, New Jersey, United States, 3. Wayne State University, Detroit, Michigan, United States, 4. Johns Hopkins University, Baltimore, Maryland, United States, 5. University of Nevada, Las Vegas, Las Vegas, Nevada, United States*

This study examines whether the effects of receiving or providing social support on cognition differ by education. Data from 602 African American adults (48-95 years) enrolled in the Baltimore Study of Black Aging—Patterns of Cognitive Aging were analyzed using multiple linear regression. We found no main effects of receiving or providing social support on global cognition. However, a significant moderation effect was observed for memory, such that received social support was more strongly associated with higher working memory among less-educated individuals than those with high levels of education, adjusting for age, sex, marital status, chronic health conditions, and depressive symptoms. Study findings demonstrate that social support and education have joint effects on memory outcomes, highlighting the importance of considering psychosocial protective factors that might alleviate, reduce, or even eliminate cognitive health disparities in African Americans.

ARE CAREGIVERS HEALTHIER?: ASSESSING CAREGIVERS' EPISODIC MEMORY IN A MATCHED AND UNMATCHED SAMPLE

Britney Veal, Jessica Yauk, and Hongdao Meng, *University of South Florida, Tampa, Florida, United States*

Recent findings using an advanced methodological technique of propensity matching have found that caregivers may have better cognitive health compared to non-caregivers. However, there are limited studies assessing how personality and other psychosocial variables may affect the relationship between caregiver status and cognition. Utilizing the healthy caregiver hypothesis (HCH), the current study examined the association between caregiving and episodic memory in a matched (N= 1,246) and unmatched (N=3,112) sample of caregivers from the 2016 wave of the Health and Retirement Study. The interaction between caregiving status and personality was also examined. Unadjusted models showed no difference between caregiver status and episodic memory in the samples; however, depression was significantly (p=<.0001) related to cognition in the unmatched sample. In adjusted models for the unmatched sample, conscientiousness (p=0.043), pessimism (p=0.006), and feeling constrained (p=0.028) were found to be significantly associated with episodic memory. In the matched adjusted models, conscientiousness was no longer a significant predictor, but number of chronic conditions was significantly related to episodic memory (p=0.001). The interaction between caregiving and extraversion also approached significance (p=0.076). Findings suggest extraverted caregivers may have better episodic memory performance. These findings highlight the importance of implementing propensity matching in caregiving research. Future research is needed to examine the relationship between coping style and personality specific domains in relation to the HCH.

LONGITUDINAL ASSOCIATIONS BETWEEN PERSONAL GROWTH AND COGNITIVE FUNCTIONING IN ADULTHOOD

Masahiro Toyama, *Marshall University, Barboursville, West Virginia, United States*

While personal growth has been found to be associated with multiple aspects of health in adulthood, its associations with cognitive functioning have not been fully understood. The present study aimed to assess both directions of such longitudinal associations. Using data from the second wave (T1) and third wave (T2) of the Midlife in the United States (MIDUS) study (N = 4,206; mean age = 56.0 [SD = 12.3]), a longitudinal measurement model containing latent variables of episodic memory and executive function was first constructed. Built on the measurement model, a structural equation model was analyzed to assess cross-lagged relationships between personal growth and the two areas of cognitive functioning, in which T1 personal growth predicted residualized changes in episodic memory and executive function, and T1 episodic memory and executive function predicted change in personal growth, controlling for covariates. The results indicated that T1 personal growth significantly predicted smaller decreases in episodic memory, whereas it did not predict change in executive function. T1 episodic memory, but not T1 executive function, significantly predicted smaller decreases in personal growth. The present findings were unique, particularly implying potential longitudinal reciprocity between personal growth and episodic memory. These findings and implications can inform future research aimed at exploring approaches to promoting personal growth and cognitive functioning among aging adults.

PREDICTED DIFFERENCES OF EPIGENETIC AGE AND DEMENTIA RISK AMONG DIFFERENT TRAJECTORIES OF LONGITUDINAL LONELINESS

Morgan Lynch, and Christopher Beam, *University of Southern California, Los Angeles, California, United States*

Different trajectories of loneliness in late adulthood may explain differences in the effects of aging on dementia risk. We tested whether greater or increasing loneliness across three time points demonstrated stronger associations between aging and dementia risk in a sample of 1,814 Health and Retirement Study participants. Dementia risk was quantified using modified Telephone Interview for Cognitive Status scores (TICSm), age was quantified using the epigenetic clock DNAm PhenoAge, and loneliness was measured with the UCLA Loneliness short-form scale. Growth mixture modeling was used to identify loneliness latent classes that best represented trajectories according to model fit statistics. Five groups were identified: low loneliness, high declining, low increasing, moderate and stable, and a moderate declining group. Multivariate analysis of variance was used to test whether class membership differentially predicted TICSm scores, PhenoAge, and the correlation between TICSm and PhenoAge.TICSm scores were statistically significantly lower (worse) for the high-declining compared to the low (-1.08 95% CI [-1.75, -0.42]) and low-increasing groups (-1.63 95% CI [-2.28, -0.98]), and the moderate group was lower than the low-increasing group (-1.11 95% CI [-1.66, -0.57] and the low group (-0.57 [-1.13, -0.002]) (p's < 0.05). No significant differences in PhenoAge or the correlation between PhenoAge and TICSm were found between groups. Analyses statistically adjusted for demographic characteristics, objective social isolation, depression, BMI, smoking, self-rated health, and polygenic risk score for cognition. Results suggest that epigenome-wide ages are unlikely to mediate the relationship between loneliness and dementia risk.

AGE-RELATED DIFFERENCES IN THEORY OF MIND: A TIME-VARYING FUNCTIONAL CONNECTIVITY APPROACH

Samuel Naranjo Rincon[1], Richard Betzel[2], and Anne Krendl[2], *1. Indiana University at Bloomington, Bloomington, Indiana, United States, 2. Indiana University, Bloomington, Indiana, United States*

Theory of Mind (ToM) refers to the act of inferring someone's inner state, such as their emotions and thoughts. Previous work also demonstrated that ToM performance declines across age, but the mechanisms underlying this are not well-understood. The brain regions underlying ToM are generally in the default mode network (DMN) – a group of brain regions particularly vulnerable to pathological aging. Recent work suggests that declines in functional connectivity (FC; correlations between brain regions) during resting state (a period of undirected thought) predict age deficits in ToM. However, these findings come from aggregated FC, ignoring potentially informative details of dynamic changes during resting state. Researching these details may provide more specificity related to social cognitive aging. To test this, 35 older adults (OA; M = 75.61; 22 female) and 40 young adults (YA; M = 21.58; 25 female) underwent resting state and task-based fMRI. During the task, they completed a standard ToM task. We conducted time-varying functional connectivity analyses in the DMN to identify dynamic changes over time. Overall, OA had more variability than YA, but variability benefitted YAs, and not OAs. This occurred specifically in a DMN subnetwork associated with contextual information in memory. These results suggest that variability is useful, but only to an extent. With respect to ToM, variability may promote how YA integrate contextual information to memory, but is ineffective for OA.

DOES PERCEIVED EFFICACY OF COGNITIVE TRAINING BIAS OUTCOMES?

Shenghao Zhang, Nicholas Gray, Neil Charness, and Walter Boot, *Florida State University, Tallahassee, Florida, United States*

Cognitive training has the potential to help older adults maintain or improve their cognitive abilities, but there has been debate regarding how susceptible cognitive outcomes in these studies are to placebo effects. Some previous research has found that expectations can shape performance on study outcomes, although this is not always a consistent finding. The degree to which perceived intervention efficacy can lead to changes in the performance of objective outcome measures typically assessed in these studies is unclear. The aim of the current study is to explore the effects of perceived effectiveness of cognitive training on actual improvements in a large sample of older adults. The current study utilized data from the Intervention Comparative Effectiveness for Adult Cognitive Training (ICE-ACT, NCT03141281) Trial. Two hundred and thirty older adults (Mean age = 72) were randomized into one of four training conditions: (1) a web-based brain game suite, Brain HQ, (2) a strategy video game, Rise of Nations, (3) Instrumental Activities of Daily Living (IADL) training, or (4) an active control condition of puzzle solving. Reasoning, memory, processing speed, and IADL performance were measured before and after the intervention. Perceived efficacy of training in those outcome domains were also measured. Bayesian ANOVA analysis showed strong evidence of group differences in perceived efficacy within all outcome domains across the training conditions whereas Bayesian regression showed moderate to strong evidence against influences of perceived efficacy on changes in performance. Discussion will focus on implications of those results on behavioral and cognitive intervention designs.

SLEEP DURATION MEDIATES THE RELATIONSHIP BETWEEN LETTER FLUENCY AND COGNITION

Hyeon Jung Kim[1], Subhranshu Banerjee[1], and Julie Blaskewicz Boron[2], *1. University of Nebraska Omaha, Omaha, Nebraska, United States, 2. University of Nebraska, Omaha, Omaha, Nebraska, United States*

Changes in cognition are a normative part of aging. Verbal fluency is widely used for assessing cognitive function, including predicting mild cognitive impairment. As people age, sleep duration and quality decrease. This has been associated with cognitive decline; individuals with low-quality sleep (fewer hours and difficulties with initiation or maintenance of sleep) are more likely to complain of poorer cognition. Lack of sleep is detrimental to verbal fluency (word production). Longer sleep has been linked to memory deficits and is a potential indicator of mild cognitive impairment. This study aimed to address the relationship between verbal fluency and cognitive function as mediated by sleep duration. Participants included 31 middle-aged adults (female, n=19;age=53.55±7.18yrs) and 24 older adults (female=14; age=70.33±3.69yrs). The MoCA assessed cognitive functioning. Verbal fluency (90 seconds each) was measured via category word (animals; semantic verbal fluency) and letter word (phonemic verbal fluency; F,A,S). Mediation models used Baron and Kenny's (1986) approach for estimating mediation effects, controlling for age and education. Category results were non-significant. However, sleep duration partially mediated the relationship between letter fluency for each letter and cognitive function, respectively (F:F(2,52)=7.31, p=.002, R2=.22; A: F(2,52)=3.80, p=.029, R2=.18; S: F(2,52)=5.47, p=.007, R2=.17). Sleep hours were negatively associated with letter fluency, meaning fewer hours of sleep improved fluency performance, which in turn was positively associated with MOCA scores (F: b=-.378, 95%CI [-0.64, 0.02]; A: b=-.172, 95%CI [-0.42, 0.01]; S: b=-.24, 95%CI [-0.64, 0.02]. This coincides with the abovementioned literature and helps further understand how sleep and cognitive performance are related.

RELIGION AND TRAJECTORIES OF COGNITIVE FUNCTION AMONG WHITE, BLACK, AND HISPANIC OLDER ADULTS

Madison Sauerteig-Rolston[1], Lisa Barnes[2], Patricia Thomas[3], and Kenneth Ferraro[1], *1. Purdue University, West Lafayette, Indiana, United States, 2. Rush Alzheimer's Disease Center, Rush University Medical Center, Chicago, Illinois, United States, 3. Purdue University--West Lafayette, West Lafayette, Indiana, United States*

Most prior research on the relationship between religious involvement and cognition among older adults is based on cross-sectional data and yields inconsistent results. We use longitudinal data from 14,161 older adults in the Health and Retirement study (HRS) to investigate whether religious involvement, measured by attendance, integration, and religiosity (i.e., beliefs, meanings, and values) is associated with trajectories of cognitive function from 2006 to 2016 among a diverse sample of respondents. We find that religiosity is associated with lower levels of cognition at baseline among White adults (b=-0.12, p < 0.001), but higher levels of cognition among Black adults (b=0.18, p < 0.05). In addition, growth curve analysis reveals that religious attendance is associated with higher cognition over time for Hispanic respondents (b=0.07, p < 0.001). Religious involvement is associated with later-life cognition, but this relationship differs for White, Black, and Hispanic older adults.

COGNITIVE AGING AND SUCCESSFUL AGING: THE ROLE OF MEMORY

Neyda Ma. Mendoza Ruvalcaba[1], Elva Dolores Arias-Merino[2], Melina Rodríguez Díaz[2], and Maria Elena Flores-Villavicencio[2], *1. UNIVERSITY OF GUADALAJARA, Guadalajara, Jalisco, Mexico, 2. Universidad de Guadalajara, CUCS, Maestría en Gerontología, Guadalajara, Jalisco, Mexico*

The cognitive functioning as a general measure, is a criterion commonly used to define and operationalize successful aging(SA). This study aims to explore the specific contributions of the memory and meta-memory to understanding successful aging (SA).(Project-Conacyt-256589)Population based, random sample included n=656 community-dwelling older adults 60-years and older (mean age=72.8, SD=7.6 years, 58% women). Memory was measured with the Digit span test backward (WAIS-IV). and meta-memory through self-report. Objective SA was operationalized as no important disease, no disability, physical functioning, cognitive functioning, and being actively engaged. Subjective SA was an appreciation if they considered themselves as successful agers. Sociodemographic and health data were also asked. Pearson´s correlation test and MANOVAs were performed.In total 11.2% met the criteria for SA, although 76% considered themselves as successful agers. 54.8 has a bad perception of their own memory, while 41.9% have objective decline. Results of the multiple regression analysis emerged on a significant model using the entered method:F=1.13,p<.01, explaining 14.9% of the variance of SA. Specifically, memory and meta-memory explained 19.5% of the variance of objective and 14.4% od subjective SA, 18.4% of the variance in the criterion of life engagement. Knowledge generated by this study reveals the specific role of the memory and metamemory on the SA, both objective and subjective. Besides, sets a scenario to promote successful and healthy aging, through alternatives centered in the improvement of memory and the judgment that is made about the own memory in older adults.

SESSION 6300 (POSTER)

COGNITIVE IMPAIRMENT: SOCIAL DETERMINANTS WITHIN AGE GROUPS AND CULTURAL CONTEXTS

AGING, COGNITION, AND COMMUNITY EXPERIENCE: CARE CONTINUA AND RISK RATIOS OF DAILY LIFE WITH MCI

Kendra Heatwole Shank, *Towson University, Towson, Maryland, United States*

Mild cognitive impairment (MCI) affects an estimated 15-30% of the population (Sachdev et al., 2015; Ward et al., 2012). Cognitive changes directly impact participation in instrumental activities of daily living that support the ability to age in place (Thoma-Lurken et al., 2018; Riley et al., 2014). To date, little is known about these initial challenges beyond self- and caregiver report. The purpose of this research was to understand the nature of out-of-home participation for individuals with cognitive change. Community-dwelling older adults with MCI and their care partners (n=10) were recruited in a suburban region. Data were collected utilizing the "go-along" interview method (Carpiano, 2009) in combination with geospatial mapping and photography. Results included three factors that influenced ongoing community participation related to cognitive changes, including the importance of familiarity of spaces developed over time, strategies related to roadways and parking, and the use of routine to create structure and to increase the support offered by others. In addition, the go-along methodology revealed additional insights about the experiential continuum of providing and receiving care, and how enacting a 'relative' risk and risk perceptions impacted participation. Results of this research offer a unique view into daily life of people with MCI and suggest ways that individuals and caregivers can be advised, and their wellbeing enhanced through continued out-of-home participation. There are also multiple applications for increasing the accessibility of community spaces for cognition inclusion. Theoretical implications are also addressed, via re-framing the selection, optimization, and compensation model for considering cognitive change.

NEUROPSYCHIATRIC SYMPTOMS AND MORTALITY FOR COGNITIVELY NORMAL OLDER MEXICAN AMERICANS

Phillip Cantu[1], Soham Al Snih[2], and Kyriakos Markides[2], *1. The University of Texas Medical Branch, Galveston, Texas, United States, 2. UTMB, Galveston, Texas, United States*

Objectives: Neuropsychiatric symptoms (NPS) present in older adults with Alzheimer's disease (AD) and other dementias are related to mortality. Research on the relationship between NPS and mortality in a non-dementia population has not been conducted. This study examines NPS as a predictor of six-year mortality among community dwelling Mexican Americans aged 80 years and older

Methods: Data included 466 cognitively normal participants from wave 7 of the Hispanic Established Population for the Epidemiologic Study of Elderly. NPS were measured using the Neuropsychiatric inventory (NPI). Cox proportional hazard modes were used to estimate the hazard ratio (HR) of mortality.

Results: The hazard ratio death at six years was 1.02 (95 % CI, 1.00-1.04) as a function of having any NPI score and 1.09 (95% CI 1.02-1.17) for number of NPI conditions, controlling for demographic and health characteristics. Apathy, irritability, and aberrant motor behavior were all independently predictors of mortality.

Conclusions: NPS may be modifiable risk factors to increase survival time or may by indicative of underlying healthy problems. NPS may be related to underlying health conditions among older adults with normal cognitive functioning.

FACTORS ASSOCIATED WITH SUBJECTIVE COGNITIVE FUNCTION IN OLDER ADULTS WITH TYPE 2 DIABETES

Min Jung Kim[1], Cynthia Fritschi[2], and Eunhee Cho[1], *1. Yonsei University, Seoul, Seoul-t'ukpyolsi, Republic of Korea, 2. University of Illinois Chicago, Chicago, Illinois, United States*

Subjective cognitive decline (SCD) could be an indicator of future cognitive impairment in older adults. Diabetes is a well-known risk factor of cognitive impairment, but little is known whether sleep and psychological problems common in older adults with diabetes can contribute to SCD. The study aimed to investigate whether self-reported sleep (sleep impairment and disturbance) and psychological problems (depressive symptoms and diabetes distress) were associated with subjective cognitive function in adults aged ≥ 60 years with type 2 diabetes. Sleep, depressive symptoms, and subjective cognitive function were self-reported using The Patient-Reported Outcomes Measurement Information System. Diabetes distress was assessed using the Diabetes Distress Scale. Covariates (age, sex, race/ethnicity, body mass index, and diabetes duration) were self-reported, and glycemic control (A1c) was measured using a fingerstick test kit. A total of 82 older adults were included (mean age = 68.32 ± 5.29 years, White 76.83%, female 56.1%). Multivariate regression analyses revealed that, after controlling for covariates and A1c, increased sleep impairment was associated with increased concerns on cognitive function reported by older adults (r = -.47, β = -.56). Increased depressive symptoms were also associated with decreased cognitive function perceived by older adults (r = -.44, β = -.47). Sleep disturbance and diabetes distress were not associated with subjective cognitive function. Sleep impairment and depressive symptoms were the two strongest predictors affecting subjective cognitive function. Improving sleep quality and addressing depressive symptoms could be an effective strategy to prevent SCD and potentially delay severe cognitive impairment in older adults with diabetes.

IMPROVEMENT OF CAREGIVER MASTERY IS RELATED TO DECREASED ANXIETY AMONG PEOPLE LIVING WITH COGNITIVE IMPAIRMENT

Yeji Hwang[1], Miranda McPhillips[2], Liming Huang[2], G. Adriana Perez[2], and Nancy Hodgson[2], *1. Drexel University, Philadelphia, Pennsylvania, United States, 2. University of Pennsylvania, Philadelphia, Pennsylvania, United States*

Anxiety is common and distressing in people living with cognitive impairment. High caregiver mastery, a positive view of one's ability to provide care, is known to be protective against anxiety in people whom they are caring for. However, the longitudinal relationship between caregiver mastery and anxiety is unknown. Our objective was to examine whether improvement in caregiver mastery was related to decrease in anxiety in people living with cognitive impairment. This was a secondary data analyses using Healthy Patterns Clinical Trial (NCT03682185), an RCT of a home-based activity intervention designed to improve circadian rhythm disorders in people living with cognitive impairment. A total of 158 participants with cognitive impairment who provided data at both pretest (T1) and posttest (T2) were analyzed. Measures included Caregiver Mastery Scale and Neuropsychiatric Inventory. We used linear regression analyses to examine the relationship between changes in caregiver mastery and changes in anxiety. The sample was primarily female (66.7%), Black (63.1%), with mean age 73.3±8.4. The mean change of anxiety frequency (T2-T1) was -0.2±1.0; anxiety frequency decreased over time. The mean change of caregiver mastery (T2-T1) was 0.4± 3.0; caregiver mastery improved over time. After controlling for age, cognition, changes in sleep impairments, changes in depression, and intervention group assignment, improvement of caregiver mastery over time (B=-0.087, SE=0.035, t=-2.51, p=0.013) was related to decreased anxiety frequency over time (R2= 0.112, F=2.31, p= 0.039). Interventions to improve caregiver mastery may alleviate anxiety symptoms in people living with cognitive impairment. Additional research and practice implications will be discussed.

WEALTH INEQUALITIES IN PHYSICAL AND COGNITIVE IMPAIRMENTS AMONG OLDER ADULTS ACROSS EUROPE AND JAPAN

Nekehia Quashie[1], Dung D. Le[2], Yoko Ibuka[2], and Martina Brandt[3], *1. University of Rhode Island, Kingston, Rhode Island, United States, 2. Keio University, Tokyo, Tokyo, Japan, 3. Technische Universität Dortmund, Dortmund, Nordrhein-Westfalen, Germany*

Although prior research has provided insights on the association between country-level factors and health inequalities, key research gaps remain. First, most previous studies examine subjective rather than objective health measures. Second, the wealth dimension in health inequalities is understudied. Third, a handful of studies explicitly focus on older adults. To bridge these research gaps, this study aims to: i) measure wealth-related health inequalities in physical and cognitive impairments; and ii) examines the extent to which welfare states moderate wealth inequalities in physical and cognitive impairments among older people across Japan and Europe. We utilized harmonized data of non-institutionalized individuals aged 50-75 for physical and cognitive impairments from the Japanese Study of Aging and Retirement (JSTAR) and the Survey of Health, Ageing and Retirement in Europe (SHARE), for (n= 31,969 and 31,348, respectively). We applied a concentration index to quantify the degree of wealth inequalities in impairments. Our multilevel linear regression analyses examined whether national public health spending and healthcare access resources explained cross-country differences in wealth inequalities in physical and cognitive impairments. Findings indicated that inequalities in both impairment outcomes favored wealthier individuals in all countries, but the magnitude of inequality varied across countries under examination. Furthermore, a higher share of public health spending, lower out-of-pocket expenditures, and higher investment in healthcare resources were associated with lower wealth inequalities especially for physical impairments. Our findings suggests that different health interventions and policies may be needed to mitigate specific impairment inequalities.

COHORT DIFFERENCES IN EARLY-LIFE SOCIOECONOMIC STATUS AND LATE-LIFE COGNITIVE IMPAIRMENT IN MEXICO

Brian Downer[1], Mariela Gutierrez[1], Silvia Mejia Arango[2], and Rebeca Wong[1], *1. University of Texas Medical Branch, Galveston, Texas, United States, 2. Colegio de la Frontera Norte, Tijuana, Baja California, Mexico*

Socioeconomic characteristics over the life course are associated with late-life cognitive impairment. However, evidence is lacking from countries like Mexico where population aging is occurring in the context of rapidly changing socioeconomic conditions. We used the Mexican Health and Aging Study to investigate differences between participants aged 60-76 in 2001 (n=5085) and 2018 (n=5947) in childhood (home with indoor toilet, parents' education) and midlife (education, longest held occupation) socioeconomic characteristics and late life cognitive impairment. Cognitive impairment was defined as a low score on >2 out of five assessments. Most participants in the 2018 cohort lived in a home with an indoor toilet as a child (58.1%) and 36.9% had parents who both completed at least some education compared to 41.9% and 28.7% of participants in the 2001 cohort, respectively. Men and women in 2018 had on average 2.34 and 1.83 more years of education than men and women in 2001, respectively. The percentage of women with no main job and men who worked in agriculture were lower in 2018 than 2001 (women: 27.0% vs. 34.6%; men: 23.3% vs. 30.4%). The 2018 cohort had lower odds for cognitive impairment when adjusting for age, sex, marital status, and living in a rural/urban community (OR=0.67 95% CI=0.56-0.81). This difference was reduced after adjusting for childhood socioeconomic measures (OR=0.76 95% CI=0.67-0.86) and was no longer statistically significant after adding midlife socioeconomic measures (OR=0.98 95% CI=0.86-1.12). These findings suggest that improved early-life socioeconomic conditions in Mexico contribute to birth-cohort differences in late-life cognitive impairment.

PSYCHIATRIC HISTORY AND LATER-LIFE COGNITIVE CHANGE: EFFECT MODIFICATION BY SEX, RACE, AND ETHNICITY

Maria Brown, and Miriam Mutambudzi, *Syracuse University, Syracuse, New York, United States*

Objective: To better understand life course influences affecting cognitive function and decline in later life, we explored sex and race/ethnicity differentials in the relationship between a history of psychiatric, emotional, or nervous problems and cognitive functioning in later life, while accounting for early life disadvantage and relevant covariates.

Methods: Multi-level growth curve models examined associations between psychiatric history and cognitive functioning, and differences by sex and race/ethnicity (SRE), in 20,155 Health and Retirement Study (1995-2014) participants aged 65 or older, by estimating cognition scores and plotting trajectories of change with age by SRE.

Results: A history of psychiatric, emotional, or nervous problems was significantly related to cognition scores and rates of decline. Hispanic and Black participants had significantly lower cognition scores at age 75 and steeper rates of decline than White females, and Black race and the Hispanic race-sex interaction erased the protective effects of being female.

Conclusions: Our findings indicate that members of minority groups with a history of psychiatric problems evidence lower cognitive function in later life, and as a result, have a greater need for community-based long-term care than their peers without this history. Future research should include longitudinal analyses of different components of cognitive function, specific psychiatric diagnoses, and life history data that capture socioeconomic and psychosocial experiences throughout the life course. Population level findings as reported here, along with aggregate findings from similar studies, can inform interventions and policies regarding support for populations that are vulnerable to mental illness and to subsequent cognitive decline.

HEALTH ACROSS BORDERS: A CROSS-NATIONAL COMPARISON OF IMMIGRANT HEALTH IN EUROPE

Mara Sheftel[1], Rachel Margolis[2], and Ashton Verdery[3], *1. Penn State University, Brooklyn, New York, United States, 2. Western University, London, Ontario, Canada, 3. The Pennsylvania State University, State College, Pennsylvania, United States*

Although older immigrants are a growing share of the total population in many countries, evidence regarding health differentials by nativity in older adulthood remains underdeveloped. We examine whether foreign-born adults 50 and older in Europe are disadvantaged in terms of multiple health domains, what drives the potential immigrant health disadvantage, and whether such differences are contextually dependent or a general feature of the immigrant experience in Europe. We use the Survey of Health, Aging and Retirement in Europe (SHARE) to estimate physical, mental, and social health of middle age and older adults by nativity in 19 countries. We examine whether nativity-based health disparities can be attributed to demographic composition, socioeconomic factors, family and social support, and life course timing of migration. Last, we examine regional differences in nativity-based health disparities. We find that immigrants aged 50 and above in Europe are more likely to report fair/poor physical health, score worse on EURO-D depression scale, and are more likely to be lonely than the native-born. Socioeconomic status and age at migration partially explain these health differences, although immigrant health disparities remain after accounting for these and other factors. We document some contextual variation within Europe. Immigrants in Eastern, Western and Northern Europe are disadvantaged compared to native-born adults in those regions, while immigrants in Southern Europe are in comparable health to their native-born peers. This article offers new insights into the ways that aging immigrant populations will reshape older adult health profiles in a diverse array of countries.

VARIATIONS IN COGNITIVE STATUS IN OLDER ADULTS WITH MEMORY DIFFICULTIES: THE ROLE OF PERSONALITY AND RESILIENCE

Elizabeth Barbour[1], Kodi van Antwerp[2], Majse Lind[2], Amanda Morgan[2], and Susan Bluck[2], *1. University of Florida, Royal Oak, Michigan, United States, 2. University of Florida, Gainesville, Florida, United States*

By approximately 70-years-old, two out of three Americans experience some cognitive impairment (Hale et al., 2020). Cognitive abilities that often decline with age include working and short-term memory (Cohen, 2019), both important for encoding and retaining information (Alloway & Copello, 2013). Depending on severity, affected individuals may face difficulties performing daily tasks. Beyond biological mechanisms, Self-Life Acceptance (Resilience; Wagnild & Young, 1993) and personality (i.e., Neuroticism, Openness; BFI-2-XS; John & Soto, 2017) may relate to variations in cognitive status. We collected measures of Self-Life Acceptance, Neuroticism, and Openness to investigate their relations to older adults' cognitive status (i.e., working and short-term memory; TICS; Brandt et al., 1988). The sample was comprised of older adults clearly experiencing memory difficulties (N = 49, Mage = 76.12). In a hierarchical regression, the interaction between Self-Life Acceptance and Neuroticism predicted higher cognitive status. Deconstructing this effect, for older people with low-to-moderate Neuroticism, having worse cognitive status was related to greater feelings of Self-Life Acceptance. These individuals show resilience; when cognitive status is worse, acceptance of oneself and life appears to 'kick in' allowing individuals to maintain well-being in the face of memory difficulties. Self-Life Acceptance, however, is not present for those high in Neuroticism. In a second regression, less Self-Life Acceptance and higher Openness were also related to better cognitive status. Our findings show psychosocial factors can predict variations in cognitive status. This work provides a window into how older individuals with different personality traits and varying capacity for resilience cope with memory loss.

UNDERSTANDING CHALLENGES OF PERSONS WITH COGNITIVE IMPAIRMENTS THROUGH THEIR LIVED EXPERIENCES

Maurita Harris[1], Elizabeth Lydon[1], Widya Ramadhani[2], Raksha Mudar[3], and Wendy Rogers[3], *1. University of Illinois Urbana-Champaign, Champaign, Illinois, United States, 2. University of Illinois Urbana-Champaign, Urbana, Illinois, United States, 3. University of Illinois Urbana Champaign, Champaign, Illinois, United States*

Older adults aging with cognitive impairments face a variety of challenges related to their memory, thinking, and concentration in their everyday activities. Understanding their lived experiences s critical to inform the development of technology and supports that can help everyday activities and improve quality of life. We have designed an in-depth interview study to explore the everyday challenges of older adults with cognitive impairments and their response strategies. We will present two case studies to illustrate the richness of the data and its value for guiding intervention design: (1) one older adult with a post-stroke cognitive impairment (PSCI) and (2) one older adult with mild cognitive impairment (MCI). As expected, these individuals reported challenges in different functional activities and described varying solution strategies. The older adult with PSCI noted challenges with completing steps and remembering things when engaging with technology-mediated social activities. This individual reported responding to these challenges by having their own method, such as writing things down or receiving assistance from others. Challenges the older adult with MCI experienced when engaging with technology-mediated social activities, long-distance travel, and caregiving were planning, completing steps, remembering things, and experiencing emotions. This individual responded to their challenges by developing visualizations, methods, routine, and receiving assistance from others. These initial insights about the range of challenges with everyday activities and response strategies highlight the value of qualitative needs assessments in understanding the needs of those aging with cognitive impairment to guide future technology and support.

EXPLORING CULTURALLY RESPONSIVE PHYSICAL ACTIVITY AS A RECRUITMENT AND RETENTION TOOL FOR AFRICAN AMERICAN WOMEN

Joyce Ogunrinde, *University of Houston, Houston, Texas, United States*

Physical activity (PA) is associated with lower cognitive decline and incident dementia for older adults. Yet, PA data (interventions) on older African American (AA) women, a population disproportionately affected by premature aging, are lacking. This limitation reduces the efficacy of PA to reduce cognitive decline, particularly for people of color and more so women of color whose race and gender create unique spaces for PA engagement. Although AA women desire to engage in PA, they face social, structural, and behavioral barriers to PA, challenges that parallel those faced in preventing premature aging (Li et al., 2018). Extant literature on AA women's PA investigates social determinants of health (SDoH) and calls for more attention as to how these factors intertwine to shape these women's PA over time (Fleury & Lee, 2006). Culturally responsive physical activity programs (CRPA) offer a framework for addressing these factors synergistically to promote PA in a way that is desirable to AA women. Specifically, CRPA provides a strength– based approach to explicate the ways PA can redress social, structural, and behavioral causes of cognitive decline and barriers to PA (cf., Joseph et al., 2020). The purpose of this poster is to explore the benefits of CRPA interventions on preventing cognitive decline. Implications include refining current models of PA as premature aging prevention measures by increasing our knowledge of the sociocultural factors shaping AA women's aging and PA behavior and providing greater insight into the mechanisms for recruiting and retaining AA women into PA-based cognitive decline interventions.

SESSION 6310 (POSTER)

FAMILY CAREGIVING I

DEMENTIA CAREGIVER PERCEPTIONS OF TELE-DEMENTIA CARE FOR VETERANS DURING THE COVID-19 PANDEMIC

Sowmya Iyer[1], Victoria Ngo[2], Marika Humber[3], Marisa Brodrick[4], Christine Gould[5], and Ranak Trivedi[6], *1. VA Palo Alto Healthcare System, Palo Alto, California, United States, 2. VA Palo Alto Health Care System, Menlo Park, California, United States, 3. VA Palo Alto Health Care System, Palo Alto, California, United States, 4. VA Palo Alto Healthcare Syste, Palo Alto, California, United States, 5. VA Palo Alto, Palo Alto, California, United States, 6. Stanford University, Palo Alto, California, United States*

The estimated 5 million persons living with dementia in the United States have been greatly impacted by the medical and psychosocial impacts of the COVID-19 pandemic, respite program closures, social isolation, and Veterans seen within the Veterans Health Administration system are particularly vulnerable. Telemedicine provides needed specialty dementia care to these patients with complex needs in their homes, and its uptake has increased during the pandemic. This qualitative, observational study explored informal caregivers' perceptions of tele-dementia care for Veterans seen at 2 sites, Palo Alto and Cleveland, via semi-structured interviews. Twenty-five caregivers (Mean age = 67y, SD=12y, 88% women) were interviewed over telephone following a tele-dementia visit. Themes that emerged from the interviews were that tele-dementia visits: (1) saved caregivers 2.6h±1.5h (Range: 0.5 to 6h) of travel time, (2) required limited preparation compared to in-person visits, (3) mitigated COVID-19 risk and avoided needs for masking and social distancing, (4) avoided behavioral challenges during appointments, and (5) allowed participation from home with minimal disruption of routine. Caregivers described significant physical challenges that made leaving the home for appointments difficult including balance issues, incontinence, and difficulties getting into vehicle. Caregivers plan to continue using tele-dementia services beyond the pandemic due to the convenience. Taken together, these findings indicate that caregivers find tele-dementia care convenient, comfortable, helpful, and timesaving and highly satisfactory. A combination of both in-person and virtual visits would be an ideal future state. This study illustrates how caregivers experience virtual visits for dementia care and will shape future intervention design.

IMPROVING CAREGIVER ASSESSMENT AND COMMUNICATION ABOUT PAIN IN RELATIVES WITH DEMENTIA

Catherine Riffin[1], Lilla Brody[2], Priya Mukhi[3], Cary Reid[4], Keela Herr[5], and Karl Pillemer[3], *1. Weill Cornell Medical College, New York, New York, United States, 2. Weill Cornell Medicine, New York, New York, United States, 3. Cornell University, Ithaca, New York, United States, 4. Weill Cornell Medicine, New York City, New York, United States, 5. University of Iowa, Iowa City, Iowa, United States*

Pain is under-detected and poorly managed in persons with dementia (PWD). Family caregivers are well situated to detect and facilitate management of pain in PWD, but they receive little guidance and training in these tasks. Our group developed the Pain Identification and Communication Toolkit (PICT), a manualized, multicomponent intervention to help caregivers recognize pain in their care recipients and communicate their observations to healthcare providers. PICT includes a) training in administering an observational pain assessment tool, b) coaching in effective pain communication, and c) building caregivers' skills through practice. To evaluate PICT's acceptability, feasibility, and preliminary efficacy, we conducted a pilot randomized controlled trial of N=34 caregivers (n=18 randomized to PICT; n=16 randomized to a control condition). Participants were from diverse racial and ethnic backgrounds (14% Black; 15% Hispanic; 8% Asian; 8% multiracial). Of the caregivers enrolled in the intervention group, 66.7% reported that PICT improved their confidence in identifying pain symptoms, and 83.3% reported that PICT improved their confidence in communicating pain-related concerns to providers. Retention was excellent: 100% of caregivers in the PICT group completed all intervention sessions (4 total); only 5% prematurely terminated the study (did not complete the 12-week post-assessment questionnaire). Notably, caregivers in the PICT group showed a significant improvement in confidence communicating with healthcare providers from baseline to 12-week follow-up (M=3.9 vs. M=4.4; p<.01). Collectively, these findings suggest PICT's potential as an intervention to help caregivers recognize and communicate about pain in PWD and that a full-scale efficacy trial with larger sample is warranted.

INFORMAL CAREGIVING NETWORKS FOR PERSONS WITH DEMENTIA SUPERIMPOSED ON COMPLEX MULTIMORBIDITY

Mi-Kyung Song[1], Sudeshna Paul[1], and Mary Beth Happ[2], *1. Emory University, Atlanta, Georgia, United States, 2. The Ohio State University, Columbus, Ohio, United States*

Informal caregiving research has focused on the primary caregiver and caregiver-patient dyad. Thus, we know little about caregiving beyond the dyadic relationship. This study was to gain a comprehensive understanding of informal caregiving networks for individuals with dementia superimposed on complex multimorbidity. We used egocentric social network analysis to obtain caregiving information of 46 patients with moderate to severe cognitive impairment, 5 chronic conditions on average, and undergoing hemodialysis (4.3 mean years). Most patients (n=35, 77.8%) were Black, 22 (47.8%) male, and mean age of 73.9 years. Starting with the primary family caregiver (FCG), up to 2 additional FCGs were recruited for each patient, totaling 76 FCGs (46 primary, 30 non-primary). Most were a child of the patient (n=39, 51.3%), female (n=57, 75%), and 54.2 years of age. Of the 46 networks, 16 (35%) included only one FCG (singletons). Multimember networks (n=30, 65%) provided longer caregiving than singletons (7.7 vs 3.8 years, p=0.008). Average network size was 2.8, and 26 (54.5%) networks had at least one male caregiver. Among the 30 multimember networks, average size was 3.8, density (proportion of possible ties) was 0.9, and mean degree and maximum degree (number of ties per member to other network members) were 2.5 and 2.8, respectively. Higher mean and maximum degrees were associated with fewer 12-month patient hospitalizations (r=-0.47, p=0.01; r=-0.43, p=0.02, respectively). Including additional caregiver informants significantly increased network size, ties and maximum degree centrality compared to those based on primary caregiver only, allowing for fuller network description.

RESOURCES AND EXPERIENCES AMONG DIVERSE DEMENTIA CAREGIVERS BY GEOGRAPHIC CONTEXT

Aya Yoshikawa[1], Erin Bouldin[2], Mónika López-Anuarbe[3], Tiffany Kindratt[4], Dominique Sylvers[5], and Noah Webster[5], *1. Texas Woman's University, Denton, Texas, United States, 2. University of Utah, Salt Lake City, Utah, United States, 3. Connecticut College, New London, Connecticut, United States, 4. The University of Texas at Arlington, Arlington, Texas, United States, 5. University of Michigan, Ann Arbor, Michigan, United States*

Rural caregivers are often underserved by caregiving services, yet little is known about how the intersectionality of geographic context and race/ethnicity relates to caregiving resources among dementia caregivers. We examined whether 1) caregiving resources and experiences differ across metro and non-metro areas; and 2) the use of caregiving resources is associated with geographic context by race/ethnicity, controlling for age, gender, and education. We analyzed a sample of caregivers of care recipients aged 65 years or older with 'probable' dementia (n= 808) in the 2017 National Health and Aging Trends Study (NHATS) and the associated National Study of Caregiving (NSOC). We defined geographic context by the recipient's residence in metro (urban) or non-metro (rural) counties and grouped formal (respite care, support groups, caregiving training) and informal (family or friend help) resources. Among minority caregivers, 47% of those living in metro and 36% in non-metro areas used a formal service, and 83% and 72%, respectively, used informal resources. Among White caregivers, estimates were 44%, 48%, 76%, and 66%, respectively. Multivariate regression analyses revealed that non-metro White dementia caregivers had 2.04 times higher odds (95% CI=1.10-3.78) of using formal resources than metro White dementia caregivers. This pattern was not observed among minority dementia caregivers. The use of informal resources did not differ across geographic contexts by race/ethnicity. Findings suggest the influence of geographic context on the use of formal caregiving resources varies by race/ethnicity. With higher rates of dementia in non-metro areas, formal caregiving resources among non-metro minority dementia caregivers need more attention.

THE ROLE OF SUPPORT IN THE LIVED EXPERIENCE OF DEMENTIA CAREGIVERS: A SYSTEMATIC REVIEW AND THEMATIC SYNTHESIS

Paria Seyyedmirza, Clark Benson, Diane Ploch Emily, Anna Linden, and Andrea Gilmore-Bykovskyi, *University of Wisconsin-Madison, Madison, Wisconsin, United States*

People living with dementia have complex care needs, which are primarily met by unpaid family caregivers. Family caregivers are often underprepared and under-supported in these roles and often experience negative health impacts associated with their caregiving responsibilities. Research suggests caregiving experiences and associated outcomes can be improved through the use of supportive resources which vary widely in design, access, and implementation. Yet how dementia caregivers perceive, identify, and experience supports in the context of their lived experience is less well understood. Understanding caregivers' un-proscribed conceptualizations of "support" holds important implications for the optimal design of supportive interventions, which are often under-utilized. The objective of this qualitative evidence synthesis was to systematically identify, appraise, and synthesize evidence regarding dementia caregivers' conceptualization of support through qualitative studies focused broadly on eliciting caregivers' reports of lived experience. Forty-one qualitative studies were analyzed and synthesized according to methods suggested by Sandelowski (2007) and Graneheim & Lundman (2004). Six themes were identified and synthesized across included studies which include a range of domains from accessibility, awareness, usability, and match of informal and formal support for caregivers' needs and the needs of their care recipient. Caregivers conceptualized support broadly, extending beyond traditional resources to address aspects of their caregiving role. Findings demonstrate that caregivers readily distinguish between formal and informal support, but do not necessarily evaluate them uniformly and are perhaps focused on the fit of support that extends beyond the caregiving role and is more aligned with how caregivers view support in their daily lives.

THEORETICAL IMPLICATIONS AND IMPACT OF SELF-COMPASSION IN CAREGIVERS OF PEOPLE LIVING WITH DEMENTIA

Claire Grant[1], and Katherine Judge[2], *1. Cleveland State University, Cleveland Heights, Ohio, United States, 2. Cleveland State University, Cleveland, Ohio, United States*

Caregivers of people living with dementia often report greater symptoms of depression, anxiety, and burden. Guided by the Stress Process Model, the study examined the impact of self-compassion on these key psychosocial well-being outcomes in a sample of dementia caregivers (N=99). Participants were 66.7% female, 67.7% White, and 74% were children/in law or grandchildren/in law, with a mean age of 38.61. Findings indicated self-compassion was a significant and unique predictor of symptoms of depression (β = -.25, p = .03), anxiety (β = -.36, p = .01), and burden (β = -.25, p = .02). Additional analyses found support for dysfunctional coping meditating the relationship between self-compassion and caregiver burden ((B = -.20, SE = .06, 95%CI[-.3242, -.0924] dysfunctional coping mediating the relationship between self-compassion and anxiety (B = -.16, SE = .05, 95%CI[-.2257, -.0302] and emotion-focused coping meditating the relationship between self-compassion and depression (B = -.06, SE = .03, 95%CI[-.1388, -.0045]. Results demonstrate the important role of self-compassion along with the impact of coping style on psychosocial well-being outcomes. Discussion will highlight the theoretical implications of these findings along with how these results can be used to develop efficacious interventions for caregivers of persons with dementia. Specifically, tailoring an intervention for dementia caregivers grounded in self-compassion theory as well as Compassion Focused Therapy and Mindful Self-Compassion Therapy may assist caregivers in developing a self-compassionate mindset and skills to more effectively cope with caregiving challenges.

UNDERSTANDING THE IMPACT OF CARE LITERACY ON PREVENTATIVE CARE: EVIDENCE FROM FAMILY CARERS IN JAPAN

Hiroko Costantini, *University of Tokyo, Tokyo, Tokyo, Japan*

To address the importance of family carers' understanding of care, encompassing their own care as well as the broader care and health social systems, this paper leverages the notion of 'care literacy'. The aim of this study is to understand the variation in care literacy and the impact of care literacy on preventative care. The empirical focus is on working family carers for older relatives in Japan, through a cross-sectional online survey that includes a novel operationalization of care literacy, established measure of health literacy, assessment of information used to understand care, and measures of preventative care. The participants' (n = 292) mean age was 53, with 44% women, and an average of 8.3 hours per week caring for their parent(s). The measure of care literacy is shown to be correlated, as expected, but distinct to health literacy (correlation 0.60). Based on regression analysis of care literacy, significant explanatory variables are health literacy (p< 0.001), gender (p=0.044), number of sources of information on care (p=0.029), and care hours (p< 0.001). In contrast, proximity in living arrangements of carer and care receiver, and severity of care needs were not significant predictors. Turning to the impact of care literacy, care literacy is a significant explanatory variable for use of preventative measures (p=0.002), in particular related to nutrition (p< 0.001), frailty (p=0.028), dementia (p=0.090) and general home renovations (p=0.018). The pattern of results from this cross-sectional analysis indicates the importance of understanding the potential for improved care literacy as an enabler of better care.

DEMENTIA FAMILY CAREGIVERS EXPERIENCES USING COMMUNITY-BASED AND HEALTHCARE SERVICES DURING COVID-19

Amanda Leggett[1], Elaina Baker[2], Hannah Lee[2], Anna Webber[2], Sarah Wallace[2], Tyson Fang[2], and Florence Johnson[2], *1. Wayne State University, Ypsilanti, Michigan, United States, 2. University of Michigan, Ann Arbor, Michigan, United States*

Family caregivers are key medical decision makers for persons living with dementia (PLwD) and play a critical role in interfacing with community-based services and the health care system. The COVID-19 pandemic, however, had dramatic impact on service utilization, with many suspended, delayed, or moved to telehealth. Emerging data suggests the pandemic posed challenges to service use for family caregivers, yet how this impacted caregiver's care practice is unknown. An in-depth qualitative interview was conducted with 100 primary family caregivers for PLwD in 2021 on care management during the COVID-19 pandemic. Watkins' rigorous and accelerated data reduction technique was used to analyze qualitative data through open and focused coding and identify themes specific to family caregiver's access to and use of community-based and health care services. Themes emerged regarding challenges and benefits of service use during the pandemic. Caregivers struggled with not being allowed to attend medical appointments with the PLwD or to speak confidentially with the physician over a PLwD's telehealth appointment. Caregivers felt physicians couldn't always read the care situation over telehealth, but appreciated not having to leave the house. Losing the consistency of in-home caregivers or respite programs put additional strain on caregivers, but many found virtual programming engaging. Grocery delivery/pickup was a new service used by many caregivers and found to be supportive of in-home care. As the pandemic evolves, finding ways to support caregivers through continued involvement in health care visits and as they access community services is critical to caregiver and PLwD health and well-being.

MENTAL HEALTH AND WELL-BEING OF OLDER CARERS DURING THE COVID-19 PANDEMIC: EVIDENCE FROM ENGLAND

Giorgio Di Gessa[1], and Debora Price[2], *1. UCL, London, England, United Kingdom, 2. The University of Manchester, Manchester, England, United Kingdom*

Older people caring at home or in the community play a vital role in supporting population health and wellbeing and in protecting health and care systems, often at cost to their own health. Yet there has been very little research or policy attention given to this group of carers during the pandemic. Exploiting longitudinal data from Wave 9 (2018/19) and the first two COVID-19 sub-studies (June/July 2020; November/December 2020) of the English Longitudinal Study of Ageing, we use logistic and linear regression models to investigate associations between changes in provision of informal care and mental health during the pandemic, controlling for socio-demographic characteristics, pre-pandemic physical and mental health, and social isolation measures.

During the first months of the pandemic, about a quarter of older people provided informal care (with ~10% caring for members living in the same household). Those caring in the household experience worse mental health during the pandemic. Even controlling for prior characteristics and lack of social interactions, those caring for family members in the household had higher odds of reporting elevated depressive symptoms (OR=1.67, 95%CI=1.07;2.62), poor self-rated health (OR=1.73, 95%CI=1.09;2.73), anxiety (OR=2.21, 95%CI=1.20;4.06) as well as lower quality of life (B=-0.85, 95%CI=-1.66;-0.05) and life satisfaction (B=-0.43; 95%CI=-0.78;-0.09) than those who were caring for friends and family outside the household. As we aim to build back society and restore the wellbeing of our populations, policies and services should be better directed to support those people who during the pandemic struggled to cope while caring for their family members.

LEFT OUT TO DRY: UNMET NEEDS AND RISK OF DEPRESSION AMONG OLDER ADULTS

Haowei Wang[1], Ashton Verdery[2], Rachel Margolis[3], and Sarah Patterson[4], *1. Tufts University, Quincy, Massachusetts, United States, 2. The Pennsylvania State University, State College, Pennsylvania, United States, 3. Western University, London, Ontario, Canada, 4. University of Michigan, Ann Arbor, Michigan, United States*

Pre-pandemic research has shown adverse consequences of having unmet care needs for older adults' mental health. Due to the broad psychological distress and increased caregiving challenges during COVID-19, older adults' vulnerabilities to unmet needs may be amplified by the pandemic, especially for those with functional limitations and intense care needs. This study aims to examine (1) the associations between unmet needs and depression among older adults before and during the COVID-19 and (2) whether the excess mental health consequences from unmet needs and COVID-19 vary by older adults' dementia status. We pool data from the 2018, 2019, and 2020 rounds of National Health and Aging Trends Study, a nationally representative sample of U.S. Medicare beneficiaries. We analyze N=6,273 older adults aged 70 years and older who had limitations with self-care, household activities, or mobility. Results show that older adults with functional limitations experienced increased risk of depression over time. Before and during the pandemic, older adults with unmet needs and older adults with probable dementia had higher risks of depression compared to their counterparts, respectively. The risk of depression was highest among older adults who had probable dementia and could not have their care needs met. For older adults without dementia, their risks of depression increased significantly from pre-pandemic to COVID-19 if they had unmet care needs. Findings demonstrate the disproportionate impacts of COVID-19 on mental health among older adults. Older adults who have cognitive impairments and unmet needs are in particular need of mental health support.

THE LONGITUDINAL EFFECT OF FINANCIAL DIFFICULTY ON CAREGIVER DEPRESSION

Susanna Mage[1], Kathleen Wilber[2], and Donna Benton[2], *1. University of Southern California, Leonard Davis School of Gerontology, Los Angeles, California, United States, 2. University of Southern California, Los Angeles, California, United States*

Informal caregivers are the backbone of the long-term healthcare system in the United States and crucial in supporting the rapidly increasing aging population. Previous studies have illustrated the negative effects that the caregiving role can have on caregiver mental health, but few studies have examined the singular role of experiencing financial difficulty on caregiver mental health. The aim of this study was twofold: to measure how financial difficulty in 2015 correlates with caregiver depression in 2015, and to examine whether financial difficulty in 2015 can predict caregiver depression in 2017. We used two-wave panel data from the National Study on Caregiving (N=1,125) to conduct both regression and lagged dependent variable (LDV) regression analyses to investigate the cross-sectional and longitudinal effect of financial difficulty on caregiver depression, respectively. Caregiver depression was measured using the 2-item version of the Patient Health Questionnaire-9 (PHQ-2), and financial difficulty was self-reported. Results show that caregivers who did not experience financial difficulty in 2015 had 0.46 times the odds of not being depressed (CI 0.30-0.70, p-value= 0.00) in 2015, compared to those who noted that they did experience financial difficulty. In performing a LDV analysis, outcomes showed that financial difficulty in 2015 was significantly associated with caregiver depression in 2017 (p-value< 0.05), implying that current reported financial difficulty may influence caregiver depression two years later. Conclusions from this work provide support for the development of financial interventions for caregivers experiencing financial difficulty that could play a role in alleviating their depressive symptoms.

WORSENING OF DEPRESSIVE SYMPTOMATOLOGY SINCE BEFORE COVID-19 AMONG CAREGIVERS OF PERSONS LIVING WITH DEMENTIA

Matthew Smith[1], Chung Lin Kew[1], Gang Han[1], Lucas Wilson[1], Shinduk Lee[2], John Fitch[1], and Marcia Ory[1], *1. Texas A&M University, College Station, Texas, United States, 2. University of Utah, Salt Lake City, Utah, United States*

This study examines factors associated with self-reported worsening of depressive symptomatology since before the COVID-19 pandemic among caregivers of persons living with dementia (PLWD). Cross-sectional baseline survey data were analyzed from 76 paid and unpaid caregivers of PLWD participating in a larger NIH-funded study assessing the feasibility of using a novel in-situ sensor system. Using the PHQ-2, caregivers were asked to report their depressive symptomatology twice: (1) retrospectively before the COVID-19 pandemic started; and (2) since the COVID-19 pandemic. A change score was calculated, and whether or not caregivers' depressive symptomatology worsened since before the pandemic served as the dependent variable. A logistic regression model was fitted, controlling for contextual items related to the caregiver, care recipient, and caregiving logistics. On average, caregivers were age 58.09(±16.92) and the majority was female (84.2%). Thirty percent of caregivers reported worse depressive symptomatology since the COVID-19 pandemic than before the COVID-19 pandemic started. Caregivers who were female (OR=25.86, P=0.028), not paid for caregiving (OR=14.59, P=0.047), had lower annual household incomes (OR=0.50, P=0.032), and whose care recipients had higher Mini-Mental State Exam scores (OR=1.78, P=0.005) were more likely to report worse depressive symptomatology since the COVID-19 pandemic. Results suggest that the COVID-19 pandemic intensified depressive symptomatology for many caregivers, and unpaid, female caregivers with fewer financial resources have been especially impacted. As the pandemic continues, support for caregivers of PLWD should be tailored to specifically meet their needs and circumstances.

SPOUSAL ASSOCIATIONS BETWEEN GRANDPARENT CAREGIVING AND WELL-BEING: FINDINGS FROM THE HEALTH AND RETIREMENT STUDY

Athena Chung Yin Chan[1], and Rodlescia Sneed[2], *1. University of Minnesota--Twin Cities, Minneapolis, Minnesota, United States, 2. Wayne State University, Detroit, Michigan, United States*

Numerous studies document the impact of grandparent caregiving on the health and well-being of grandparents; however, there has been little dyadic research on how the caregiving and health-related outcomes of one grandparent influence partner couples The purpose of this study was to determine the interdependence of grandparents' intensity of caregiving and well-being (i.e., depressive symptoms and self-rated health) over time. Participants were 7,133 dyads of American grandparents aged ≥ 50 who participated in the Health and Retirement Study, a population-based study of community-dwelling adults, in 2010 and 2012. Data on hours of grandparent caregiving in the past two years, depressive symptoms, and self-rated health were obtained via self-report. Two longitudinal, dyadic path analyses were conducted using the Actor-Partner Interdependence Model. Within individuals (actor effects), greater depressive symptoms and better self-rated health at baseline, predicted greater depressive symptoms and better self-rated health two years later. Between spouses (partner effects), an individuals' greater depressive symptoms predicted the spouses' greater depressive symptoms. However, grandfathers' better self-rated health predicted subsequent better grandmothers' self-rated health, but not vice versa. Further, greater depressive symptoms among grandmothers predicted lower subsequent caregiving intensity among both grandmothers and grandfathers. Additionally, better self-rated health among grandfathers predicted better self-rated health and lower subsequent self and spousal grandparenting caregiving intensity. Our findings demonstrate that depressive symptoms, self-rated health, and caregiving intensity are interrelated among grandparent couples. Interventions for improving well-being and caregiving outcomes that focus on couples may be more effective than those that focus on individuals.

CONVERSATIONS ON THE COSTS OF CAREGIVING: COMPARING CAREGIVERS' AND FINANCIAL ADVISORS' PERCEPTIONS

Alexa Balmuth, Julie Miller, Lauren Cerino, Adam Felts, Lisa D'Ambrosio, and Joseph Coughlin, *Massachusetts Institute of Technology, Cambridge, Massachusetts, United States*

Costs of caregiving go beyond physical, mental, and emotional; the financial costs are astronomical. On average, family caregivers spend 26% of their income on caregiving (AARP 2021). As the need for family caregivers grows due to longer lifespans (AARP 2020), incorporating the topic of caregiving into financial planning for longevity conversations becomes increasingly necessary. Drawing on data from the MIT AgeLab Caregiver Panel, a research panel of over 1400 family caregivers, and from the MIT AgeLab Preparing for Longevity Advisory Network, a research panel of over 900 financial professionals, this presentation will describe mixed methods research findings that highlight caregivers' and financial professionals' attitudes and perceptions toward caregiving as a topic within client-advisor conversations. Results demonstrate that many caregivers wish they had financially planned for the costs of caregiving more than they did. However, caregivers rarely turn to their financial advisors for support; many perceive their value to be strictly financial and are unaware of their advisors' ability to support them. Despite caregivers' doubts, most financial professionals feel equipped and willing to have caregiving-related conversations with clients. Additionally, while over three-quarters of financial professionals reported making referrals to outside resources for caregiving-related support, some critical avenues – including social workers and therapists, support groups, and respite care providers – were underutilized. Implications of these findings for caregivers and professionals of various industries will also be discussed.

DEVELOPING A RESOURCE FOR LEVERAGING POPULATION DATA SETS TO ADVANCE CAREGIVING SCIENCE

Rebecca Goodwin[1], Katherine Ornstein[2], Catherine Elmore[1], Rebecca Utz[1], Djin Tay[1], Lee Ellington[3], Ken Smith[1], and Caroline Stephens[1], *1. University of Utah, Salt Lake City, Utah, United States, 2. Johns Hopkins, University, Baltimore, Maryland, United States, 3. University of Utah and Huntsman Cancer Institute, Salt Lake City, Utah, United States*

Older adults often rely on other people to help care for them as they age. Caregiving has predominantly been studied through a primary caregiver lens with few studies focusing on the wider caregiving network. However, it is challenging to collect new data about family caregivers, particularly in contexts of serious illness and end of life. Selection and attrition effects, underrepresentation of marginalized or minoritized racial and ethnic groups, and low response rates can bias findings in prospective clinical research. Analyzing existing datasets, particularly population-based data (e.g., registries with linked administrative, health, and vital records) may hold promise to advance our understanding of the role families play throughout the caregiving and bereavement continuum to optimize the health and well-being of older adults. Little is known, however, about existing population-based datasets available for research on family caregiving. We conducted a scoping review of published literature and data repositories to identify datasets relevant for family caregiving research, explore the research reuse of these datasets, and describe potential validity and reliability concerns. Synthesized findings reveal: 1) methodological approaches for identifying the presence and type of caregivers and their level of engagement; 2) inclusion and measurement of key outcome variables; and 3) sampling and study design issues. We describe and compare a selection of high-value existing datasets relevant to family caregiving research. This new research information resource will advance research use of population datasets to improve care for older adults and their family caregivers across the lifespan.

THE ROLE OF THIRD PLACES IN REDUCING LONELINESS AMONG CAREGIVING SPOUSES

Yeon Jin Choi, and Jennifer Ailshire, *University of Southern California, Los Angeles, California, United States*

Loneliness is a public health concern that is associated with poor mental and physical health. Caregiving spouses of community-dwelling older adults often have high levels of caregiving burden, which make them more vulnerable to social isolation and loneliness. There has been a growing interest in third places as mediums for social interaction. Research on third places shows a positive association of greater access to third places with social networks and social health. However, this has not been tested in the context of caregiving. In this paper, we examined the role of various types of third places in reducing loneliness among caregiving spouses. We used the 2006-2016 Health and Retirement Study and the National Neighborhood Data Archive to examine the relationship between the availability of third places per square mile and loneliness. Third places include food outlets (e.g. grocery stores), eating and drinking places (e.g., restaurants, coffee shops), commercial establishments (e.g., department stores), entertainment organizations (e.g., museum), exercise facilities (e.g., fitness), religious organizations (e.g., churches), civic and social organizations (e.g., social clubs), personal care services (e.g., barbershops, beauty salons), and social services for older adults (e.g., senior centers). We found that caregiving spouses living in neighborhoods with greater availability of third places had lower levels of loneliness. We also found gender differences in the association. For instance, greater availability of eating and drinking places was associated with loneliness only among females. Increasing access to places that provide opportunities for social interactions may prevent social isolation and reduce loneliness among caregiving spouses.

CONTEXTUAL FACTORS RELATED TO CAREGIVER IDENTITY DISCREPANCY IN EMERGING ADULT CAREGIVERS

Anastasia Canell, and Grace I. L. Caskie, *Lehigh University, Bethlehem, Pennsylvania, United States*

Approximately 12-18% of unpaid family caregivers to older adults in the U.S. are 18-25 years old, yet minimal research focuses on this subgroup of caregivers (Levine, 2005). Because caregiver identity theory postulates that the extent to which informal caregivers integrate their caregiving roles and duties into their identity may relate to caregiver distress (Montgomery & Kosloski, 2012), contextual factors related to higher reported caregiver identity discrepancy should be assessed. In a sample of 135 emerging adult informal caregivers, the current study compared caregiver identity discrepancy across two factors: level of caregiving responsibility and caregiver gender. Caregiving responsibility had four groups: (1) primary with minimal help (n=54), primary but receiving some help (n=51), secondary (n=18), or shared (n=12). Caregiver identity discrepancy was measured using the five subscales of the Family Caregiver Identity Scale (Eifert et al., 2019). Caregiver identity discrepancy differed significantly by caregiving responsibility (p<.001) and gender (p=.046). Emerging adult caregivers identifying as women reported statistically more caregiver identity discrepancy in family obligation (p=.003) and master identity (p=.036) domains than men. Caregiving responsibility showed statistically significant differences in role engulfment (p<.001), loss of shared identity (p<.001), family obligation (p=.013), and master identity (p=.010) domains of identity discrepancy. Emerging adult caregivers identifying as the primary caregiver with minimal help from others reported significantly more identity discrepancy than all other groups across subscales. These results demonstrate that young caregivers who have little support in task responsibilities and identify as a woman may be at particular risk for experiencing caregiver identity discrepancy.

SESSION 6320 (POSTER)

FRAILTY (HEALTH SCIENCES POSTERS)

A PHENOMENOLOGICAL STUDY ON THE PERCEPTION OF FRAIL ELDERLY IN SUBJECTIVE HEALTH AWARENESS AND SUCCESSFUL AGING

Jisu Seo[1], Rhayun Song[2], Moonkyoung Park[2], and Ahyun Ryu[2], *1. Nursing, Daejeon, Taejon-jikhalsi, Republic of Korea, 2. Chungnam National University, Daejeon, Taejon-jikhalsi, Republic of Korea*

BackgroundFrailty is a multi-dimensional concept including physical, functional, and psychological aspects. The frail elderly have been assessed by various instruments, yet the classification of being frail is not often consistent with the perception of individuals. PurposeThis study aimed to explore the perception of frail older adults in subjective health awareness and successful aging. Methods9 participants who met the following inclusion criteria: older than 70 years, defined as frail status screened by frailty index, and signed the consent form. Data was collected through in-depth interview with recording, and evaluated by phenomenological approach of Colazzi. Results The content analysis on the perception of 9 participants on subjective health awareness yielded 7 theme-clusters and 3 categories: (a)Recognize frailty, (b) Vague and endless emotions, (c)Reflecting on the past and thinking about death. The participants described ‘recognizing frailty through senility’ as a subjective health awareness. The perception of participants on successful aging was structured 6 theme-clusters and 4 categories: (a)Sustainable health, (b)The goal of successful goodbye, (c)Responsibility for parenting, (d) The best wisdom that aging gives life. The participants described ‘living in the present and successfully parting with it’ as a successful aging. ConclusionThe participants who were categorized as frail status did not perceive themselves as frail. Many participants perceive being frail as natural process of aging, and their successful aging as sustainable health and successful goodbye. It is pertinent to understand the meaning of successful aging and subjective health awareness of frail older adults to provide effective intervention to help them.

SCREENING OF US VETERANS AT HIGH RISK FOR OUTCOMES FOLLOWING COVID-19 BY FRAILTY STATUS

Catherine Park[1], Aanand Naik[1], Molly Horstman[1], Benjamin Seligman[2], Ariela Orkaby[3], Orna Intrator[4], Kristine Lynch[5], and Javad Razjouyan[1], *1. Veterans Affairs, Houston, Texas, United States, 2. David Geffen School of Medicine at UCLA, Los Angeles, California, United States, 3. VA Boston, Boston, Massachusetts, United States, 4. Canandaigua VA Medical Center, Canandaigua, New York, United States, 5. University of Utah, Salt Lake City, Utah, United States*

Frailty increases risk of adverse outcomes in the presence of stressors such as COVID-19 infection. We examined the association between different levels of frailty and outcomes following COVID-19 infection. This is a retrospective cohort study of US Veterans aged ≥50 years, active Veterans Health Administration (VHA) care users, and tested positive for COVID-19 between 02/15/2020 and 09/30/2021. VHA frailty index (VA-FI) was calculated from one year prior to the COVID-19 testing and divided into three groups: robust (≤0.1), prefrail (0.1-0.2), and frail (>0.2). The risk of hospitalization, ICU admission, ventilator use, and in-hospital mortality were calculated using logistic regression adjusted by age, sex, body-mass-index, and race. The performance of VA-FI in predicting outcomes was compared to age or Charlson comorbidity index (CCI) using area under the curve (AUC). Of 204,426 COVID-19 positive Veterans, 32,965 were hospitalized (age: 71.4±10.4 years, BMI: 29.5±7.1 kg/m2). We observed higher odds of hospitalization (frail, adjusted odds ratio (aOR)=8.64; prefrail, aOR=2.57), ICU admission (frail, aOR=1.58; prefrail, aOR=1.32), ventilator use (frail, aOR=1.97; prefrail, aOR=1.57), and mortality (frail aOR=2.15; prefrail, aOR=1.55) in frail and prefrail compared to robust Veterans. We observed that VA-FI had higher AUC in predicting hospitalization (AUC 0.75) independent of age (0.59) and CCI (0.63). Veterans with COVID-19 who were frail and prefrail had a higher risk of hospitalization, ICU admission, ventilator use, mortality compared to robust. VA-FI may be a useful tool at the time of COVID-19 diagnosis to triage patients at risk for adverse outcomes.

ASSOCIATION OF LOWER URINARY TRACT SYMPTOMS WITH INCIDENT FRAILTY AND MORTALITY AMONG OLDER COMMUNITY-DWELLING MEN

Peggy Cawthon[1], Scott Bauer[2], Charles E. McCulloch[3], Kristine Ensrud[4], Kaiwei Lu[5], Rebecca Scherzer[5], Kenneth Covinsky[3], and Lynn M. Marshall[6], *1. California Pacific Medical Center Research Institute, San Francisco, California, United States, 2. UCSF and San Francisco VA, San Francisco, California, United States, 3. UCSF, San Francisco, California, United States, 4. University of Minnesota Medical School and Minneapolis VA Health Care System, Minneapolis, Minnesota, United States, 5. San Francisco VA, San Francisco, California, United States, 6. OHSU-PSU School of Public Health, Portland, Oregon, United States*

Lower urinary tract symptoms (LUTS) are associated with increased risk of new mobility and functional limitations among older men. Our objective was to evaluate the longitudinal relationship between baseline LUTS severity and incident frailty or all-cause mortality among 3667 community-dwelling non-frail men age >70 years from the Osteoporotic Fractures in Men (MrOS) study. LUTS severity at analytic baseline was defined using the American Urologic Association Symptom Index (AUASI). Phenotypic frailty was defined at baseline and 2-year follow-up visits using modified Fried criteria and classified as robust (0), intermediate stage (1-2), or frail (3-5); men classified as frail at analytic baseline were excluded. Vital status was assessed every 4 months. Since the proportional odds assumption was not met, we used multivariable multinomial logistic regression to estimate odds ratios (OR) for the association between baseline LUTS severity and incident frailty or death at follow-up compared to robust. OR were adjusted for demographics, health-behaviors, comorbidities, and cognition. After a mean follow-up of 2.3 years, 37% of men were categorized as robust, 46% were intermediate stage, 9.2% developed incident frailty, and 7.9% had died. Per 4 point higher AUASI, the adjusted odds incident frailty versus robust was 1.23 (95% CI 1.12, 1.34). Odds of death versus robust was not statistically significant (OR=1.05, 95% CI 0.94, 1.18). In conclusion, non-frail men with greater LUTS severity at baseline have slightly greater odds of incident frailty within 2 years. Clinicians should be aware that LUTS severity is a prognostic marker for developing frailty in older men.

ALIGN-CARE: IMPLEMENTATION AND FEASIBILITY OF NEW GERIATRIC SURGERY CO-MANAGEMENT MODEL FOR PHYSICAL AND SOCIAL FRAILTY

Fred Ko[1], Stephanie Chow[1], Abigail Baim-Lance[1], Amy Park[1], Gabrielle Schiller[2], Minji Kim[1], Kavya Sreevalsan[1], and William Hung[1], *1. Icahn School of Medicine at Mount Sinai, New York, New York, United States, 2. CUNY School of Public Health, Astoria, New York, United States*

Pre-operative geriatric evaluation in frail older patients that addresses both medical and psychosocial needs is often not completed prior to surgery, leaving frail older adults ill prepared for surgery. The ALIGN-CARE interprofessional co-management model uniquely serves to standardize care and coordination amongst the surgeon, geriatrician and social worker in ambulatory settings to allow a greater window of time to intervene for surgical optimization. Program elements include assessment of preoperative medications, functional status, cognition, nutrition, What Matters Most, advance care planning (ACP), and social determinants of health. Recommendations and action items from the geriatric-social work team are presented to surgeon and primary care physicians for follow-up and optimization. Program and process elements recorded in a REDCap database facilitate longitudinal evaluation of ALIGN-CARE model implementation feasibility. Initial data of 9 frail surgical oncology patients indicate increases in meaningful ACP discussions, patient-oriented decisions regarding surgery candidacy, and surgeon referrals for inpatient geriatric consultation post-operatively as a result of ALIGN-CARE. Current analyses to assess feasibility and quality of the

program include thematic coding of program documents, semi-structured interviews of key stakeholders (surgeons, geriatricians, social workers, patients), and quantitative analysis of program outcomes, including uptake of program elements and process measures. Planned areas of analytic focus include workflow, cross-specialty coordination, and patient and primary care engagement and activation. We anticipate identifying specific barriers and facilitators of ALIGN-CARE implementation in our evaluation to aid the dissemination and upscaling of interprofessional co-management programs aimed to improve outcomes and quality of life for frail, older surgical patients.

CLINICAL TRIAL OF METFORMIN FOR FRAILTY PREVENTION IN COMMUNITY-DWELLING OLDER ADULTS WITH PRE-DIABETES

Sara Espinoza, Chen-pin Wang, Joel Michalek,
Daniel MacCarthy, Tiffany Cortes, Becky Powers, and
Nicolas Musi, *University of Texas Health Science Center at San Antonio, San Antonio, Texas, United States*

Background: Metformin may reduce frailty through improving insulin resistance and inflammation, aging mechanisms known to increase frailty risk. We describe a randomized clinical trial of metformin for frailty prevention in community-dwelling older adults with pre-diabetes and provide baseline characteristics of randomized participants.

Methods: Older adults (65+ years) are studied in this randomized, double-blind, placebo-controlled trial of metformin (max 2,000 mg/day). Pre-diabetes, required for inclusion, is assessed by 2-hour oral glucose tolerance test (OGTT). Individuals with glomerular filtration rate < 45 mL/min and frail individuals (Fried criteria) are excluded. The primary outcome, frailty, is assessed by both Fried criteria and frailty index. Secondary outcomes are physical function (short physical performance battery), lower extremity strength (Biodex), 6-minute walk, inflammation (systemic and skeletal muscle tissue), muscle insulin signaling, insulin sensitivity (insulin clamp), glucose tolerance (OGTT), and body composition (dual-energy x-ray absorptiometry). Subjects are followed for 2 years with safety assessments every 3 months and frailty assessment and OGTT every 6 months.

Results: 145 participants (49% female, 35% Hispanic) are randomized. Mean age is 71.8 ± 5.4 years (range: 65-88), body mass index is 30.8 ±6 kg/m2, and Hemoglobin A1c is 5.6 ±0.4%. Using Fried criteria, 63.4% have frailty score of 0, 30.3% a score of 1, and 6.2% a score of 2.

Conclusion: Metformin is being examined as a potential therapeutic agent to prevent frailty in older adults with pre-diabetes. Findings from this trial may have future implications for screening and treatment of pre-diabetes in older adults for the prevention of frailty.

DEPRESSIVE SYMPTOMS MEDIATE THE ASSOCIATION OF FRAILTY PHENOTYPE SYMPTOMS AND COGNITION FOR FEMALES BUT NOT MALES

Nicholas Resciniti[1], Anwar Merchant[2], and
Matthew Lohman[2], *1. University of Southern California, Los Angeles, California, United States, 2. University of South Carolina, Columbia, South Carolina, United States*

We aimed to evaluate whether depressive symptoms mediated the relationship between frailty phenotype and cognitive function by sex. Frailty phenotype symptoms, cognitive function scores, and depressive symptoms were measured in 3,705 community-dwelling US adults from the Health and Retirement Study (HRS) from 20012-2016. Fried's frailty phenotype criteria (weakness, slowness, physical inactivity, low weight, and exhaustion) were used as a continuous score for frailty symptoms (0-5). Global cognition was measured by the Telephone Interview for Cognitive Status (range: 0-35). The Centers for Epidemiologic Studies-Depression Scale (CES-D) was used as a continuous measure to assess depressive symptoms (0-8). We used mediation analysis to estimate the direct and indirect effects of frailty symptoms on cognitive scores to evaluate the role of depressive symptoms as a potential mediator. Males had a larger total effect (β= -0.43; 95% CI: -0.66, -0.02; p< 0.001) for lower cognitive score for each increase in frailty symptom compared to females (β= -0.28; 95% CI: -0.47, -0.08; p=0.02), suggesting all five frailty symptoms was associated with 2.15 lower cognitive scores for males and 1.50 for females. A significant indirect effect from frailty phenotype to cognition was found through depressive symptoms for females (β= -0.03; 95% CI: -0.06, -0.00; p=0.02) but not males (β= -0.04; 95% CI: -0.08, 0.00; p=0.07). These results highlight the importance of identifying individuals with frailty and depressive symptoms to monitor and provide interventions to preserve cognitive function

FRAILTY AND OSTEOARTHRITIS IN OLDER CHILEANS

Cecilia Albala[1], Carlos marquez[2], Barbara Angel[3],
Rodrigo Saguez[3], and Lydia lera[3], *1. INTA, Universidad de Chile, Santiago de Chile, Region Metropolitana, Chile, 2. INTA, Universidad de chile, Macul, Region Metropolitana, Chile, 3. INTA, Universidad de chile, Santiago de Chile, Region Metropolitana, Chile*

The adverse consequences on health of frailty, make it early diagnostic very important. The coexistence of frailty with osteoarthritis, a frequent condition especially in older women, has been less studied Objective. to study the association between frailty and self-reported osteoarthritis

Methods: Cross-sectional study in994 people65 years and older (72.1%women, mean age72y±6.7) from the Alexandros cohort, designed to study disability associated with obesity in community-dwelling people60y and older living in Santiago/Chile. The frailty phenotype was defined as having ≥3 from the5 following criteria: weak handgrip dynamometry, unintentional weight loss, fatigue/exhaustion, five chair-stands/slow walking speed and low physical activity. Self-reported osteoarthritis was registered.We found a prevalence of osteoarthritis was much higher in women than in men (49.4% vs22.9%, p<0.01) Osteoarthritis was present in46.5% of frail people and30% of the robust ones (p=0.01). Frailty was present in53.3% of women with OA in and11.8% of men with OA. The crude OR for the association of frailty with Osteoarthritis was significant only for women (OR=1.43;95% CI:1.06-1.93). After sex and age adjusted logistic regression for frailty in Ostroarthritis, the OR for frailty was OR=1,39;95%IC (1,04-1,85), p=0,025, but in women with osteoarthritis the adjusted OR for frailty increase to OR=11.98 (5.637-13.23)Considering the severe consequences of frailty over health, the high burden of Osteoarthritis, its high frequency in women, and the strength of the association between both conditions, the screening for frailty is highly recommended In older women with Osteoarthritis

INTERVENTIONS TO PREVENT THE FRAILTY IN OLDER WOMEN WITH FRAILTY: A SYSTEMATIC REVIEW AND META-ANALYSIS

Ha Na Jeong, Sun Ju Chang, Joo Ri Kim, and
Gi Won Choi, *Seoul National University, Seoul, Seoul-t'ukpyolsi, Republic of Korea*

Background: Frailty is a health challenge related to adverse health outcomes in older adults. Older women are more likely to be frail than older men. However, few studies have reviewed the effectiveness of interventions for older women with frailty is scant. Objective: This systematic review aimed to explore the properties of interventions and to investigate their effectiveness in preventing the progression of frailty in older women with pre-frailty or frailty.

Methods: Narrative synthesis was conducted to identify the contents, outcome variables, and findings of the interventions. Then, a meta-analysis was performed to evaluate the effectiveness of exercise interventions on grip strength, sit-and-reach, sit-to-stand, and timed up and go tests.

Results: Twenty-six studies were selected, including 14 randomized controlled trials and 12 quasi-experimental studies. These studies implemented exercise (96.2%), nutrition (15.4%), hormone replacement (7.7%), toileting strategies (3.8%), and laughter interventions (3.8%). The selected studies assessed physical, psychological (11.5%), and cognitive health (11.5%), as well as quality of life (19.2%). The meta-analysis found significant effects of aerobic and resistance exercise interventions on the sit-to-stand (SMD = 1.30, 95% CI [0.70, 1.90], $p < 0.001$) and timed up and go scores (SMD = -0.56, 95% CI [-0.93, -0.19], p = 0.003).

Conclusion: Exercise interventions are essential to improve physical health, in particular mobility, in older women with pre-frailty or frailty. Future studies should consider theoretical frameworks and evaluate psychological and cognitive health as well as quality of life to develop and provide effective interventions to prevent the progression of frailty in older women.

BLOOD-BASED BIOMARKER CHANGES IN A PHASE 2B TRIAL ASSESSING LOMECEL-B IN OLDER ADULTS WITH FRAILTY

Kevin Ramdas[1], Danial Mehranfard[1], Eric Naioti[2],
Geoff Green[1], Lisa McClain-Moss[1], Dan Gincel[1],
Joshua Hare[1], and Anthony Oliva[1], *1. Longeveron Inc., Miami, Florida, United States, 2. Longeveron, Inc., Miami, Florida, United States*

Aging frailty (AF) is a multidimensional geriatric syndrome that is characterized by physical and cognitive symptoms, increasing the vulnerability of affected older adults to adverse health outcomes. Mechanistically, a low-grade chronic inflammatory state (inflammaging), endothelial dysfunction, and decreased regenerative capacity are thought to be major contributors to AF pathophysiology. Lomecel-B is an allogenic medicinal signaling cell(MSC) formulation that can potentially ameliorate AF through pleiotropic mechanisms, including anti-inflammatory, pro-vascular, and pro-regenerative activities. We completed a Phase 2b randomized, double-blinded, placebo-controlled trial designed to assess Lomecel-B benefits for AF via change versus placebo in the six-minute walk test(6MWT), to assess the dose-response relationship, and to evaluate bioactivity via changes in blood-based biomarkers. Enrolled subjects were aged 70–85 years with mild-to-moderate AF, a reduced 6MWT of 200-400m, and Tumor Necrosis Factor-α of ≥ 2.5pg/mL indicative of inflammaging. In total, 143 subjects received a single intravenous infusion of Lomecel-B at doses of 2.5 x 107 cells (25M, N=35), 5.0 x 107 cells (50M, N=30), 1.0 x 108 cells (100M, N=33), or 2.0 x 108 cells (200M, N=16), or placebo (N=29). Safety and efficacy assessments were performed at 1, 3, 6, and 9 months post-infusion. Increases in 6MWT and decreases in serum levels of the blood-based biomarker Soluble-Tie-2 were observed at 9 months in the Lomecel-B groups versus placebo. Notably, both observations were seen in a dose dependent fashion with 200M showing the highest effect. Based on the findings, a next-phase trial is being developed to advance this clinical program and will be presented.

POLYPHARMACY, FRAILTY, AND DISABILITY-FREE SURVIVAL IN COMMUNITY-DWELLING HEALTHY OLDER INDIVIDUALS

A R M Saifuddin Ekram[1], Robyn Woods[2], Joanne Ryan[2],
Sara Espinoza[3], Julia Gilmartin-Thomas[4], Raj Shah[5],
Mark Nelson[6], and Michael Ernst[7], *1. Monash University, Nunawading, Victoria, Australia, 2. Monash University, Melbourne, Victoria, Australia, 3. Sam and Ann Barshop Institute, UT Health San Antonio, San Antonio, Texas, United States, 4. Victoria University, Melbourne, Victoria, Australia, 5. Rush University, Chicago, Illinois, United States, 6. Menzies Research Institute, University of Tasmania, Hobart, Tasmania, Australia, 7. The University of Iowa, Iowa City, Iowa, United States*

BACKGROUND: Polypharmacy and frailty are two common geriatric syndromes. We examined the association between polypharmacy and frailty and if, together, they predicted disability-free survival (DFS), defined as time to the first event of dementia, persistent physical disability or death.

METHODS: We included 19,114 participants from the "ASPirin in Reducing Events in the Elderly" (ASPREE) clinical trial. Polypharmacy was defined as regular, concomitant use of five or more prescription medications. Frailty was assessed using a modified Fried phenotype and a deficit accumulation frailty index (FI) of 66 items. The association between polypharmacy and frailty was assessed by multinomial logistic regression. In addition, Cox regression was used to determine the association between polypharmacy-exposed frailty and DFS.

RESULTS: Individuals with polypharmacy (vs. < 5 medications) were 55% more likely to be pre-frail (Relative Risk Ratio or RRR: 1.55; 95%Confidence Interval or CI:1.44, 1.68) and three times more likely to be frail (RRR: 3.34; 95%CI: 2.64, 4.22) according to Fried phenotype. Frail individuals had a two-fold reduction in their survival free of dementia/disability (Hazard ratio or HR: 2.16; 95%CI: 1.56, 2.99), whereas frail individuals with polypharmacy had a four-fold reduction (HR: 4.24; 95%CI: 3.28, 5.47). Effect sizes were more prominent when frailty was assessed using the FI than when assessed by Fried phenotype.

CONCLUSION:

Polypharmacy was significantly associated with pre-frailty/frailty. Polypharmacy-exposed pre-frailty/frailty increased the risk of death, dementia or physical disability among older adults. Addressing polypharmacy in older people could ameliorate the impact of frailty on individuals' functional status, cognition and survival.

DEVELOPMENT OF A TRANSITIONAL CARE PROGRAM FOR FRAIL OLDER ADULTS BETWEEN HOSPITAL AND HOME

Ji Yeon Lee, Eunhee Cho, Sue Kim, Gwang Suk Kim, Kyung Hee Lee, and Chang Oh Kim, *Yonsei University, Seoul, Seoul-t'ukpyolsi, Republic of Korea*

Frail older adults particularly need transitional care between hospital and home due to physical function decline and psychological instability after discharge. This study aimed to develop a transitional care for frail older adults in Korea who are discharged home following hospitalization. The Returning Home (Rehome©) program was established through the three phases according to the Medical Research Council's 2013 guidelines. 1) Identifying the evidence base phase included a systematic review of literature and needs assessments from interviews with frail older adults. The core intervention components (e.g., geriatric assessment, transitional care planning, home visits, phone follow-up, community service liaison, and family engagement) were determined. 2) At the phase of identifying theory, the transition theory was selected and modified to fit the target population in the context of the Korean healthcare system. 3) Phase three was for the modeling process and outcomes. Based on the result from phases 1 and 2, the Rehome program was developed considering clinically applicable strategies. The final Rehome program consisted of a comprehensive geriatric assessment at admission; structured discharge/transitional care planning (e.g., medication review, education for chronic disease management, emergencies, and geriatric syndromes, and community resource) at discharge; a home visit and six phone follow-up calls up to 12 weeks after discharge; and emotional support and engagement of the family during the entire period. The Rehome program showed good content validity. The Rehome as a frailty-focused transitional care program could improve the transition through implementing a tailored intervention that meets the care needs of these vulnerable populations.

RISK OF FRAILTY ASSOCIATED WITH COGNITIVE DECLINE, SENSORY IMPAIRMENTS, AND FUNCTIONAL LIMITATION IN OLDER ADULTS

Jinhee Shin, Gwang Suk Kim, and Agani Afaya, *Yonsei University, Seoul, Seoul-t'ukpyolsi, Republic of Korea*

The purpose of this study was to examine the effects and risk factors of cognitive decline, sensory impairment, and functional limitation associated with frailty among older adults. We conducted secondary data analysis using data from the Korean Longitudinal Study of Aging (2006–2018). The participants of this study consisted of 1,789 older adults over the age of 65 in South Korea who had never experienced frailty at the beginning of the survey (2006). Participants were classified into two groups, frailty and non-frailty, based on frailty events over time. We used Kaplan–Meier analysis to determine the effects of frailty-related group differences on cognitive decline (K-MMSE), sensory impairment (visual and hearing), and functional limitation (K-ADL) from 2006 to 2018. To determine the risk factors associated with frailty, the Cox regression analysis was performed. This study established that over time, approximately 71.2% of the older adults (n = 1,274) developed frailty. The study also revealed that over time, both physical (sensory impairment and functional limitation) and psychological factors (cognitive decline) could lead to frailty. We also identified that demographic (age, female), physical (BMI, chronic disease, hearing, vision, and K-ADL), and psychological (K-MMSE) factors were associated with frailty. This study provides an opportunity for healthcare professionals and policymakers to implement intervention programs tailored to ensure regular monitoring prevention and among of these risk factors.

TRAJECTORIES OF SKELETAL MUSCLE MASS AND FAT MASS AND THEIR IMPACTS ON MORTALITY IN OLDER JAPANESE ADULTS

Satoshi Seino[1], Yu Taniguchi[2], Miki Narita[1], Takumi Abe[1], Yu Nofuji[1], Yuri Yokoyama[1], Shoji Shinkai[3], and Yoshinori Fujiwara[4], *1. Tokyo Metropolitan Institute of Gerontology, Itabashi, Tokyo, Japan, 2. National Institute for Environmental Studies, Tsukuba, Ibaraki, Japan, 3. Kagawa Nutrition University, Sakado, Saitama, Japan, 4. Tokyo Metropolitan Institute of Gerontology, Tokyo, Tokyo, Japan*

Skeletal muscle mass and fat mass have differential impacts on mortality between men and women. We aimed to determine age-related trajectories of skeletal muscle mass index (SMI) and fat mass index (FMI) among men and women and to examined their impacts on mortality risks. This prospective study included 1,770 (863 men and 907 women) aged ≥65 years who participated in health check-ups; the total number of observations was 6,110. SMI and FMI were determined using segmental multi-frequency bioelectrical impedance analysis, and their age-related trajectories from age 65–90 years were examined using group-based semiparametric mixture models. SMI and FMI age-related trajectories for all-cause mortality were determined by multivariate-adjusted hazard ratios (HRs) and 95% confidence intervals (CIs). SMI and FMI trajectories were classified into three trajectories in both sexes: the low- (28.6% and 34.0%), middle- (56.0% and 47.5%), and high-trajectory (15.4% and 18.5%) groups in men and the low- (27.6% and 40.9%), middle- (51.6% and 48.1%), and high-trajectory (20.8% and 11.0%) groups in women. The median follow-up was 5.3 years; 101 (11.7%) men and 56 (6.2%) women died. Compared with the low-trajectory groups, male multivariate-adjusted HRs for mortality in the middle- and high-trajectory groups were 0.89 (95% CI: 0.57–1.39) and 0.34 (0.13–0.93) for SMI, and 0.76 (0.47–1.23) and 1.13 (0.60–2.14) for FMI, respectively. Corresponding female multivariate-adjusted HRs were 1.00 (0.50–2.02) and 1.64 (0.62–4.36) for SMI, and 0.74 (0.38–1.43) and 0.37 (0.12–1.14) for FMI. Maintaining high skeletal muscle mass is important for prolonging life expectancy, especially in men.

VULNERABILITY TO ANTICHOLINERGIC MEDICATION ASSOCIATED FRAILTY IN LOW-INCOME MINORITY OLDER ADULTS

Lana Sargent[1], Matthew Barrett[2], Huma Nawaz[2], Marissa Mackiewicz[2], Youssef Roman[2], Patricia Slattum[2], Sarah Hobgood[2], and Elvin Price[2], *1. VCU School of Nursing, Ashland, Virginia, United States, 2. Virginia Commonwealth University, Richmond, Virginia, United States*

Low-income minority older adults are highly susceptible to drug adverse effects of medications due to aging, comorbidities, and polypharmacy. Several studies have demonstrated anticholinergic medication is associated with frailty, supporting the hypothesis for mechanistic peripheral nervous system effects. The goal of this cohort study is to determine peripheral nervous system effects of anticholinergic medication exposure with frailty by conducting a sensitivity analysis using multiple anticholinergic tools. Spearman correlation matrix and intraclass correlation coefficients (ICC) are used to determine the function of five clinical Anticholinergic Burden Scales (ACBS): Anticholinergic Burden Scale (ACB), Anticholinergic Drug Scale (ADS), total standardized daily doses (TSDD), and Cumulative Anticholinergic Burden scale (CAB). Ordinal logistic regression and area under the curve (AUC) are used to evaluate anticholinergic burden-associated frailty models. The cohort included 80 individuals (mean age = 69 years; 55.7% female, 71% African American). Among individuals prescribed anticholinergics, 33% are robust, 44% pre-frail, and 23% frail. All scales are highly correlated with each other ($p < 0.001$), ICC3 = 0.66 ($p < 0.001$, CI 95% 0.53-0.73). All five of the scales predicted pre-frail and frail status ($p < 0.05$) with low misclassification rates for frail individuals (AUC = 0.70 – 0.80). Considering ACBS are highly correlated and all predict frailty; all of the scales can be used in future frailty research; however, the CAB and TSDD consider both potency and dose. Additional research is necessary to understand the peripheral nervous system effects of anticholinergic drug exposure and if deprescribing can improve frailty status.

EXPLAINABLE MACHINE-LEARNING FOR PREDICTING PREOPERATIVE FRAILTY PHENOTYPE USING ELECTRONIC HEALTH RECORDS

Mamoun Mardini, Catherine Price, Patrick Tighe, and Todd Manini, *University of Florida, Gainesville, Florida, United States*

Pre-operative frailty among patients is strongly associated with poor post-operative outcomes. Operationalizing frailty in clinical practice is challenging due to the lack of resources and pragmatic complexities. Feasible tools are needed to cover the scarcity in this area. Harnessing electronic health records (EHR) to screen pre-operative frailty and its related post-operative outcomes would be important for decision making and planning care management. This study aimed to validate an EHR-based machine learning model for pre-operative frailty ascertainment. Measures of the frailty phenotype (slowness, weight loss, exhaustion, low physical activity, and grip strength) were collected on approximately 14,000 patients (aged 65-100 years) by nurses housed in the UF Health pre-surgical center. Patients with at least 3 out of 5 syndromic components were considered frail. We utilized an explainable machine learning algorithm, eXtreme Gradient Boosting (XGBoost), to build our models to predict pre-operative frailty phenotype. We extracted the important predictors that contributed to predicting the outcome and evaluated their relationship with the outcome. The machine learning model achieved an area under the curve (AUC) of 0.71 in recognizing pre-operative frailty across all surgical specialties. The top five predictors for frailty phenotype were hemoglobin level, sex, education level, history of COPD, and diabetes. Using explainable machine learning approaches on EHR data provides a moderate mapping of the frailty phenotype in pre-operative settings. Funding: UF Claude D. Pepper Older Americans Independence Center P30AG028740 and R01 AG055337.

SESSION 6330 (POSTER)

GLOBAL AGING AND HEALTH

RISK FACTORS OF DISABILITY AMONG COMMUNITY-DWELLING OLDER ADULTS WITH HYPERTENSION IN THAILAND: THE HART STUDY

Utoomporn Wongsin, and Tuo-Yu Chen, *Taipei Medical University, Taipei City, Taipei, Taiwan (Republic of China)*

About 60% of the older adults in Thailand experience hypertension, a condition that increases the risks of disability. However, little to no study has investigated modifiable risk factors to prevent disability in this segment of population in Thailand. Therefore, this study aims to investigate factors associated with disability among community-dwelling older adults aged 60 years or above with hypertension in Thailand. Longitudinal data (wave-1 [2015] and wave-2 [2017]) were from the Health, Aging, and Retirement in Thailand (HART) survey. Descriptive analysis and logistic regression analysis were employed to analyze the data. Outcome variables were difficulty with activity of daily living, hearing-related disability, vision-related disability, and pain-related disability in wave-2. Sociodemographic information, health behaviors/health status, mental illness, chronic diseases, and disability at baseline were independent variables. The results showed that older age significantly predicted difficulty with activity of daily living and hearing-related disability among community-dwelling older adults with hypertension in Thailand. Drinking alcohol significantly predicted vision-related disability. No factors were found to be a significant factor for pain-related disability. Our analysis provided useful information for the prevention of disability among older adults with hypertension in Thailand.

GLOBAL DIFFERENCES IN ADAPTATION TO SOCIETAL AGING: A CROSS-SECTIONAL COMPARISON OF 143 COUNTRIES

Cynthia Chen[1], Kenwin Maung[2], Jemima Koh[3], and John W. Rowe[4], *1. National University of Singapore, Singapore, Singapore, 2. University of Rochester, Rochester, New York, United States, 3. National University of Singapore, Singapore, Singapore, 4. Columbia University, New York City, New York, United States*

Societal ageing is our success story of advancing public health and medicine in reducing the risk of premature death, the control and prevention of diseases, and improvement in social and economic development. Almost all countries are experiencing growth in size and proportion of older persons. In 2019, 703 million older persons were aged 65 and above, projected to double to 1.5 billion by 2050. We construct a multidimensional ageing Index that extends the Ageing Society Index, to account for global differences in societal ageing from 2015 to 2019 for 18 OECD countries. The Index is a weighted sum of scores for five domains that are important for societal ageing: well-being, productivity and engagement, equity, cohesion, and security. We compare the overall index and domain scores between countries. High-income countries dominated the top rankings. The overall Ageing Society Index ranged between 35.0 for Gabon in Africa to 74.6 for Switzerland in Europe. Top-performing countries were high-income countries from the European and Oceania regions, while the worst-performing countries were countries from the African region. Domain scores ranged from 19 (India) to 91.6 (Singapore) for well-being, 12.8 (Mozambique) to 88.5 (Finland) for equity, 32.8 (Gabon) to 88.8 (Uzbekistan) for cohesion, and 27.8 (Madagascar) to 88.8 (Switzerland) for security. Our multidimensional index helps identify specific societal gaps for policymakers to address. Furthermore, the cross-country comparison can be instructive for policymakers to adapt the experiences of successful countries to domestic policies.

THE IMPACT OF EARLY CONDITIONS ON THE PREVALENCE OF DIABETES ACROSS THREE COHORTS OF OLDER ADULTS IN MEXICO

Rafael Samper-Ternent[1], Jesús-Daniel Zazueta-Borboa[2], Neil Mehta[3], cesar González[4], and Rebeca Wong[1], *1. University of Texas Medical Branch, Galveston, Texas, United States, 2. Netherlands Interdisciplinary Demographic Institute, 's-Gravenhage, Zuid-Holland, Netherlands, 3. UTMB, Galveston, Texas, United States, 4. University of COlima, Colima, Colima, Mexico*

In low-and-middle-income countries like Mexico the impact of disadvantaged early childhood conditions (ECC) on later-life health in not well known and may be changing across birth cohorts. Our objective is to examine the impact of ECC on the propensity to have diabetes in three different cohorts of older adults aged 60-69 (born in 1930-1939, 1940-1949, 1950-1959). We examine to what extent differences in ECC, sociodemographic characteristics, and lifetime obesity explain the differences in the prevalence of diabetes across the cohorts. We use five waves of data from the Mexican Health and Aging Study (n=10,313). We estimate a series of logistic regression models and use counterfactual analyses to identify the roles of ECC and lifetime obesity on cohort-specific diabetes prevalence and on differences in diabetes prevalence across cohorts. Our results suggest that improvements in ECC would decrease prevalence of diabetes by 12.5% in the 1930-1939 cohort and 10% in the 1950-1959 cohort. However, the rise of obesity at age 50 counters this effect and leads to higher prevalence of diabetes in both cohorts. Our models show that if everyone had a normal weight at age 50, the prevalence of diabetes would decrease by 31.3% for the 1930-1939 cohort, 27.3% for the 1940-1949, and 26.7% for the 1950-1959 cohort. Despite improvements in socio-economic conditions during childhood in Mexico, the increase in lifetime obesity appear to offset the benefits derived from better ECC resulting in higher rates of diabetes.

EVERYTHING HAS CHANGED FOR THE WORSE: EXPERIENCES OF ELDERS DISPLACED BY ARMED CONFLICT IN ETHIOPIA

Getachew Gebeyaw[1], Shambel Dessale[1], Eyayu Kasseye[1], and Margaret Adamek[2], *1. University of Gondar, Gondar, Oromiya, Ethiopia, 2. Indiana University, Indianapolis, Indiana, United States*

In November 2020 an outbreak of ethnically and politically motivated armed conflict started in Tigray, Ethiopia and expanded to the Amhara and Afar regions, bringing a devastating impact upon civilians and disadvantaged groups. Persons living in those areas, including elders, were forced to flee and seek refuge at internal displacement centers. The purpose of this study was to investigate the challenges faced by older individuals fleeing the war zone and settling in internal displacement centers during Ethiopia's armed conflict. A qualitative descriptive case study was used in this cross-sectional investigation. Purposive sampling was used to identify 13 displaced older adults. Data from the in-depth interviews with elders were supplemented with key informant interviews and observations. Narrative data was analyzed using thematic analysis. Findings revealed that the older adults faced a variety of challenges in the war zone while escaping their homes and in the displacement center, all of which negatively impacted their physical and psychosocial well-being. Elders fled on foot and walked for three days without food to reach the internal displacement center. In addition to food shortage, other themes included loss of significant others, family disintegration, and lack of care and support. The findings call attention to the need for practical access to social and economic integration of elders in the aftermath of war as well as ongoing psychosocial intervention. In Ethiopia and in other war-affected areas, displaced older people need tailored support.

ETHIOPIAN CENTENARIANS: HEALTH CONDITIONS AND SENSORY/COGNITIVE FUNCTIONALITY

Samson Chane[1], and Margaret Adamek[2], *1. Bahir Dar University, Bahir Dar, Oromiya, Ethiopia, 2. Indiana University, Indianapolis, Indiana, United States*

Globally, the centenarian population is expected to increase in the coming three decades reaching 3 million by 2050. In Ethiopia, like other Sub-Saharan African countries, information about the health condition, sensory and cognitive functionality of centenarians is scanty. This study examined the health conditions and sensory/cognitive functionality of Ethiopian centenarians. A qualitative case study design was employed. Nine centenarians (1 woman, 8 men) between age 100 and 108 were identified using snowball sampling. Data were generated through in-depth interviews and analyzed using descriptive analysis. All 9 were Orthodox Christians and lived in rural areas either with their wives (3) or other relatives. Four centenarians could read and write, two attended grade eight and nine, and three were non-literate. Before retirement the centenarians engaged in different occupations as farmers (4), shoemaker, government employee, school teacher, priest, “bounty hunter” and mechanic. Most perceived that their sensory and cognitive functionality was normal until their later 90s except for minor complaints. Centenarians faced walking difficulty (5), joint tightness (4), back pain (4), fatigue, dental issues, stuttering, hypertension (3), insomnia, diabetes, anorexia, severe headache, constipation and anxiety. Two centenarians identified themselves as escapers. Centenarians faced hearing defect (4), sight problems, and a decrease in taste and smell. Two reported proper functioning of their sensory organs. Despite various health problems, the Ethiopian centenarians aspired to live longer resiliently. Findings call for further study and the need for social workers, caregivers, and health care practitioners to consider the health conditions, sensory and cognitive functionality of centenarians.

LIFE ON THE STREETS IS HORRIBLE: OLDER RURAL-URBAN MIGRANTS COPE WITH HOMELESSNESS IN ETHIOPIA

Getachew Gebeyaw[1], Messay Kotecho[2], and Margaret Adamek[3], *1. University of Gondar, Gondar, Oromiya, Ethiopia, 2. Addis Ababa University, Addis Ababa, Adis Abeba, Ethiopia, 3. Indiana University, Indianapolis, Indiana, United States*

The prevalence of homelessness among older adults in Ethiopia is growing. While prior studies examined the push factors and challenges of homeless elders, little is known about how older people in Sub Saharan Africa cope with homelessness. This study explored the coping strategies of homeless older people in Kobo Town, Ethiopia. Purposive sampling was used to identify 10 homeless older people and four key informants. Study participants were homeless for a year or longer. Thematic analysis was used to analyze the data collected through in-depth interviews. To cope with the challenges faced on the street, homeless older people used various strategies including begging, holy water, drying leftover food, using river water for hygiene and sanitation, sleeping in church compounds, and creating their own social networks. Despite their efforts, the coping strategies used by elders were not sufficient. In the absence of family and government support, study participants relied heavily on begging to meet their survival needs. The findings call attention to the need for a national income support program and other supportive services for older adults. Homelessness is the product of a failing support system. Despite Ethiopia having a Plan of Action for Older Persons and Social Protection Policy for Vulnerable Groups, these policies have not been effectively implemented leaving older adults with no safety net. This study calls for the development of new policies to empower older people in Ethiopia and prevent them from turning to begging as their only recourse.

SESSION 6340 (POSTER)

GRIEF AND THE LIFE SPACE

MEASURING A GOOD DEATH: AN ASSESSMENT ACROSS FOUR COUNTRIES

Sarah Clem, *University of Maryland, Baltimore, Baltimore, Maryland, United States*

A good death is often viewed as a common goal in end-of-life care, yet our understanding of what qualifies as a good death is still under development. Previous studies have attempted to conceptualize our understanding of a good death and have highlighted the need to improve our measurement of this construct. The present study examines a measure of a good death across four countries. Data for this study were derived from the Four-Country Survey on Aging and End-of-Life Medical Care (2017), in which participants were sampled using a random digit dial method. The study relies on a sample of 4,239 participants from the US, Italy, Japan, and Brazil. Confirmatory Factor Analysis (CFA) was employed to fit a measurement model to the full sample for a measure of the importance of a good death. Once model fit was deemed sufficient, a multi-group CFA was used to assess invariance across the four countries. Model fit was adequate at the configural and metric levels, highlighting that across the four countries importance of a good death was measured and understood the same. However, the model failed at the scalar level of invariance, implying that indicators for the importance of a good death are valued differently across the four countries. Further developing our understanding of a good death and how it is measured is essential for improving quality end-of-life care. This study identifies a quality measure of good death while simultaneously highlighting the limitations in using such a measure in a transnational context.

THINGS LEFT UNDONE: RELATION OF GRIEF TO SENSE OF PURPOSE IN BEREAVED OLDER ADULTS

Shubam Sharma[1], Emily Mroz[2], and Susan Bluck[3], *1. Kennesaw State University, Kennesaw, Georgia, United States, 2. Yale University, New Haven, Connecticut, United States, 3. University of Florida, Gainesville, Florida, United States*

Sense of purpose is grounded in life experiences (Ko et al., 2019) and can be threatened by the loss of a loved one. The death of a spouse in late life can be particularly disruptive when the bereaved struggle with perceptions of unfinished business with the deceased. This mentality may also derail their sense of life purpose. This study examined the association between persistent grief symptomatology (Prigerson et al.,1995) and sense of purpose (Ryff, 1989) in conjugally-bereaved older adults (N = 53; Mage = 81.59). Unfinished business constructs (i.e., unfulfilled wishes, unresolved conflict; Holland et al., 2018) were tested as mediating grief-purpose relations. Older adults who reported greater grief symptomology also experienced lower sense of purpose ($r = -.27$, $p < 0.05$). Extent of unfulfilled wishes fully mediated the relation between grief symptomology and sense of purpose ($t = -2.26$, $p < 0.05$); unresolved conflict did not act as a mediator. Findings indicate that the association between experiencing pervasive grief symptomology and a disrupted sense of purpose may be due, in part, to ongoing rumination about unfulfilled wishes: missed opportunities to meaningfully engage with one's spouse before death. Results are poignant given recent COVID-19 physical distancing requirements that separated older couples during spouses' dying days, potentially prompting unfulfilled wishes across bereavement. Findings highlight the need for palliative care practices that facilitate optimization of relationships at end of life and grief support practices that re-ignite purpose after difficult spousal loss.

SOCIAL SUPPORT AND STRAIN AS PREDICTORS OF MULTIMORBIDITY FOLLOWING A MARITAL TRANSITION

Emily Denning[1], Jason Newsom[1], Anda Botoseneanu[2], Heather Allore[3], Corey Nagel[4], David Dorr[5], and Ana Quiñones[6], *1. Portland State University, Portland, Oregon, United States, 2. University of Michigan Dearborn, Dearborn, Michigan, United States, 3. Yale University, Guilfrod, Connecticut, United States, 4. University of Arkansas for Medical Sciences, Little Rock, Arkansas, United States, 5. Oregon Health & Science University, Portland, Oregon, United States, 6. Oregon Health and Science University, Portland, Oregon, United States*

Marital transitions (MTs; widowhood or divorce) are stressful events that impact the health of older adults. This study examined the impact of social support and social strain on multimorbidity trajectories using data from the Health and Retirement Study (HRS). Participants were 377 adults age 50+ with a single MT between years 2006 and 2016. We used piecewise growth curve modeling to investigate whether social support and strain from one's spouse, children, family, or friends, measured prior to transition, predicted trajectories of chronic conditions (count of 8 conditions: hypertension, diabetes, cancer, lung disease, heart disease, stroke, arthritis, and cognitive impairment) following MT. Covariates included sex, age, education, race/ethnicity, and wealth. On average, chronic conditions were increasing before MT, B = .172, SE = .021, p < .001, and after MT, B = .211, SE = .031, p <.001. Participants had an average of 2.2 chronic conditions at MT. Spousal support prior to MT was associated with fewer chronic conditions at MT, B = -.863, SE = .427, p = .043, whereas support and social strain from friends were each associated with more chronic conditions at MT (support: B = .772, SE = .354, p = .025; strain: B = 1.288, SE = .387, p = .001). Support from children was positively associated with more chronic conditions following MT, B = .212, SE = .084, p = .011, which may reflect adult children providing support in response to parental health decline.

CHANGES IN LIFE-SPACE WITH LOSS OF RELATIVES AND FRIENDS AMONG OLDER ADULTS: RESULTS FROM THE UAB STUDY OF AGING

Amelia Driggers[1], Richard Kennedy[2], and David Buys[1], *1. Mississippi State University, Mississippi State, Mississippi, United States, 2. University of Alabama at Birmingham, Birmingham, Alabama, United States*

Increasing age brings greater risk of the death of friends and family (hereafter referred to as loss). Loss may impact individuals' life-space mobility (LSM); however, no research has explored relationships between loss and LSM trajectories. Using the UAB Study of Aging, we examined differences in LSM trajectories of 1000 community-dwelling older Alabamians (65+years) with and without loss during the study period. We assessed LSM using the UAB Life-Space Assessment (LSA), a validated instrument measuring individuals' ability to move through zones ranging from their bedroom to out of town. We assessed loss every 6 months using a standard bereavement questionnaire capturing spousal, other relative, or friend loss. We used piecewise linear mixed effects models to compare LSA trajectories. Those who do not experience loss had a baseline mean LSA score of 49.5 and show a decline of 0.08 points per year (p < 0.001). Those that do experience loss had a baseline LSA score of 60 and decline by 1.0 point per year before the loss (p < 0.001), accelerating to 1.8 points per year after the loss (p < 0.001). Those with loss do not experience acute decline post loss but do have an acceleration of the pre-existing decline. More research is needed on this topic to better understand the impact of loss on LSM trajectories; but this finding suggests that more public health and clinical interventions may be needed for those who experience loss. Specifically, bereaved individuals may benefit from social, mental, or healthcare services for loss-related challenges.

THE RELATION BETWEEN DEATH PREPARATION AND LIFE SATISFACTION AMONG KOREAN OLDER ADULTS

Suha You, and Giyeon Kim, *Chung-Ang University, Seoul, Seoul-t'ukpyolsi, Republic of Korea*

Objectives: There is a growing interest in death preparation as an important process to achieve ego integrity at the last stage of life. However, in South Korea, conversations about death remain taboo especially with older adults. Thus, this study aims to examine the association between preparation for one's death and life satisfaction among Korean older adults.

Methods: Data for this study were drawn from the 2020 National Survey of Older Koreans conducted by the Korean Ministry of Health and Welfare. The sample was limited to adults aged 65 and older (N=10,097). The survey measured preparation for death, life satisfaction, and various covariates (e.g., sociodemographic characteristics, physical conditions, psychological conditions). Hierarchical multiple regression analysis was used to examine whether death preparation influences life satisfaction among Korean older adults.

Results: Results from hierarchical multiple regression showed that after adjusting for covariates, those who reported more preparations for death mentally (B=.054, p<.001) and materially (B=.035, p<.001) were more likely to have greater satisfaction in life than their counterparts.

Conclusion: Findings suggest that it is necessary to generate proper information and recognition about death at the government level and activate discourses on death preparation in later life.

SESSION 6350 (POSTER)

HEALTH, MENTAL HEALTH, AND SOCIAL SERVICE INTERVENTIONS

POETRY AND UNCOVERING THE MYSTERY OF SOCIAL PROBLEMS: AN ARTS-BASED INQUIRY TO AGING CARE

Heng Wu, and Peter Szto, *The University of Nebraska at Omaha, Omaha, Nebraska, United States*

This research focuses on a current social welfare problem: unemployment and the loss of employer-based health insurance among non-elderly adults aged 18 to 64. The literature covers this social problem in terms of health status, access to medical care, employed versus unemployed working-age adults, mitigating the risks of unemployment, and loss of health insurance via the Consolidated Omnibus Budget Reconciliation Act of 1985 (COBRA) and the Health Insurance Portability and Accountability Act of 1996 (HIPAA). As good as the findings are, they are methodologically limited by looking at only half the story. This research asks a different question: how might the humanities and arts-based perspective address the social problem? It aims at answering why the employment status is related to health and health insurance. Chinese poetry has a long rich tradition of expressing insights about the inner life since antiquity to the present. These reflections include practice wisdom and keen observations on aging. This poster presents case findings on the use of Chinese poetics to inform aging care in the West. Each case provides discussions on why social welfare system comes up short to solve the problem and how the social welfare system can be effectively changed. Researchers use survey data to compliment Chinese poetic insights about employment status and insurance status to illustrate the correlation between respondents' health status with versus without employment. Findings are hoped to interpret the role of family as a social unit where it consists in social welfare along with the speculative inquiry of poetry.

INTERGENERATIONAL TRANSMISSION OF "SEVA": ELDERS MODEL SELFLESS SERVICE IN SOUTH ASIAN HOMES FOR CHILDREN

Connie Corley, Laura Sherwood, Dibendu Ghosh, and David Willis, *Fielding Graduate University, Santa Barbara, California, United States*

Life course theory is a framework for examining the role of elders in modeling altruistic behavior or "seva" (selfless service) in two homes for children: Unatti (Bhaktapur, Nepal) and Ramana's Garden (Rishikesh, India). Two American women, compelled to impact the plight of children subject to poverty, trafficking and/or caste discrimination (Dalits, the former "untouchables"), each founded homes 20+ years ago and modeled selfless service exemplified by children, some now in "emerging adulthood," who are giving back to their communities. In this intergenerational/intercultural multiple case study, narratives of the program founders now in mid- to late adulthood are presented along with narratives of six young adults who continue to provide nurturance to younger children and engage in projects to educate and feed residents of the homes and nearby communities. The life course principle of time and place situates the children in areas of their countries with relatively low literacy rates. The founders saw the value of education to empower young people, especially girls, to expand their opportunities and serve as role models for children coming into the homes after them. The linked lives principle is evident through shared relationships with the founders as these young people navigate political crises, disasters like the Nepal earthquake, and health crises like the Covid-19 pandemic. Some become leaders themselves as they have been mentored over their life course. A sense of agency is experienced in their young adulthood as more choices for their lives become available as an alternative to subsistence existence and early marriage/childbearing.

DOES DEPRESSION IMPROVE DURING RETIREMENT AMONG BINGE DRINKERS?

Antonia Diaz-Valdes[1], Christina Sellers[2], and Julian Ponce[3], *1. Universidad Mayor, Las Condes, Region Metropolitana, Chile, 2. Simmons University, Boston, Massachusetts, United States, 3. University of California, Berkeley, California, United States*

Data from the Health and Retirement Study (1992-2016) was used. All non-institutionalized respondents aged 50+ were included in our sample (n=12,618). Mixed models were conducted to study the association between transitioning to retirement and depressive symptoms (CESD) among retirees, and to test the mediation effect of alcohol use.

Results: Those retired for at least 6 years had increased probability of binge drinking. Additionally, binge drinking mediated the association between the retirement transition and depressive symptoms, making the effect stronger for those retired for 3 to 5 years ($p< 0.05$), and weaker and no significant for those retired for 6+ years ($p>0.05$). Thus, the decrease on depressive symptoms was higher for those retired between 3 to 5 years when being binge drinkers. Discussion and Implications: Addressing depressive symptoms and binge drinking among older adults is sorely needed. Binge drinking was associated with decreased depressive symptoms, consistent with the self-medication hypothesis. Treatment and screening for depression as well as binge drinking are especially important as both are associated with increased mortality. Treating depression would reduce the risk of increased alcohol use and its detrimental effects on health.

MERGING AN AGE FRIENDLY UNIVERSITY WITH AN AGE FRIENDLY HEALTH CARE SYSTEM: CASE STUDY FINDINGS

John Schumacher[1], Nicole Brandt[2], Barbara Resnick[3], Anissa Nahabedian[2], Mojdeh Heavner[4], Giora Netzer[3], Lara Wilson[5], and Raya E Kheirbek[6], *1. University of Maryland, Baltimore County, Baltimore, Maryland, United States, 2. University of Maryland, Baltimore, Baltimore, Maryland, United States, 3. University of Maryland, Baltimore, Maryland, United States, 4. University of Maryland School of Pharmacy, Baltimore, Maryland, United States, 5. University of Maryland Shore Regional Health, Chestertown, Maryland, United States, 6. University of Maryland School of Medicine, Baltimore, Maryland, United States*

Age Friendly Health Systems (AFHSs) and Age Friendly Universities (AFUs) are distinct entities in the “Age Friendly” ecosystem. While Age Friendly entities function independently, they typically exist in close proximity (e.g., universities and community hospitals); yet they remain isolated in their Age Friendly efforts. We report on a collaboration between a mid-Atlantic Age Friendly University and a new AFHS using case study methodology. Our goal is to inform and inspire key stakeholders responsible for creating innovative healthy aging communities. The collaboration began with a shared stakeholder team who articulated focus areas and overlapping goals. A charter document was developed articulating commitments and responsibilities. Using a Quality Improvement (QI) approach, projects targeted the hospital's older patient needs that linked to the AFHS 4 M's of Matters, Medications, Mobility, and Mentation. University graduate students and faculty volunteered to teach and mentor hospital staff on the QI projects: 1) Get to Know Me Boards filled by staff caring for hospitalized older adults (Matters); 2) Medical Intensive Care Unit discharge opioid medication deprescribing (Medication); 3) UMove Mobility Screening addressing functional status (Mobility); 4) UB-2 Delirium Screening (Mentation). Data collection across projects demonstrated proof-of-concept and identified implementation challenges around communication, screening, data entry, and data extraction from electronic medical records. During Covid-19 pandemic, the collaboration allowed QI projects to conduct multiple Plan-Do-Check-Act cycles while contributing to the Age Friendly goals of both organizations. Partnerships between academic institutions and hospitals foster development of evidence- based healthy aging communities and provide opportunities for continuing education and research.

HELP-SEEKING FOR SUICIDE RISK AMONG MIDDLE- TO OLD-AGE ADULTS

Xiaochuan Wang, Susanny Beltran, and Kim Gryglewicz, *University of Central Florida, Orlando, Florida, United States*

Suicide is a major public health concern. Suicide rates have increased steadily in the U.S. and are highest among middle-aged (ages 45-64) and older (age 75+) adults. Help-seeking represents an important coping behavior that can mitigate suicide risk. However, research on this topic is sparse, especially among older adults. To address this gap, a systematic review of the existing literature describing help-seeking for suicide risk among middle- to old-age adults was conducted. Using PRISMA guidelines, we searched electronic databases (e.g., ProQuest, EBSCOhost, PsycINFO, PubMed, Medline) and key journals with suicide and/or gerontology focuses for peer-reviewed publications in English between 2010-2020. The search yielded 4,732 unduplicated publications. After screening articles for relevance based on titles and abstracts, 52 articles were reviewed in full text. A total of 24 articles met inclusion criteria and were included in this review. The articles reviewed included a range of topics, including prevalence of service utilization, service use prior to suicide-related behaviors, and correlates of help-seeking. Overall, prevalence of service utilization was generally low and varied by suicidal history (e.g., greater prevalence among those with a history of suicide attempt, as compared to those with suicide ideation but no attempts). The systematic review also identified key service use facilitators (e.g., higher suicide literacy, previous or current suicidality) and barriers (e.g., stigma). Results of this systematic review highlight the need for future research and tailored services to improve suicide prevention and intervention strategies for middle-aged and older adults.

ACHIEVING UNIVERSAL HEALTH COVERAGE FOR OLDER ADULTS: A REVIEW OF GHANA'S NATIONAL HEALTH INSURANCE SCHEME

Samuel Asante[1], and Grace Karikari[2], *1. Northeastern State University, Broken Arrow, Oklahoma, United States, 2. University of North Dakota, Grand Forks, North Dakota, United States*

Universal Health Coverage (UHC) is defined by the World Health Organization (WHO) as ensuring that all people receive quality health services they need without financial hardship. Predicated on the idea of providing universal healthcare to all Ghanaians, Ghana's National Health Insurance Scheme (NHIS), established in 2003, has done considerably well among some age categories than others. While most studies on this healthcare program have focused on the health-seeking behaviors among users, its implementation, financial sustainability, and the role of national politics in its administration, little has been done to understand the program's effectiveness in achieving a universal health coverage for and its impact on older Ghanaians. Consistent with WHO's objective of achieving UHC, as enshrined in the Global Strategy on Aging and Health, this review examines Ghana's progress toward achieving UHC for all. The paper specifically provides a narrative review of the National Health Insurance Scheme in advancing the interest and welfare of older Ghanaians. Findings revealed that not all individuals considered as older adults, either conventionally or legally, are beneficiaries of the programs; that WHO's objective of obtaining needed care without financial hardship may be far from reach for most older Ghanaians; and the program only offers basic protection to current beneficiaries. We address these areas of concern to achieving UHC. We also make recommendations for a path forward where all stakeholders—older adults, families, healthcare providers, and policymakers—involved can play a role in ensuring all eligible older adults get the quality of health care they deserve.

SUBTYPES OF FRAILTY AND NONFRAIL HEALTH IMPROVEMENT OF DISABILITY PREVENTION PROGRAM: LATENT CLASS ANALYSIS

Ya-Mei Chen[1], Wan-Yu Chiu[1], Hui-Fen Mao[1], Ling-Hui Chang[2], and Shwu-Chong Wu[3], *1. National Taiwan University, Taipei City, Taipei, Taiwan (Republic of China), 2. National Cheng Kung University, Tainan City, Tainan, Taiwan (Republic of China), 3. College of Public Health, Taipei City, Taipei, Taiwan (Republic of China)*

Frailty has become a public health priority in many advanced countries. However, the effects of national implemented intervention remained unclear. Taiwan implemented a disability prevention program nationwide targeting on people aged 65 and over in 2019. We aimed to identify the subtypes of function outcomes of the national disability prevention programs and compare the different outcome subtypes between frail and non-frail older adults. The current study analyzed participants' outcomes before and after the program. Two years of data (2019-2020) from the national disability program were used for analysis. Among the participants, 622 were frail (3.8%), and 13084 are non-frail (81.3%). Outcomes were nine domains of Kihon checklist assessed, including nutrition, depressive mood, oral function, fall risk, cognitive function, socialization, independent function, mobility and health knowledge. Latent Class Analysis is used to identify the subtypes of classes in frailty and non-frail older adults. Four classes of outcomes subtypes for frail and non-frail older adults were identified, and both of them have groups of multi-aspect improvement and no improvement groups. The other two classes for frail people were cognitive and independent function improvement group and social and fall risk improvement group, whereas non-frail group had independent function improvement group, and independent and mobility function improvement group. The similar groups identified indicated both frail and non-frail can benefited and not benefited from the program. The two different subtypes identified benefited from the program. Further study investigating the characteristic of people in different outcome subtypes may shed some light for future tailored-made disability prevention.

PUBLIC MENTAL HEALTH SERVICE USE AMONG US ADULTS AGE 50+ COMPARED TO YOUNGER AGE GROUPS

Namkee Choi, and Diana DiNitto, *University of Texas at Austin, Austin, Texas, United States*

Despite increasing numbers of older-adult mental health service users, few studies have examined their use of public mental health services. Using the 2018 and 2019 Mental Health-Client Level data (N=4,291,737 in 2018 and N=4,513,946 in 2019 for those age 18+), we examined age group differences in the types of mental disorders diagnosed in outpatient-only, both outpatient and inpatient, and inpatient-only service settings. Of all users, 25.3% were age 50-64 and 6.7% were age 65+. Multivariable logistic regression results, controlling for gender, race/ethnicity, census region, and alcohol/substance use disorder, showed that compared to the 30-49 age group, the 50-64 and 65+ age groups had higher odds of having depressive disorder in outpatient-only settings (aOR=1.28 [95% CI=1.28-1.29] and aOR=1.08 [95% CI=1.08-1.09] for the 50-64 and 65+ age groups, respectively). Both older groups also had higher odds of delirium/dementia disorder in all three service settings. In addition, they had consistently higher odds of a diagnosis of schizophrenia or other psychotic disorder in all three service settings (aOR=1.88 [95% CI=1.86-1.89], aOR=1.70 [95% CI=1.65-1.74], and aOR=1.44 [95% CI=1.39-1.49] in outpatient, both outpatient and inpatient, and inpatient-only settings, respectively). Community mental health centers (CMHC) are on the frontlines in serving vulnerable communities and received increased federal funding during the COVID-19 pandemic. Our findings indicate that CMHCs also need programs dedicated to and tailored for older adults. More research is also needed on older adults who receive public mental health services and unmet mental health needs among low-income older adults with serious mental illness.

PARTNERING TO DEVELOP COUNTY-LEVEL DATA PROFILES

Karon Phillips[1], and Megan Wolfe[2], *1. Trust for America's Health, Silver Spring, Maryland, United States, 2. Trust for America's Health, Washington, District of Columbia, United States*

Building robust data systems that include information on the health of older adults is crucial to developing programs and services that meet their health and social needs. Organizations and agencies can use this information to target resources and identify community partners, as well as using data to support grant applications. But there are challenges to building such systems, even within the public health system, due to lack of expertise, funding, and access to underlying data sources. Through its Age-Friendly Public Health Systems initiative, Trust for America's Health's has worked directly with several state public health departments to explore opportunities to develop and expand their county-level data profiles on older adults. This session will highlight the unique collaborations and partnerships between departments of health and other institutions, including academia, to develop data profiles. Through these innovative partnerships, departments of health have been able to develop dynamic data profiles that they share with aging services providers to discuss strategies to support their older adults in their communities. Best practices and lessons learned through the profile development process will also be discussed.

OLDER ADULT'S PERCEPTION OF PRIMARY HEALTH CARE REFORM IN A LOW-MIDDLE-INCOME COUNTRY (LMIC): IMPACT ON GERIATRIC CARE

Theresa Abah, *California State University, Sacramento, Sacramento, California, United States*

Health reforms are intended to provide equitable and beneficial care across population groups, it also transforms service delivery. We sought to identify current or potential implementation gaps that divert improvement efforts in service delivery, and practices that prevent holistic approaches in caring for older adults, especially in developing nations. This study examined a major health reform initiative in a LMIC aimed at integrating defragmented health organizations under one management, it also looked at extent to which reform agendas align with primary health care (PHC) principles. Using purposeful random sampling design, this quantitative study obtained participants' views of care received in 12 sites and 2 states in Nigeria. A total of 218 participants aged 50 years and older in both rural and urban areas. Partial correlations were carried out after accounting for other variables of interest. Findings show there was no significant differences in attributes of primary care received by geography, gender or by state. Although Ondo state scored higher than Federal Capital Territory in previous performance evaluations (66% and 43% in 2015), respondents from both states received only two out of the seven primary care attributes recommended by the World Health Organization. First contact (access to care) and Care continuity, p <.01 and p, 0.5, (d = 0.202 and 0.179) were significant. Overall, our findings suggest that performance improvement at management level dominated reform efforts over service delivery. It is unclear how this aligns with providing older adults with the health care that they need.

EFFECTS OF A SPECIFIC NARRATIVE GROUP PRACTICE ON HEALTH OUTCOMES OF CHINESE OLDER ADULTS: AN RCT STUDY

Esther Chow, and Sai-fu Fung, *City University of Hong Kong, Kowloon, Hong Kong*

In view of the rising chronicity during older adulthood, a specific narrative group practice is developed to improve well-being. Narrative therapy (NT), views people as experts in their own lives, and have accrued their life wisdom through their lifespan. To test its effects, a randomized controlled trial design was used to assess and compare outcomes between the intervention and waitlist-controlled group. A total of 157 older adults were recruited, 82 of which was randomly assigned to 9 intervention groups to receive four 2-hour NT sessions, recording difficult life circumstances, through narrative conversations, which made them stronger. Quantitative assessment of well-being, and depression were conducted at baseline (T0), at the end of treatment (T1), and at two (T2) and 8 months after treatment (T3). By employing the SEM parallel-process latent growth curve model, the results from the 4 waves of longitudinal data suggesting that the NT intervention have positive impact the participants, in particular the improved well-being of the participants contributed to the reduction of depressive symptoms with standardised estimate -0.502, p = 0.007. The estimated model fulfilled the criteria of mediocre fit, with TLI = 0.943; CFI = 0.969; RMSEA = 0.053. No adverse reaction was recorded in any of the cases mentioned at all study-sites. These findings have significant theoretical and practice implications for both health and social care professions. NT offers an effective practice to develop a strength- and meaning-based group practice and ground a new theory for to develop a constructive perspective to late life development.

MOTIVATIONAL FACTORS AFFECTING THE INTENTION TO VOLUNTEER IN ELDER CARE AGENCIES: A PILOT STUDY

Rong Fu[1], and Qi Xu[2], *1. Siena College, Loudonville, New York, United States, 2. China Agricultural University, Beijing, Beijing, China (People's Republic)*

The rapid rise of the aging population and the “4-2-1” family structure in China calls for speeding up the construction of the elderly care service system. To facilitate this process, it is desirable to encourage voluntary participation in elder care agencies. This study aims to identify motivational factors that may affect the intention to volunteer in elder care agencies in China. Data were collected in a sample of 199 residents of Beijing, China. Our results revealed gender differences in the demographic and socioeconomic factors that affect the volunteer intention. For men, earning more than 12,000 Yuan (about $1900) significantly increased the intention to participate in voluntary services (p = .043). For women, those younger than 60 years of age were more willing to participate in voluntary services than their older counterparts (p = .014). Participants identified three key motivational factors for providing volunteer services in elder care agencies: (1) to show love and kindness to older adults; (2) to fulfill oneself and take social responsibilities; and (3) to gain more life experience. We also found that most participants prefer to provide spiritual comfort services (e.g., chatting, shopping) and life care services (e.g., cooking, house cleaning) than other types of services. Our study suggested that effective interventions should be designed and implemented to match volunteering resources to the needs of elder care agencies in China.

A META-ANALYSIS OF MUSIC THERAPY AND SLEEP QUALITY: TRENDS AND IMPLICATIONS FOR OLDER ADULTS

Noell Rowan[1], Angie Sardina[2], Tina Newsham[2], Richard Pond[2], Lenis Chen-Edinboro[1], Christine Leist[3], Daniel Johnson[2], and Michele Erich[4], *1. University of North Carolina Wilmington, Wilmington, North Carolina, United States, 2. UNC Wilmington, Wilmington, North Carolina, United States, 3. Appalachian State University, Boone, North Carolina, United States, 4. Novant Health New Hanover Regional Medical Center, Wilmington, North Carolina, United States*

Music therapy (MT) has been an established healthcare profession in the United States for over seven decades. MT interventions are non-pharmacological approaches, administered by board-certified music therapists, designed to promote physical, emotional, cognitive, and spiritual well-being. One aspect of health where MT may be of use to older adults is in improving poor sleep quality, which is associated with increased risk for morbidity and mortality. Many pharmacological treatments for insomnia and other conditions carry adverse effects. Investigating the impact of evidence-based non-pharmacological interventions (e.g., MT) on sleep could be beneficial, particularly among older adults who are at greater risk for polypharmacy-related challenges. The purpose of this study was to investigate the average effect of MT on sleep quality via a meta-analysis across 46 studies (N=2912). This study included a review of the effects of MT on sleep, the characteristics of strongest and weakest MT interventions, the role age plays on the efficacy of MT, and differences in effects between adults with and without dementia. Results revealed robust improvements in sleep quality, as a function of MT. These improvements were observed among teams that included a professional music therapist. Clinical and practical implications will be discussed, particularly as they apply to older adults and interprofessional practice.

IN THE WEEDS: UNDERSTANDING CANNABIS USE AMONG OLDER ADULTS

Isabelle Sheck, and H. Shellae Versey, *Fordham University, Bronx, New York, United States*

The existing literature from the past decade shows an increase in the prevalence of cannabis use among older adults (OA) aged 50-65. Most commonly, studies have reported OA using cannabis to manage symptoms related to chronic pain, arthritis, insomnia or disordered sleep, and anxiety. Recent recreational cannabis legislation in several states has also contributed to increasing rates of cannabis use among older adults. Despite an increase in recreational and medicinal cannabis consumption, few studies have focused on cannabis attitudes and behaviors among older adults. Within the past ten years, studies reporting cannabis behavior have been limited to samples of younger adults. This paper provides a comprehensive review of qualitative and quantitative studies of cannabis use among older adults (OA). Additional research detailing the characteristics of cannabis use among OA is needed, including frequency, motivation, type of cannabis (medicinal/recreational), route of administration, suppliers, and social networks associated with cannabis use. This systematic review adds to our knowledge about aging and substance use addressing a gap in the literature regarding drivers of cannabis use among OA. Implications of this research extend to gerontological, public health, and community research as cannabis continues to become more easily accessible in various states.

SESSION 6360 (POSTER)

POLICY, FINANCING, AND DELIVERY SYSTEMS

PROTECTING RETAIL CUSTOMERS FROM GIFT CARD PAYMENT SCAMS

Dionne Bailey[1], and Marti DeLiema[2], *1. University of Minnesota, Minneapolis, Minnesota, United States, 2. University of Minnesota - Twin Cities, Saint Paul, Minnesota, United States*

Older adults are frequently targeted by scams and fraud, a persistent and growing problem in the U.S. According to the Federal Trade Commission, gift cards were the most common method of payment requested by fraud criminals in 2021. The purpose of this AARP-sponsored study is to investigate gift card payment scams by analyzing the retail sector for current interventions and opportunities to protect customers from fraud. Through secret shopping at 23 retail locations in a large U.S. city, we documented the existing status of merchant controls designed to prevent suspicious gift card purchases, as well as how these measures work in practice. At each location, the "secret shopper" attempted to purchase between $400-$1000 in gift cards from a sales clerk, while another researcher stood in line nearby to observe the interaction. Nearly 80% of retail stores had signs warning customers about gift card frauds. Fewer than 50% imposed limits on the purchase amount; more than 40% required manager approval, and five of the transactions resulted in manager involvement. Current retail measures would only limit purchases in around 22% of gift card frauds and would completely halt about 9% of transactions. Results indicate that despite warnings, retailers are not doing enough to protect customers from fraud. New policies are needed to advocate for reduced gift card purchase limits, increase public awareness, educate retail employees on the red flags, and enforce anti-money laundering rules to limit fraud.

BUDGET IMPACT ANALYSIS OF NONPHARMACOLOGICAL INTERVENTIONS FOR COMMUNITY-DWELLING PEOPLE LIVING WITH DEMENTIA

Eric Jutkowitz, Mauricio Lopez Mendez, and Peter Shewmaker, *Brown University, Providence, Rhode Island, United States*

Non-pharmacologic dementia care interventions significantly reduce the risk of a nursing home admission for people living with dementia. We used an evidence-based mathematical model to evaluate the budget impact for a healthcare payer that independently implemented four non-pharmacologic dementia care interventions that reduce the risk of transitioning to a nursing home for people living with dementia: 1) MIND, an at-home care coordination intervention; 2) NYU Caregiver (NYUCI), provides caregivers with counseling and ad-hoc support; 3) Alzheimer's and Dementia Care (ADC) program, a clinic based care coordination intervention; and 4) Adult Day Services Plus (ADS-Plus), an adult day based care coordination intervention. Healthcare payer costs included Medicare and Medicaid expenditures. We simulated a cohort of 302,630 community-dwelling people with dementia, which is the number of people who were diagnosed with dementia in 2018. We applied each intervention's inclusion criteria to determine the proportion of the cohort that would receive the interventions. Some people may die or enter a nursing home before receiving the interventions. MIND, NYUCI, ADC, and ADS-Plus reduced annual payer expenditures (relative to $25,000, which is the average amount Medicare-Medicaid pay per person with dementia) on average by 0.67%, 0.23%, 0.13%, and 0.58%, respectively over 5 years. Cost savings for the interventions varied by demographics. African American females between ages 95-100 who received NYUCI had the largest cost savings ($2,750.57). White females between ages 65-70 who received ADC had an increase in payer costs ($2,397.07). On average, non-pharmacologic dementia care intervention do not increase a healthcare payer's budget.

SUPPLEMENTAL PAYMENTS AND NURSING HOME STAFFING: A CASE STUDY OF INDIANA

Hari Sharma, and Lili Xu, *University of Iowa, Iowa City, Iowa, United States*

Adequate reimbursements are key to improving quality in nursing homes (NHs), but Medicaid payments remain low. Indiana implemented Medicaid supplemental payment program to non-state government (NSGOs) owned NHs to boost Medicaid payment rates. Under the program, NSGOs contribute the state-share of the supplemental payments through intergovernmental transfers allowing the state to claim federal matching funds. The supplemental payments are distributed between NSGOs and NHs but little is known about whether NHs invested the supplemental payments to improve staffing levels. In this study, we examine whether NHs receiving supplemental payments, proxied by NSGO-ownership, have higher staffing hours per resident day (HPRD) for registered nurse (RN), licensed practical nurse (LPN), and certified nurse aide (CNA) compared with NHs without supplemental payments. We use facility-year data on NSGO ownership (State of Indiana), staffing levels (Nursing Home Compare), and facility and resident characteristics (LTCfocus.org) on 500 NHs from 2009 to 2017. We use difference-in-difference (DD) regressions with year and facility fixed effects to estimate the potentially causal effect of NSGO ownership on NH staffing controlling for facility and resident characteristics. DD estimates suggest that NSGO-ownership is associated with decreased staffing level across all three types of staffing. More specifically, RN staffing decreased by 0.019 HPRD ($p< 0.05$), LPN staffing decreased by 0.041 HPRD ($p< 0,05$), and CNA staffing decreased by 0.089 HPRD ($p< 0.001$). Policymakers should increase the transparency of supplemental payment programs and audit the expenditures to ensure that supplemental payments are tied to quality improvement.

VARIATION AND CONSISTENCY IN ALLOCATION OF HCBS: MASSACHUSETTS AGING SERVICES ACCESS POINTS

Signe Flieger[1], Gabrielle Katz[2], and Christine Bishop[2], *1. Tufts University School of Medicine, Boston, Massachusetts, United States, 2. Brandeis University, Waltham, Massachusetts, United States*

Massachusetts' 27 Aging Services Access Points (ASAPs) are nonprofit organizations responsible for guiding clients and families in their geographic service areas through a maze of financial and functional eligibility criteria to receive needed home and community-based services (HCBS). These services aim to sustain function and promote engagement for older adults and persons with disabilities, and to maintain individuals in the community rather than in residential settings. Payment for HCBS flows from numerous state and Federal funding programs, including but not limited to state Medicaid waivers and Older American Act programs. We conducted semi-structured interviews with 10 ASAP directors and gathered information from documentary sources to delineate the pathways to funded HCBS that these agencies open for clients. We identified variation in the 27 ASAPs' contractual relationships with service providers. State data revealed variation in budgetary resources and area population characteristics. These nonprofit corporations appear to flexibly adapt to local conditions and needs. Understanding variation across ASAPs will support analysis of client data to examine whether ASAP processes result in different service outcomes for similar clients. Alternate payment models for health services (managed care, managed long-term services and supports, accountable care organizations) are broadening their reach, encouraging health systems to recognize the importance of functional supports and services. Some health systems are charging their own dedicated units with assigning HCBS to enrollees, avoiding the ASAPs. Understanding and modeling the allocation of services by the ASAPs will allow investigation of trends in services for persons with varying needs under various payment methods.

EVALUATING THE STAFFING METHODOLOGY MODEL IN THE VETERANS HEALTH ADMINISTRATION'S COMMUNITY LIVING CENTERS

Lana Brown[1], Shelly Lensing[2], Sheila Cox Sullivan[3], Teresa Odom[3], Jade Moore[3], Pamela Billings[4], and Lisa Minor[3], *1. Central Arkansas Veterans Healthcare System, North Little Rock, Arkansas, United States, 2. Central Arkansas for Veterans Healthcare System, North Little Rock, Arkansas, United States, 3. Veterans Health Administration, Washington, District of Columbia, United States, 4. Veterans Health Administration, Nashville, Tennessee, United States*

The project purpose was to describe nursing hours per patient day (NHPPD) within the Veterans Health Administration (VHA) and to evaluate Staffing Methodology in the VHA Community Living Centers (CLCs) by comparing Staffing Methodology targeted NHPPD with actual NHPPD. Data were compiled retrospectively for each CLC unit over a one-year timeframe for calendar year 2019. VHA had 134 CLCs including 390 nursing units. Nursing units without 6 months of actual NHPPD data were excluded from the data set. For descriptive analyses, actual NHPPD were averaged across months for each unit. The percent of target was calculated as this average divided by the NHPPD target times 100. The percentage of months each unit met the targeted NHPPD was calculated. After data exclusions, the final data set included 322 nursing units from 133 CLCs. The mean for actual hours as a percent of target was 121.6% (95% CI, 118.5 to 124.7%) indicating that the units' average hours across 2019 were 21.6% significantly higher than target. Also, half of units met their targets 91.7% of months as reflected by the median. The actual NHPPD significantly differed across months ($p< 0.001$) with the 2019 months of January and October having the highest NHPPD. Similar results were seen for NHPPD as a percent of target. Veteran safety is a VHA priority and appropriate nurse staffing is key to providing care that improves Veteran outcomes and reduces adverse events. Further exploration is needed on how nurse staffing in the CLCs impacts Veteran outcomes, safety, and satisfaction.

MINNESOTA'S 2021 LGBTQ AGING NEEDS ASSESSMENT

Rajean Moone, *University of Minnesota, St Paul, Minnesota, United States*

Every decade Minnesota embarked on a needs assessment of lesbian, gay, bisexual, transgender and queer (LGBTQ) older adults which has provided important insights into aging within these communities. In 2021, a research team replicated these past monumental studies into this Minnesota 2021 LGBTQ Aging Needs Assessment. 485 individuals responded to the survey, either online or by paper. Of those, 354 met the inclusion criteria and are included in the results. Like the 2012 study, LGBTQ older adults who participated in the study were more likely to be a caregiver than compared to the general population. At the same time they were less likely to have a caregiver and less likely to have children. Half of the participants experienced some form of discrimination and the vast majority more knew someone who experienced discrimination due to their sexual orientation or gender identity. Positively, study participants were more likely to have completed a health care directive and more likely to volunteer than the general population. Possibly one of the most striking changes over the last two decades is that 85% of respondents were confident they would receive sensitive services. In 2012 only 18% and 2002 only 9% expressed the same confidence. In congruence with the past studies, the majority of respondents continue to desire LGBTQ welcoming senior services rather than LGBTQ segregated services.

SESSION 6370 (POSTER)

REMINISCENCE AND LIFE REVIEW

FROM PILOT TO PRODUCT: EVOLUTION OF A REMINISCENCE THERAPY INTERVENTION FOR PERSONS LIVING WITH DEMENTIA

Silvia Orsulic-Jeras[1], Farida Ejaz[1], Miriam Rose[1], Sara Powers[2], Ashlee Cordell[1], Christa Wilk[1], and Lisbeth Sanders[3], *1. Benjamin Rose Institute on Aging, Cleveland, Ohio, United States, 2. The Benjamin Rose Institute on Aging, Cleveland, Ohio, United States, 3. LifeBio Inc., Marysville, Ohio, United States*

Reminiscence therapy (RT) and life story work are effective techniques for eliciting engagement in persons living with dementia (PLWD) and helping inform direct care staff about residents' lives and preferences to facilitate quality person-centered care. However, there are challenges in bringing such programs to scale in a feasible and cost-effective way. Two studies were conducted to test development and evolution of an RT program, LifeBio Memory. A pilot study of the original LifeBio protocol was conducted with 238 residents in 16 Ohio nursing homes. Most residents (88%) indicated at posttest that they enjoyed telling their life stories, and 87% would recommend the program to other residents. However, manually gathering and processing life story data led to challenges with feasibility. Subsequently, novel software was developed to streamline the process using machine learning and artificial intelligence via a tablet application. Acceptability and feasibility were examined in two rounds, 9 months apart, of seven focus groups (n=35) conducted with PLWD, family care partners, and residential care staff. Audiotapes of the groups were transcribed; thematic data analysis was used to generate a list of recommended changes and showed high levels of acceptability and feasibility. Based on these results, it was determined that LifeBio Memory was preferred for obtaining life story information over the previous manual method (e.g., handwriting life story notes). Potential barriers to implementing the new platform in residential care settings were also identified. Implications include the importance of maintaining person-centered care practices when creating technological solutions to address PLWD needs.

MULTIPLE SCALES OF SOCIAL RELATIONS IN REMINISCENCE ACTIVITIES FOR OLDER ADULTS

Jessica Robbins-Panko, *Wayne State University, Detroit, Michigan, United States*

Memory, especially autobiographical memory, is central to personhood in contemporary North America and Europe (Herskovits 1995). Cultivated practices of reminiscence, in which older adults are prompted to remember events and experiences from the past, can be pleasurable, meaningful, and therapeutic activities that shape personhood and contribute to wellbeing (Coleman, 1999; Sherman, 1987). Although reminiscence practices include both individual (e.g., Butler, 1963; Woods et al., 2018) and social (Hash et al., 2021; Sass et al., 2021) elements of remembering, less attention has focused on the myriad scales of social relations that are part of reminiscence activities. Moreover, the mechanisms through which reminiscence creates positive transformations remain unclear (Menn et al., 2020). Anthropological theories of personhood show that social relations at multiple spatiotemporal scales play key roles in transforming personhood (Carsten, 1995; Robbins, 2021), thus suggesting a nuanced framework within which to understand how social relations shape personhood and contribute to wellbeing for older adults. Drawing on a systematic review of interdisciplinary literature on reminiscence activities for older adults, this paper documents the multiple scales of social relations (interpersonal, institutional, regional, [trans]national) that are part of reminiscence activities, and interpretively analyzes their significance for personhood and wellbeing. Key findings of this study are: 1) collective memory plays an important role in reminiscence activities; and 2) fostering reminiscence activities that focus on meaningful elements of the shared past can promote wellbeing for older adults. These findings have implications for 1) refining gerontological theories of reminiscence, and 2) improving reminiscence-based practices for older adults.

THE TELLEGACY PROGRAM

Jeremy Holloway, *University of North Dakota, Fargo, North Dakota, United States*

Emerging research displays how social isolation and loneliness (SIAL) before and during the Coronavirus pandemic are linked to health issues caused by SIAL. These issues are estimated to increase the risk of early death by 26 percent, the equivalency of smoking 15 cigarettes a day. The program started soon after the pandemic as an intergenerational program created to combat SIAL among older adults. University students, known as Legacy Builders, connect through virtual or via phone conversations to communicate meaningfully with the older adult. Students are prepared with a curriculum on mindfulness, SMART goal-setting, growth mindset, visualization goal-setting exercises, and reminiscence therapy as well as the skill and art of listening. At the end of the encounters, a legacy book is given to the older adult with a description of the older adult's life shared during their conversations with the Legacy Builder. The UCLA Loneliness Scale was utilized along with older adult self-reports. Sixteen residents in a memory care facility, ages 58 to 86, with multiple levels of dementia participated in the program of Summer 2021. The UCLA Loneliness Scale revealed that 13 of the 16 residents originally reported that they feel lonely or isolated. After 5 weeks of participation 7 out of the 16 residents report that they felt less lonely. Qualitative analysis showed improved perceptions of aging and an interest in Geriatrics among the student participants. These results also displayed positive older adult perceptions of the younger generation, and similar responses of the younger generation towards older adults.

SESSION 6380 (POSTER)

SUCCESSFUL AGING (POSTERS)

TOPICS ADDRESSED IN CENTENARIAN RESEARCH: A SCOPING REVIEW OF PUBLICATIONS SINCE 2000

Daniela Jopp[1], Charikleia Lampraki[1], Kim Uittenhove[1], Flavien Delhaes[2], Daniele Zaccaria[3], Carla Gomes Da Rocha[4], Garnelle Ziade[1], and Melanie Becker[5], *1. University of Lausanne, Lausanne, Vaud, Switzerland, 2. University of Geneva, Geneva, Geneve, Switzerland, 3. University of Applied Sciences and Arts of Southern Switzerland, Manno, Ticino, Switzerland, 4. HES-SO Valais-Wallis, Sierre, Valais, Switzerland, 5. University of Zurich, Zurich, Zurich, Switzerland*

Over the past decades, centenarians have increasingly attracted the attention of the research community. This development reflects the constant rise of the numbers of very old individuals, but also the need to better understand longevity mechanisms and what characterizes life at age 100. This scoping review provided an overview of trends in centenarian research from all disciplines since 2000, and identified the most frequently mentioned and neglected topics. Scientific articles meeting the following eligibility criteria were included: (1) publication between 2000 and 2021; (2) in English, French or German language; (3) study population of at least 95 years of age on average, or, for studies with larger age ranges, provision of specific insights for the

95+ group. Following the standard procedures for scoping reviews, we identified a total of N = 3955 articles. After removal of duplicates and exclusion due to unmet criteria, we used content coding to identify research themes of N = 1117 articles. Data confirmed that research articles offering findings on centenarians have increased substantially over the past two decades. Content coding led to 37 main topics: Most frequently, studies addressed higher-order topics such as physical, biological, and mental (e.g., cognitive), which were mostly investigated within disciplinary boundaries. Few multidisciplinary articles examined content domains in conjunction. The least investigated topics in centenarian research included the sub-domains of pain, stress, anxiety, and psychiatric disorders. In sum, findings inform the research community about the existing centenarian research, suggest that multidisciplinary publications are infrequent, and offer guidance for future studies.

IMPACT OF COGNITIVE RESERVE IN OBJECTIVE AND SUBJECTIVE SUCCESSFUL AGING

Neyda Ma. Mendoza Ruvalcaba,
Elva Dolores Arias-Merino,
Maria Elena Flores-Villavicencio, and
Melina Rodríguez Díaz, *University of Guadalajara, Guadalajara, Jalisco, Mexico*

Cognitive reserve (CR) refers to the capacity of the brain to withstand changes due to age or disease-related pathology, showing how flexibly and efficiently the individual makes use of available brain resources. This study aims to explore the contributions of the CR to understanding successful aging (SA).(Project-Conacyt-256589)Population based, random sample included n=656 community-dwelling older adults 60-years and older (mean age=72.8, SD=7.6 years, 58% women). CR was measured by their main indicators: education, life-long learning, being bilingual, participation, use of information and communications technology. Objective SA was operationalized as no important disease, no disability, physical functioning, cognitive functioning, and being actively engaged. Subjective was an appreciation if they considered themselves as successful agers. Sociodemographic and health data were also asked. Pearson´s correlation test and MANOVAs were performed.In total 11.2% met the criteria for SA, although 76% considered themselves as successful agers. CR was significantly related to subjective and objective criteria of SA(p<.000), except to no-important diseases. CR explains in general 20% of the variance in objective SA, specifically explains 28% of variance in the criteria of high cognitive function, 18% of the variance in disability, 11.3% of life engagement, 8% of physical functioning, and 2% of disease-free criteria. Also, CR explains 10% of the variance in subjective SA. This study has shown that CR the is related to SA, this set possible targets for cognitive interventions to promote resiliency of the brain not only for preventing cognitive pathologies, but also for encouraging successful and healthy aging in older adults.

OLDER ADULTS SHARE CHALLENGES IN THEIR LIFE STORY: SENSE OF PURPOSE AS A RESOURCE FOR RESILIENCE

Semper Habib[1], Ameesha Narine[1], Susan Bluck[2], and Shubam Sharma[1], *1. Kennesaw State University, Kennesaw, Georgia, United States, 2. University of Florida, Gainesville, Florida, United States*

Maintaining a sense of purpose promotes mental and physical well-being in older adults (Musich et al., 2018). Drawing on one's sense of purpose is thus important for late life resilience. How older adults' sense of purpose manifests in their everyday lives remains understudied. This study used qualitative methods to amplify older adults' voices regarding purpose and resilience through analysis of their life stories. This study 1) explored what factors contribute to maintaining purpose in older adulthood, and 2) identified how older adults draw on their purpose during major challenges, particularly in the context of the COVID-19 pandemic. Eighteen older men and women (Mage = 79.1; including the young-old, old-old, and oldest-old) participated in semi-structured life story interviews that asked about participants' individual interpretations of purpose in their lives and their experiences navigating the COVID-19 pandemic. Thematic analysis was conducted using established methods (Braun & Clarke, 2012). To address the first research question, analyses revealed that older individuals largely maintain their purpose through engaging in acts of service to others, fostering connections with close others, and actively setting and achieving goals. Regarding the second question, older adults described how drawing on purpose through acts of service and connections with others fostered resilience through the COVID-19 pandemic. Overall, older adults' own expressions of their life stories illuminated how they are guided by purpose. Findings demonstrate the functionality of purpose in late life and how purpose can be practically fostered, specifically within the context of universally challenging experiences such as the COVID-19 pandemic.

BENEFITS OF VOLUNTEERING ON RESILIENCE WITH AGING: A CASE STUDY

Sanghee Lee[1], Jinmoo Heo[2], and Sanghee Chun[3], *1. Korea University, Seoul, Seoul-t'ukpyolsi, Republic of Korea, 2. Yonsei University, Seoul, Seoul-t'ukpyolsi, Republic of Korea, 3. Brock University, St. Catharines, Ontario, Canada*

As the study of volunteering among older adults continues to evolve, questions of the benefits of volunteering are of growing interest to many researchers. Volunteering may develop resilience in older adults as it can serve as a coping strategy as they recover from adverse events or other life challenges. We explored the perceived benefits of volunteering on resilience in later life among older adults who perform Korean traditional dance on voluntary basis. We used a qualitative design with a case study method. In this study, older adults' volunteer dance performing was taken as a case. A case design enables researchers to understand social and cultural phenomenon in depth using a wide range of data collection and analysis methods. Thirteen volunteer performers of Korean traditional dance whose ages ranged between 61-74 years were recruited for in-depth interviews (11 females and 2 males). The analysis of the transcripts generated five themes related to the benefits of volunteering: (1) finding a sense of self-worth through serving others, (2) finding a sense of purpose, (3) experiencing gratitude, (4) renewing a younger self, and (5) building companionship. The findings of this study provided an empirical support showing how volunteering experience benefited resilience among the volunteers in the face of challenges associated with aging by maximizing positive physical, social, and psychological outcomes through involvement in voluntary dance performance. The findings also provide guidance for researchers and practitioners in positions to better serve older adults and thereby suggest volunteering as a resilience strategy in later life.

SWISS CENTENARIANS: PRELIMINARY FINDINGS FROM THE SWISS100 PHONE STUDY

Daniela Jopp[1], Stefano Cavalli[2], Armin von Gunten[3], Francois Herrmann[4], Mike Martin[5], and Kim Uittenhove[1], *1. University of Lausanne, Lausanne, Vaud, Switzerland, 2. University of Applied Sciences and Arts of Southern Switzerland, Manno, Ticino, Switzerland, 3. Lausanne University Hospital, Prilly, Vaud, Switzerland, 4. Geneva University Hospitals, Thônex, Geneve, Switzerland, 5. University of Zurich, Zurich, Zurich, Switzerland*

Increase in very old individuals is observed in all developed countries around the world. The number of centenarians has also been rising, requiring the investigation of the characteristics of these exceptionally long-lived individuals as well as their experience of life at age 100. In the present study, we present findings from the first nation-wide Swiss centenarian study SWISS100. Given the ongoing COVID-19 pandemic, we conducted a telephone study with centenarians and a family member as proxy informant, using a mixed-methods approach to investigate specific characteristics, their life circumstances and their experience during the pandemic. Recruitment was conducted with the help of the national address registry. A total of 64 centenarians and 62 family members participated, leading to data for 119 centenarians. Centenarians were on average 102 years old, with a range of 100 to 108 years. In line with higher survival rates in females, 76% were women and 24% were men. Most centenarians had received basic education and had completed an apprenticeship. Concerning their residence, 43% lived in private homes and 57% lived in institutions. Of those living in private, half lived alone, one fourth lived with their spouse and one fourth lived with a child. The majority was widowed. Over 80% had children. Although over 70% of the centenarians reported health restrictions, 60% reported good to excellent subjective health. Over 90% of the sample were aware of COVID-19. Despite substantial COVID-19-related restrictions, life-satisfaction was high. Overall, Swiss centenarians show health-related vulnerability but also psychological resilience.

VOLUNTEERING AND RISK OF HEART ATTACK IN LATER LIFE: THE MODERATING ROLE OF PURPOSE IN LIFE?

Mallory Bell[1], and Kenneth Ferraro[2], *1. Purdue University, Center on Aging and the Life Course, Lafayette, Indiana, United States, 2. Purdue University, West Lafayette, Indiana, United States*

Background and Objectives: Although research on the health benefits of volunteering has proliferated in recent decades, most studies are cross-sectional, and none prospectively examine the relationship between volunteering engagement, purpose in life, and heart attack. Research design and methods: This study uses seven waves of data (2006-2018) from the Health and Retirement study--a nationally representative survey of adults over age 50 (N=5,093). Event history analysis using Cox proportional hazards were used to examine if volunteering engagement in later life reduced the risk of first heart attack and if the effects of volunteering vary by level of purpose in life.

Results: Results reveal that volunteering, and doing so at a low time commitment, reduces the risk of first heart attack in later life. Additionally, the effect of volunteering varies by sense of purpose in life, such that volunteers with a strong sense of purpose in life had the lowest risk of heart attack. Implications: The findings of this study will inform public health and policy interventions dedicated to extending and improving later life health.

PURPOSE IN LIFE, STRESS REACTIVITY, AND COGNITIVE AGING: A LONGITUDINAL INVESTIGATION

Niccole Nelson, and Cindy Bergeman, *University of Notre Dame, Notre Dame, Indiana, United States*

This study examined (1) the time-varying relationship between purpose in life and perceived stress reactivity, (2) the trajectory of perceived stress reactivity as it relates to both within- and between-person purpose in life, as well as (3) the predictive utility of perceived stress reactivity and its rate of change on cognitive ability and allostatic load. The sample comprised 933 participants from the Notre Dame Study of Health & Well-being, a 10-year study of annual questionnaire packets and biennial daily diary bursts. Analyses included three-level multilevel models from which random effects were extracted and used to predict allostatic load and cognitive ability. Results indicated that individuals were affectively reactive to perceived stress, and that perceived stress reactivity declined over time. Considering the effects of purpose in life on these processes, there were two cross-level interaction effects indicating (1) more purposeful individuals were less stress reactive than less purposeful individuals, and (2) more purposeful individuals declined less in negative affect over time than less purposeful individuals. There was also preliminary evidence for a within-person interaction effect between yearly purpose in life and daily affective reactivity such that when individuals felt particularly purposeful, they also tended to be less stress reactive. Finally, higher perceived stress reactivity, as well as less decline in this construct, was predictive of better cognitive ability. These findings indicate purpose in life buffers against environmental and maturational effects on negative affect, and that perceived stress reactivity may indicate a different, more adaptive process than affective reactivity to experienced stressors.

SOURCES OF INTRINSIC MOTIVATION IN LATER ADULTHOOD: A QUALITATIVE ANALYSIS

Melinda Heinz, Nathan Benton, and Laura Gleissner, *Upper Iowa University, Fayette, Iowa, United States*

A distinct sense of purpose and motivation is increasingly recognized as a contributing factor in successful aging and prolonged health in older adults. While prior studies have established the relationship between intrinsic motivation, defined purpose, and health outcomes, it is essential for care providers and researchers to understand the underlying sources of purpose and motivation for older adults. This study examined qualitative data collected over a two-week period from a sample of older adults (N = 15) in the Midwest. Participants documented daily, through written journal entries and photography, aspects of their lives that they felt illustrated sources of purpose and motivation. The journal entries were then transcribed, aggregated, coded, and analyzed for potential themes. Two researchers coded the data; and a codebook was used to increase coding consistency. Using latent thematic analysis, three distinct themes developed from the dataset. First, engagement in behaviors and activities that incorporated aspects of mindful practices, particularly sensory awareness and grounding, proved to be motivating for many of the participants. The second theme discovered that participants found purpose in active social participation, where a subtheme regarding the impact of technology on maintaining relationships emerged. In the third theme, a goal-oriented mindset proved to be a key aspect of ongoing motivation, with a particular focus on cognitive and physical development, lifelong learning, and planning for the future. Overall, the data pointed to three distinct themes that can be used to foster ongoing opportunities for greater meaning in the lives of older adults.

LAY PERSPECTIVES ON SUCCESSFUL AGING IN ROMANIA

Angélique Roquet[1], Mariana Barbut[2], Cornelia Pocnet[3], and Daniela Jopp[1], *1. University of Lausanne, Lausanne, Vaud, Switzerland, 2. Lausanne University Hospital, Lausanne, Vaud, Switzerland, 3. lausanne university, Lausanne, Vaud, Switzerland*

Successful aging is a topic of world-wide interest, yet much work focuses on specific and highly industrialized countries, such as the USA. The present study investigated lay perspectives of the concept of successful aging in young, middle-aged, and older adults from Romania. Ninety-three participants aged between 20 and 84 years were asked about definitions and determinants of successful aging. Based on a previous study, codes were developed to capture common themes among the answers, resulting in 14 categories. Participants mentioned four themes on average to describe successful aging, which varied by sociodemographic, health and psychological variables: individuals of younger age, with higher levels of education, in better health and those more satisfied with their aging mentioned more themes. Regarding specific topics, Social resources and Health were mentioned most frequently, followed by Quality of life, Financial situation, and Attitudes/Mechanisms. Young adults were more likely to mention Social resources, Success/Respect, and Aging themes, while older adults mentioned more often Meaning of life themes. Finally, we found that the themes mentioned were related to self-perception of aging, particularly among older adults: Older adults more satisfied and with positive views own aging were more likely to mention Social resources, Independence, and Attitudes/Mechanisms themes, while those with negative views on aging were more likely to mention Micro-environment themes. In sum, findings support the multidimensionality of lay perspectives of successful aging and offer insights on the understanding of successful aging in Eastern Europe, including topics and links to general and personal aging experiences.

MODELS OF OLDER ADULT GROUP ENGAGEMENT TO IMPROVE HEALTH MANAGEMENT

Mary Hynes[1], Nicole Anderson[2], Monika Kastner[3], and Arlene Astell[1], *1. University of Toronto, Toronto, Ontario, Canada, 2. University of Toronto, North York, Ontario, Canada, 3. North York General Hospital, Toronto, Ontario, Canada*

We are studying the use of peer-to-peer group intervention as a means of promoting older adult health self-efficacy and self-management. To explore how older adults have worked together to improve health behaviors, a scoping review was conducted of older adult peer coaching in health maintenance or health improvement groups. Seventeen studies met all search criteria, including interventions examining the value of peer support in self-management of diabetes, a peer led program for fear of falling, and the effect of self-help groups on quality of life. Two models of peer engagement were identified: peer support and mutually supportive environments. Ten studies trained older adults to be peer mentors or leaders with training periods varying from two days to 30 weeks, although many did not include details of the training. The other seven studies examined mutually supportive environments for peer engagement such as a clinician-led with peer-support model, an app-based program with a social support component, and a prevention focused mutual support group. These studies included research comparing self-care and quality of life results after self-help group therapy and a study that analyzed the impact and role of volunteering at a seniors' centre on maximizing member self-efficacy. While all studies reported on peer self-health engagement, there were many different goals ranging from evaluating health improvement programs to comparing peer and professional health group leadership. One consistent theme was improved perceived self-efficacy though peer group engagement.

SESSION 6390 (POSTER)

TECHNOLOGY

THE IMPACT OF BEHAVIORAL LIFESTYLE INTERVENTION ON INFLAMMATORY CYTOKINES IN OLDER ADULTS WITH TYPE 2 DIABETES

Rozmin Jiwani[1], Monica Serra[2], Sara Espinoza[3], and Darpan Patel[2], *1. UTHSCSA, San Antonio, Texas, United States, 2. UT Health San Antonio, San Antonio, Texas, United States, 3. Sam and Ann Barshop Institute, UT Health San Antonio, San Antonio, Texas, United States*

Chronic inflammation, a hallmark of type 2 diabetes (T2D) and adiposity, increases the risk for age-related co-morbidities, including physical frailty. This study aimed to examine the effects of a mobile technology-enhanced behavioral lifestyle educational intervention on frailty and associated clinical, inflammatory, and laboratory outcomes in overweight older adults with T2D. Twenty participants (≥65 years, BMI ≥25 kg/m2) with T2D were recruited to complete a single-arm 6-month lifestyle intervention modified from the Action for Health in Diabetes (Look AHEAD) study, enhanced with technology for self-monitoring of diet and physical activity. Clinical assessments were collected at baseline and end of the study and analyzed with paired t-tests. Inflammatory cytokines (interleukin [IL]2, IL4, IL6, IL8, IL10, granulocyte-macrophage colony-stimulating-factor [GM-CSF], interferon [IFNγ], tumor necrosis factor [TNFα]) were quantified using a commercially available multiplex kit (Millipore Sigma, Burlington, MA, USA). Clinical lab analysis was performed by Quest Diagnostics (Dallas, TX, USA). Eighteen participants completed the study (71.5±5.3 years; 56% female; 50% Hispanic). At baseline, 13 participants were pre-frail, 4 were frail based on Fried frailty criteria. Inflammatory cytokines and liver enzymes values were within normal limits. At follow-up, the following outcomes significantly improved: frailty score -44% (p=0.01), BMI -3% (P< 0.00), alanine transaminase -18% (p=0.03), aspartate aminotransferase -13% (p< 0.00), IL2 -33% (p=0.01), IL4 -31% (p=0.05), IFNγ -36% (p=0.03), GM-CSF -43% (p=0.03). No other significant differences were observed. The results suggest the efficacy of a technology-enhanced lifestyle intervention on frailty and associated clinical, inflammatory, and laboratory outcomes in overweight older adults with T2D.

TIME-VARYING ASSOCIATIONS BETWEEN SOCIAL INTERACTION MODALITY AND POSITIVE AFFECT DURING TIMES OF CHALLENGE

Tiana Broen[1], Yoonseok Choi[1], Theresa Pauly[2], Elizabeth Zambrano Garza[1], Denis Gerstorf[3], and Christiane Hoppmann[1], *1. University of British Columbia, Vancouver, British Columbia, Canada, 2. University of Zurich, Zurich, Zurich, Switzerland, 3. Humboldt Universität zu Berlin, Berlin, Berlin, Germany*

The COVID-19 pandemic compromised psychological wellbeing, especially given public health guidance that restricted social contact. Engaging in daily social interactions is especially important for maintaining wellbeing, and virtual interactions may be a surrogate for face-to-face interactions when in-person contact is not possible. Embracing the idea that virtual communication may facilitate social connectedness, this project seeks to better understand the potential of virtual social interactions for supporting wellbeing. Using repeated-daily-life-assessments from an adult lifespan sample (N=164, Mage=42.53 years), we examined how number of virtual and face-to-face social interactions were associated with positive affect in individuals' daily lives. We expected that face-to-face interactions would have a stronger relationship with positive affect than virtual social interactions, but that engaging in virtual interactions would be positively related to affect during these unprecedented times. In line with our hypotheses, number of daily in-person (r(812)=0.14, p<.001) and total number of social interactions (r(812)=0.14, p<.001) were associated with higher positive affect at the bivariate level; number of daily virtual social interactions showed a positive trend with affect (r(812)=0.06, p=.07). Multilevel models including quantity of face-to-face and virtual interactions indicate that only face-to-face interactions were associated with concurrent elevations in positive affect (b=0.58, p=.03) and overall higher positive affect (b=0.72, p<.001). Future analyses will examine whether social interactions involving close ties are more powerful drivers of positive affect than distal ties, whether everyday closeness to others mediates the relationship between social interaction modality and positive affect, and we will unpack age as a moderator in these relationships.

FACTORS RELATED TO MOBILE INTERNET USE AMONG MIDDLE-AGED AND OLDER ADULTS: A MODERATING EFFECT OF DISABILITY

Eunjin Yang, and Kyung Hee Lee, *Yonsei University, Seoul, Seoul-t'ukpyolsi, Republic of Korea*

Although mobile devices are preferred as internet access devices, and the number of older adults with and without disabilities is rapidly increasing, little is known about the disability moderating effect on mobile internet use among older adults. This study examined the moderating effect of disability on older adults' mobile internet usage. This study was a secondary data analysis using 2020 Digital Divide Survey in South Korea. A total of 3,629 participants aged 55 and above were included. With the complex sample design in mind, multiple regression analysis was conducted to identify factors related to mobile internet use and test the moderating effects of disability on mobile internet use. Older adults with disabilities used mobile internet less than older adults without disabilities. However, disability status had a moderating effect on the relationships between mobile internet use and (1) operational skills of mobile devices (B=0.31, P=.004), (2) skills of internet use (B=1.46, P<.001), (3) motivation to use digital devices (B=0.46, P=.01), and (4) attitude towards new technology (B=0.50, P=.002). The results revealed that these positive relationships were stronger among older adults with disabilities than those without disabilities. Although older adults and people with disabilities are considered vulnerable populations for technology adoption, disability creates a stronger positive association between several factors and actual mobile internet use. Therefore, policymakers and practitioners should deliver tailored information and technological education for older adults with disabilities. Older adults with disabilities could be the primary beneficiaries of various mobile services.

STAKEHOLDER ENGAGEMENT IN THE DESIGN OF A FALL RISK PREDICTION SYSTEM FOR SOCIALLY VULNERABLE OLDER ADULTS

George Demiris[1], Nancy Hodgson[1], Therese Richmond[1], Marjorie Skubic[2], Sean Harrison[1], Justine Sefcik[3], Sungho Oh[1], and HanNah Cho[1], *1. University of Pennsylvania, Philadelphia, Pennsylvania, United States, 2. University of Missouri, Columbia, Missouri, United States, 3. Drexel University, Philadelphia, Pennsylvania, United States*

Falls and fall-related injuries are significant public health issues for adults 65 years of age and older. Fall-related injuries are among the most expensive medical conditions. Mild cognitive impairment (MCI) and housing conditions are each independent risk factors for multiple falls among older adults and there is increasing evidence of the adverse effect of MCI on balance, stride, gait speed and increasing fall risk. We developed an innovative technology-supported intervention called Sense4Safety to 1) identify escalating risk for falls through real-time in-home passive sensor monitoring (using depth sensors); 2) employ machine learning to inform individualized alerts for fall risk; and 3) link 'at risk' socially vulnerable older adults with a tele-coach who guides them in implementing evidence-based individualized plans to reduce fall-risk. The purpose of this study was a) to examine preferences and attitudes of low-income older adults towards an in-home sensor-based system to inform fall prevention strategies; and b) solicit feedback from and validate the intervention protocols by clinical experts in fall prevention, fall risk assessment and geriatrics. We conducted one hour interview sessions with a total of 10 older adults and 10 clinical experts. Sessions were transcribed and analyzed. Findings included perceived benefits and challenges, recommendations for refinement of the intervention (including educational components and different visualization approaches for sensor data) and the role of family members or trusted others in addressing fall risk. We highlight clinical and ethical implications resulting from the use of passive monitoring for socially vulnerable older adults with MCI.

DIGITAL TECHNOLOGY USE AND INTERGENERATIONAL INTEGRATION: THE MEDIATING ROLE OF DIGITAL LITERACY

Hayoung Park, Bomi Choi, Susanna Joo,
Yoon-Myung Kim, and Hyoun K. Kim, *Yonsei University, Seoul, Seoul-t'ukpyolsi, Republic of Korea*

This study aimed to analyze the mediating effect of digital literacy on the association between digital technology use and intergenerational integration in later life. The sample included 315 older Korean adults aged 65 and above (M=68.83, SD=4.19, range=65-84) who participated in an online survey in December 2021. The participants' use of digital technology was measured by the sum of thirteen questions about how often they used each digital technology in their daily lives. Intergenerational integration was measured by the sum of thirty questions concerning awareness of understanding and empathizing with characteristics and cultures between generations to live harmoniously in the times through communication and cooperation. The mediating variable, digital literacy, was measured by the sum of thirty-five questions from the New Media Literacy Scale, asking individuals' ability to find, evaluate, and communicate information in a digital society. Age, gender, education level, household income, marital status, and living conditions were controlled for to reduce confounding effects. According to the mediation path analysis using SPSS PROCESS macro and bootstrapping, digital literacy significantly mediated the effects of digital technology use on intergenerational integration in later life; the higher the level of digital technology use, the higher the level of digital literacy, and this had a positive effect on the level of awareness of intergenerational integration among older adults. This study is significant in that it confirms the mechanism underlying the link between digital technology use and intergenerational integration and provides a new empirical model to promote intergenerational integration in terms of digital aging.

PREDICTORS OF MHEALTH MINDFULNESS USE IN OLDER ADULT CAREGIVER POPULATION

Danielle Llaneza[1], and Elissa Kozlov[2], *1. Rutgers University, Piscataway, New Jersey, United States, 2. Rutgers School of Public Health, Piscataway, New Jersey, United States*

Caregivers of older adults with MCI have multiple competing demands that limit their ability to seek mental health care, despite being at high risk for stress, anxiety, burnout, and depression. MHealth mindfulness interventions have preliminary efficacy to reduce distress for caregivers, but it is unknown which caregivers are most likely to use and benefit from mHealth mental health interventions. Understanding older adult caregiver mHealth use is an important step in providing personalized mental health care. This study investigated caregiver characteristics that predicted mHealth mindfulness mobile application use in a sample of n=58 caregivers of older adults with MCI. Using linear regression models, it was determined that years spent caregiving, having someone to help with caregiving tasks and education level were all significant predictors of the total amount of minutes spent using the mindfulness application. Our results contribute to the growing body of literature on mHealth strategies to address caregiver distress. Future work should address the expansion of mHealth innovations for older adults and their care persons.

TECHNOLOGY USE AMONG OLDER CHINESE ADULTS: BENEFITS ON SUBJECTIVE WELL-BEING

Dannii Yeung, Natalie Chow, and Edwin Chung, *City University of Hong Kong, Kowloon, Hong Kong*

The growth of Information and Communication Technology (ICT) in recent years has led policy-makers and researchers to look into how these developments affect older adults' daily lives. The educational attainment of older people in Hong Kong is relatively low, with more than 60% of them only completing primary education or having no formal education. Therefore, their utility of ICT remains low as compared with that of their Western counterparts. One of the objectives of this study is to understand the usage of various forms of ICT among older Chinese adults, including technology use in social, financial, medical, and leisure domains. This study also investigates whether social technology use (such as social media, instant messages, video call) could contribute to better subjective well-being through enhancing their social support. A total of 452 older adults joined this study (M=68.7 years, SD=6.27, Range=60-89; 66.7% female). Among the four domains of ICT, higher usage was observed in the social and leisure domains, particularly among the young old. However, among the participants aged 75 and above, more than 70% of them did not use any form of ICT due to a lack of ICT knowledge. The mediation analyses reveal significant indirect effects of social technology use on life satisfaction (B=0.19, SE= 0.08, p=.010) and positive emotions (B=0.02, SE=0.02, p=.014) through social support, thereby suggesting that social technology use could increase older adults' perceived support from friends, which subsequently improves their life satisfaction and positive emotions. Practical implications of these findings will be discussed.

IMPLEMENTING A HYBRID TELEHEALTH HOME-BASED TRANSITIONAL CARE PROGRAM: PRE-IMPLEMENTATION CHALLENGES

Lauren Penney[1], Teresa Damush[2], Dawn Bravata[2],
Cathy Schubert[3], Alaina Preddie[2], Sean Baird[2], and
Ashley Schwartzkopf[4], *1. South Texas Veterans Health Care System, San Antonio, Texas, United States, 2. Richard L. Roudebush VA Medical Center, Indianapolis, Indiana, United States, 3. Richard L. Roudebush VA Medical Center in Indianapolis, Indianapolis, Indiana, United States, 4. Richard L Roudebush VA Medical Center, Indianapolis, Indiana, United States*

The reach of home-based clinical programs for medically complex, older adults can be limited by geographic scope. Implementing telehealth versions can expand reach but create constraints for comprehensive assessments and technological barriers for users. We describe challenges and lessons learned during the pre-implementation period for the randomized trial of a hybrid video -modality of the Geriatrics Resources for Assessment and Care for Elders (GRACE) Program at the Indianapolis Veterans Health Care System. In TeleGRACE, a health technician makes home visits to facilitate clinical activities (e.g., medication reconciliation) using telehealth technology for a clinical team (social worker, nurse practitioner) who conduct the visits remotely. Data used in this one-year pre-implementation evaluation included: periodic reflections with the clinical and evaluation staff, planning and interdisciplinary team meeting fieldnotes, and interviews with clinical team members. Data were summarized by selected constructs from the Consolidated Framework for Implementation Research; implementation challenges and problem solving were identified. Pre-implementation challenges occurred in: assuring assessment devices worked correctly for and were trusted by staff (e.g., connectivity, virtual stethoscope), technician fit with existing GRACE team, ensuring technician welfare (e.g., COVID-19 exposure, guns in the home), caseload balance amid staffing shortages, travel logistics, and sampling to adequately power the trial. Building on an existing strong team dynamic and a culture of feedback for quality improvement, challenges were addressed through pilot-testing, monitoring for barriers and impacts, and group reflecting conversations. Adaptations to the initial plan resulted in a more focused and targeted implementation effort to test the model and its effectiveness.

IMPLEMENTATION OF LIFE STORY TECHNOLOGY IN RESIDENTIAL CARE SETTINGS: BENEFITS AND BARRIERS

Christa Wilk[1], Ashlee Cordell[1], Silvia Orsulic-Jeras[1], Sara Powers[2], Farida Ejaz[1], and Beth Sanders[3], *1. Benjamin Rose Institute on Aging, Cleveland, Ohio, United States, 2. The Benjamin Rose Institute on Aging, Cleveland, Ohio, United States, 3. LifeBio, MARYSVILLE, Ohio, United States*

Life story work is a promising intervention in residential care settings to engage persons with dementia (PWD) in meaningful conversation and promote person-centered care. Utilizing technology to streamline the life story collection process brought gerontologists and tech developers together to create LifeBio Memory™: an app which utilizes machine-learning and artificial-intelligence to collect life story data more efficiently than collection by hand. This presentation highlights focus group findings related to the benefits and barriers of this adaptation. Two waves (Time 1 and Time 2) of 60–90-minute (mean=80 SD=14.31) focus groups were conducted via Zoom nine months apart to evaluate the acceptability and feasibility of LifeBio Memory™. In Time 1 (n=35), community-dwelling PWD, residential care staff, and current/former LifeBio program users were asked to provide feedback on 1) their experience with the original version of LifeBio and 2) a prototype of the app. A thematic analysis yielded a list of recommended changes utilized to develop the app. In Time 2 (n=28), participants were asked to provide feedback on 1) training, 2) experience using the app, 3) implementation feasibility, 4) impact on person-centered care. A second thematic analysis was conducted. Across time 1 and 2, participants reported high levels of acceptability and feasibility for the LifeBio Memory™ concept and provided valuable feedback to the tech developers related to future implementation barriers of such technology. This presentation will discuss focus group findings related to 1) benefits of the adaptation, 2) barriers to using the tablet app, 3) implementation of the adaptation.

PATTERNS OF SOCIAL COMMUNICATION IN MINORITY ADULTS: ASSISTIVE AND INTERACTIVE TECHNOLOGY USE DURING COVID-19

Akankshya Chataut[1], Sarah Hubner[1], and Julie Blaskewicz Boron[2], *1. University of Nebraska Omaha, Omaha, Nebraska, United States, 2. University of Nebraska, Omaha, Omaha, Nebraska, United States*

Literature suggests aging adults are more likely to be socially isolated, particularly given the COVID-19 pandemic. This has been associated with diminished well-being and increased morbidity and mortality. Assistive and interactive technologies (AITs) may help reduce isolation by bolstering communication. However, rapid advancement of AITs can create new barriers, especially for marginalized/underserved communities. The purpose of this study was to explore isolation and AITs in a majority-non-white sample. Data collected were part of a larger survey. Participants (N=80: Non-White=92.5%, Black=36.5%, Hispanic=36.5%) completed a Qualtrics survey via Amazon Mechanical Turk. Respondents included younger (YA: N=34, ages:19-34, M=27.7±4.6), middle-aged (MA: N=27, ages:35-49, M=41.9±4.1), and older (OA: N=20, ages:50-70, M=57.6±6.5) adults. Surveys consisted of likert-style and free-response questions. Content analysis with inductive coding was performed independently by two reviewers. Qualitative results suggested most adults used AITs regularly. Phone-based functions (texting/calling, smartphone-use) were favored for communication between 2020-2021. These functions were the largest group reported for all ages, although YA reported them more frequently (65%) compared to MA (48%) and OA (59%). Data also suggested that people had more in-person interaction at the time of survey completion (majority September 2021), compared to one-year previous (46.4%). Increased distanced socialization negatively correlated with overall socialization (r(78)=-.231, p=.05). Results suggest that although AITs are widely used, they may not adequately reduce isolation, particularly for those relying on them for primary contact. This may be especially true for underrepresented adults. Future research should investigate if this trend is universal and if existing AITs are sub-optimal in specific populations.

A WHOLE NEW WORLD: EXPLORING VIRTUAL REALITY USE AND PERCEPTIONS WITH COMMUNITY-DWELLING OLDER ADULTS

Mary Milnamow, Emily Quinones-Visot, Lillian Agyemang, and Louanne Bakk, *State University of New York, University at Buffalo, Buffalo, New York, United States*

Virtual reality (VR) is an emerging technology that can facilitate and support active engagement and social interactions through shared immersive experiences. While limited evidence suggests VR can improve the health and well-being of older adults in residential and clinical care settings, research has not examined the potential benefits of a shared VR experience with community-dwelling older individuals despite their increased risk for social isolation. This exploratory, longitudinal study used a mixed-methods approach to assess the impact of VR programming among persons 65+ years of age with limited mobility attending a Program of All-Inclusive Care for the Elderly (PACE) and participating in a group-level VR intervention (n=9). Quantitative measures pertaining to health, well-being, social isolation, and comfort with technology were collected at baseline, six weeks, and twelve weeks. Qualitative, semi-structured focus groups were also conducted to assess participants' perceptions of the VR intervention. Paired sample t-test results indicated improvements over time in participants' pain level, well-being, and comfort in relation to using VR technology (p <.05). Qualitative data illustrated that participants were extremely receptive to using VR and found the experience pleasurable, realistic, and exciting. The most common themes suggested VR programming was regarded as a highly immersive, stimulating experience that can bolster camaraderie and positive feelings. Moreover, participants felt empowered by the experience. These findings demonstrate that utilizing VR programming with community-dwelling older adults can provide interactive and engaging experiences. The potential benefits of this intervention provide a basis for developing programming that can improve well-being and connectedness.

DIGITAL PHENOTYPING TO UNDERSTAND HEALTH-RELATED OUTCOMES: A SCOPING REVIEW

Kyungmi Lee[1], Sidharth Kumar[2], Frank Puga[2], Andres Azuero[2], Arif Kamal[3], Carolyn Pickering[2], and J. Nicholas Dionne-Odom[2], *1. The University of Alabama at Birmingham, Hoover, Alabama, United States, 2. The University of Alabama at Birmingham, Birmingham, Alabama, United States, 3. Duke University, Durham, North Carolina, United States*

Modeling passive data collected by smartphones, or digital phenotyping, may help detect the early signs of declines in daily health and lead to steps to prevent declines. Health-related outcomes have been typically acquired through self-report measures, however this broad approach has several limitations, such as recall and social desirability bias. A potential solution is digital phenotyping. Guided by the Arksey and O'Malley methodological framework, the aim of this scoping review was to identify studies that modeled passive smartphone-sensor data into behavioral markers that correlate or predict health-related outcomes. A literature search of peer-reviewed or conference studies in PubMed, Scopus, Compendex, and HTA yielded 3,170 articles. 40 studies met the inclusion criteria. Studies were organized and assessed for their: 1) data collection approaches (e.g., smartphone passive sensor data and questionnaire), 2) feature extraction (e.g., converting bedtime or wake time into sleep), 3) data analytics (e.g., identifying accelerometer data into sleep patterns using machine learning), 4) behavioral markers, which is observing the activity pattern for an extended period of time and then modeling the activities into appropriate behaviors, and 5) health-related outcomes. The findings of this study demonstrate how to transform passive smartphone-sensor data into behavioral markers that correlate or predict health-related outcomes, which could provide information for more grounded predictive use and successful implementation of digital phenotyping in future research.

TAILORED INTERNET-BASED SEXUAL EDUCATION FOR OLDER ADULTS: NEEDS ASSESSMENT AND ALGORITHM DEVELOPMENT

Liza Berdychevsky[1], Galit Nimrod[2], and Wendy Rogers[3], *1. University of Illinois at Urbana-Champaign, Champaign, Illinois, United States, 2. Ben-Gurion University of the Negev, Beer Sheva, HaDarom, Israel, 3. University of Illinois Urbana Champaign, Champaign, Illinois, United States*

Many older adults are sexually active, but ageism fuels the neglect of older adults' sexuality in research and sexual education. The purpose of this study was to (1) assess older adults' willingness to adopt technology tools to receive innovative, tailored sexual health education via the internet, (2) investigate their sexual health needs, and (3) contribute to development of an assessment tool and tailoring algorithm. Tailoring is a precision approach that matches educational content to users' needs instead of offering the same suboptimal one-size-fits-all content to everyone. We conducted an online survey using Qualtrics research panels of older adults (N = 836, with equal representation by gender and balanced representation in each 5-year cohort from age 60 to 80+). We found that 30% reported they were likely to try tailored internet-based education for older adults; an additional 34% were unsure. The results establish priority areas in sexual health needs, including behavioral patterns, knowledge gaps, health-related constraints, and attitudinal and communicational issues. These components provide the basis for the tailoring assessment questionnaire. Respondents also rated the personal relevance of 28 educational modules covering sex in later life (e.g., sexual ageism, sex as quality-of-life issue, sex-related communication, body image, health conditions, gender-specific issues, sexual attitudes, broadening sexual definitions and repertoires, sexual adaptations, inhibitions, sex aids/toys/robotics, medications/treatments, orgasm, self-stimulation/masturbation, dating, risk-taking, celibacy, LGBTQIA+, sexual rights, abuse). Statistical relationships between sexual health needs and personally relevant modules contribute to the development of a tailoring algorithm for creating educational bundles matched to older adults' unique needs.

DIGITAL TECHNOLOGY USE AND SOCIAL CAPITAL: THE MODERATING EFFECT OF SOCIAL CLASS

Bomi Choi, Hayoung Park, Susanna Joo, Yoon-Myung Kim, and Hyoun K. Kim, *Yonsei University, Seoul, Seoul-t'ukpyolsi, Republic of Korea*

This study aims to elucidate the heterogeneous associations between digital technology use and social capital by social class. The sample comprises 315 Korean older people who are 65 years old or older and participated in an online survey. Digital technology use was measured by the frequency of independent use in four areas of digital technology: primary, cultural, economic, and public areas. Social capital was measured with ten items asking the perceived support availability from both online and offline relationships. Social class was measured with education, household income, and subjective social position to reflect both objective and subjective aspects of social class. Using SPSS 25 PROCESS Macro 3.5, linear regression with moderation analyses was performed. A simple slope and the region of significance were tested for a significant interaction. Results showed that subjective social position significantly moderated the relationship between digital technology use and social capital. The positive association between digital technology use and social capital was strengthened when the level of subjective social position was higher. Education and household income did not moderate the relationship between digital technology use and social capital. The results of this study indicate that the effects of digital technology use vary depending on perceived aspects of social class. This study also demonstrates that people with higher social classes enjoy more benefits from digitalization, supporting digital inequality among the older population.

BOLSTERING SOCIAL CONNECTEDNESS DURING COVID-19: COMMUNICATION BETWEEN ESSENTIAL CONTACTS AND OLDER ADULTS

Joanna George[1], Sarah Hubner[2], and
Julie Blaskewicz Boron[3], *1. Oklahoma State University College of Osteopathic Medicine, Tulsa, Oklahoma, United States, 2. University of Nebraska Omaha, Omaha, Nebraska, United States, 3. University of Nebraska, Omaha, Omaha, Nebraska, United States*

Social isolation may increase morbidity and mortality, particularly for aging adults. Research suggests that COVID-19 has significantly disrupted social networks, exacerbating isolation and risk. However, the extent of disruption and its implications for older adults and their essential contacts (ECs) is unknown. ECs, those who provide support/engagement to older adults, play a significant role in networks and help shape communication patterns. Understanding the effects of COVID-19 on social connectedness between ECs and older adults is vital to promoting their well-being. The purpose of this study was to investigate ECs' patterns of communication with adults aged 60+ during the COVID-19 pandemic , considering preferences, needs, and barriers. Self-identified ECs (N=546, Aged 19+, MAge=44.3±14.2) completed a Qualtrics survey via Amazon Mechanical Turk. Participants were ECs for community-dwelling (CDECs=57.3%) and institutionalized adults (IECs=42.7%). In addition to likert-style questions, the survey included free-response sections, examining communication quality, frequency, and method. Content analysis was conducted independently by two reviewers, using inductive coding. Qualitative results revealed distanced communication was widely utilized. Audiovisual/video communication was more frequently noted as desirable by IECs (32.8%) than CDECs (11.85%). Further, preference for audiovisual communication negatively correlated to expression of COVID-19-related barriers (IECs=12.5%, CDECs=7.7%, (r(546)= -.128, p=.01). Comparisons suggested that IECs reported absence of in-person contact with older adults more frequently than CDECs (recent contact=Never: 51% and 13.4% respectively). This may support the utility of video-communication to meaningfully supplement connectedness in the absence of in-person contact. The experiences described can reveal avenues for loneliness interventions and may guide future technology innovations.

COMMUNICATION BETWEEN OLDER ADULTS AND ESSENTIAL CONTACTS: ISOLATION AND ASSISTIVE AND INTERACTIVE TECHNOLOGIES

Dinesh Karki[1], Sarah Hubner[1], and
Julie Blaskewicz Boron[2], *1. University of Nebraska Omaha, Omaha, Nebraska, United States, 2. University of Nebraska, Omaha, Omaha, Nebraska, United States*

Essential contacts (ECs), people providing support/engagement to older adults, are vital to their physical and socio-emotional well-being. Research suggests that COVID-19 has significantly affected the connectedness of aging populations and their ECs, limiting interaction and potentially weakening support networks. Assistive and interactive technologies (AITs) may be useful for mitigating disruptions by facilitating communication. The goal of this study was to explore AIT preferences and needs of ECs for connecting with adults aged 60+. Participants completed a Qualtrics survey via Amazon Mechanical Turk. An initial sample (N=580,MAge=44.3±14.3,White=81%) was collected (December 2020-February 2021). A minority sub-sample (N=79,MAge=38.9±11.6,Non-White=87.3%) was subsequently accrued (September-December 2021). Participants were initial/minority-ECs for community-dwelling (initial-CDECs=57%,minority-CDECs=89%) and institutionalized adults (initial-IECs=43%,minority-IECs=11%). Minority respondents overwhelmingly identified as CDECs. Results revealed that recent ,"daily/often" phone-based, video-based, and in-person communication were all, more-frequently reported in minority-ECs compared to the initial-EC sample. Phone-based communication was most-frequent in minority-IECs (61%,versus initial-IECs=49%), but was relatively ubiquitous among all (minority-CDECs=49%,initial-CDECs=43%). Initial-CDECs had the least video-based contact (17%); the remaining groups were relatively similar (minority-CDECs=36%,minority-IECs=33%,initial-IECs=32%). CDECs reported the most in-person communication (minority-CDECs=70%,versus initial-CDECs=49%); IECs reported the least (minority-IECs=44%, versus initial-IECs=14%,). Results suggest that this minority sub-set may communicate more, respectively. This may be influenced by population and data-collection-time differences. Still, CDECs may have maintained better access to in-person communication and relied less-heavily on distanced networks through the pandemic. Ultimately, individual characteristics (i.e., ethnicity) and experiences (i.e., COVID-19) may drive communication patterns and end-user needs; this could inform innovation. Future investigation into these topics is warranted.

LEVERAGING VIDEO CONFERENCING TECHNOLOGY TO FACILITATE SOCIAL ENGAGEMENT IN OLDER ADULTS

George Mois[1], Elizabeth Lydon[2], Shraddha Shende[3], Madina Khamzina[3], Dillon Myers[4], Raksha Mudar[3], and Wendy Rogers[3], *1. University of Illinois Urbana-Champaign, Urbana Champaign, Illinois, United States, 2. University of Illinois Urbana-Champaign, Champaign, Illinois, United States, 3. University of Illinois Urbana Champaign, Champaign, Illinois, United States, 4. OneClick, Philadephia, Pennsylvania, United States*

Social engagement is critical for maintaining well-being and quality of life in older adults. However, typical age-related changes across bio-psychosocial dimensions as well as age-related conditions such as mild cognitive impairment (MCI), pose many challenges for older adults to remain socially connected. The development of technologies, specifically video conferencing, can be leveraged as a tool to facilitate the delivery of social engagement opportunities, both enhancing access and minimizing social isolation. For successful adoption of these tools, the needs and preferences of older adult users must be considered. We employed an iterative research process for designing and developing a social-engagement intervention using a platform called OneClick.chat. We provide community-dwelling older adults with opportunities to engage in casual conversations and reminisce with others on topics of shared interests (e.g., nature, food, hobbies). Our iterative design process involved an interdisciplinary team of engineers, human factors specialists, gerontologists, and neuropsychologists. We also evaluated the system with eight participants (aged 50-64) who provided their insights pertaining to the content, delivery, perceived ease of use, usefulness, and potential adoption of this video-conferencing platform. Based on the feedback received, we have optimized the intervention in preparation for a randomized controlled trial. Furthermore, we provide key insights related to the implementation of social engagement through video technologies with the aim of facilitating social connectivity. Our learnings can be used to guide future work involving video-technology-based interventions to facilitate social connectivity for older adults with varying cognitive abilities.

THE ASSOCIATION BETWEEN SUBJECTIVE AGE AND TECHNOLOGY USE AMONG OLDER ADULTS

Tomoko Ikeuchi[1], Tomoko Wakui[1], Sakiko Itoh[2], Hiroyasu Miwa[3], and Kentaro Watanabe[3], *1. Tokyo Metropolitan Institute of Gerontology, Tokyo, Tokyo, Japan, 2. Osaka University, Suita, Osaka, Japan, 3. National Institute of Advanced Industrial Science and Technology, Kashiwa, Chiba, Japan*

Background: Subjective age (SA) (i.e., felt age) has been found to be a biopsychosocial marker of aging. This study examined the associations between SA and frequency of technology usage of older adults.

Methods: Data were collected via an online survey conducted in 2020. The study analyzed participants aged 65 to 89 (M = 71.9, SD = 3.91) years resided in Japan (N = 1855, 54.3% women). SA was indexed by asking participants to specify in years how old they felt. Proportional discrepancy scores (PDS) ((SA - chronological age) / chronological age) were calculated to indicate younger or older SAs and used as an independent variable. Participants were asked about the frequency of computer, smartphone, flip phone, and SNS use.

Results: Nearly 90% reported using computers for more than 2-3 days a week, 64.3% smartphones, 22.9% flip phones, and 36.6% SNS. Logistic regression analyses revealed that lower PDS (i.e., feeling younger) was associated with a significantly higher frequency of smartphone use (OR: 0.75; 95% CI: 0.59, 0.96) after adjusting for age, gender, education, and subjective health. No such association was found for computer, flip phone, and SNS use. Implications: Older adults who use smartphones daily may feel younger than those who do not. Since the present study was administered during the COVID-19 pandemic, the daily use of smartphones may have helped older adults stay in touch with friends and family members and obtain information they need. The use of smartphones possibly contributed to better mental health outcomes while practicing social distancing.

REMEMBER STUFF: A PILOT FEASIBILITY TRIAL OF DYADIC-FOCUSED TECHNOLOGY TO SUPPORT PEOPLE WITH ADRD

Sneha Manoharan[1], Matthew Schroeder[2], James Slaven[3], Anna Higbie[4], Mary Ellen Mullholand[5], and Nicole Fowler[6], *1. Regenstrief Institute, Inc, Indianapolis, Indiana, United States, 2. Regenstrief Institute, Inc., Indianapolis, Indiana, United States, 3. Indiana University, Indianapolis, Indiana, United States, 4. Regenstrief Institute, Indianapolis, Indiana, United States, 5. Eperture, LLC, Fishers, Indiana, United States, 6. Indiana University School of Medicine, Indianapolis, Indiana, United States*

Technology to support caregivers of people with Alzheimer's disease or related dementias (ADRD) with tasks may be the next frontier for caregiving research. This single-arm 90-day pilot trial tested the usability, feasibility, and acceptability of a software system called RememberStuff® (R/S) by Eperture. We also tested R/S's impact on caregiver burden. R/S includes a web-based portal where caregivers add information to a touch screen used by patients. R/S is organized around four main features– Calendar, Messaging, Activities, and Remember, a personalized task list. We collected data from dyads at baseline, 30-, 60-, and 90-days. Measures included the Healthy Aging Brain Care (HABC) monitor, System Usability Scale (SUS), and satisfaction scales indicating caregiver's willingness to use and behavioral intention. We approached caregivers of patients with ADRD seen in primary care clinics. Of the 469 participants reached, 278 (59.28%) refused, 156 (33.26%) were ineligible due to nursing home placement and 35 dyads were enrolled (7.46%). Among enrolled participants, 65.7% completed data up to 90 days. 73.5% of the caregivers lived with the patients. Mean caregiver age was 59.1 years; 67.7% are female; 88.2% are white. Willingness to use R/S was consistent across time from 30 days (M=3.9, SD=0.7) through 90 days (M=3.8, SD=1.1), while usability decreased (30 days M=57.7, SD=7.5 to 90 days M=54.9, SD 8.7). Caregiver's overall HABC monitor also decreased from baseline (M=29.0,

SD=13.1) to 90 days (M=27.2, SD=12.2) indicating less burden at 90 days. These findings support the feasibility of R/S technology to support caregivers of people with ADRD.

SERIAL MEDIATION BY DIGITAL ASSISTANCE, INTERNET SELF-EFFICACY, DIGITAL CITIZENSHIP, AND UNMET NEEDS

Susanna Joo, Bomi Choi, Hayoung Park, Changmin Lee, Yoon-Myung Kim, and Hyoun K. Kim, *Yonsei University, Seoul, Seoul-t'ukpyolsi, Republic of Korea*

Although many social services are getting digitalized with the rapidly growing digital technology, there is little information available on the specific process of meeting personal needs in digital aging contexts. The present study examined the serial mediation model from digital assistant to unmet needs via internet self-efficacy and digital citizenship. An online survey was used to collect data in December 2021, and the sample included 223 older Korean adults aged 65 and above (M=68.79, SD=4.18, range=65-84) who owned at least one digital device. Unmet needs, the dependent variable, was the number of problems (e.g., housing, physical functioning) that participants responded to as 'unmet.' The independent variable was digital assistance, meaning getting help from friends or others when having problems with the digital device. The first mediator was internet self-efficacy, and the second mediator was five subtypes of digital citizenship (internet political activism, technical skills, local/global awareness, critical perspective, and networking agency). Covariates were gender, age, education, and income. SPSS Process Macro was utilized for serial mediation analysis. The result showed that only a serial mediation path from digital assistance to unmet needs via internet self-efficacy and internet political activism was significant. Additionally, a simple mediation path from digital assistance to unmet needs via internet political activism was significant. Technical skills, local/global awareness, critical perspective, and networking agency did not reveal significant mediational paths. Findings imply providing digital assistance system may be useful to reduce unmet needs among older adults by enhancing self-efficacy and political participation in the current digitalized world.

A COMPARISON OF TRADITIONAL REMOTE MONITORING (RPM) DEVICES VERSUS A NOVEL, TOILET SEAT–BASED MONITORING DEVICE

Carla VandeWeerd, Erica Sappington, Lydia Poon, Chidi Okeahialam-Iheanyi, and Mitchell Roberts, *UFHealth Precision Health Research Center-The Villages, The Villages, Florida, United States*

As the aging population increases, older adults are disproportionately susceptible to cardiovascular disease(CVD). Routinely monitoring vital signs can alleviate CVD's burden. Current telemonitoring technologies targeting vital signs can be complex, generating inconsistent outputs and suboptimal adherence. In response, Casana developed the Heart Seat(THS), a passive toilet seat-based remote patient monitoring (RPM) device. This study aimed to compare older adults' (1) adherence between traditional telemonitoring(TT) devices and THS and (2) satisfaction across devices. A randomized control study (UFIRB202100869) was conducted in an active lifestyle retirement community-The Villages, Florida. Using a crossover design, participants (N=49) with CVD were followed for 12 weeks (8/12/2021-12/21/2021), beginning in TT or THS Arm and crossing over arms at 6 weeks. Adherence was calculated daily as ≥1 use for ≥90 seconds for THS, and ≥1 use of the blood pressure cuff and scale for TT. Descriptive statistics and t-tests were used to evaluate adherence rates and participant's experience and perception of RPM devices. Participants mean age was 73.4 years (SD=7.1,51% female). The majority (94%) of participants had previous experience using telemonitoring devices (e.g. scale, blood-pressure cuff, smartwatch) and 87.7% strongly agreed to feeling comfortable with at-home health monitoring. Overall, participants demonstrated greater adherence to THS than TT (t(48)=4.86, p<.001). These findings suggest older adults are becoming increasingly experienced and comfortable with at-home monitoring of health parameters. Overall, adherence was greatest in THS, suggesting that passive, easy-to-use telemonitoring devices may increase adherence, promote real-time health monitoring, and support adverse event prevention in older adults.

INTERNET LITERACY FROM GRANDCHILDREN OR YOUNGER GENERATION: A NEW DIRECTION FOR GERONTECHNOLOGY

Ananya Sarker[1], Jeffrey Kahana[2], and Eva Kahana[1], *1. Case Western Reserve University, Cleveland, Ohio, United States, 2. Mount Saint Mary College, Newburgh, New York, United States*

Internet literacy offers a modern set of tools that can help older adults achieve the three pillars of successful aging, especially in the post-pandemic world. In the United States, older adults have shown significant growth in the usage of the internet and online services. However, information and social connectivity for older adults with lower incomes and education levels still lag. The current pandemic raises the public question of whether internet access and education should be deemed as a basic human right. Internet access is even more critical for older adults who need additional technology access and training, tailored to fit their varying experience, disability, and cognitive ability levels. The pandemic has demanded numerous technological skills for daily life: videoconferencing to carry on work, ordering groceries, taking exercise classes online, talking to family members and healthcare providers, and now registering for vaccination. Thus older adults need help with technology use more than ever. We need awareness of the "digital divide" and collaboration from designers, developers, services, products, and programs or interventions from various public and private sources. Identifying social and logistical barriers to technology literacy, we propose a conceptual model of using intergenerational training strategies to ameliorate the digital divide experienced by older adults. In this paper, we will review successful intergenerational programs like Students to Seniors, and Zoomers to Boomers, and introduce a similar model for internet literacy. The intergenerational mentoring model is advocated due to its wide-ranging potential benefits for both the older generation and the younger generation.

UNDERSTANDING THE ADOPTION OF A MOBILE APPLICATION TO SUPPORT WORKFLOW OF HEALTHCARE AIDES

Christine Daum[1], Antonio Miguel-Cruz[2], Hector Perez[1], Emily Rutledge[1], Sharla King[2], and Lili Liu[1], *1. University of Waterloo, Waterloo, Ontario, Canada, 2. University of Alberta, Edmonton, Alberta, Canada*

Healthcare aides are unlicensed support personnel who provide direct care, personal assistance and support to persons living with health conditions. Workflow issues have a negative impact on health care aides' job satisfaction and quality of care. The implementation of information communication technologies could improve workflow. In collaboration with an industry partner, we developed a mobile application intended to support the workflow of health care aides who provide services to long-term care residents living with dementia. The purpose of this study was to investigate the technology acceptance and usability of a mobile application in a real-world environment when used by health care aides of a care facility. We used a sequential explanatory mixed methods approach. Our study included pre and post paper-based questionnaires with no control group (n=60). This was followed by two focus groups with a subsample of health care aides informed by qualitative description (n=12). We found: (a) acceptance of the mobile application was high; (b) usefulness was the strongest predictor of intention to use the mobile application, and (c) intention to use the mobile application predicted usage behaviour. Focus group findings supported the quantitative findings and highlighted participants' strong belief that the mobile application was useful, portable, and reliable. An area for improvement was user interface adjustments. Overall, these results support the assertion that our mobile application assisted health care aides in addressing their workflow issues and thus, has potential to improve the quality of care provided.

SESSION 6400 (POSTER)

TECHNOLOGY AND AGING

EXPLORING COMMUNICATION DISPARITIES IN LATE OLD AGE THROUGH THE LENS OF COMMUNICATION INFRASTRUCTURE THEORY

Carrie Leach, and Thomas Jankowski, *Wayne State University, Detroit, Michigan, United States*

Health disparities are driven, in part, by communication disparities. Those who face the greatest health burdens often have the least communication resources to draw on to help them to manage and cope. As part of a multi-year, multi-level community engaged study to understand how to reduce the communication disjuncture between community-based service providers and older adults age 75 and older, we draw on data collected from 1,609 older adults through in-depth interviews (n=20) and a random sample survey (n=989) in one county in Michigan, along with a random digit dial telephone survey (n=600) conducted statewide. Findings point to key channels for disseminating information to hard-to-reach older adults being healthcare professionals and home delivered mail. Despite optimistic reports that technology usage and adoption rates are increasing for older users, findings suggest that old adults continue to face digital exclusion. Challenges with connecting through interpersonal networks are discussed. Limited resources for connecting with others through technology combined with increased social distancing due to the pandemic may exacerbate older adults' diminishing social networks and dwindling communication resources to draw upon for managing their health in later old age. Understanding how to connect with the hard-to-reach is pressing particularly as connecting via tele-health normalizes. This information may be employed to inform strategies for disseminating information to older adults, including those ages 75 and older who are hardest-to-reach, and likewise, outreach and recruitment by researchers to engage them in studies that aim to reduce health disparities.

DOES TRUST IN SOCIAL SECURITY INHIBIT ACCEPTANCE OF ASSISTIVE TECHNOLOGY FOR ADL HELP?

Tomoko Wakui[1], Sakiko Itoh[2], Hiroyasu Miwa[3], Tomoko Ikeuchi[1], and Kentaro Watanabe[3], *1. Tokyo Metropolitan Institute of Gerontology, Tokyo, Tokyo, Japan, 2. Osaka University, Suita, Osaka, Japan, 3. National Institute of Advanced Industrial Science and Technology, Kashiwa, Chiba, Japan*

In 2000, Japan introduced a mandatory long-term care insurance program to facilitate aging-in-place of older care recipients; there has been a great demand for assistive technologies such as AI (artificial intelligence) and robots in care settings to reduce the burden of caregivers and long-term care costs in society. This study examined the relationship between the trust in social security and acceptance of assistive technology for ADL help and discussed the challenges in introducing technology in a well-developed social security system. An online survey was conducted in August 2020 among community-dwelling individuals aged between 40 and 89 across Japan to find out their acceptance of help provided via AI or robotics technology in five dimensions of ADL. In addition, a 5-point Likert scale was used to assess the trust in social security.A total of 4,047 respondents were analyzed in this study. The respondents' mean age was 60.6 (SD=11.3), and 53.2% of them were female. Of those, 13.2% preferred help from humans in ADL, while for 86.8%, the use of some assistive technology was acceptable. Logistic regression revealed that the female and younger respondents and those who had better health and had completed higher education were more likely to accept AI or robotics technology in all/some ADL if they needed assistance; those with higher trust in social security, however, were less likely to accept technology (OR=.894; p=.011).The challenges in introducing assistive technology under a well-developed social security system will be discussed.

EXAMINATION OF THE DIGIAGE CYBER-SENIORS PILOT STUDY FOR OLDER ADULTS FROM LOWER INCOME COMMUNITIES

Skye Leedahl, Alexandria Capolino, Melanie Brasher, Kristin Fratoni-Souza, and Erica Estus, *University of Rhode Island, Kingston, Rhode Island, United States*

The University of Rhode Island (URI) team implemented a pilot program designed to bridge the digital divide between older adults and younger generations. Through this project, the goal was for older Rhode Islanders to become digitally literate by engaging them in a formal program that provides digital devices (i.e., Apple iPads), connectivity (i.e., internet connection through HotSpots), and training by supervised and trained university student mentors. This project specifically worked to promote social and economic equity by recruiting participants from lower-income communities and areas hit hardest by the COVID-19 pandemic, including those who speak English and Spanish. The final sample (N=124) for the study was primarily female (79%) and low income (82%). They were 41% Non-White and 23% Spanish speaking with 23% having a college degree or more. We conducted preliminary analysis on the first 38 participants who completed both a pre- and post-survey. Based on these analyses, the program participants have shown statistically significant improvements in frequency of tablet use (p<.05), digital competency across all questions (p<.05), quality of life (p<.05), and social isolation (p<.05). In addition, the loneliness and depression questions/variables are trending in the expected direction, so it is possible that with a more robust sample size we may see significant improvement in these areas as well. This presentation will describe the key elements of the pilot intervention and explain the findings from the full sample. The presentation will also discuss the plan for state-wide implementation of the program.

THE EXPLORATION OF CORRELATES OF LONELINESS AMONG COMMUNITY-DWELLING OLDER PEOPLE'S TECHNOLOGY LITERACY

Suk-Young Kang[1], Jeungkun Kim[2], and Antonina Poplawski[3], *1. Binghamton University, State University of New York, Binghamton, New York, United States, 2. Kangnam University, Youngin, Kyonggi-do, Republic of Korea, 3. Binghamton University, Binghamton, New York, United States*

Social isolation is a major public health risk among older adults, even considered to be as harmful as smoking. The aim of this study was to explore the benefits of digital literacy and the correlates related to levels of loneliness on older people.Mail-survey data were collected from community-dwelling adults over the age of 65. There were 192 total participants, with information from 180 people being included in the analysis.The six-item De Jong Loneliness Scale was used to measure levels of loneliness. Among the 180 participants, the mean was 2.02 (SD = 1.68).Regression analysis revealed that the equation explained 48.2% of variance (adjusted R-squared = .446) in levels of loneliness (F (11,162) = 13.682, p <.000). Variance inflation factor (VIF) values were smaller than 10, indicating that multicollinearity among the correlates was not an issue. Correlates of levels of loneliness included aging anxiety, depression, social network, and self-evaluated technology literacy with computer software programs compared to peers. Results confirmed the correlates related to loneliness among older people identified in previous studies. This shows quality of life related to mental health may be improved by a positive attitude towards technology use.This study further found that digital literacy affects loneliness when controlling for income, depression, level of network, and physical health.Participants who could increase their digital literacy are interested in more opportunities on how to use new technology. Policy changes that allow for lifelong learning options could support this, while also decreasing levels of social isolation and loneliness.

EXISTING KNOWLEDGE ASSOCIATED WITH SMART HOME HEALTH TECHNOLOGIES IN THE CARE OF OLDER PERSONS: A SYSTEMATIC REVIEW

Yi Jiao (Angelina) Tian[1], Nadine Andrea Felber[2], Félix Pageau[3], Delphine Roulet Schwab[4], and Tenzin Wangmo[2], *1. Institute for Biomedical Ethics, University of Basel, Basel, Basel-Stadt, Switzerland, 2. University of Basel, Basel, Basel-Stadt, Switzerland, 3. University of Laval, Quebec City, Quebec, Canada, 4. School of Nursing Sciences, University of Applied Sciences and Arts Western Switzerland, Lausanne, Vaud, Switzerland*

As a greater part of the global population reaches the golden age, smart home technologies are said to allow older persons to remain independent at a place of residence, or "home", of their own choice. Though their development has been making their way to the market, there has not been a systematic review of the empirical literature on the knowledge associated with their use for persons who are 65 years or older. Hence, we conducted a systematic review of empirical peer-reviewed English, German, and French articles in ten electronic databases. Data was textually described, separated into key characteristics, logged into a customized data extraction document, and analysed using narrative synthesis. The search across ten databases revealed 144 empirical papers that were admissible to our inclusion criteria. Of which, we discovered 5 first-order categories of benefits and 5 of barriers of smart home health technologies with further sub-themes that together form the concurrent array of existing knowledge. These categories included, for example, allows older persons to live independently at home, reminds older persons to promote self-care, and alternatively, concerns about usability, cost, and social acceptance. These systematically-derived categories of benefits and barriers could be a starting point for researchers interested in caregiving for older persons to conduct further empirical and reflective research. Furthermore, having this understanding of existing challenges and opportunities associated with smart home health technologies then allows the research and technical communities to collaborate upon a joint foundation to inform policy and improve caregiving for the global aging population.

IMPACT OF OLDER ADULTS' INTERNET USE ON THE ECONOMIC BURDEN OF INFORMAL CAREGIVING

Jeehoon Kim[1], Heesoo Joo[2], and Sally Hageman[1], *1. Idaho State University, Pocatello, Idaho, United States, 2. University at Albany, Albany, New York, United States*

Objectives: Digital technology enables older adults to live independently by handling health-related tasks or shopping/banking online, thus can reduce care burden. This study examines the impact of older adults' Internet use on formal and informal care hours and its influence on estimating cost savings with active and potential Internet users.

Methods: Medicare beneficiaries ages 65 and above with functional difficulties were sampled from the 2015 National Health and Aging Trends Study (N=1,806). Care is measured by total hours for help older adults received in the past month, separated by formal and informal care. Internet use for health-related tasks and shopping/banking were measured. A survey weighted two-part model with gamma distribution was estimated. The cost savings of informal caregiving was estimated by a replacement approach.

Results: Older adults' health-related Internet use substantially reduced informal care hours by 27.7% (19.8 hours per month, p < .05), but not for formal care hours. A monthly estimated cost reduction of informal caregiving was $3,094 per an older adult with functional difficulties by applying 2020 median wage of home health aide workers. The annual savings in the cost of informal caregiving associated with older adults' health-related Internet use is estimated to be $8.1 billion with the active users and additionally $20.1 billion with the potential health-related Internet users in the US. Discussion: Promoting health-related Internet use among older adults with functional difficulties to relieve economic burden of informal caregiving will be discussed.

DIGITAL LITERACY AND ASSOCIATED FACTORS IN COMMUNITY-DWELLING OLDER ADULTS IN SOUTH KOREA: A QUALITATIVE STUDY

Jiwon Baek[1], JiYeon Choi[2], Heejung Kim[1], Soyun Hong[1], Yesol Kim[1], Seongmi Choi[1], and Eunkyung Kim[1], *1. Yonsei University, Seoul, Seoul-t'ukpyolsi, Republic of Korea, 2. Yonsei University College of Nursing, Mo-Im Kim Nursing Research Institute, Seoul, Seoul-t'ukpyolsi, Republic of Korea*

Background: Digital literacy has gained growing importance in the health agenda. However, the level of digital information use and access among Korean older adults is still low at 54%. It is important to understand digital literacy among older adults to provide healthcare and social connectivity, especially during the COVID-19 pandemic. Objective: This study aims to explore the digital literacy and identify barriers to learning and using digital devices among community-dwelling older adults in urban South Korea.

Methods: A qualitative study was conducted using a semi-structured interview guide according to the DigComp 2.0 framework which emphasizes the competencies for full digital participation in five categories: information, communication, content creation, safety, and problem solving. Our sample consisted of 14 older adults (age 68 – 79, 12 women).

Results: Participants reported varying competency of using digital devices for search, communication, and self-management of lifestyle and health. They actively sought help from family and community members to troubleshoot issues related to installation, maintenance, setup software or applications. However, they were passive or evasive in the use of digital devices because of concerns about invasion of privacy or personal information. They struggled to use digital devices owing to physical and cognitive changes associated with aging.

Conclusion: Our findings depict current state and barriers of digital literacy in urban older adults in Korea.

SESSION 6410 (POSTER)

THE COST OF CARING: RISK AND REWARD

CAREGIVER DEPRESSION AND PROGRESS TOWARD VALUES: AN AUTOREGRESSIVE CROSS-LAGGED PANEL MODEL

Jacob Gossner[1], Elizabeth Braungart Fauth[1], Joshua Novak[2], Michael Levin[1], and Spencer Bradshaw[1], *1. Utah State University, Logan, Utah, United States, 2. Auburn University, Auburn, Alabama, United States*

Acceptance and Commitment Therapy (ACT) is an established in-person therapy but can be provided self-guided online. Recently, online ACT has been adapted to support dementia family caregivers. A primary goal of ACT is to connect individuals with their self-identified values, with the assumption that increased progress towards values will lead to improved well-being. While there are established negative associations between depression and progress towards values, the lagged influence of progress toward values at one time point on another time point within intervention is less understood. Our sample was 51 dementia caregivers who completed an online self-guided ACT intervention. Participants were 80.3% female, 53% spouse, with a mean age of 65.98 (SD =11.66). We created an auto-regressive cross-lagged panel model to examine longitudinal associations between progress towards values and depressive symptoms at three time points. Controlling for time 1 (pre-intervention) depressive symptoms, progress towards values at time 1 significantly predicted depression at time 2 (β = -.427, p < 0.01) and progress towards values at time 2 (β = .716, p < 0.001). Depression at time 2 significantly predicted progress towards values at time 3 (β = -.515, p < 0.001) and depressive symptoms at time 3 (β = .580, p < 0.001). The R^2 range from .30-.43. Our analyses suggest that participants' initial progress toward values strongly negatively predicted their subsequent depressive symptoms, which then predicted later progress towards values. These findings demonstrate the potential reciprocal relationship between progress towards values and depressive symptoms within ACT intervention.

CAREGIVING STRESSORS AND MENTAL HEALTH AMONG OLDER DEMENTIA CAREGIVERS: THE MEDIATING ROLE OF LIFE DISRUPTION

Fei Wang, and Elliane Irani, *Case Western Reserve University, Cleveland, Ohio, United States*

Providing care to a loved one with dementia can take a mental toll on older adult caregivers who struggle to balance their caregiving duties and self-care. However, few caregiving studies focus on older adults as caregivers. Further, the extant research mainly investigates stressors directly related to the demands of caregiving without accounting for the disruptions in different areas of life triggered by dementia caregiving. Guided by the Stress Process Model, we examined how life disruption mediates the association between caregiving stressors and caregiver mental health. A total of 360 older adult caregivers (age 65 or above) of individuals with dementia (age 65 or above) in the U.S. were selected from the 2017 National Study of Caregiving. An index of life disruption was created based on seven types of life challenges due to caregiving, such as constriction of social life and job-caregiving conflict. Results from a path analysis show that both objective and subjective caregiving stressors (i.e., care assistance and role overload) were positively associated with life disruption, which in turn, were positively associated with depressive symptoms and anxiety. Caregiver socio-demographics and self-rated health were included in the analysis as covariates. These findings inform a novel clinical assessment framework for practitioners to identify the unique challenges faced by older dementia caregivers in the U.S. Moreover, this study elucidated life disruption as a modifiable factor to mitigate mental health problems in this population. Future research should compare the effects of different types of life disruption on mental health among older dementia caregivers.

UNDERSTANDING THE PREDICTIVE FACTORS THAT INFLUENCE THE PERCEIVED BURDEN OF DEMENTIA CAREGIVERS

Kaitlyn Lucas[1], and Katherine Judge[2], *1. Cleveland State University, Westlake, Ohio, United States, 2. Cleveland State University, Cleveland, Ohio, United States*

Burden is a significant negative outcome for caregivers of individuals with dementia. Guided by the Stress Process Model, the following study examined the impact of several novel constructs on burden including: compassion for others, family functioning, coping styles, and positive and negative affect. Data were gathered through Amazon Mechanical Turk from 102 dementia caregivers. Participants were 62% female, 72% Caucasian with a mean age of 39.5 years old. Burden was significantly related to positive affect (r =-.31, p =.01), negative affect (r =.56, p =<.01), family functioning (r =.43, p <.01), and dysfunctional coping (r =.37, p <.01). Compassion for others was not correlated with burden. Multiple regression analysis results found the set of predictors accounted for 65.0% of the total variance in burden (F(5,96) = 14.17, p < .01, R2= .65), with positive affect (β = -.26, p = .01), negative affect (β = .19, p= .05), and dysfunctional coping (β = .31, p= .01) predicting significant and unique variance. Results from mediation analyses indicated dysfunctional coping mediated the relationship between positive affect and burden (effect= -.14 95% bootstrap CI= -.26, -.04) as well as the relationship between negative affect and burden (effect= .24, 95% bootstrap CI= .07, .48). A mediating relationship between dysfunctional coping and family functioning and burden was not supported. Discussion will highlight the implications of the study findings in developing innovative caregiver programs aimed at reducing dysfunctional coping and the broader theoretical implications of the role of affect in family caregivers of individuals with dementia.

SUFFERING BUT SATISFIED: OLDER ADULTS' LIFE SATISFACTION WITHSTANDS DEPRESSION AND DEMENTIA

Samuel Van Vleet[1], Danica Bass[2], Yenifer Morales Mejia[2], Jeanné Dube[2], Brandee McKinney[2], Kailee Prentice[2], Logan Guillory[2], and Michael Barnett[2], *1. Miami University, Oxford, Ohio, United States, 2. The University of Texas at Tyler, Tyler, Texas, United States*

Among older adults with neurocognitive disorders, lower life satisfaction has been linked with poorer aspects of physical and mental health that affect quality of life, including depression. However, these associations between life satisfaction and mental health problems have not been found universally. In this study, we further investigated life satisfaction and depression within clinical and healthy older adult populations. Older adults (N = 98), ages 60 to 90 years either with (n = 25) or without (n = 73) a neurocognitive diagnosis, were administered self-report questionnaires measuring depression and life satisfaction. Results showed that although depression was negatively correlated with life satisfaction among both samples, older adults with dementia had higher depression scores but equivalent life satisfaction scores as older adults without dementia. In fact, both the clinical and healthy samples of older adults averaged on the positive or satisfied half of the life satisfaction scale. Older adults with neurocognitive disorders may generally experience higher depressive symptoms, yet despite challenges to quality of life, they seem to find satisfaction in their daily lives. This may stem from older adults viewing current depressive symptoms as a relatively short-term problem while evaluating life satisfaction across their whole lives. The best protective factors for older adults suffering from dementia and depression may therefore be found both in their present and in their past.

SESSION 6411 (POSTER)

COGNITION AND ALZHEIMER'S DISEASE

ATIP LEVELS ARE ASSOCIATED WITH LESS AMYLOID-B BURDEN IN POSTMORTEM BRAINS OF OLDER ADULTS WITH ALZHEIMER'S DEMENTIA

Caglar Cosarderelioglu[1], Alma Plaza-Rodriguez[2], Pablo Iglesias[1], C. Conover Talbot[1], D. Brian Foster[1], Robert N. Cole[1], Jeremy Walston[1], and Peter M. Abadir[1], *1. Johns Hopkins University, Baltimore, Maryland, United States, 2. Krieger School of Arts and Sciences, Baltimore, Maryland, United States*

Angiotensin system, aging, and Alzheimer's disease are tightly linked. Of the brain angiotensin receptors, the subtype 2 receptor (AT2R) is relatively less studied. Canonically, the AT2R functions through nitric oxide release, and its activation has been linked to vasodilatation and neurite outgrowth as well as anti-inflammation. How AT2R signals is not known, however, an AT2R-binding protein (ATIP) has been recently described. Controversies exist on the link between ATIP and AT2R functions. Here, we describe the development of the first non-antibody based ultra-sensitive and specific quantitative mass spectrometry assay for ATIP. Using a technique that permits targeted analysis of multiple peptides across multiple samples in a single mass spectrometry run, known as TOMAHAQ, we have identified specific human tryptic peptides that permit quantification of ATIP abundance. We have used this method to quantify ATIP in postmortem frontal cortex samples of older adults (n= 60) with Alzheimer's dementia (AD). We correlated levels of ATIP to brain RAS receptors, and biomarkers of AD pathogenesis including oxidative stress, inflammation, mitochondrial dysfunction as well as amyloid-β, and tau burden. Our results show that ATIP expression (ANLKNPQIMYLEQELESLK sequence of ATIP) is positively correlated with neuronal nitric oxide synthase (nNOS) ($p = 0.009$, $r = 0.337$). Furthermore, expression of ATIP is negatively correlated with amyloid-β load in several brain regions including hippocampus ($p= 0.014$, $r= -0.317$), entorhinal cortex ($p= 0.010$, $r= -0.331$), frontal cortex ($p= 0.023$, $r= -0.294$), and overall ($p= 0.004$, $r= -0.365$). These results highlight a potential protective role for ATIP in Alzheimer's disease.

IS CEREBRAL AMYLOID ANGIOPATHY A PRECIPITATING EVENT IN THE ETIOLOGY OF ALZHEIMER'S DISEASE

Steven Edland[1], Chris Zarow[1], Benjamin Shifflett[2], Margaret Flanagan[3], and Lon White[4], *1. University of California, San Diego, San Diego, California, United States, 2. University of California, San Diego, La Jolla, California, United States, 3. Northwestern University, Evanston, Illinois, United States, 4. Pacific Health Research and Education Institute, Honolulu, Hawaii, United States*

Amyloid plaque and cerebral amyloid angiopathy (CAA) are early neuropathologic changes observed in the setting of clinical Alzheimer's disease (AD), typically preceding biomarker evidence of intraneuronal tau neurofibrillary tangle (NFT) development and associated cognitive decline. Here we apply structural equation models to explore the potential causal associations between amyloid-beta lesions (i.e. plaques and CAA) and NFTs as they affect cognitive performance in the elderly.Brain autopsy data used in this study are from the Honolulu Asia Aging Study (HAAS) of Japanese American men from the state of Hawaii (n=600), and the Nuns Study (NS) of Roman Catholic Sisters largely from the upper midwestern United States (n=378). Cognitive performance within three years of death was assessed by multi-domain dementia rating scales.We found that neocortical neuritic plaque and CAA effects on cognitive performance were mediated by neocortical NFTs for both the HAAS ($p < 0.002$) and NS ($p < 0.043$). There were no direct effects of neuritic plaque and CAA after controlling for the mediating effect of NFTs ($p > 0.54$).These data are consistent with the hypothesis that the association between neuritic plaque and CAA on cognition is mediated by NFT load. This may inform our understanding of the etiology of NFT lesion pathology in aging and AD. The disruption of arterial smooth muscle function by CAA has predictable effects on glymphatic processes and on the regulation of capillary blood flow. These effects are plausibly relevant to the AD neurodegenerative process, and these pathways deserves continued attention by the AD research community.

DETECTION OF PRECLINICAL AND PRODROMAL ALZHEIMER'S DISEASE USING A MULTIDISEASE DIAGNOSTIC PLATFORM

Cassandra DeMarshall[1], Jeffrey Viviano[1], Sheina Emrani[2], George Godsey[1], Abhirup Sarkar[1], Benjamin Belinka[1], David Libon[2], and Robert Nagele[2], *1. Durin Technologies Inc., Mullica Hill, New Jersey, United States, 2. Durin Technologies Inc., Mullica Hill, New Jersey, United States, 2. Rowan University School of Osteopathic Medicine, Stratford, New Jersey, United States*

AD-related pathological changes begin in the brain long before symptoms emerge. In the present study, we demonstrate the utility of a panel of AD-related autoantibodies capable of detecting AD at the earliest points along the AD continuum, including preclinical AD, years before the onset of symptoms, and prodromal AD (mild cognitive impairment, MCI). Using a customized panel of AD-specific autoantibody biomarkers and Luminex xMAP® technology, sera from ADNI subjects with preclinical AD or MCI were screened to demonstrate preclinical and prodromal AD detection. A panel of eight autoantibodies with increased titer in MCI and preclinical AD relative to controls was evaluated using Random Forest and Receiver Characteristic Operating curves for their ability to distinguish diseased subjects from age- and sex-matched controls, as well as from individuals with other neurodegenerative and non-neurodegenerative diseases. Results showed that this panel of biomarkers was capable of differentiating patients with MCI from age- and sex-matched controls with high overall accuracy, sensitivity, and specificity. These biomarkers also identified cognitively normal subjects who later converted to MCI and AD. Furthermore, this autoantibody biomarker panel distinguished MCI and preclinical AD subjects from Parkinson's disease and breast cancer subjects, demonstrating excellent disease specificity. Results demonstrate the utility of our blood-based autoantibody biomarker panel as an accurate, non-invasive, and inexpensive diagnostic screener, not only for the detection of prodromal AD, but also the earlier, preclinical stages of AD pathology. This multi-disease diagnostic platform has been demonstrated to be useful for multiple neurodegenerative diseases including AD, Parkinson's disease and Multiple Sclerosis.

INTEGRATIVE MULTI-OMICS ANALYSIS REVEALS THE CRITICAL ROLE OF PBXIP1 GENE IN AGING-RELATED ALZHEIMER'S DISEASE

Zuyun Liu, Jingyun Zhang, and Xiaoyi Sun, *Zhejiang University School of Medicine, Hangzhou, Zhejiang, China (People's Republic)*

Alzheimer's disease (AD) is a neurodegenerative disorder, and its strongest risk factor is aging. A few studies have explored the relationship between aging and AD, while the underlying mechanism remains unclear. We assembled data cross multi-omics (i.e., epigenetics, transcriptomics, and proteomics, based on frozen tissues from the dorsolateral prefrontal cortex) and neuropathological and clinical traits from the Religious Orders Study and Rush Memory and Aging Project (ROSMAP). Aging was assessed using six epigenetic clocks (including Horvath clock, Hannum clock, Levine clock, Horvathskin clock, Lin clock, and Cortical clock) that capture mortality risk in literature. After accounting for age, we first identified a gene module (including 263 genes) that was related to most epigenetic clocks (e.g., P=3.61×10−5 for Levine clock) and three neuropathological traits of AD (i.e., β-amyloid, Tau tangles, and tangle density). Interestingly, among 20 key genes with top intramodular connectivity of the module, PBXIP1 was the only one that was significantly associated with all three neuropathological traits of AD at the protein level after Bonferroni correction. Furthermore, PBXIP1 was associated with clinical diagnosis of AD in both ROSMAP and two independent datasets. The results suggest the critical role of PBXIP1 in aging-related AD and support the potential and feasibility of using multi-omics data to investigate mechanisms of complex diseases. However, more validations in different populations and experiments in vitro and in vivo are required in the future.

LOCI RESPONSIBLE FOR RACIAL DISPARITY BETWEEN WHITE AND BLACK AMERICANS IN ALZHEIMER'S DISEASE

Stanislav Kolpakov Nikitin, and Igor Akushevich, *Duke University, Durham, North Carolina, United States*

We tested the following genotype-related mechanisms generating race-dependent disparity in Alzheimer's Disease (AD) risk: i) the frequencies of SNPs with genotypes associated with AD are higher in the Black subpopulation; ii) the effects on AD risk of genotypes associated with increased AD risk is higher in the Black subpopulation; iii) there is a small group of SNPs with a large difference in the effects on AD race-dependent risk generating disparities; alternatively, the disparities are generated by a collective effect of multiple SNPs with minor or moderate effects. We modified the GWAS algorithm to use it with the Cox regression multivariable model and the outcome accounting for race-related differences in AD risk. Using the modified GWAS we have identified loci in charge for the disparity between Whites and Blacks and used the results along with SNPs of a special interest which were identified from the literature in the Cox multivariable regression model and generalized Oaxaca-Blinder approach. The following genes had the strongest effects on racial disparities: i) NYAP1 neuronal tyrosine-phosphorylated phosphoinositide-3-kinase adaptor; ii) RPA3-UMAD1 loci RPA3 replicates protein A, interacting with gastric tumor and hepatocellular carcinoma; iii) TOMM40 associated with an increased risk of developing late-onset AD; iv) ACE - responsible for making the enzyme which converts angiotensin which regulates blood pressure; v) PSME3IP1 - proteasome activator subunit 3 interacting protein 1; vi) MARCHF1 regulator of glucose-tolerance and lipid storage and vii) LINC01146 which belongs to coagulation cascade pathway and linked to hepatocellular carcinoma.

A NOVEL FRAMEWORK LINKING MNEMONIC AND HIPPOCAMPAL INTEGRATION TO LATE-LIFE REAPPRAISAL EFFICACY

Bruna Martins-Klein[1], Irina Orlovsky[2], and Kristin Heideman[3], *1. University of Southern California, Los Angeles, California, United States, 2. University of Massachusetts Amherst, Amherst, Massachusetts, United States, 3. Yale Child Study Center, New Haven, Connecticut, United States*

Socioemotional theories suggest that surviving challenging experiences enhances emotional resilience with age, yet the role of memories is overlooked in most models of emotion regulation. In parallel, cognitive accounts focus on age-related memory deficits associated with overlapping hippocampal neural representations across unique memories (neural dedifferentiation). We propose a novel framework supporting enhanced late-life reappraisal via hippocampal dedifferentiation of memory representations across current and past experiences. We review classic studies supporting mood benefits from integrated positive narratives following adverse autobiographical events. We also discuss multivariate neuroimaging evidence supporting overlapping hippocampal representations and ventromedial prefrontal cortex (vmPFC) involvement in meaning-making processes. We posit that greater hippocampal dedifferentiation across life memories may facilitate associative binding of current and past stressors as well as reappraisals in vmPFC. This process may provide avenues for generalizing past reappraisals to novel contexts and reducing cognitive demands of reappraisal. In addition, we discuss the possible age-related facilitation of this process, as a greater number of life experiences may become increasingly integrated with one another over the lifespan. These integrated neural associations may serve to make reappraisals from the past more readily accessible and applicable in new contexts over time, increasing routes to positive narratives following stress. We discuss future directions for testing components of the proposed model using multivariate neuroimaging methods. We conclude by briefly reviewing the possible clinical impact of mnemonic emotion regulation in promoting emotional well-being among older adults, using a strengths-based approach that leverages wisdom from experience and neural processes facilitated with age.

SPATIALLY RESOLVED MAPPING OF CELL-SPECIFIC SENESCENT PROFILES IN AGING MOUSE BRAIN

Chase Carver, and Marissa Schafer, *Mayo Clinic, Rochester, Minnesota, United States*

Cellular senescence is a conserved mechanism of aging characterized by cell cycle arrest and secretion of a senescence-associated secretory phenotype comprised of proinflammatory cytokines, chemokines, proteases, and growth factors that disrupt cellular homeostasis by promoting sterile inflammation and aberrant tissue remodeling. Tissue microenvironment, induction mechanism, and duration since senescence onset contribute to senescent cell heterogeneity, making identification challenging. Senescent cell contribution to age-related cognitive decline suggests that the hippocampus may be a key brain region for uncovering functional identities of senescence. Therefore, our goal is to contextually and spatially map senescent cells in comparison of cell-type specific morphological, transcriptional, and functional features that distinguish them among highly-ordered brain microenvironments. GeoMx Digital Spatial profiling was used to investigate cell identity and senescence markers in the aging brain to develop transcriptomic profiles from 22-24-month old mice. We also adapted Imaging Mass Cytometry with a curated panel of antibody-labeled proteins in fixed brain sections. We observed that senescent-like phenotypes of cells from myeloid and non-myeloid origin accumulate in the hippocampus and cortex, whereas CD45+ immune cells primarily accumulate in the white matter regions, in close proximity to microglia and GAL3+ cells. We profiled differences in ramified and ameboid microglia, in comparison of young and old mice, with emphasis on the chemotactic microenvironment involving activation of inflammatory signals. These advanced, multiplex imaging modalities enable in-depth characterization of senescent cell features in the aging brain. Beyond morphological profiling, we demonstrate enhanced resolution and detection of individualized senescence in the aging brain.

HOW INTERPLAY BETWEEN INFLAMMASOME AND MIRNA IS ASSOCIATED WITH ALZHEIMER'S DISEASE

Anatoliy Yashin[1], Deqing Wu[1], Konstantin Arbeev[1], Alexander Kulminski[1], Eric Stallard[1], Jonas Mengel-From[2], Olivia Bagley[1], and Svetlana Ukraintseva[1], *1. Duke University, Durham, North Carolina, United States, 2. University of Southern Denmark, Odense, Syddanmark, Denmark*

The results of recent analyses showed that neuroinflammation—a key contributor to Alzheimer's disease (AD)—is activated by protein complexes known as inflammasomes. The NLRP3 inflammasome protein complex is mostly studied in the central nervous system; it includes a protein encoded by the NLRP3 gene. Connections between inflammasomes, neuroinflammation, and AD may be regulated by small non-coding RNAs called microRNAs. These molecules have multiple ways to influence AD. For example, microRNA miR-107 may influence AD through regulation of the BACE1 gene expression involved in Aβ production. It remains unclear whether interplay of miR-107 and NRLP3 is associated with AD and whether mechanisms of such interplay differ among participants of LLFS and other studies. To address these questions, we evaluated associations with AD of interactions between genetic variants (SNPs) located in DNA encoding miR-107 and NLRP3 in participants of the LLFS and Framingham Heart Study using a logistic regression model with an interaction term. The facts that both datasets deal with data on related individuals and that many SNPs from either miR-107 or NLRP3 are in linkage disequilibrium were accounted for in these studies. The analysis of the Framingham data showed that the association with AD of the interaction between SNPs from miR-107 and the NLRP3 gene was statistically significant(p=6.71E-03; Bonferroni correction=7.14E-03). The association of the same interaction with AD was replicated in the analysis of LLFS data. These results indicate that in addition to regulating BACE1 expression and Aβ production, miR-107 may influence AD in interaction with the NLRP3 gene.

SLEEP IS REQUIRED FOR ODOR EXPOSURE TO CONSOLIDATE MEMORY AND REMODEL OLFACTORY SYNAPSES

Rashmi Chandra[1], Fatima Farah[2], Fernando Muñoz-Lobato[1], Anirudh Bokka[2], Kelli Benedetti[1], Fatema Saifuddin[1], Miri VanHoven[2], and Noelle L'Etoile[1], *1. University of California, San Francisco, San Francisco, California, United States, 2. San Jose State University, San Jose, California, United States*

Olfactory dysfunction precedes dementia in several neurodegenerative disorders such as Alzheimer's disease (AD) or Parkinson's Disease (PD), and AD/PD are associated with progressive sleep abnormalities. However, how sleep affects cognitive performance remains unclear, perhaps due to the complexities of the human nervous system. Here we demonstrate that the transparent model organism C. elegans which has well defined neural connection sleeps after repeated odor trainings. This provides us with a platform to dissect how sleep affects memory at a synaptic resolution. We identified that sleep after training is required for the animal to retain a long-term memory of the odor. We found that if animals do not sleep in the first two hours after training, memory is not consolidated. After identifying the neurons that are required for the memory, we show that the sensory-interneuron connections within the circuit are downscaled after sleep. Therefore, we found a time-specific requirement of sleep that modulates synaptic downscaling to preserve memory. Conversely, lack of sleep post-training erases the long-term memory and destabilizes the synaptic downscaling, indicating that modulating the amount of sleep is sufficient to modulate memory. These results make C. elegans an excellent tool to ask what molecular mechanisms, cell biological processes and circuit level reorganizations are engaged during sleep to promote memory. This understanding will provide insights into the functions of sleep that affects cognitive performance in neurodegenerative diseases.

SLEEP, COGNITION, AND BRAIN FUNCTION IN OLDER ADULTS WITH CHRONIC KIDNEY DISEASE AND MILD COGNITIVE IMPAIRMENT

Thanakrit Jeamjitvibool, Mary Hannan, and Ulf Bronas, *University of Illinois Chicago, Chicago, Illinois, United States*

Older adults with chronic kidney disease (CKD) are at risk for cognitive impairment and commonly report sleep disturbances. The association between sleep and brain function remains unclear. This cross-sectional study investigated the relationship between sleep, cognition, and brain function in older adults with CKD and mild cognitive impairment (MCI). Older adults with CKD and MCI (n=37, age=68 + 4.93, eGFR=43.7 + 10.98, 73%=Black, 70%=Female), were evaluated via a comprehensive cognitive function battery and brain MR-imaging. Seven-day actigraphy was scored utilizing the Cole-Kripke algorithm to evaluate sleep quality and duration. Ordinary least square regression controlling for age and education quality indicated that >9 hours of sleep, as compared to < 7 hours of sleep, was associated with worse executive function (unstandardized beta=-6.86, 95% CI:-13.19, -0.53, p=.04). Less sleep (< 8 hours) was associated with better learning/memory (unstandardized beta=2.61, 95% CI: 0.84, 4.38, p=.01). Better sleep efficiency was associated with increased global cerebral blood flow (unstandardized beta=3.30, 95% CI: 0.65, 5.95, p=.02). Longer sleep time (>9 hours), as compared to shorter sleep time (< 7 hours), was associated with worse mean diffusivity (unstandardized beta=0.12, 95% CI: 0.03, 0.20, p=.01). Shorter sleep time (< 8 hours, compared to >=8 hours) was associated with better fractional anisotropy of the cingulum (unstandardized beta=0.03, 95% CI: 0.01, 0.05, p=<.001). Sleep duration and quality may be related to cognition and brain function in older adults with CKD and MCI providing a possible avenue for interventions to improve cognitive outcomes in this population.

NEUROCORRELATES BETWEEN THEORY-OF-MIND AND BILINGUALISM IN GRAY MATTER VOLUME OF YOUNG AND OLDER ADULTS

W. Quin Yow[1], Xiaoqian Li[1], Kwun Kei Ng[2], Janice Jue Xin Koi[2], and Juan Helen Zhou[2], *1. Singapore University of Technology & Design, Singapore, Singapore, 2. National University of Singapore, Singapore, Singapore*

The experience of being bilingual may accrue cognitive reserve against age-related declines in older adults. Early bilingualism, e.g., second language age-of-acquisition (L2AoA), has been shown to be associated with better theory-of-mind (ToM) performance in older adults (Yow et al., 2021). Here, we aim to understand the brain structural correlates associated with bilingualism and ToM performance in normal aging. Forty-six young (YA, aged 19-30, M=21.87) and 51 older adult bilinguals (OA, aged 54-77, M=63.61) completed 1) ToM assessments, where they viewed vignettes and answered questions about the protagonists' mental states, 2) an anatomical MRI scan, 3) a demographic questionnaire including L2AoA and years of education, and 4) a general cognitive ability assessment by the Montreal Cognitive Assessment (MoCA) test. As expected, ANCOVA on ToM composite scores revealed a significant main effect of age – YA showed better ToM performance than OA, F(1,93)=9.48, p=.003, controlling for education and MoCA scores. Importantly, MRI data were preprocessed to obtain gray matter volume (GMV), proxy of neuronal density, of 430 brain regions. Partial least square correlation analysis identified one significant multivariate pattern linking individual differences in GMV with ToM score and L2AoA (48.7% covariance explained, p=.014). Regardless of age, larger GMV in several regions including prefrontal, frontal, medial temporal, and superior temporal cortices were associated with earlier L2AoA (p=.003) and higher ToM score (p=.004), indicating shared variance between ToM and L2AoA in brain morphology. Findings suggest that earlier bilingual acquisition might promote brain maturation that would preserve ToM ability well into later stages of life.

SESSION 6420 (POSTER)

TELEHEALTH, TECHNOLOGY, AND DEVICES

DEVELOPMENT OF A MOBILE INTERVENTION TO SUPPORT HEALTHY EATING IN PERSON WITH CO-OCCURRING FRAILTY AND DEMENTIA

Oleg Zaslavsky, Kuan-Ching Wu, Shao-Yun Chien, and Kimiko Domoto-Reilly, *University of Washington, Seattle, Washington, United States*

New behavioral solutions are needed to improve health in persons with co-occurring frailty and dementia. Using dementia-specific principles of human-centered design, we developed a mobile intervention that includes a patient-facing app and clinician interface to promote a Mediterranean-style eating plan in this population. Our design processes were as follows. We first solicited iterative input from experts in dementia, accessible design, and technology concerning language, cognitive load, and overall accessibility needs in persons with early dementia. Next, we recruited seven people with mild dementia and their partners for interviews, experience sampling, and usability studies. Our primary findings were: 1) participants have basic knowledge of healthy eating tenets and want to learn more; 2) participants are unaware of anything specific to improve in their diet; 3) participants value simple meals with few ingredients; 4) participants strongly rely on physical cookbooks. Based on the results, we developed a high-fidelity prototype of the patient-facing mobile app, divided into tasks: 1) First time onboarding; 2) Setting the first dietary goal; 3) Finding a recipe; 4) Filter/sort for recipes; 5) Food tracking tool; 6) Mastering a dietary goal and starting a new one; 7) Reviewing progress. The resultant product was iterated in usability studies and informed a final prototype for further testing. In parallel, a web-based clinician interface was developed through individual interviews, a survey of potential end-users (n=24), and two rounds of usability studies (n=3 in each round). The online clinician product features these interactive modules: dashboard, tracking manager, patient portal, and individual patient page

ELECTIVE TELEMEDICINE: ARE OLDER WOMEN IN THE POSTPRIMARY TREATMENT PHASE OF EARLY BREAST CANCER INTERESTED?

Caroline Buse, Kirsten Nyrop, Erin O'Hare Kelly, and Hyman Muss, *UNC Chapel Hill, Chapel Hill, North Carolina, United States*

Explosive growth in the use of telemedicine occurred during the COVID-19 pandemic. Telemedicine has the potential to lessen healthcare burden for older adults with frequent appointments, physical and cognitive disabilities, and reliance on caretakers. To benefit from telemedicine, patients must have the capacity to engage with technology, for which inexperience and access may pose barriers. This study aimed to better understand the perspectives of older women with non-metastatic breast cancer on telemedicine, in regards to visit convenience, completeness, and interpersonal satisfaction. In this qualitative study, semi-structured interviews were conducted in a convenience sample of women age 65+, post-primary treatment for Stage I-III breast cancer, who received in-person outpatient care at NC Cancer Hospital before transitioning to telemedicine after March 2020. Patients were interviewed about their perceptions of telemedicine (telephone, video) as compared to in-person visits. Audio files of interviews were transcribed and reviewed to identify themes established a priori in the interview protocol. 15 patients (telephone=5, video=10) were consented and interviewed (July-October 2021), mean age=74. 13/15 participants reported that they preferred a hybrid care model that included telemedicine care over in-person care alone. COVID-19, physical disability, and transportation burden were associated with telemedicine preference. Comfort with familiar patient-provider interaction and lack of physical exam were associated with in-person appointment preference. Patient-clinician conversations and clinic protocols guiding use of telemedicine should take into account newness of diagnosis, patient comfort and familiarity with the care team, travel burden, disability, and whether the physical exam is or is not essential.

ARE PAIN APPS USABLE? MHEALTH LITERACY FRAMEWORK

Mary Milidonis[1], and Carolyn Menges[2], *1. Cleveland State University, HUDSON, Ohio, United States, 2. Cleveland State University, Cleveland, Ohio, United States*

Older adults are at risk for low health literacy and not adhering to self-care. Health professionals are shifting their practices to emphasize wellbeing through health promotion. Mobile pain applications may be a tool to improve health communication and individualize care. Mobile health apps do not always consider the needs of the older adult who may be less comfortable and confident with technology. The purpose of this qualitative review is to explore mobile pain applications for adults with a health literacy framework, and identify facilitators and barriers to usability. Databases that reviewed apps included Google, Google Scholar, ScienceDirect, PubMed, CINAHL plus full text, APTA EBP database, MEDline, and SportDiscus. Fifty-three apps found. Excluded criteria: if there was a cost, targeted for children, and without pain diary. Six apps identified to be specifically relevant to pain intensity, location quality, and impact on life. Mobile Application Rating System (MARS) tool assessed engagement, functionality, aesthetics, information quality, and subjective quality. All apps were engaging, allowed for tracking symptoms and life impact over time. Some apps were difficult to navigate, did not offer education support. Two of the apps individualized pain. Two apps are on only accessible on one app platform. One app allowed for feedback about the app design. Pain mobile health applications can improve tracking, managing and understanding pain for improved mobility and social engagement for older adults. The use of health literacy frameworks with mobile health applications may increase accessibility to care.

ENHANCING TELEHEALTH CLINICAL SERVICES AND CHRONIC DISEASE SELF-MANAGEMENT FOR OLDER ADULTS DURING COVID-19

Nicolette Castagna[1], and Lisa Granville[2], *1. Florida State University College of Medicine , Tallahassee, Florida, United States, 2. Florida State University College of Medicine, Tallahassee, Florida, United States*

During the pandemic, providers shifted to telemedicine to ensure patient safety. Under a federally funded cooperative agreement, the Florida State University College of Medicine's Department of Geriatrics partnered with a Federally Qualified Health Center to assess rural older adults' perceptions about telehealth and identify potential barriers. The quality improvement study used a convenience sample to survey patients aged ≥ 65 (n=62) at one rural clinic. 54.8% of respondents indicated they would not use telehealth for any care or preferred to receive most or all care in person. Conversely, 32.8% indicated a willingness to receive some care via telehealth. The survey also assessed the need for self-management devices, including blood pressure cuffs. There was not a consistent positive relationship between persons requesting devices and those who were telehealth willing. Devices were distributed to enhance telehealth visits and at-home monitoring. Clinic staff provided patients hands on training for device use and connection to EMR. Informal qualitative reports suggest patients are more empowered to utilize telehealth services and self-manage conditions. COVID-19 also limited access to community blood pressure screenings. The Tallahassee Senior Center and FSU Physician Assistant program distributed devices to community-dwelling older adults. PA students provided hands on training to aid in device familiarity and digital connectivity. Almost all older adult participants aged >60 strongly agreed "after the presentation I feel ready to use the blood pressure cuff at home." Clinical and community-based activities can help older adults who lack digital fluency feel more confident in using telehealth services and self-management devices.

MULTIMODAL AFFECTIVE ANALYSIS OF FACIAL AND VOCAL EXPRESSIVITY USING SMARTPHONE AND DEEP LEARNING ANALYSIS

Heejung Kim[1], Youngshin Cho[1], Sunghee Lee[2], and CHAEHYEON Kang[1], *1. Yonsei University, Seoul, Seoul-t'ukpyolsi, Republic of Korea, 2. BRFrame, Seoul, Seoul-t'ukpyolsi, Republic of Korea*

Limited expressivity of emotion is one of the most common symptoms of major depression, particularly in older adults. Although assessing facial and vocal expressivity is very important for accurate clinical evaluation of geriatric depression, research has rarely examined older adults via telehealth technology. This study aims to quantify facial and vocal expressivity via a multimodal affective system with deep learning. A total of 19 Korean adults aged over 65 years with severe depressive symptoms participated in this research. Using smartphone video recording, 1,429 facial and vocal data were collected between July and December 2020. Recorded videos were transmitted automatically to the cloud system. Basic facial movements were extracted using combined video frames and mel spectrogram images. Compared to the AI hub of Korean images from big data, mood status was classified into seven categories (anger, disgust, fear, happiness, neutrality, sadness, and surprise). Frequencies of each mood were coded into continuous variables for each participant in each recording. When comparing video and text prediction to determine "true labels," the overall accuracy was 0.69, with F1 scores ranging from

0.57 to 0.79. In addition, the most common emotions were angry, happy, neutral, sad, and surprised. This study suggests that smartphone-recorded video could function as a useful tool for quantifying mood expressivity. This study established a preliminary method of affective assessment for older adults for telecare use based on socially assistive technology at a distance from the clinic.

ACCEPTABILITY OF ANIMATRONIC PETS AMONG COMMUNITY-DWELLING VETERANS LIVING WITH DEMENTIA AND THEIR CAREGIVERS

Melissa Harris[1], Edwin Alcorn[2], and Judith Davagnino[2], *1. Duke University, Durham, North Carolina, United States, 2. Durham VA Health Care System, Durham, North Carolina, United States*

Animatronic pets can improve psychosocial outcomes among older adults, but little is known about in-home use by Veterans living with dementia and the perceptions of informal caregivers regarding these tools. This quality improvement project examined the usability and acceptability of animatronic pets by community dwelling Veterans living with dementia from the perspective of informal caregivers. Usability and acceptability were examined through a structured telephone interview with 17 caregivers. Usability was operationalized as frequency of: pet use by the Veteran (1=Not at all, 4=Daily or all of the time), and reminders provided by caregivers (1=Not at all, 4=Daily or all of the time). Acceptability was defined as perceived benefit (measured using an acceptability tool; 0= Not at all, 2=A great deal beneficial) and satisfaction (measured using acceptability tool with close and open-ended response items) as reported by caregivers. Results indicated high usability (71% of Veterans used the pet daily with reminders provided by 30% of caregivers) and acceptability (Benefit: (M=1.5/2, SD=0.7); Satisfaction: 94% of caregivers would continue to encourage use of the animatronic pet by the Veteran and recommend one to others). Open-ended responses suggest that they may be less satisfying to those who lost a real pet or did not have an affinity for pets earlier in life. Animatronic pets can be used with minimal assistance by Veterans with dementia and are acceptable to informal caregivers. As VA initiatives support provision of these pets, additional research is needed to examine their broader impact on Veterans living with dementia specifically.

COMMUNICATION WITH HEALTHCARE PROVIDERS DURING THE PANDEMIC: EXPERIENCES OF OLDER ADULTS

Logan Sweeder[1], Andrea Sillner[2], Marie Boltz[3], and Kimberly Van Haitsma[4], *1. The Pennsylvania State University, State College, Pennsylvania, United States, 2. Pennsylvania State University Ross and Carol Nese College of Nursing, University Park, Pennsylvania, United States, 3. Penn State, Pennsylvania State University, Pennsylvania, United States, 4. Pennsylvania State University, University Park, Pennsylvania, United States*

The COVID-19 pandemic introduced many societal changes, including the need to use technology to communicate with healthcare providers. For many this was a new form of communication. This study examines (1) who older adults identified as healthcare providers and (2) reflected on how communications with formal healthcare providers changed during the pandemic. This data is a subset of a cross-sectional descriptive survey that was distributed electronically to a sample of community-dwelling older adults aged 65 years and older (N=323). Qualitative data was analyzed using thematic analysis. Quantitative data was analyzed using descriptive statistics. Participants averaged 72.7 years of age and 74.5% were retired. Just over ¼ of the sample identified nurses as part of their formal healthcare team; however, participants who identified nurses as formal healthcare providers had fewer negative themes regarding telehealth communication with healthcare providers compared to those who did not. They were also more likely to support in-person and technology driven communication models in the future. Telehealth remains an evolving form of primary healthcare that was utilized throughout the COVID-19 pandemic. Many older adults in our study considered it a resource that requires further optimization while others were staunch opponents to its continued employment in healthcare settings. Nurses are a vital part of our healthcare system and frequently interact with patients and families to coordinate care. Further research should examine how different scopes of nursing practice can support the implementation of telehealth to improve care delivery among community-dwelling older adults.

TURNING REAL-WORLD DATA INTO ACTIONABLE EVIDENCE FOR HEALTHCARE INTERVENTIONS IN NEURODEGENERATION

Rachel Poulsen, Jun Ha Chang, Danish Bhatti, Matthew Rizzo, and Jennifer Merickel, *University of Nebraska Medical Center, Omaha, Nebraska, United States*

Background: Age-related neurodegenerative disorders, including Alzheimer's disease and Parkinson's disease (PD), progressively reduce mobility and quality of life (QoL). Real-world mobility from actigraphy predicts PD disease severity. This pilot analysis assessed utility of actigraphy to screen early physical function-related QoL decline in PD. Method: Mobility was monitored for 4 weeks using wrist-worn ActiGraph recordings in 27 participants with idiopathic PD (age = 67.78 ± 5.64, 19 males). Days with >600 mins of wear time during non-sleep times were analyzed ($\mu = 29.78$ days ± 3.78). Typical activity was quantified as average steps per hour. Participants completed demographic and health assessments. Disease severity and physical function QoL were measured using the clinically-validated Unified PD Rating Scale (MDS-UPDRS) and Short Form-36 (SF-36), respectively. Disease severity, QoL, and typical activity were compared using Spearman correlations.

Results: Lower typical activity from actigraphy was associated with more severe motor symptoms (MDS-UPDRS; $r = -0.40$, $p = 0.04$) and with increased impairment in physical function QoL ($r = 0.50$, $p < 0.01$). Daily activity from actigraphy did not predict symptom severity of non-motor and motor-related complications. Discussion: Pilot results show utility of actigraphic metrics for indexing real-world mobility and QoL declines in neurodegenerative disorders, in line with broader efforts to turn real-world data into actionable evidence for healthcare interventions. Ongoing discovery in larger populations should yield robust, clinically-relevant indices of daily activity in aging and neurodegenerative impairment.

IMPACT OF EHR IMPLEMENTATION IN NURSING HOMES ON FINANCIAL PERFORMANCE

Neeraj Dayama[1], Holly Felix[2], Rohit Pradhan[3], Michael Morris[4], and Saleema Karim[5], *1. Texas Tech University Health Sciences Center, Lubbock, Texas, United States, 2. University of Arkansas for Medical Sciences, Little Rock, Arkansas, United States, 3. West Liberty University, West Liberty, West Virginia, United States, 4. The University of Texas Health Science Center at Tyler, Tyler, Texas, United States, 5. Virginia Commonwealth University College of Health Professions, Richmond, Virginia, United States*

Nursing homes (NHs) are a critical part of the US healthcare system providing care to the sick and fragile elderly, and research suggests that they can benefit from the implementation of health information technology (HIT). However, for multiple reasons—exclusion from HITECH incentives; limited financial wherewithal; hazy return on investments (ROI), they have lagged in HIT implementation compared to other significant components of the US healthcare system. Utilizing the resource-based view (RBV) of the firm, the purpose of this study was to examine the longitudinal impact of HIT on NH financial performance potentially building a sustainable economic argument for its implementation. To examine this relationship, we merged data from five different sources between the years 2009-2013-: Health Information and Management Systems Society, LTCFocus, Online Survey Certification and Reporting/Certification and Survey Provider Enhanced Reporting, Area Health Resource Files, and Medicare Cost Reports. The outcome variable was financial performance which was measured in four ways: operating cost and revenue, operating margin, and total margin. The independent variable of interest was HIT implementation and was measured using a novel HIT Adoption Score (HAS) reflecting NH implementation of five different HIT applications. Four separate multivariate linear regression models were estimated, and we included a series of organizational and market characteristics in the analyses. We report a positive association between NH implementation and improved profitability (operating margin) ($p \leq 0.01$), and lower operating cost ($p \leq 0.05$). Our results, suggesting a potential business case for EHR implementation within NHs, have important policy and managerial implications that are discussed.

RACIAL/ETHNIC DISPARITY IN 4M-BASED PRIMARY CARE DELIVERY VIA TELEHEALTH IN PROVIDER SHORTAGE AREA

Rain Lee[1], Yi Hyun Kim[2], Laurie Kim[3], ji won Yoo[3], Andrea Maxi[1], and Chelin Hong[4], *1. Yeshiva University, New York, New York, United States, 2. University of California, Berkeley, Berkeley, California, United States, 3. University of Nevada, Las Vegas, Las Vegas, Nevada, United States, 4. Monash University, San Diego, California, United States*

Background: Telehealth is a promising alternative to primary care delivery in provider shortage areas. The purpose of this study was to evaluate the implementation of the 4Ms (i.e., Medication, Mentation, Mobility, What Matters) framework in telehealth-based primary care in provider shortage areas by ethnic status.

Methods: This study was a retrospective analysis of 184 older adults (60+) representing 5% of the total sample at urban primary care in ethnically and racially diverse populations. Data were retrieved from July 2020 to September 2021. 14 trained primary care providers participated in this study and provided the 4Ms as following: 1) Medication (e.g., deprescribe or reduce high-risk Medication); 2) Mentation (e.g., depression and cognition assessment with brief counseling); 3) Mobility (e.g., mobility and home safety assessments); 4) What matters (e.g., advance care planning). The current study measured components of the 4Ms per telehealth visit by ethnic/race status (white vs. non-white).

Results: Overall, advance care planning (i.e., what matters) was the most discussed via telehealth (79%), followed by mobility (46.2%), Medication (16.8%), and Mentation (14.7%). To examine the disproportion of accessing telehealth by patients' racial background, the independence test of chi-square showed that non-white populations were less likely to have access to telehealth than white patients ($p = .02$).

Conclusion: There was an ethnic and racial disparity in the 4M framework application via telehealth in an urban primary care clinic. To sustain telehealth for patients in a healthcare shortage, ethnically and culturally specific training is needed, and linguistically diverse curricula are recommended.

THE EFFECTIVENESS OF INTERNET-BASED INTERVENTIONS IN REDUCING STRESS EXPERIENCED BY OLDER INFORMAL CAREGIVERS

Abdulmajeed Altukhys, and Richard Beaulaurier, *Florida International University, Miami, Florida, United States*

Purpose: This systematic review assesses and provides a critical review of the effectiveness of internet-based interventions to decrease informal caregiver stress. Method: A systematic review of the following databases: PsycINFO, Social Service Abstract, Social Work Abstract, PubMed, and Cochrane Library was conducted using terms related to informal caregivers and internet-based interventions from January 2010-February 2022. Only data conducting interventions in the U.S. included. This systematic review reviewed the quality of articles on the methods of randomized and non-randomized trials using the approaches recommended by the Cochrane Handbook for systematic review for intervention. The review was reported using a PRISMA chart.

Results: Eight studies met the review criteria. Most of the studies showed positive benefits in reducing caregiver stress. There were no clear patterns as to the variables such as study duration and complexity of intervention associated with better outcomes, although earlier studies typically had more negative outcomes.

Conclusions: Internet-based interventions can develop solutions to decrease the physical and psychological consequences resulting from caregiving and can help empower older caregivers of people with chronic diseases. Internet-based interventions were mainly effective in reducing aspects of caregiver stress and improving their well-being. Further studies can assess outcomes for older informal caregivers and their recipients' health, different technology delivery methods, and the cost of such interventions are needed to examine the psychological impacts of COVID-19 on older informal caregivers.

IMPACT OF VIBRATION ON TREMOR IN OLDER ADULTS WITH PARKINSON'S DISEASE

Ingrid Pretzer-Aboff[1], R.K. Elswick[1], Amanda Watson[2], Minglong Sun[3], Woosub Jung[3], Ken Koltermann[3], Gang Zhou[4], and Leslie Cloud[5], *1. Virginia Commonwealth University, Richmond, Virginia, United States, 2. University of Pennsylvania, Philadelphia, Pennsylvania, United States, 3. College of William & Mary, Williamsburg, Virginia, United States, 4. William & Mary, Williamsburg, Virginia, United States, 5. Virginia Commonwealth University School of Medicine, Henrico, Virginia, United States*

This was a randomized trial to explore the safety and efficacy of the RMBand (Resonate Forward LLC, Delaware) device to alleviate Parkinson's Disease (PD) tremors. The RMBand applies vibration to the proximal arm and was worn on the side of tremor dominance. Thirty subjects with PD and associated tremors were randomized to receive high vs. low-frequency vibration. Tremor assessments occurred for 20 minutes before, during 20 minutes of continuous vibration, and for 20 minutes immediately post-vibration in a single 60-minute session. Assessments (MDS-UPDRS part 3 and FTM tremor scale) were performed during each of the 3 phases by blinded raters. A quantitative assessment of tremor was performed throughout the session using wearable sensors on the distal arms. Linear mixed models were used for group comparisons. No significant difference was observed between the high and low dose groups in the MDS-UPDRS part 3 or FTM tremor scale (p=0.83 and 0.48 respectively), which may be due to the crude nature of these scales. Quantitative wearable sensor data were used to assess total time with tremors during the pre-vibration, vibration, and post-vibration periods. Time with tremor during the pre-vibration period was significantly greater than that during and post-vibration (p< 0.0001) for both dose groups, suggesting that vibration therapy applied to the proximal arm may suppress PD tremor. No significant adverse events related to vibration therapy occurred. In conclusion, the RMBand appears safe and possibly effective for suppressing PD tremor. Further study is warranted.

IMPROVING HOME-CARE SERVICES FOR HIGH-RISK OLDER ADULTS USING PEER-LED VIDEO VISITS TO HOME

Shiv Lamba[1], Sandra Garcia[2], Elizabeth Bast[3], Lauren Penney[4], Ana Palacio[3], Sonia Madera[3], Orna Intrator[5], and Stuti Dang[6], *1. Washington University, St. Louis, Missouri, United States, 2. University of Miami, Miami, Florida, United States, 3. Miami VA Healthcare System, Miami, Florida, United States, 4. South Texas Veterans Health Care System, San Antonio, Texas, United States, 5. Canandaigua VA Medical Center, Canandaigua, New York, United States, 6. Miami Veterans Affairs Healthcare System, Miami, Florida, United States*

Older Veterans at high-risk for institutionalization often require home- and community-based services (HCBS). Yet, current HCBS delivery often fails to meet the needs of high-risk Veterans due to decreased veteran engagement in outpatient programs and limited HCBS capacity. A promising approach to address these gaps is the use of Veteran-Peers to make home-visits. Peer-2-PACT is a peer-led needs-assessment intervention for high-risk older veterans. Two trained peers conducted a checklist-guided virtual and/or in-person home-assessment to identify unmet needs and home-safety concerns. Veterans with access, acceptance and ability for video-capable technology were offered video-visits. We report on the feasibility of video home-visits in this high-risk group, and the experience of the video-visits using the visit-data and interviews with peers.Eight of 27 Peer-2-PACT Veterans successfully completed initial video-visit to home. The video-visit participants (n=8) were age 74±9; Non-Hispanic Black (50%); males (100%), compared to initial in-person home-visit participants (n=19), age 75.3±10.8; Non-Hispanic Black (47%); males (89%). The commonest needs identified during video-home-visits were home-safety devices 5(62.5%), housing assistance 4(50%), and medication refills 2(25%). Peers report that identifying veterans suitable for video-visits was challenging. During video-visits, depth-perception by peers is limited and sometimes needed in-person follow-up. Main advantages of video-visits was ability to identify unmet needs, engage veterans, provide care during COVID, and tele-present to remote clinicians. Preliminary data suggest that peer-conducted video home-visits is a feasible way to identify unmet needs in some high-risk older adults. This is particularly important improve care of Veterans who live at a distance from the facility.

DOES AGE, RACE, AND/OR RURALITY DETERMINE OLDER VETERANS' ABILITY TO ACCESS VA VIDEO CONNECT

Linda Sawyer[1], Christine Cigolle[2], Kristin Phillips[3], Janette Dunlap[4], and Dennis Sullivan[5], *1. Central Arkansas VA Healthcare System, Sherwood, Arkansas, United States, 2. VA Ann Arbor, Ann Arbor, Michigan, United States, 3. Ann Arbor VA, Ann Arbor, Michigan, United States, 4. North Florida South Georgia VA, Jacksonville, Florida, United States, 5. Central Arkansas VA, North Little Rock, Arkansas, United States*

The purpose of this project was to determine whether ability to use VA Video Connect (VVC) by older Veterans (OV) differed by age, race, or rurality. A service to help older Veterans learn to use VVC was developed. As part of an ongoing QI project, demographics, willingness to attempt a VVC test call and outcomes of test calls were collected on all referrals. Descriptive statistics, Chi-square, and Fisher's exact test were used to examine differences in success rates by group. Of the 66 OV (age 60+) referred by their primary care providers, we were able to contact 63 by phone. Of those, 46 (73%) scheduled a VVC test call, 7 (11%) chose not to participate, and 10 (16%) were already using VVC for appointments. Of the 40 who continued the VVC test call, 31 (77.5%) were successful without issues, 7 (17.5%) were successful with help resolving issues, and 2 (5%) disconnected before finishing the call because it became too difficult. Of the 63 OV contacted, 38 (57.5%) had a successful VVC test call. However, those residing in rural (vs. urban) settings were less likely to have a successful test call (43% vs. 57%, p=0.04). There was no statistically significant difference in success rates for the test calls between whites vs. non-whites (52% vs. 48%, p= 0.2), or those aged 75 years or above vs. 60-74 years (53% vs. 46%, p=0.6). More work is needed to identify barriers to use of VVC, especially among OV living in rural settings.

INTERGENERATIONAL VIRTUAL YOGA INTERVENTION INVOLVING OLDER ADULTS AND COLLEGE STUDENTS: A PILOT STUDY

Nancy Martens, PhD[1], Debra Schutte[2], Thomas Templin[2], and Morgan Cinader-Galvan[3], *1. Wayne State University, Birmingham, Michigan, United States, 2. Wayne State University, Detroit, Michigan, United States, 3. Michigan State University, Flint, Michigan, United States*

Social isolation is common in older adults and students and is associated with poor health outcomes. While evidence suggests active and yoga interventions improve health, interventions encouraging intergenerational social interaction are limited. The objective was to implement and evaluate a twice-weekly, 6-week, intergenerational yoga intervention delivered virtually. Specific aims included evaluation of feasibility and acceptability, examination of estimates of efficacy on health outcomes, and examination of age cohort effects on acceptability, feasibility, and efficacy. Older adults were recruited through a community activity center and randomized to the control group (N=10) (Mage= 70.05, SD 5.83) or intergenerational older adult treatment group (N=11) (Mage= 72.32, SD= 5.81) with students (N= 12) (Mage= 25.98, SD= 5.64). Older adult outcome measures included Center for Epidemiological Studies Depression Scale (CES-D), PROMIS Social Isolation Scale (SI), Meaning-in-Life Questionnaire, and Tilburg Frailty Index; outcomes for the students included the CES-D, SI, and Image of Aging Scale. Outcomes were assessed at week 0, 3, 6, and 12 (6-weeks post-intervention). Attrition was minimal; 81% of older adults and 80% of students received the full intervention. Using the Acceptability of Intervention Measure, 77.8% of older adults and 100% of college-age adults indicated their willingness to participate again. There were no significant intergenerational effects; however, the effects of yoga were in the expected direction with significant values in CES-D, $P < .01$ and Meaning-in Life, $P < .01$. While the acceptability and feasibility of the intervention were supported; additional research is needed to strengthen the intergenerational component of the intervention.

FEASIBILITY AND ACCEPTABILITY OF A WEB-BASED COGNITIVE TRAINING PLATFORM FOR OLDER ADULTS: THE BREAKFAST TASK

Sharon Sanz Simon[1], Daniel Ben-Eliezer[2], Maria Pondikos[1], Yaakov Stern[1], and Daniel Gopher[2], *1. Columbia University, New York City, New York, United States, 2. Technion Israel Institute of Technology, Haifa, Hefa, Israel*

Background: Developing efficient cognitive training for the older population is a major public health goal due to its potential cognitive benefits. A promising cognitive training target is executive control, critical for multitasking in everyday life. The aim of this pilot study was to establish the feasibility and acceptability of the Breakfast Task in older adults, a new web-based cognitive training platform that simulates real-life multitasking demands. Research Design and

Methods: A community-based sample of 24 cognitively healthy participants aged between 60 and 75 (M = 69.12, SD = 3.83) underwent an online 5-session training protocol. Each session lasted 40 minutes and occurred twice a week at participant's homes. Game performance was recorded, and participants completed questionnaires at baseline and after the intervention.

Results: Feasibility metrics showed overall high recruitment (82.7%), adherence and retention rates (100%). Acceptability was considered good based on participant`s quantitative and qualitative responses. On average, participants rated the game as interesting, enjoyable and did not report difficulties in accessing the game online or in understanding the instructions. Moreover, participants showed a learning curve across sessions, improvement in most game outcomes and benefits from the emphasis change approach. Discussion and Implications: The findings provide preliminary support for the feasibility and acceptability of the Breakfast Task training platform with community-dwelling older adults and demonstrate potential cognitive benefits. Results suggest the value of further research investigating the Breakfast Task features and dose-response relationship, as well as its efficacy in older adults via larger randomized controlled trials.

SMART HOME DATA VISUALIZATION FOR PROACTIVE HEALTH MONITORING OF COMMUNITY DWELLING OLDER ADULTS

Katherine Wuestney[1], Javier Ramirez[2], Diane Cook[2], and Roschelle Fritz[1], *1. Washington State University, Vancouver, Washington, United States, 2. Washington State University, Pullman, Washington, United States*

The role of Ambient Assistive Living and smart home technologies, which utilize unobtrusive sensors to detect changes in health, is becoming increasingly important in the delivery of healthcare services to older adults. However, these technologies must be designed to meaningfully incorporate into clinicians' decision making. Research has shown when clinicians are engaged in the design process of smart home systems, the accuracy and efficacy of the systems are improved. We present the process undertaken by a team of nurse researchers and computer science engineers to design clinically meaningful behavior markers derived from smart home sensor data that can be used by nurses to proactively identify changes in patient status. During the first phase of design, nurse researchers qualitatively analyzed time series from smart home sensors installed in the homes of community dwelling older adults and identified patterns in these data related to significant health changes. From this analysis, we assembled a candidate list of 15 sensor-based behavior metrics, such as percent time spent in each room or frequency of bathroom use. During the second phase of design, we will build on lessons we learned from participatory design to create behavior markers and visualizations that are inspired by clinical experience. These include visualizing behavior change over time, highlighting behavioral anomalies at multiple time scales, and calculating markers that are not directly observable such as time spent out of home.

Lessons learned from clinicians using the data visualizations to proactively screen for health changes in near real time will also be discussed.

FINDINGS FROM HIGH USERS OF VIDEO TELEHEALTH TO DELIVER OCCUPATIONAL THERAPY SERVICES DURING COVID-19

Megan Gately[1], Dylan Waller[2], Emily Metcalf[1], and Lauren Moo[1], *1. VA Bedford Health Care System, Bedford, Massachusetts, United States, 2. VA Portland Health Care System, Portland, Oregon, United States*

Occupational therapy (OT) helps older adults improve their ability to perform day-to-day tasks. Veterans Health Administration (VHA) is the single largest employer of occupational therapy (OT) practitioners in the United States and a forerunner in telehealth. As a result of COVID, OT video visits increased by nearly 2000% from 2019 to 2020. To ascertain barriers and facilitators to this shift in care delivery, we conducted interviews between January and April 2021 with OT practitioners (N=27) who were high users of VA Video Connect (VVC), VHA's videoconferencing software. OT participants were from rural and urban settings, and had completed an average of 536 VVC appointments each in 2020. Participants used VVC to deliver a variety of OT services, including mental health groups and home safety interventions. Facilitators to VVC included, a) Patient characteristics, such as positive perceptions of VVC and technological skill, b) OT clinician characteristics, like flexibility, level of experience, and desire to increase patient access to care, and, c) VHA's telehealth infrastructure. Barriers included, a) Patients' lack of familiarity or skills with technology, particularly older patients, b) challenges translating traditionally hands-on care to video, and c) unreliable internet connectivity, particularly for rural patients. This study broadens our understanding of video telehealth service delivery for care which has historically been delivered in brick-and-mortar settings. Understanding challenges and enablers to video telehealth highlights opportunities to increase access to those who face barriers, such as older, rural patients.

IMPROVING VIDEO DEVICE USAGE AMONG OLDER RURAL VETERANS WITH USER-CENTERED DESIGN

Hillary Lum[1], Lynette Kelley[2], Kathryn Nearing[3], Leah Walker[4], Gerhardt Johnson[4], and Steven Barczi[4], *1. University of Colorado Anschutz Medical Campus, Aurora, Colorado, United States, 2. Department of Veteran Affairs, Denver, Colorado, United States, 3. VA Eastern Colorado Geriatric Research Education and Clinical Center, Denver, Colorado, United States, 4. Department of Veterans Affairs, Madison, Wisconsin, United States*

The Veterans Administration (VA) established pathways to provide VA-issued tablets and increased access to internet for Veterans without these resources. Veterans aged above 65, experience barriers with telemedicine such as access and usability. We sought to improve the usability and experience of telemedicine for rural, older Veterans receiving a VA-issued tablet by modifying materials and qualitatively evaluating their experience with set-up and preparing for their first appointment, guided by user-centered design. We conducted a rapid exploratory evaluation, to understand Veteran and care partner experiences setting up VA-issued tablets and logging into their first appointment using standard 9-page instructions. We interviewed telehealth technicians, and providers to better understand patient barriers from their perspective. Using insights from interviews and evidence-informed guidelines on educational materials for older adults, we created a two-page guidance. A group of Veterans and care partners reviewed the materials and provided feedback. Received feedback provided 17 suggestions, 8 of which were utilized, including enlarging graphics, clarifying abbreviations (or wording), consolidating the instructions further and emphasizing pertinent information further. Modified materials reduced standard written instructions from nine pages to two. Feedback suggests that updated materials are helpful, aesthetically pleasing and preferred over current materials. Utilizing user-centered design methods, addressed barriers experienced by older, rural Veterans with initial telemedicine device and appointment set-up. Veterans, care partners, providers, and telehealth technicians perceived materials adapted for older adults as supportive of video device usability, helping to alleviate barriers that prevent Veterans from initiating telemedicine.

REMOTE TELEASSESSMENT AND TELEREHABILITATION OF A COMPREHENSIVE EXERCISE TRAINING PROTOCOL FOR OLDER ADULTS

Savitha Subramaniam[1], Edwina Wilson[2], and Tanvi bhatt[1], *1. University of Illinois at Chicago, Chicago,, Illinois, United States, 2. University of Illinois at Chicago, Chicago, Illinois, United States*

Background: With the increased implementation of interactive technologies for assessment and rehabilitation, it would be optimal to exhibit the reliability of physical assessment measures via tele-assessment. Aim: To determine the test-retest and intra-rater reliability of physical function outcome measures routinely used in the balance and gait rehabilitation using real-time online tele-assessment.

Methods: Community-dwelling healthy older adults (N=30) participated in three experimental tele-assessment sessions. During each session, a real-time online tele-assessment was performed on five major domains that evaluate balance and gait function: lower limb strength and endurance (30-second chair stand test), aerobic endurance (2-minute step test), static balance (One-legged stand test), dynamic balance (4-step square test), and gait (Tinetti).

Results: Coefficient of determination (R2) was used to determine the test-retest (TRT) and intra-rater (IR) reliability for all outcome variables. Excellent reliability was shown by Tinetti (TRT-1.0; IR-1.0) and one-legged stand test (non-dominant leg TRT-0.92; IR-0.97 and dominant leg TRT-0.89; IR-0.92). Excellent to good reliability was shown by 4-step square test (TRT-0.89; IR-0.74), 2-min step in place test (TRT-0.85; IR-0.78), and 30-second chair stand test (TRT-0.86; IR-0.80).

Conclusion: The reliability of individual outcome measures ranged from good to excellent, suggesting that these outcomes have sufficient sensitivity for detecting change with telerehabilitation.

SESSION 6430 (POSTER)

CANCER

FACTORS INFLUENCING CANCER SURVIVORSHIP AMONG NIGERIAN WOMEN

Darlingtina Esiaka[1], Candidus Nwakasi[2], Runcie Chidebe[3], Khadijat Banwo Fatai[4], and Gloria Orji[5], *1. Robert Wood Johnson Medical School, Rutgers University, Newark, New Jersey, United States, 2. Providence College, Providence, Rhode Island, United States, 3. Health and Psychological Trust Center, Abuja, Federal Capital Territory, Nigeria, 4. Project PinkBlue, Abuja, Federal Capital Territory, Nigeria, 5. Network of People Impacted by Cancer in Nigera, Abuja, Federal Capital Territory, Nigeria*

Breast cancer is the most common cancer globally and among Nigerian women. With technological and medical advancements, especially in the early detection of chronic illnesses, there is a reduction in cancer deaths, and more women are living as cancer survivors in Nigeria. Despite the increase in the number of cancer survivors, many survivors struggle with life after cancer diagnoses. In this study, we interviewed 30 Nigerian women (Mage = 42.00) who completed cancer therapy in the past 12 months and above, to explore how women who underwent cancer therapy perceive their healing, health, and quality of life. An example of one of the interview questions is “How did cancer diagnoses affect your normal way of life?” Each interview lasted an average of 1 hour. Participant responses were transcribed, and theme coded for analysis. We found that fear of reoccurrence, loss of sense of purpose, shame from physical mutilation related to mastectomy, poor psychological health, social isolation, and ill-treatment from other members of the community were recurring themes across all of the women’s responses. The presence of cancer survivors' support groups and religiosity were important for the experience of life after a cancer diagnosis. Our findings draw attention to the need for interventions targeting cancer survivors. The result further indicates that addressing community perceptions of breast cancer is imperative to ensure the health of breast cancer survivors, especially in low-resource countries.

SOCIAL SUPPORT DYNAMICS FOR SOUTH ASIAN BREAST CANCER PATIENTS: AN ANALYSIS CONDUCTED USING ATLAS CAREMAPS

Ranak Trivedi[1], Ambri Pukhraj[2], Shreya Desai[3], Rishabh Shah[2], Rashmi Risbud[4], Lidia Schapira[2], Dolores Gallagher-Thompson[2], and Karl Lorenz[5], *1. Stanford University, Palo Alto, California, United States, 2. Stanford University, Stanford, California, United States, 3. Veterans Affairs Palo Alto Health Care System, Menlo Park, California, United States, 4. University of California, Davis, Davis, California, United States, 5. Veteran Affairs Palo Alto Health Care System, Stanford, California, United States*

With a rise in the prevalence and a drop in mortality rates of breast cancer among South Asians (people with heritage from India, Pakistan, Nepal, Bhutan, Sri Lanka, Maldives, and Bangladesh), globally and in the US, there is an increasing number of South Asians managing breast cancer. The South Asian Family Approaches to Disease (SAFAD) study aims to better understand how South Asian breast cancer survivors are supported while managing breast cancer. We conducted semi-structured interviews to complete an adapted version of Atlas CareMaps, a visual representation of survivors' care networks at the time of the interview. Thirteen South Asian breast cancer survivors were enrolled. Survivors were on average 47y (SD=9.1y) and reported being diagnosed with stage 0 (n=1), stage 1 (n=3), stage 2 (n=6), or stage 4 (n=3) breast cancer. Analyses of the Atlas CareMaps suggest 1) South Asian breast cancer survivors received support from 13.7±3.5 individuals, while providing care to 3.3 ± 2.2 individuals; 2) at more advanced stages of breast cancer, patients provide less support to others (Stage 1=3.8±2.2, Stage 4=1.7±1.5); 3) older survivors received more support from abroad (< 40y=2.0±2.2, patients 50+=5.3±3.3). Atlas CareMaps can provide useful insights into the rich care networks of South Asian breast cancer survivors which can be used to develop clinical programs.

UNDERSTANDING THE CARE NETWORKS OF INFORMAL CAREGIVERS OF SOUTH ASIANS WITH BREAST CANCER USING ATLAS CAREMAPS

Ranak Trivedi[1], Ambri Pukhraj[2], Shreya Desai[3], Akanksha Jain[4], Rashmi Risbud[5], Lidia Schapira[2], Dolores Gallagher-Thompson[2], and Karl Lorenz[6], *1. Stanford University, Palo Alto, California, United States, 2. Stanford University, Stanford, California, United States, 3. Veterans Affairs Palo Alto Health Care System, Menlo Park, California, United States, 4. Veterans Affairs Palo alto Health Care System, Menlo Park, California, United States, 5. University of California, Davis, Davis, California, United States, 6. Veteran Affairs Palo Alto Health Care System, Stanford, California, United States*

Breast cancer rates are increasing among individuals with a South Asian heritage, i.e., from India, Pakistan, Nepal, Bhutan, Sri Lanka, Maldives, and Bangladesh. Informal caregiving is vastly understudied among this population, despite being influenced by cultural mores such as collectivism, cancer-related stigma, and gender roles. The South Asian Family Approaches to Disease (SAFAD) study took a mixed-methods, observational approach to describe the care networks of informal caregivers via an adapted version of Atlas CareMaps. Thirteen caregivers (43.9+/-14.8y, 30.8% female) were interviewed and included 6 husbands, 1 wife, 2 daughters, 1 son, 1 brother, and 1 friend of the breast cancer survivors. Semi-structured interviews were designed to develop an adapted Atlas CareMap, a visual representation of the caregivers’ care network at the time of the interview. Atlas CareMaps depicted the number of people supported by caregivers, and who provide support; their relationship; the frequency, intensity, and type of care; and modes of communication used. Immediate or extended family members were the most common people included. Results indicated that: 1) caregivers reported 8.8□3.5 individuals in their care network, provided care to 3.5+/-1.8 individuals and received care from 7.3+/-3.5 individuals; 2) caregivers primarily received emotional support from others; 3) their survivors’ care teams were often included as a source of support and medical knowledge for survivors, but only three noted that the care teams supported them directly. Describing these networks is a key step to developing culturally-concordant programs that can support South Asian caregivers, even as they care for breast cancer survivors.

CANCER CARE IN ELDERLY: CHALLENGES AND REQUIREMENTS OF INFORMAL CAREGIVERS

Esha Chakravarty[1], and Indrani Chakravarty[2], *1. Calcutta Metropolitan Institute of Gerontology, London, London, United Kingdom, 2. Calcutta Metropolitan Institute of Gerontology, Kolkata, West Bengal, India*

The affect of Covid -19 and changes in healthcare has shifted most of cancer care of elderly to home settings. Calcutta Metropolitan Institute of Gerontology (CMIG), Regional Resource and Training Centre in Ageing studied the daily tasks, requirements and emotional burden of caregivers in West Bengal, India. Caregivers of lung cancer, liver cancer and colorectal cancer patients (n=500) completed questionnaires provided by CMIG. The mean age of cancer patients was 72.5 years. CMIG found that 47% of the caregivers were the spouses of elderly patients, 33% were their adult children and 20% were other family members. Forty six percent of the caregivers were found to care for patients with metastatic disease, 33% cared for co morbidities, 63% cared for those undergoing chemotherapy or radiotherapy. Ninety eight percent of the caregivers provided assistance with Activities of Daily Living, 75% in administering medicine, 47% helped in pain management, 39% helped in hospital visits or deciding to call doctor. Twenty one percent of the caregivers reported poor health and 16% were not confident of the quality of care they provided. Sixty six percent reported suffering from stress and perceived cancer as a family disease, 45% thought they lacked social support. Of the adult children who provided care, 78% resported they needed more training to provide quality cancer care and transitioning to formal care would improve results. This study will help influence State policies for allocation of resources for training for cancer caregivers, build support groups for stress management and create cancer care helplines.

THE ROLE OF VIRTUAL PEER HEALTH SUPPORT IN ALTERNATIVE ILLNESS APPRAISALS AND PATIENT SELF-REAPPRAISAL AFTER CANCER

Gul Seckin, *University of North Texas, Hickory Creek, Texas, United States*

Technology is transforming how older adults find health-related support and get connected with others who cope with similar healthproblems. This study examined the relationship between virtual peer health support and alternative appraisals of illness experience in old age among people who use the Internet for cancer related support (N=157, Age Range: 50-79, Mean = 57). Regression models with interaction terms examined whether and to what extent virtual peer health support was associated with differential illness appraisal as well as and post-diagnosis self-reappraisal. Results demonstrated that a) perceived benefits of virtual peer health support is a significant predictor of self-reported self-reappraisal ($\beta = .24, p < .01$) b) appraisals of illness experience as a traumatic event and/or as a life challenge are both significantly associated with virtual peer health support ($\beta = .18, p < .05$ and $\beta = .23, p < .01$), and c) appraisal of illness experience as a personal growth growth opportunity is not significantly associated with virtual peer health support ($\beta = .10, p < .23$). These results suggest the statistical interactions of the virtual peer health support with illness appraisals are significant predictors of self-reappraisal post-diagnosis. Specifically, those who appraised cancer to have been a traumatic experience and/or life challenge for them perceived virtual peer support to be positively influential on their self-perception after cancer diagnosis, which is in contrast to those who perceived cancer experience as an opportunity for personal growth and thus possibly not deriving further significant additional benefits from virtual peer support.

"HOW WILL I LIVE THIS LIFE I AM TRYING TO SAVE?": EXPLORING DUALITIES IN CANCER SURVIVORSHIP EXPERIENCES IN NIGERIA

Candidus Nwakasi[1], Darlingtina Esiaka[2], Runcie Chidebe[3], Khadijat Banwo Fatai[4], and Gloria Orji[5], *1. Providence College, Providence, Rhode Island, United States, 2. Robert Wood Johnson Medical School, Rutgers University, Newark, New Jersey, United States, 3. Health and Psychological Trust Center, Abuja, Federal Capital Territory, Nigeria, 4. Project PinkBlue, Abuja, Federal Capital Territory, Nigeria, 5. Network of People Impacted by Cancer in Nigera, Abuja, Federal Capital Territory, Nigeria*

Objectives. Cancer mortality rate is high in Nigeria with about 102,000 new cases and 72,000 deaths per year. Cancer incidence rate is projected to increase with its rapidly aging population and growth — emphasizing its growing cancer burden. Due to Nigeria's weak health system, limited cancer therapy and expert oncological services, lack of cancer education and awareness, and sub-optimal implementation of its national cancer control plan, there is an increase in the risk of poor outcomes from cancer. To further understand the mechanism behind the poor outcomes, we explored cancer survivorship experiences of breast cancer survivors in Nigeria. Methods. The study employed a qualitative descriptive method. Semi-structured interviews were conducted with a purposive sample of 30 female breast cancer survivors in Abuja, Nigeria (Mage = 42 years). Their responses were transcribed, coded, and analyzed for themes. Results. The four major themes identified were: 1) life after cancer diagnosis (hope vs despair), 2) faith and religion (coping with faith vs issues with religion), 3) accessing cancer therapy (alternative therapy vs orthodox therapy), and 4) relationship with medical providers (encouragement from medical providers vs hinderance from medical providers). Discussion. Cancer death rates may be high but there is also a growing number of survivors in Nigeria. It is crucial to improve the health and well-being of Nigerians from the time of diagnosis until end of life, thus, the focus of cancer survivorship. The findings point to the critical need for policies to help strengthen cancer survivorship in Nigeria.

DEVELOPMENT AND EVALUATION OF A WEB-BASED DECISION AID FOR LUNG CANCER SCREENING FOR OLDER CHINESE AMERICANS

Chien-Ching Li[1], Alicia K. Matthews[2], Xiaojun Gao[3], and Krystal Cheung[3], *1. Rush University, Chicago, Illinois, United States, 2. University of Illnois at Chicago, Chicago, Illinois, United States, 3. University of Illinois at Chicago, Chicago, Illinois, United States*

Low dose computed tomography (LDCT) lung cancer screening is effective in reducing lung cancer mortality. In the United States, Chinese Americans are disproportionately impacted by lung cancer compared to other Asian subgroups. Our prior study showed that over 25% of older Chinese male smokers met eligibility for LDCT screening based on the CMS guidelines. However, in general, cancer screening rates among Chinese Americans are lower compared to other Americans. Therefore, we developed a culturally and logistically web-based decision aid (DA) for LDCT screening "Lung Decision Coaching Tool (LDC-T)" to improve the older Chinese American's knowledge of lung cancer and screening and to facilitate the decision making with the physician. Compared to traditional paper-based DA, the LDC-T DA has key elements including video, pack-year calculator, eligibility determination, and visual aids to support comprehension and shared decision-making. We conducted acceptability and usability tests among 22 older Chinese American smokers. The tool was highly received by participants for its usefulness and ease to use. Over 80% reported the way of information presented in LDC-T is "good or very good" and the length of the information is "just right". Overall, the majority were satisfied with the LDC-T DA (95%) and agreed that the tool includes sufficient information for people to make the screening decision (90%) and prepare shared decision making with their healthcare providers (81%). Our study results will inform strategies for reducing lung cancer disparities among Chinese Americans and other underserved smokers thus filling important gaps in the literature.

THE HOPES AND FEARS OF OLDER ADULT, LONG-TERM CANCER SURVIVORS: RACIAL AND GENDER DIFFERENCES

Gary Deimling[1], Spencier Ciaralli[2], Dyanna Burnham[1], and Colleen Kavanagh[1], *1. Case Western Reserve University, Cleveland, Ohio, United States, 2. Augustana University, Sioux Falls, South Dakota, United States*

Understanding the impact of cancer on the hopes and fears of older adult (age 60+), long-term (5 years +) survivors is important for assessing their quality of life after cancer. Prior quantitative research has shown the important role that cancer plays in the health and psycho-social well-being of survivors in the years and even decades after diagnosis and treatment. This presentation extends that research by examining both quantitative data and survivors' narratives revealing important issues survivors face such as altered sense of self/identity, feelings of social isolation, key sources of social support as well as cancer and other health-related concerns. These are examined in the context of broader existential issues related to their hopes and fears for the future and differences by race, gender and cancer type are also presented. The data analyzed are from an NCI funded, 10-year longitudinal study based on in-person interviews with 321 survivors of breast, colorectal and prostate cancer to document how cancer-related factors have affected their aspirations for the future. The findings are discussed in the context of how the issues that survivors identified as affecting their hopes and fears may be integrated into the dialogue clinical staff can have with older survivors and their families as part of after-cancer care.

ASSOCIATION OF PSYCHOSOCIAL FACTORS WITH MORTALITY IN OLDER FEMALE SURVIVORS OF CANCER

Jennifer King[1], Kimberly Lind[2], Kristin Morrill[2], and Cynthia Thomson[2], *1. University of Arizona, Marana, Arizona, United States, 2. University of Arizona, Tucson, Arizona, United States*

Understanding factors associated with survival after a cancer diagnosis among older adults is critical as the population ages and cancer survivorship increases. The purpose of this study was to: (1) identify clusters of postmenopausal cancer survivor characteristics by demographic and lifestyle factors; 2) describe the characteristics of each cluster; and 3) evaluate the association of cluster assignment with survival. Participants from the Women's Health Initiative (WHI) who reported either a prevalent cancer diagnosis at baseline (n=14294) or were diagnosed with a first primary incident cancer within the first 10 years of WHI (n=12934) were included. Latent class analysis was used to identify survivor clusters using psychosocial variables. Clusters were characterized using descriptive statistics. We tested for differences in cluster characteristics using ANOVA and Chi-square tests as appropriate. Cox proportional hazards regression was used to evaluate the association between cluster and mortality. Prevalent (n=7) and incident (n=9) cancer survivors clusters were identified. Among both (prevalent and incident) sets of clusters, age at WHI baseline, age at menopause, race, ethnicity, income, education, body mass index, diet quality, smoking, alcohol consumption and exercise all differed by cluster (p<.0001 for all). The most racially and ethnically diverse cluster had higher mortality rates compared to the largest most homogenous cluster; hazard ratio (95%CI) 1.30 (1.15, 1.48) and 1.33 (1.16, 1.53), respectively. Understanding how clusters of risk factors influence cancer survival in postmenopausal women will inform future interventions to improve outcomes and reduce health disparities for cancer survivors.

CANCER SURVIVORSHIP, AGING, AND SEXUAL HEALTH: GENDERED EXPERIENCES OF SEXUAL BEHAVIOR AND BODY IMAGE

Spencier Ciaralli[1], Gary Deimling[2], Dyanna Burnham[2], and Colleen Kavanagh[2], *1. Augustana University, Sioux Falls, South Dakota, United States, 2. Case Western Reserve University, Cleveland, Ohio, United States*

Previous research on aging has studied sexual health as well as cancer. However, less is known about the intersections of cancer survivorship, aging, and sexual health, particularly as it pertains to the gendered experiences of body image. The select studies available that consider the role of sex and intimacy after cancer have provided wholly quantitative or qualitative analyses. This study provides a mixed-methods approach of cancer survivorship and aging as it pertains to sexual health, particularly examining prostate, colorectal, and breast cancer survivors. In their narratives as to how cancer has influenced their sexual behavior, female breast cancer survivors construct their experiences around body image satisfaction. Men who are prostate cancer survivors note struggles around "performance" and impotence. Common issues for both men and women with colorectal cancer survivorship identify body image and impotence as affecting their sexual behavior. An underlying theme throughout all aging cancer survivors' narratives is the role of relationships and the perceptions of their partner. Race, marital status, and education are also examined. The data analyzed are from an NCI funded, 10-year longitudinal study based on in-person interviews with 321 cancer survivors. The findings illustrate the importance of medical professionals providing wholistic after-care that is inclusive of aging survivors' sexual health, relationships, and perception of self.

INFORMATION SEEKING IN OLDER ADULT RURAL CANCER SURVIVORS: UNMET NEEDS AND SEARCH EXPERIENCES

Susan LaValley, Christina Crabtree-Ide, Kathryn Glaser, Rodney Haring, Martin Mahoney, Elisa Rodriguez, Christy Widman, and Elizabeth Bouchard, *Roswell Park Comprehensive Cancer Center, Buffalo, New York, United States*

Cancer survivors over the age of sixty-five have specialized supportive care needs related to maintaining their health and quality of life after treatment. However, cancer survivors living in rural areas may experience barriers like limited digital infrastructure and/or low health literacy when attempting to access necessary informational resources. This project sought to identify older adult rural cancer survivors' domains of unmet informational support and experiences searching for supportive informational resources. Data from a survey administered to cancer survivors (N=292 with complete age data) in rural areas of Western New York (RUCA codes 7-10) were analyzed using descriptive statistics. Variables of interest included Internet access, information-seeking activities, cancer-related topics of interest, and information search experiences. Fifty-four percent of participants in the sample self-identified as over the age of 65. Among older adult cancer survivors, 62% reported using the Internet. The following topics were identified as unmet cancer survivorship information needs: (1) decreasing the risk of cancer recurrence, (2) new symptoms that warrant contacting one's doctor, and (3) medical advances in treatment. Most older adult respondents (70%) were confident in their ability to find needed health information but 40% were concerned about the quality of the information they found and 31% found their search experience frustrating. While rural cancer survivors have access to digital resources and report confidence in their ability to find survivorship information, our findings highlight the need for tailored information on cancer survivorship and interventions to support information appraisal and selecting high quality informational sources.

SESSION 6440 (POSTER)

COGNITION AND LIFECOURSE DEVELOPMENT

POTENTIAL PREDICTORS OF HEALTH LITERACY IN OLDER ADULTS

Stephanie Rubinstein, Gillian Fennell, and Elizabeth Zelinski, *University of Southern California, Los Angeles, California, United States*

Objective: Being able to effectively communicate health care needs and understanding health-related information is particularly important as people grow older. In this study, we sought to identify the factors related to subjective health literacy among older adults.

Methods: We examined eight potential predictors of health literacy: subjective memory, cognition, objective health literacy, self-rated health, age, sex, race, education, depression. Our data was derived from a large sample (N=1,272) of participants aged 50 and older who took part in the Health and Retirement Study (HRS; 2008 wave and 2009 internet survey).

Results: Controlling for all other variables, subjective memory ($b = .15$, $p = .02$) was positively and self-rated health ($b = -.09$, $p < 0.001$) was negatively associated with subjective health literacy. Neither objective health literacy, cognition, nor age were significantly associated with subjective health literacy. Women reported better health literacy than did men ($b = .09$, $p = 0.01$). The predictors in this model explained 9% of variation in subjective health literacy. Discussion: These findings may be better understood as we take into consideration the interplay between health literacy, cognition, education, and subjective memory established in extant literature. We discuss the implications of our findings as they relate to healthcare decision-making as well as plans for future research.

ADHD POLYGENIC RISK AND COGNITIVE PERFORMANCE IN LATER LIFE

Marrium Mansoor[1], and Benjamin Katz[2], *1. Virginia Tech Gradueate School, Blacksburg, Virginia, United States, 2. Virginia Tech, Blacksburg, Virginia, United States*

Attention-Deficit/Hyperactivity Disorder (ADHD) affects approximately 4.4% of adults in the US and impacts multiple domains of daily life including education, workplace performance and interpersonal relationships. Although an increasing number of individuals with ADHD are now entering later life, there is very little research on how ADHD risk may impact cognitive function during aging. As such, there is value in understanding the association between polygenic risk for ADHD and cognition during different stages of later life. This study utilized data from the Health and Retirement Study which surveys 37,000 Americans biennially and aimed to determine if there was an influence of ADHD risk on cognitive performance when individuals were young-old (ages 65-74) or middle-old (ages 75-84). Only participants who responded in 2006, 2016, and to the Venous Blood Study were selected. The resulting sample size of 403 African-ancestry individuals (AA) and 2286 European-ancestry individuals (EA) was compared on executive function-focused measures as well as delayed recall measures. Results showed that there was no significant effect of ADHD risk on memory-related measures at both time-points for AA and EA individuals. However, there was a statistically significant association between ADHD risk and performance on the executive function measure for EA older adults who were middle-old ($p = 0.028$), but not when they were young-old; no such association was observed for AA adults. This finding suggests that ADHD risk may influence cognition among older adults and has significant implications for treatment and care of individuals with ADHD throughout the life course.

LONGITUDINAL EFFECTS OF HYPERTENSION ON COGNITIVE PERFORMANCE IN OLDER ADULTS

Allison Moll, and John L. Woodard, *Wayne State University, Detroit, Michigan, United States*

Hypertension impacts many older adults, but it is still not clear whether it has a negative effect on cognitive performance in older adults. The purpose of this study was to assess the longitudinal effect of hypertension on cognition in older adults (Mage=75.6 years, SD=8.3). Participants came from the National Alzheimer's Coordinating Center database. The cognitive assessment included the MoCA, Digit Span, Trail-Making Test A and B, WAIS-R Digit Symbol, Category Fluency, and Letter Fluency. Linear mixed effects modeling examined the random and fixed effects of clinician-assessed hypertension, months since first study visit, sex, age, and the interaction between hypertension and time since first visit on cognitive performance across five annual study visits. Results showed that hypertension had a significant main effect on Category Fluency, Trails B, Letter Fluency, and Digit Span–Forward and Backward. However, effect sizes were quite small (ηp2 range: 3.93x10-4 – 1.73x10-3). Main effects of age and months since first visit were significant predictors of all cognitive measures, such that older age was associated with worse cognitive performance and more months since the first visit was associated with better cognitive performance. This positive association is perhaps suggestive of practice effects across study visits. A significant interaction between hypertension and months since first visit for Category Fluency and Trails B showed that hypertensives and non-hypertensives performed differently at the initial visit but similarly by the last visit. However, effect sizes were small (ηp2 range: 3.86–9.64x10-4). These results suggest hypertension effects on cognition in older adults are minimal.

LIFE COURSE CONDITIONS AND COGNITION IN A NATIONALLY REPRESENTATIVE SURVEY OF OLDER ADULTS

James Iveniuk, Ellen Compernolle, Riddhi Gupta, Jen Hanis, and Louise Hawkley, *NORC at the University of Chicago, Chicago, Illinois, United States*

By the time people reach older adulthood, their cognitive function may be conserved, or in decline, in part due to their social experiences over their entire life course. Researchers have gained a greater understanding, over recent decades, of the importance of life-course events for cognition in later life. Nevertheless, our understanding of many of these factors, especially in childhood, remains limited. Drawing upon Round 2 of the National Social life, Health, and Aging Project (NSHAP; N=3,377), and data linked to the 2010 census, the 1940s census, and air pollution data, we undertake a whole-life-course approach to understanding the determinants of cognitive function in older adults. Building on the work of the Lancet Commission on risk factors for dementia, we considered health conditions, low education,incarceration, and brain injury (ever); poor health behaviors and low social contact (current); and air pollution (average over past five years). We also considered adverse childhood experiences,, and home conditions in 1940. Similar to other studies, we found that female gender, identifying as white, and being born in the US were significantly associated with better cognitive function. Higher depression and lower social contact were associated with worse cognition. There were no significant associations between cognition and early childhood factors - with the exception that growing up in an urban area was associated with better cognitive function. Experiencing jail time was also negatively associated with cognitive function. Findings point towards the need for a more expansive consideration of life course conditions, as they impact cognition in late life.

COGNITIVE RESERVE, PHYSICAL HEALTH, AND COGNITIVE FUNCTIONING IN OLDER ADULTS

Alyssa MacLean, and Jessica Strong, *University of Prince Edward Island, Charlottetown, Prince Edward Island, Canada*

Prior research has shown positive relationships between cognitive reserve (CR), physical health, and cognition, meaning that higher levels of physical health and CR are associated with higher cognitive functioning and vice versa. A group of community-dwelling older adults (N = 45, mean age = 70.5 years) completed a measure of CR (Life Experiences Questionnaire; LEQ), as well as cognitive tests, with number of physician diagnosed health conditions and number of medications measuring physical health. Initially, we ran correlations with the intention of running a mediation model (physical health factor as the independent variable, LEQ as the mediator, and cognitive test scores as dependent variables). Significant correlations were found between physical health and CR (r = -0.44, p = .01) with a medium effect size, and between CR and some test scores. However, there were no correlations between physical health and cognitive scores. Therefore, using linear regression analyses, the LEQ significantly predicted scores on some tests of executive functioning (DKEFS: Colour-Word Interference Test; Trial 3: F(1,39) = 7.42, p = .010), and processing speed (DKEFS: combined colour naming/reading: F(1,32) = 4.32, p = .046). However, the LEQ did not significantly predict verbal fluency, any set-switching tests, or a set-switching and inhibition test. Additionally, when physical health was added to the model, there was no significant improvement. The results suggest that CR may predict some types of executive functioning test scores, but not other executive functioning tests. Additionally, physical health did not predict cognitive test scores in this sample.

AGING AND LONGITUDINAL EFFECTS ON NUMERACY

Ryan Best[1], Katherine Carman[2], and Andrew Parker[3], *1. West Virginia University, Morgantown, West Virginia, United States, 2. RAND Corportation, Santa Monica, California, United States, 3. RAND Corporation, Pittsburgh, Pennsylvania, United States*

Numeracy, the ability to competently make use of numbers and numerical information, is a skill associated with diverse positive outcomes across the lifespan. Numeracy is related to increases in education attainment, economic success, and the quality of health and financial decisions (e.g., Chesney, Bjälkebring, & Peters, 2015; Reyna et al., 2009; Smith, McArdle, & Willis, 2010). More generally, numeracy correlates positively with measures of fluid and crystallized intelligence, but accounts for a unique portion of the variance in models predicting risk comprehension (Cokely et al., 2012) and performance in many decision-making tasks (e.g., Peters et al., 2006; Peters, 2012). Age effects on cognitive functioning are well established, generally describing declines in fluid abilities and increases or stability in crystallized abilities (for a review, see Salthouse 2010), but little is known about the longitudinal trajectory of numeracy into older age. The current study investigates longitudinal age effects on numeracy using a sample of 524 adults (2008 Agerange = 20-78) from the RAND American Life Panel. Participants completed a numeracy measure in both 2008 and 2019, a span of 11 years. Results show that numeracy scores generally decreased between measurement points (β = -.24, t = -2.27, p = .03) and that increased age was predictive of a larger decrease in numeracy scores (β = -.02, t = -2.07, p = .04). Results are discussed as they relate to cognitive aging and how the trajectory of numeracy compares to other cognitive constructs.

COHORT SHIFTS IN POPULATION COGNITIVE AGING

Patrick O'Keefe[1], Scott Hofer[2], Stacey Voll[2], Graciela Muniz Terrera[3], Linda Wänström[4], Sean Clousten[5], and Joeseph Rodgers[6], *1. Oregon Health and Science University, Portland, Oregon, United States, 2. University of Victoria, Victoria, British Columbia, Canada, 3. Ohio University, Athens, Ohio, United States, 4. Linkoping University, Linkoping, Ostergotlands Lan, Sweden, 5. Stony Brook University, Stony Brook, New York, United States, 6. Vanderbilt University, Nashville, Tennessee, United States*

Declines in cognitive functioning with increased age, on average and individually, is well documented and demonstrated to be related to genetics and a variety of life course risk factors, many of which are modifiable. Related to population cognitive aging is the phenomenon of the Flynn effect, the finding of increasing cognitive test scores across successive cohorts of young adults (e.g., Flynn 1987). This cohort effect has been repeatedly observed, in a wide variety of contexts, for over 30 years, with evidence that it has been occurring for at least a century. Our research looks at the interaction of the population cognitive aging and the Flynn effect. Using data from the English Longitudinal Survey of Ageing (ELSA) we show that, indeed, later born cohorts show significant (and meaningful) differences from earlier born cohorts. Using nonlinear Bayesian modeling we find that, on certain measures, later born cohorts have higher initial ability. This higher ability leads to a persistent advantage for later born cohorts, even as they experience (or will experience) cognitive decline. Additionally, we find that the advantage for later born cohorts is not present for every measure. Later born cohorts show an advantage for verbal fluency and episodic memory, however there is no cohort advantage on orientation scores. The lack of measurable differences on orientation is likely due to ceiling effects on orientation, which suggests that any substantial decline on that measure is indicative of pathology. We discuss the potential factors underlying both population cognitive aging and recent birth cohort trends.

EARLY LIFE ADVERSITY, ALLOSTATIC LOAD, AND COGNITIVE FUNCTION AMONG MIDDLE-AGED AND OLDER ADULTS

Danielle D'Amico[1], Maya Amestoy[2], and Alexandra Fiocco[3], *1. Toronto Metropolitan University, York, Ontario, Canada, 2. University of Toronto Scarborough, Thornhill, Ontario, Canada, 3. Toronto Metropolitan University, Toronto, Ontario, Canada*

Early life adversity (ELA) is consequential for poor cognitive health in mid to late life. ELA is associated with higher allostatic load (AL), a biological indicator of physiological dysregulation due to cumulative wear-and-tear from chronic stress. Higher AL is also associated with poorer cognitive function across the lifespan. To date, however, a paucity of research has investigated AL as a mechanism through which ELA impacts cognition. Using cross-sectional data from the Midlife in the United States (MIDUS) Study, the objective of this study was to investigate the mediating role of AL in the relationship between ELA and cognitive performance (global cognition, episodic memory, executive function) among middle-aged and older adults without cognitive impairment (n=1541, mean age=53±12, 53% female). ELA, including physical, emotional, and sexual experiences, was measured retrospectively using the Childhood Trauma Questionnaire. AL was composed of 20 biomarker proxies of neuroendocrine, metabolic, inflammatory, and cardiovascular systems, stratified by sex. Cognitive performance was evaluated using a battery of neuropsychological tests from the Brief Test of Adult Cognition by Telephone. Controlling for age, education, and ethnicity, AL significantly mediated the relationship between ELA and global cognition (ß=-0.01,95%CI[-0.02,-0.003]) and executive function (ß=-0.01,95%CI[-0.02,-0.003]) such that higher ELA was associated with higher AL, and higher AL was associated with poorer global cognition and executive function. No such effects were found for episodic memory. Consistent with the biopsychosocial lifespan model of cognitive aging, findings suggest that ELA may become biologically embedded over time to negatively impact cognitive function in later adulthood in a domain-specific manner.

FAMILY FLYNN EFFECTS AND LINKS TO MIDDLE-AGE HEALTH OUTCOMES

Linda Wänström[1], Patrick O'Keefe[2], Sean Clousten[3], Frank D. Mann[4], Graciela Muniz Terrera[5], Stacey Voll[6], Scott Hofer[6], and Joeseph Rodgers[7], *1. Linkoping University, Linkoping, Ostergotlands Lan, Sweden, 2. Oregon Health and Science University, Portland, Oregon, United States, 3. Stony Brook University, Stony Brook, New York, United States, 4. Stony Brook University, New York, New York, United States, 5. Ohio University, Athens, Ohio, United States, 6. University of Victoria, Victoria, British Columbia, Canada, 7. Vanderbilt University, Nashville, Tennessee, United States*

The Flynn effect (Flynn, 1984; 1987) refers to increases in cognitive performance, for later-born cohorts. It has been documented globally, occurring for more than a century. In a meta-analysis, Pietschnig and Voracek (2015) noted that the effect may be even stronger in adults than in children, though little research has addressed this topic (or its implications) for aging adults. Similarly, overall life-time health has improved, and incidences of cognitive impairment have decreased during the last two decades (Clouston et al., 2021). Using multilevel growth curve models, we found family Flynn effects in the National Longitudinal Survey of Youth; children in families with later-born mothers, and later-born first children, had higher PIAT math scores, and steeper developmental slopes. Although the link from childhood and adolescent cognitive function to later life outcomes has been well studied, research that takes advantage of the Flynn effect to facilitate interpreting that link is lacking. Clouston et al. (2021) emphasized the value of the Flynn effect in investigating links between childhood cognitive functioning and later adult Alzheimer's disease and related dementia (ADRD) risks. We linked our family level results to middle-age maternal health outcomes (factors that are related to ADRD risks). Canonical correlation analyses showed that mothers (at ages 40+ and 50+) from families with higher score levels and slopes tended to have better mental and physical health. Our results, showing a Flynn effect in child and adolescence scores, at the family level, with links to adult health, persisted after controlling for a known selection bias.

PHYSIOLOGICAL DYSREGULATION AS A PREDICTOR OF COGNITIVE DECLINE

Elizabeth Mahon[1], Sharon Stein Merkin[2], Margie Lachman[1], Arun Karlamangla[3], and Teresa Seeman[2], *1. Brandeis University, Waltham, Massachusetts, United States, 2. University of California Los Angeles, Los Angeles, California, United States, 3. University of California, Los Angeles, Los Angeles, California, United States*

Preclinical indicators of disease such as inflammation, cortisol and glucose dysregulation, and multisystem dysregulation (allostatic load) are related to individual differences in the level of cognitive functioning across adulthood. This study examined whether individual biological systems and allostatic load are related to differential patterns of change in cognitive functioning over 9 years. Data are from the Midlife in the United States (MIDUS) study second (biomarker and cognitive) and third waves (cognitive). The sample includes 863 men and women who ranged in age from 35 to 85 when the data were first collected. MIDUS biomarkers include a comprehensive range of biological and anthropometric measurements reflecting cardiovascular functioning, glucose metabolism, lipid metabolism, inflammation, HPA axis function, as well as sympathetic and parasympathetic nervous system function. Summary indices of dysregulation in each of these major systems as well as an overall index of multi-system dysregulation, or allostatic load were examined in relation to 9-year changes in episodic memory and executive functioning from the Brief Test of Adult Cognition by Telephone. Regression analyses, controlling for preexisting diseases and medications, showed that higher allostatic load was associated with decreased executive functioning over time for those who started out with higher cognitive performance at baseline, after adjusting for age, gender, race, English language, education, neurological conditions, medication use and smoking. Identifying biomarkers as antecedents of cognitive changes in midlife and old age, can potentially aid in the early detection of cognitive impairments and increase the possibilities for preventive interventions.

SESSION 6450 (POSTER)

COGNITIVE FUNCTION (HEALTH SCIENCES POSTERS)

USEFULNESS OF REVISED SIMPLIFIED SHORT-TERM COGNITIVE SCREENING TEST (STMT-R) IN ACUTELY ILL GERIATRIC PATIENTS

Hiroshi Yamamoto[1], Kenichi Ogawa[1], Yasushi Hisamatsu[1], and Tatsuya Ishitake[2], *1. Yamamoto Memorial Hospital, Imari-city, Saga, Japan, 2. Kurume University School of Medicine, Kurume-city, Fukuoka, Japan*

Background: Dementia can be a major cause of mortality and morbidity in geriatric patients. So, it would be essential to assess their mental state.Aims: We aim to appraise the impact of cognitive dysfunction on the long-term prognosis on STMT-R as a quicker and sensitive cognitive identification in acutely ill geriatric patients.

Methods: The inclusion criteria were to measure geriatric patients by STMT-R at admission, age≧50yo and being non-critical ill. Between October 2014 and September 2015, 836 were enrolled (52.4% female, mean age: 78.9 years). STMT-R≦4 was considered as cognitive dysfunction. Following the collection of clinical data, survival was subsequently measured for 7-8 years until January 2022. Cox's proportional hazards regression models were used to evaluate the hazard of death according to the dementia severity, with adjustment for potential covariates. Survival was estimated using Kaplan-Meier method.

Results: Among enrolled subjects, 144 were unable to complete the test due to severe dementia (ITG). 433 had cognitive dysfunction (STMT-R≦4; CDG) and 259 didn't have cognitive dysfunction (STMT-R>4; NCDG). The survival curves for death among three groups were significantly decreased in the CDG and ITG compared with the NCDG. The risks for mortality in the ITG and CDG are 3.92 (hazard ratio; 95% confidence interval:2.74-5.61, p< 0.001) and 1.82(1.33-2.51, p< 0.001) compared with the NCDG as reference.

Conclusion: 1) It was suggested that severity of cognitive dysfunction at admission has independently an impact on survival rate in acutely ill geriatric patients.2) STMT-R may also be useful for the future bedside or remote cognitive assessment.

ASSOCIATION BETWEEN SUBJECTIVE COGNITIVE DECLINE AND STRENGTH TRAINING IN US ADULTS AGED 45+ YEARS

Matthew Schroeder[1], Molly Waring[2], Nicole Fowler[3], and Sherry Pagoto[2], *1. Regenstrief Institute, Inc., Indianapolis, Indiana, United States, 2. University of Connecticut, Storrs, Connecticut, United States, 3. Indiana University School of Medicine, Indianapolis, Indiana, United States*

Subjective cognitive decline (SCD) can be an early marker for Alzheimer's disease and related dementias. Data supports physical activity to delay cognitive impairment and to improve cognitive functioning. We examined strength training engagement by middle-aged and older US adults with and without SCD. We used data from 121, 059 participated aged 45 years or older from the 2019 Behavioral Risk Factor Surveillance System (BRFSS) from 31 states and Washington, D.C. SCD was assessed by asking participants if they had experienced confusion or memory loss during the past 12 months (yes/no). Participants reported how often they engaged in strength training (e.g., using weight machine, free weights) in the past month. We dichotomized strength training engagement as meeting physical activity recommendations (2+ times weekly) or not (< 2 times weekly). An adjusted logistic regression model, controlling for confounding variables, estimated the likelihood of strength training in relation to SCD. Analyses were weighted; results are nationally representative. SCD was reported by 11.0% (SE: 0.2%) of middle-aged and older US adults. Three in 10 (29.1%; SE: 0.7%) of US middle-aged and older adults who reported SCD engaged in strength training 2+ times a week compared to 34.0% (SE: 0.3%) of US adults without SCD (aOR, 0.9; 95% CI: 0.9-1.0). While middle-aged and older US adults with SCD were less likely to strength train than those without SCD, only a third engaged in recommended strength training regardless of SCD status. Primary care providers should encourage strength training among middle-aged and older adults regardless of cognitive status.

HIGHER PHYSICAL FITNESS CLUSTERS SHOWED GREATER GLOBAL COGNITIVE OUTCOMES IN MIDDLE- TO OLDER-AGED ADULTS

Joshua Gills[1], Megan Jones[1], Anthony Campitelli[1], Sally Paulson[2], Kelsey Birk[3], Jennifer Myers[4], Jordan Glenn[4], and Michelle Gray[1], *1. University of Arkansas, Fayetteville, Arkansas, United States, 2. St. Elizabeth Healthcare, Cincinnati, Ohio, United States, 3. Neurotrack Technologies, Inc., Redwoods City, California, United States, 4. Neurotrack Technologies, Redwood City, California, United States*

Approximately, 6 million individuals in the United States are living with Alzheimer's disease. A new diagnosis occurs every 67 seconds, which will triple the rates by 2050. Recently, physical dysfunction has been associated with cognitive decline; however, usually, this is examined in one dimension of physical fitness (PF). A more robust way including multiple domains of PF would be beneficial in examining the relationship between PF and cognition. Therefore, the purpose of this investigation was to examine cognition in clustered PF variables among middle to older-aged adults. Participants (n=216;73% female) enrolled and completed a DXA scan, RBANS, handgrip, sit-to-stand power with TENDO, dual-task (4-meter and 10-meter), and 6-minute walk distance test. A hierarchal cluster analysis was utilized to identify PF cluster for participants, a one-way ANOVA was used to assess differences in cognition between clusters. Cluster 1 (C1;n=29) was characterized with the highest physical fitness values, cluster 2 (C2;n=74) was in-between C1 and C3, cluster 3 (C3;n=113) had the lowest values among PF variables. C1 had significantly higher global cognitive and visuospatial scores compared to C3 ($p< 0.05$). C1 and C2 had significantly higher values on line orientation and figure recall than C3 ($p< 0.05$). Data showed high PF clusters had higher global cognitive values when compared to lower PF clusters. Moreover, higher PF showed greater visuospatial and delayed memory values compared to lower PF. Clustering PF tasks served as a practical tool evaluating cognition—this may be useful for future interpretation of cognitive decline where higher PF represents higher overall cognition.

THE RELATIONSHIP BETWEEN SKIPPING BREAKFAST AND DEMENTIA: A RETROSPECTIVE COHORT STUDY IN OSAKA

Hitomi Chikama[1], Reiko Kanaya[2], Yasushi Takeya[3], Hiroshi Toki[4], Ryohei Yamamoto[3], and Miyae Yamakawa[3], *1. Osaka University, Suita City, Osaka, Japan, 2. Osaka University, Osaka, Osaka, Japan, 3. Osaka University, Suita, Osaka, Japan, 4. Health and Counseling Center, Suita, Osaka, Japan*

In Japan, annual medical checkups are carried out to prevent lifestyle diseases. Studies have found that skipping breakfast is a risk factor for diabetes, and potentially also dementia. This retrospective cohort study aimed to evaluate the relationship between skipping breakfast and dementia in people with diabetes. The eligible cohort was anyone on the National Health Insurance Database of Osaka who had a checkup in FY 2013 and had diabetes (N = 283,410). The cohort was divided into two groups, those who skipped breakfast more than three times a week (7.38%) and those who did not. The database does not allow individuals to be identified. People with diabetes were defined as those prescribed diabetes drugs in the year before the checkup or with HbA1c of 6.5% or higher at the checkup. People with dementia were defined as those prescribed anti-dementia drugs between April 2014 and December 2017. Data also included body mass index (BMI), smoking, sex , age, and prescription of hypolipidemic or blood pressure drugs. Logistic regression analysis was used, with odds ratio (OR) and 95% confidence interval . Being male, younger, smoking, having lower BMI or HbA1c levels, and drug prescriptions were associated with skipping breakfast. Skipping breakfast was associated with dementia (OR 1.26, 1.14–1.41), as was lower BMI and being older. For people with diabetes, skipping breakfast is a risk factor for obesity and dyslipidemia, which are associated with dementia. This study therefore provides evidence for a health behavior approach to eating breakfast in people with diabetes.

ASSOCIATION OF SUBJECTIVE AND OBJECTIVE COGNITION WITH DISEASE AWARENESS: EVIDENCE FROM BLOOD BIOMARKERS DATA

Zhuoer Lin[1], Mingqi Fu[2], and Xi Chen[1], *1. Yale University, New Haven, Connecticut, United States, 2. Wuhan University, Wuhan, Hubei, China (People's Republic)*

Impaired cognitive ability and its misperception contribute to poor decision-making of older adults; yet their impact on health-related decisions is less known. We examined how self-perceived and actual cognition were associated with chronic disease awareness using a nationally representative sample of Chinese older adults. Blood biomarkers data were collected in 2015 to identify participants' dyslipidemia and diabetes status. Among participants with identified dyslipidemia or diabetes, disease awareness was defined as self-reported diagnosis of the conditions as of 2018. Objective and subjective cognition were respectively assessed using the Mini-Mental State Examination and self-rated memory. The associations of subjective and objective cognition with chronic disease awareness were determined by weighted logistic regressions. Among 4,578 adults aged 60 and older with complete measurements, 1,442 and 759 individuals were identified having dyslipidemia and diabetes, with proportions of disease awareness being 38.0% and 58.1%, respectively. Individuals with mild (Odds Ratio [OR]=0.63; 95%CI: 0.45-0.89) or severe cognitive impairment (OR=0.46; 95%CI: 0.29-0.72) had lower odds of dyslipidemia awareness; and those with severe cognitive impairment had lower odds of diabetes awareness (OR=0.43; 95%CI: 0.23-0.79) than cognitively intact counterparts. However, adjusting for objective cognition, older adults with better subjective cognition had lower odds of dyslipidemia (OR=0.80; 95%CI: 0.63-1.02) and diabetes (OR=0.71; 95%CI: 0.55-0.92) awareness. Such associations were stronger for individuals with rural status, lower education, or living without children. Our findings highlight the great challenges deteriorated cognitive function and misperception may pose to chronic disease awareness, as well as the importance of targeted supports particularly for those more disadvantaged.

SENSORY IMPAIRMENT, COGNITIVE FUNCTION, AND DEPRESSION AMONG CHINESE OLDER ADULTS

Shu Xu, and YanJhu Su, *University of Massachusetts Boston, Boston, Massachusetts, United States*

Sensory impairment (SI) is a contributor to poor mental health and cognitive decline for older adults, and the likelihood of having sensory impairment increases with age. However, the association between sensory impairment and cognition is still under-investigated and the potential mechanisms for the SI-cognition link is still not clear. This study examines the relationships between sensory impairment, depression, and cognitive function among older adults in China. Using nationally representative data from the China Health and Retirement Longitudinal Study 2018, we conducted cross-sectional analysis on adults age 60 years and older (n=7,026). Sensory impairment is defined as having vision impairment (VI) only or hearing impairment (HI) only or dual sensory impairment (DSI). Cognitive function was measured by the Mini-Mental State Examination and depression were assessed by the 10-item Center for Epidemiologic Studies Depression scale. Descriptive analysis showed that 10.66% of older adults experienced sensory impairment. Linear regression analyses revealed that HI and DSI were associated with cognitive declines among older Chinese adults (HI: β=-0.75, p<.01; DSI: β=-1.45, p<.01). SEM results showed that depression partially mediate the relationship between SI and cognition. Sensory-impaired older adults were more likely to have depression (HI: β=1.71, p<.001; DSI: β=4.76, p<.001), which lead to worse cognitive function (HI: β=-1.09, p<.001; DSI: β=-2.80, p<.001). Models were controlled for age, gender, education, social activities, and other covariates. Findings suggest that Chinese older adults experiencing sensory loss are at greater risk of cognitive function declining and that depression play an important role in the relationship between SI and cognition.

IMPLEMENTATION BARRIERS AND FACILITATORS OF COGNITIVE STIMULATION THERAPY ACROSS CARE SETTINGS

Milta Little[1], Kim Johnson[2], Francis Karia[2], and Eleanor McConnell[2], *1. Duke University, Hillsborough, North Carolina, United States, 2. Duke University, Durham, North Carolina, United States*

Cognitive Stimulation Therapy (CST) is an evidence-based treatment for people living with dementia that is not in widespread use in the United States. To better understand barriers and facilitators to implementation of CST, we conducted virtual focus groups of newly trained facilitators of Cognitive Stimulation Therapy (CST). Of 12 facilitators trained, representing two settings of care (The Program for All-inclusive Care of the Elderly and a Continuing Care Retirement Community), 4 facilitators, representing Social Work n = 2, Speech Therapy n = 1, and Recreation Therapy n = 1, participated. We analyzed interview transcriptions using framework analysis guided by constructs from the Consolidated Framework for Implementation Research (CFIR). Themes that emerged across constructs were 1) balancing competing personal, stakeholder, and organizational needs; 2) lack of mastery experiences and the need for opportunities for more practice, reflection, and feedback from trainers; 3) building a community of facilitators to provide peer support; 4) logistical concerns; and 5) identifying appropriate participants who would most benefit from CST. The barriers to implementation imposed by the ongoing COVID-19 pandemic were also a cross-cutting theme. Many of these barriers are readily managed, and professionals who implement CST in their sites should be aware of and take into consideration these barriers and facilitators.

IMPROVING COGNITION IN OLDER CANCER SURVIVORS USING NONPHARMACOLOGIC INTERVENTIONS: A SYSTEMATIC REVIEW

Jennifer Blackwood[1], and Abigail Simone[2], *1. University of Michigan-Flint, Flint, Michigan, United States, 2. University of Michigan--Flint, Flint, Michigan, United States*

Cancer-related cognitive dysfunction (CRCD) is a side-effect of chemotherapy, particularly among young and adult populations. Results indicate CRCD is also prevalent in older adult populations. While various non-pharmacological interventions for cognitive impairments have been studied in young cancer and older adult populations, limited information is available regarding non-pharmacologic interventions for older adults with cancer. The purpose of this systematic review is to describe the current non-pharmacologic interventions for CRCD in the older adult cancer population. Databases searched included PubMed, MEDLINE, CINAHL, and EMBASE. Articles meeting inclusion criteria were appraised by 2 reviewers independently. The Cochrane Risk of Bias Assessment was used to assess study quality. The search located 3441 articles; 4 met inclusion criteria. Cognitive domains assessed by included studies comprised executive function (n=2), attention (n=1), learning/memory (n=2), perceptual-motor (n=1), and a general measure of global cognitive function (n=3). Two studies used exercise interventions and 2 employed cognitive training interventions. One exercise intervention improved executive function, while attention and learning/memory improved following cognitive training. However, a limited number of studies utilizing non-pharmacological approaches for treating cognitive impairment in this population showed high methodological heterogeneity. Non-pharmacologic interventions demonstrated positive outcomes for CRCD, however, methodological concerns in the included studies prevented definitive recommendations from being made. Findings may guide additional studies needed in this field in order to make more robust conclusions.

INFLAMMATORY BIOMARKERS ASSOCIATED WITH COGNITIVE FUNCTION AND DEMENTIA

Jiachen Chen[1], Yuan Fang[1], Kathryn Lunetta[1], Joanne Murabito[2], and Margaret Doyle[3], *1. Boston University School of Public Health, Boston, Massachusetts,* *United States, 2. Boston University, Boston, Massachusetts, United States, 3. University of Vermont, Colchester, Vermont, United States*

Neuroinflammation is an important contributor to the pathogenesis of dementia, but the role of circulating inflammatory markers is unclear. The aim of the study is to identify circulating inflammatory biomarkers associated with cognitive function in the Framingham Heart Study Offspring cohort. We used OLINK inflammation panel to measure 92 inflammation protein biomarkers using stored plasma samples at Offspring examination 7 (1998-2001) from 879 participants (52% female, mean 61 years range 40 to 88 years, 22% APOE e4 carrier). Cognitive function was assessed with seven tests derived from a neuropsychological (NP) testing battery representing four cognitive domains collected closest to the 7th examination. 68 proteins with at least 50% values above the limit of detection (LOD) were clustered with hierarchical clustering, and data below LOD were replaced with LOD/√2. We identified nine clusters of highly correlated proteins and created cluster composite scores on the first principal component of each. Adjusting for age, sex and education, five of the seven NP tests are nominally associated ($p < 0.05$) with at least one of the protein clusters, and five of the nine clusters are associated with at least one of the NP tests. The executive function test Trails B–Trails A is nominally associated with three clusters, and the Boston Naming Test 30 items version with two clusters, both sharing one common cluster which includes IFN-γ-inducible chemokines involved in inflammatory conditions. Future analyses will explore individual protein associations with cognitive test performance and incident dementia and will investigate the biological relevance of the identified clusters.

PREFRONTAL BLOOD FLOW DURING DUAL-TASK WALKING IN ADULTS WITH AND WITHOUT MILD COGNITIVE IMPAIRMENT

Cristina Udina Argilaga[1], Stella Avtzi[2], Turgut Durduran[2], Andrea Rosso[3], Miriam Mota[4], Joan Ars[1], and Marco Inzitari[1], *1. Parc Sanitari Pere Virgili, Barcelona, Catalonia, Spain, 2. Institut de Ciències Fotòniques, The Barcelona Institute of Science and Technology, Barcelona, Catalonia, Spain, 3. University of Pittsburgh, Pittsburgh, Pennsylvania, United States, 4. Vall Hebron Research Institute (VHIR), Barcelona, Catalonia, Spain*

Background: Blood flow differences in the prefrontal cortex (PFC) during dual-task walking are thought to indicate various degrees of neural efficiency. Individuals with poorer neural resources might need higher activation to meet behavioral performance. We aim to assess PFC cerebral blood flow (CBF) among older adults with and without mild cognitive impairment (MCI) during dual-task using functional Diffuse Correlation Spectroscopy (fDCS).

Methods: We assessed PFC CBF with DCS during dual-task paradigm: 1)Normal Walk(NW); 2)Forward-count(FWC); 3)Backward-count(BWC); 4)Obstacle negotiation(WWO). We assessed demographics, clinical variables, physical and cognitive function in those with MCI vs normal cognition (NC). Linear mixed effects models assessed changes of CBF across the tests in the dual-task paradigm and differences between MCI and NC.

Results: 49 older adults (median age=78 years, 51% women, 34 MCI) were included. MCI were older, with higher frailty, polypharmacy and comorbidity. Compared to NC, MCI showed worse cognitive and physical performance scores and lower Gait Speed (GS) during NW and WWO but not during FWC and BWC. N=12 were unable to perform BWC. CBF change from NW to FWC was higher in MCI compared to NC (estimate=0.35, 95%CI [0.03, 0.67], p=0.03). CBF change from NW to BWC and WWO was not different between groups. There was no effect of age or clinical covariates.

Conclusions: Higher NW-FWC CBF change seems due to the cognitive load of FWC in MCI. Higher activation in MCI compared to healthier counterparts could be explained by compensatory mechanisms. Further research should focus on better understanding dual-task related neural mechanisms.

THE EQUIVALENCE OF CANTAB AS A COGNITIVE FUNCTION MEASURE FOR CHINESE STROKE SURVIVORS: A PILOT STUDY

Fanfan Li[1], Huanzhi Zhu[1], Bei Wu[2], Hanzhang Xu[3], Jing Wang[4], and Juan Li[5], *1. Naval Military Medical University, Shanghai, Shanghai, China (People's Republic), 2. New York University, New York, New York, United States, 3. Duke University, Durham, North Carolina, United States, 4. University of North Carolina at Chapel Hill, Chapel Hill, North Carolina, United States, 5. Huashan Hospital affiliated to Fudan University, Shanghai, Shanghai, China (People's Republic)*

This study aims to investigate the equivalence between Cambridge Neuropsychological Test Automated Battery (CANTAB) and Montreal Cognitive Assessment, Changsha version (MoCA-CS) as cognition measures for Chinese stroke survivors. Sixteen stroke survivors were recruited from stroke center in Shanghai, China. Participants completed Paired Associates Learning (PAL) task in CANTAB, MoCA-CS and questionnaire about demo-social characteristics. Pearson correlation and hierarchical regression were used for equivalence analysis. CANTAB-PAL task performances (PAL First Attempt Memory Score, PALFAMS, PAL Total Attempts 2 Patterns, PALTA2) were significantly associated with score of MoCA-CS and delayed recall ($\beta=0.528$, p=0.014; $\beta=0.198$, p=0.043; $\beta= -3.885$, p=0.017; $\beta= -1.600$,p=0.026, respectively) after controlling for age, gender and education. The results suggest CANTAB-PAL is a reliable tool for measuring Chinese stroke survivors' cognitive function. Future studies are needed to establish the equivalence of CANTAB in multitasks in larger sample of Chinese stroke survivors.

DOES NEGATIVE AFFECT MODERATE THE RELATIONSHIP BETWEEN SUBJECTIVE COGNITIVE CONCERNS AND OBJECTIVE FUNCTIONING?

Bradley Dixon, Kylie Kadey, and John L. Woodard, *Wayne State University, Detroit, Michigan, United States*

The onset of Alzheimer's disease can be insidious, slowly affecting an individual's cognitive abilities. Previous research demonstrated that informant-reported cognitive decline was associated with significantly worse baseline and longitudinal cognitive performance than was a participant's subjective perceptions of decline. What remains unclear is how negative affect (i.e., depressive symptoms) could moderate the relation between objective cognitive performance and subjectively perceived cognitive concerns (participant vs. informant). Using the National Alzheimer's Coordinating Center (NACC) database, we performed moderated multiple regressions to test whether Geriatric Depression Scale (GDS) score showed different relationships with cognitive measures (animal/vegetable fluency, digit span, Boston Naming Test, digit-symbol coding (DSC), Wechsler Memory Scale Logical Memory, Trail-Making Test, and Mini-Mental State Examination) for participant- and informant-reported cognitive decline (yes/no). Participants were aged ≥65 years and were cognitively healthy at baseline. Informants lived with the participant or visited the participant weekly (N = 9,354). Participant-reported cognitive concern interacted significantly ($p<.05$) with negative affect only for animal fluency while informant-reported cognitive concern interacted significantly with DSC. Depressive symptoms were associated more strongly with cognitive performance for participants who did not report a subjective cognitive decline compared to those who did report a subjective cognitive decline. Participant age showed significant negative relationships with all measures while GDS score showed significant negative relationships with all measures except immediate Logical Memory recall, regardless of decline status. In conclusion, negative affect generally did not moderate the relationship between participant- or informant-reported cognitive concerns and objective cognitive functioning except for animal category fluency and DSC.

PREVALENCE AND FACTORS ASSOCIATED WITH MOTORIC COGNITIVE RISK IN A COMMUNITY-DWELLING OLDER SCOTTISH POPULATION

Donncha Mullin[1], Lucy Stirland[1], Tom Russ[1], Michelle Luciano[1], and Graciela Muniz Terrera[2], *1. University of Edinburgh, Edinburgh, Scotland, United Kingdom, 2. Ohio University, Athens, Ohio, United States*

Motoric Cognitive Risk (MCR) syndrome combines slow walking and self-reported cognitive complaints. It is a quick and simple way of identifying individuals at high risk of developing dementia. MCR has not been described in a Scottish population to date. This study describes the prevalence and associated factors of MCR in a community-dwelling sample of older Scottish people. The MCR concept was derived in the Lothian Birth Cohort 1936 (LBC1936) - a highly phenotyped cohort of over 1000 people followed up every 3 years since 2004. Uniquely, participants in LBC1936 had their IQ measured at age 11 in 1936. Authors found MCR prevalence of approximately 5.4% at baseline. Using logistic and linear regression analysis, as appropriate, they found that participants' age, depressive symptoms and cognitive measures of executive function were significantly associated with an increased likelihood of have MCR, but that IQ aged 11 was not associated. This study found rates of MCR in Scotland are within the typical range for this age group, albeit on the lower end. Interestingly, IQ at age 11 was not significantly associated with MCR, which was unexpected given MCR's prognostic value for dementia. That tests of executive function were associated with MCR adds further credence to the hypothesis that walking speed and executive function are linked. This points to further important work to ascertain if increasing walking speed can improve executive function.

SEX DIFFERENCES IN THE ASSOCIATION BETWEEN BODY COMPOSITION AND 2-YEAR CHANGE IN COGNITIVE FUNCTION

Daehyun Lee[1], Miji Kim[2], Hyung Eun Shin[2], Jae Young Jang[2], and Chang Won Won[2], *1. Kyung Hee Univierisity, Seoul, Seoul-t'ukpyolsi, Republic of Korea, 2. Kyung Hee University, Seoul, Seoul-t'ukpyolsi, Republic of Korea*

In the process of aging, the loss of lean mass and increase in fat mass are associated with cognitive decline. This study investigated sex differences in the association between body composition and changes in cognitive function in community-dwelling older adults in Korea. A total of 1,420 participants (aged 70–84 years, 54.2% men) of the Korean Frailty and Aging Cohort Study with data from baseline and 2-year follow-up surveys were included. Body composition was measured using dual-energy X-ray absorptiometry and cognitive function was assessed using the Korean version of the Consortium to Establish a Registry for Alzheimer's Disease Assessment Packet. The total fat mass was lower in men than in women ($p< 0.001$), whereas total lean mass was higher in men than in women ($p< 0.001$). Total body fat mass was positively associated with the time taken to finish the Trail Making Test-A only in women (standardized beta coefficient [ß]= -1.371, p=0.018), and a negative association was observed between trunk fat mass and digit span total only in men (ß= -0.092, p=0.039). Appendicular lean mass was significantly positively associated with word list recognition only in women (ß=0.087, p=0.010) and was significantly positively associated with digit span total (ß=0.108, p=0.027) and digit span forward (ß=0.081, p=0.025) only in men. The results of this study indicated that higher fat mass was associated with the protection of decline in cognitive function only in women, while lean mass was positively associated with a change in cognitive function in both sexes.

COPING WITH COGNITIVE DECLINE AMONG OLDER ADULTS WITH MILD COGNITIVE IMPAIRMENT OR MILD DEMENTIA: A SCOPING REVIEW

Youngmin Cho[1], Donruedee Kamkhoad[2], and Anna Beeber[3], *1. University of North Carolina - Chapel Hill, Chapel Hill, North Carolina, United States, 2. The University of North Carolina at Chapel Hill School of Nursing, Chapel Hill, North Carolina, United States, 3. Johns Hopkins University, Baltimore, Maryland, United States*

As cognitive impairment progresses, Persons with Mild Cognitive Impairment or Mild Dementia (PwMCI or MD) have trouble in adapting to changes in their cognitive functioning and, as a result, develop challenges in daily activities. If these challenges are not appropriately addressed, PwMCI or MD can experience poor health outcomes and quality of life. Coping, behavioral and cognitive efforts to regulate the distress from a certain stressful situation, is widely regarded as a fundamental determinant of health outcomes. We conducted a scoping review to understand what coping strategies PwMCI or MD used, and facilitators and barriers of the use of these coping strategies. Using the PRISMA-ScR guideline, we reviewed peer-reviewed empirical studies exploring coping experiences for cognitive impairment among community-dwelling PwMCI or MD. We used thematic synthesis to generate themes relevant to the coping strategies and the facilitators and barriers. Of 1267 studies identified, 12 qualitative studies were reviewed. Under three dimensions of coping strategy (i.e., problem-solving, emotional, and maladaptive coping strategies), six themes were identified: independent coping (e.g., use of reminder and practice of cognitive activities), collaborative/dependent coping (e.g., asking help as needed), reframing, expression of unpleasant feelings, comparing self to others, and avoidance. The themes for facilitators and barriers were social response to one's cognitive impairment, assistance from informal care partners, and support from professionals. These findings can provide not only a better understanding of how people cope with their cognitive impairment but can also provide rationale for developing interventions to maximize the use of coping strategies.

MENTAL-SOMATIC MULTIMORBIDITY IN GROUP-BASED TRAJECTORIES OF COGNITIVE FUNCTION FOR MIDDLE-AGED AND OLDER ADULTS

Siting Chen[1], Corey Nagel[2], Anda Botoseneanu[3], Heather Allore[4], Jason Newsom[5], Stephen Thielke[6], Jeffrey Kaye[1], and Ana Quiñones[7], *1. Oregon Health & Science University, Portland, Oregon, United States, 2. University of Arkansas for Medical Sciences, Little Rock, Arkansas, United States, 3. University of Michigan Dearborn, Dearborn, Michigan, United States, 4. Yale University, Guilfrod, Connecticut, United States, 5. Portland State University, Portland, Oregon, United States, 6. University of Washington, Seattle, Washington, United States, 7. Oregon Health and Science University, Portland, Oregon, United States*

Somatic and mental multimorbidity contributes to cognitive decline. The study aims to identify distinct trajectories of cognitive performance among middle-aged and older adults, and to examine the contribution of specific somatic and mental multimorbidity combinations on subsequent risk of cognitive impairment. We used group-based trajectory modeling to identify trajectories of cognitive impairment risk among participants in the Health & Retirement Study during years 1998-2016 (N=20,372). We included time-invariant sociodemographic factors (sex, race/ethnicity, education) to quantify their association with trajectory class membership, and time-varying multimorbidity combinations to examine their relative impact on observed trajectories. Four somatic-mental multimorbidity combinations were analyzed: somatic multimorbidity (two or more of the following: heart disease, lung disease, hypertension, arthritis, diabetes, cancer), stroke-multimorbidity (any somatic including stroke); depressive-multimorbidity (any somatic including high depressive symptoms); and stroke and depressive multimorbidity (including both stroke and high depressive symptoms). We identified three trajectory classes of cognitive impairment: low baseline risk with gradual increase (55.1%); low baseline risk with rapid increase (32.8%); and high baseline risk with gradual increase (12.1%). In the group with low baseline risk with rapid increase, stroke-multimorbidity (OR: 2.40, 95%CI: 2.11, 2.74) and depressive-multimorbidity (OR: 1.65, 95%CI: 1.50,1.81) each had higher odds of cognitive impairment relative to somatic multimorbidity. Similarly, stroke and depressive multimorbidity (OR: 3.46, 95%CI: 2.85, 4.21) was associated with higher odds of cognitive impairment compared with somatic multimorbidity. This study highlights the importance of risk modification for somatic and mental multimorbidity combinations from mid-life to inform interventions to sustain cognitive performance.

PSYCHOSOCIAL WORKING CONDITIONS IN MIDLIFE AND COGNITIVE AND PHYSICAL IMPAIRMENT IN OLDER AGE

Shireen Sindi[1], Shadi Kiasat[1], Ingemar Kåreholt[2], and Charlotta Nilsen[2], *1. Karolinska Institutet, Solna, Stockholms Lan, Sweden, 2. Jönköping University, Jönköping, Jonkopings Lan, Sweden*

Background: Psychosocial working conditions have been associated with cognitive and physical impairment among older adults. However, less is known on whether psychosocial working conditions are associated with a combination of cognitive and physical impairments. The aim of this study was to investigate the associations between midlife psychosocial working conditions and physical and cognitive impairment among older adults, and to assess whether there are sex differences in these associations.

Methods: The data were derived from two Swedish nationally representative surveys (n=839) with a follow-up time of 20-24 years. Multinomial and binary logistic regressions were used to assess the associations between work stressors according to the job demand-control model, and a combination of cognitive and physical impairment.

Results: Low control jobs were significantly associated with higher odds of both cognitive and physical impairment as well as a combination of cognitive and physical impairment. Passive jobs (low control, low demand) were associated with higher odds of cognitive impairment, and cognitive and physical impairment in combination. Active jobs (high control, high demand) were associated with lower odds of cognitive impairment. Sex-stratified analyses showed stronger associations among men than among women. Among men passive jobs were significantly associated with both cognitive and physical impairment. Low strain jobs were significantly associated with less physical impairment.

Conclusions: These results highlight the importance of midlife psychosocial working conditions for late-life physical and cognitive impairment, and especially among men. Jobs characterised by higher control, lower strain and active jobs may promote resilience and cognitive reserve among older populations.

SKELETAL MUSCLE ADIPOSITY IS ASSOCIATED WITH LOWER COGNITION IN AFRICAN CARIBBEAN WOMEN

Adrianna Acevedo-Fontanez, Ryan Cvejkus, Allison Kuipers, Joseph Zmuda, Caterina Rosano, and Iva Miljkovic, *University of Pittsburgh, Pittsburgh, Pennsylvania, United States*

Objective: Skeletal muscle adiposity (SMA) increases with aging and is recognized as a major risk factor for cardiometabolic diseases, disability, and mortality among older adults. Obesity is related to dementia and cognitive decline yet the relationship between SMA and cognition remains ill defined. The objective of this study was to assess SMA and cognitive function among African Caribbean women.Design and

Methods: Cross-sectional analysis of 448 African Caribbean women in the Tobago Health Study (mean age, 55 years; range, 39-84 years). Cognition was assessed by the Digit Symbol Substitution Test (DSST), a test of information processing speed with a range of 0-90; higher scores suggest better cognitive function (faster information processing speed). Calf SMA (muscle density) was assessed with computed tomography (Stratec XCT-2000). Linear regression was used to assess the association of SMA with DSST adjusted for age, education, muscle area, waist circumference, alcohol intake, smoking, physical activity, diabetes, and hypertension.

Results: Participants had a BMI of 30.7 kg/m2. Mean (SD) DSST scores and SMA were 39.2 (13.1) and 71.7 (5.3) mg/cm3, respectively. After full adjustment, we found that one SD greater skeletal muscle adiposity was associated with a 1.40 lower DSST score (p-value=0.025).

Conclusions: Our findings suggest that in African Caribbean women, greater SMA is associated with slower information processing speed, an early indicator of future dementia risk. Future studies using an expanded battery of cognitive tests and longitudinal follow-up should further advance our understanding of the role of SMA and dementia risk among African ancestry populations.

ASSOCIATIONS BETWEEN PRESCRIPTION OPIOID AVAILABILITY AND LONGITUDINAL CHANGES IN COGNITION IN OLDER ADULTS

Nafisseh Warner, Andrew Hanson, Phillip Schulte,
Elizabeth Habermann, David Warner, and
Michelle Mielke, *Mayo Clinic, Rochester, Minnesota, United States*

Opioids are frequently prescribed to alleviate pain symptoms in older adults, yet the relationships between prescription opioid availability and long-term cognitive function are incompletely defined. We evaluated the associations between prescription opioid availability and neuropsychological function and incident mild cognitive impairment (MCI) by performing a secondary analysis of the Mayo Clinic Study of Aging (MCSA), a longitudinal population-based observational cohort study with participants enrolled between 11/1/2004 and 4/1/2019 aged 65 years or older at the time of enrollment and without dementia. A total of 4,218 participants (51% male) were included with median age of 76 (interquartile range 72, 82) years. In multivariable analyses, each receipt of an opioid prescription, regardless of duration, resulted in an additional -0.007 (95% CI: -0.009, -0.005) change in global cognitive z-score (p< 0.001), with significant effects seen in the domains of memory (-0.005, 95% CI: -0.007, -0.003; p< 0.001), language (-0.002, 95% CI -0.003, 0.000; p=0.024) and attention (-0.004, 95% CI: -0.006, -0.002; p< 0.001) but not visual-spatial function (0.000, 95% CI: -0.001, 0.001; p=0.897). Among 2,963 cognitively unimpaired subjects with longitudinal follow-up, 769 (26%) developed incident MCI. Receipt of any opioid prescription during follow-up was associated with incident MCI in adjusted analysis (hazard ratio 1.21, 95% CI: 1.04, 1.42; p=0.014). In conclusion, prescription opioid availability was associated with cognitive decline across multiple domains and with incident MCI. These findings suggest that prescription opioid availability may have long-term effects on cognitive function.

SESSION 6460 (POSTER)

COMMUNICATION AND LANGUAGE ACROSS CARE SETTINGS

THE ASSOCIATION BETWEEN SMARTPHONE USE AND HEALTH BEHAVIORS AMONG OLDER ADULTS WITH DISABILITIES

Eunjin Yang, *Yonsei University, Seoul, Seoul-t'ukpyolsi, Republic of Korea*

People actively use smartphones to maintain and improve their health in the digital era. With this, evidence exists of the positive effect of smartphone use on the well-being of people with disabilities. This study aimed to examine the preferred sources of health information among older adults with disabilities and the association between smartphone use and healthy behaviors. This study is based on data from the 2017 national survey on persons with disabilities carried out in South Korea. A total of 4,014 participants aged 60 and above were included. Logistic regression analysis was carried out to verify the association between smartphone use and health behaviors. As the study reports, 37.7% were smartphone users and 62.3% were non-smartphone users. Among health information resources, participants identified mass media, medical institutions, and acquaintances as the first, second, and third preferred sources, regardless of smartphone use. However, a higher proportion of non-smartphone users reported having no health information available to them compared to smartphone users (5.7% vs. 1.3%, respectively). Regarding health behaviors, older adults with disabilities who use smartphones are more likely to have regular health checkups (Odd Ratio [OR], 1.51), cancer screenings (OR 1.33), dental examinations (OR 1.26), and exercise (OR 1.47), and to consume a balanced diet (OR 1.23) compared to non-smartphone users. Although these results do not prove causal relationship, smartphone use is associated with healthy behaviors in this population. Considering that healthy lifestyles are crucial to achieving active aging, resolving the disability digital divide is needed for older adults with disabilities.

DETECTING NARCISSISM FROM DAILY LANGUAGE USE: A MACHINE LEARNING APPROACH

Shiyang Zhang[1], Sibo Gao[2], and Karen Fingerman[3], *1. University of Texas at Austin, Austin, Texas, United States, 2. School of Human Ecology, Austin, Texas, United States, 3. The University of Texas at Austin, Austin, Texas, United States*

High-quality social contacts are important for older adult's emotional well-being whereas narcissism, characterized by self-centeredness, may undermine the quality of personal relationships. Narcissism may be associated with poorer quality relationships because narcissistic adults are more self-centered in their daily social interactions. The current study examined the associations between linguistic features of conversation throughout the day and narcissism using a machine learning approach. Older adults aged 65–89 (N = 281, Mage = 74.07) wore an unobtrusive electronically activated recorder (EAR) throughout the day for 4 to 6 days. The EAR was activated 30 seconds every 7 minutes to capture conversations occurring in a natural setting. The sound files that contained participant's speech (N = 28,243) were transcribed verbatim. We used Linguistic Inquiry and Word Count (LIWC) to extract linguistic features from the transcriptions (nfeature = 81; e.g., function words, affective processes). Linguistic features were analyzed using random forest algorithm which is a supervised machine learning method that can evaluate features' performances in predicting older adult's narcissism. The model reached an accuracy of 62% and results showed that total word count, more auxiliary verbs (e.g., will), more swear words (e.g., damn), and less assent (e.g., agree) were the most powerful predictors of narcissism. Drawing on sound files collected from real-life interactions, findings indicate higher usage of aggressive and disagreeable words among more narcissistic individuals, which probably leads to poorer quality relationships with social partners. Interventions aiming to improve contact quality and emotional well-being may consider individuals' word use in daily interactions.

CAN YOU HEAR ME? A MEDICAL STUDENT-LED QUALITY IMPROVEMENT INITIATIVE FOR HOSPITALIZED PATIENTS WITH HEARING LOSS

Stephanie Rennke, Rachel Warren, Wynton Sims, Shreya Menon, Sasha Binford, Megan Rathfon, and Margaret Wallhagen, *University of California, San Francisco, San Francisco, California, United States*

In acute care settings hearing loss (HL) is associated with impaired patient-provider communication, increased length of stay, and increased mortality. COVID-19 has exacerbated this problem with the widespread use of masks and eye shields which muffle speech and prevent lip reading. Our 800-bed tertiary care medical center lacked a standardized approach to identify patients with HL and address communication barriers. Three first year medical students spearheaded the initiative as part of a health systems improvement curriculum with support from a faculty coach and a faculty researcher. From September 2020 to October 2021, the students met with stakeholders, leadership and champions and unit staff, identified the current state and completed a gap analysis through interviews, surveys, and direct observation. The pilot in May 2021 included two week-long PDSA cycles on one hospital unit to: 1) screen patients aged 65 and older using the validated 10-item HHIE-S questionnaire, 2) implement an education and awareness campaign with bedside signage, posters, and conferences and 3) provide a personal amplifier (purchased in bulk by the medical center) with verbal and written instructions. A total of 29 patients screened positive and were given personal amplifiers. Post-pilot interviews reported increased provider awareness and knowledge around best communication practices. Patients and staff reported limited amplifier use due to poor sound quality, small dials, poorly fitting ear buds and a short battery life. Based on these results the team recommended discontinuing the personal amplifiers and identifying other communication tools including higher quality personal amplifiers and speech to text applications.

PERSON-CENTERED LANGUAGE-BASED STRATEGIES USED BY HOME CARE WORKERS WHO CARE FOR PERSONS LIVING WITH DEMENTIA

Reanne Mundadan, Marie Savundranayagam, Joseph Orange, and Laura Murray, *Western University, London, Ontario, Canada*

Several studies recommend language-based strategies for communication with persons living with dementia. Language-based strategies improve coherence, clarity, reciprocity, and continuity of interactions. Person-centered communication (PCC) strategies are the gold standard, including facilitation, recognition, validation, and negotiation. Only one study has examined the overlap between language-based strategies and PCC in long-term care. Little is known about which language-based strategies support PCC in home care. Accordingly, this study investigated the overlap between language-based strategies and PCC in home care interactions. Conversation analysis of 30 audio-recorded routine care interactions between home care workers and persons living with dementia was conducted. The overlap between communication-units coded for PCC and 33 language-based strategies was analyzed. Of 11,347 communication-units, 2,664 overlapped with PCC. For facilitation, 21% were yes/no questions and 15% were announcements of action/intent. For recognition, 25% were yes/no questions and 22% were affirmations. For validation, the majority (81%) of communication-units were affirmations and positive feedback. Finally, for negotiation, 60% of communication-units were yes/no questions. This is the first study examining naturalistic interactions between home care workers and persons living with dementia. The findings highlight the person-centeredness of language-based strategies. Yet only six of 33 language -based strategies occurred in the top 50% of overlapping communication-units. Home care workers in this study use a uniform set of person-centered language-based strategies, illustrated by the frequent use of yes/no questions overlapping with most PCC indicators. Our findings emphasize the need for training among home care workers in the use of diverse language-based strategies that are potentially person-centered.

SESSION 6470 (POSTER)

DRIVING

PSYCHOMETRIC EVALUATION OF CARS: A BRIEF SCREENING INSTRUMENT FOR DRIVING SAFETY

Angela Curl, *Miami University, Oxford, Ohio, United States*

Driving is critical to mobility, autonomy, freedom of choice, and engagement for older adults, but many eventually stop driving. While poor health often eventually leads to driving cessation, some drivers do not realize that their driving is impaired. The 4-item CARS instrument of driving safety has been created to serve as a screening tool by health professionals during assessments and routine appointments (Curl, 2014). To assess the construct validity of CARS, data were collected in 2015-2016 by The Knight Alzheimer's Disease Research Center from cognitively impaired (N=42) and cognitively healthy participants (N=229), as well as "collateral sources" who answered the CARS items about the respondents' driving. Vision problems and cognitive impairment, both known predictors for driving problems, were correlated with CARS scores. Results indicate that worse eyesight in the right eye is correlated with higher CARS scores (Spearman rho = -.17, p<.01), but not the left eye. Poor eyesight (i.e., less than 20/40 vision) was correlated with higher CARS scores (Spearman rho = .12, p<.05). However, cognitive impairment (very mild/mild dementia vs. healthy cognitive functioning) was not statistically significant. Total CARS scores were moderately correlated for respondents and their collateral sources, r = .32, p<.01. Results indicate that this instrument may be more useful as a tool for initiating difficult conversations about driving safety than for identifying older adults who are at higher risk for negative driving outcomes. Future research is needed to identify additional/alternative items with greater psychometric support.

VISUAL PROCESSING SPEEDS DIFFERENTIATE OUTCOMES OF DRIVING EVALUATIONS OF CONTROLS AND MEDICALLY AT RISK DRIVERS

Anne Dickerson, and Victoria Penna, *East Carolina University, Greenville, North Carolina, United States*

Visual processing speed is considered a critical factor for determining driving capacity in older adults. The specific research questions were: 1) is there a statistically significant difference in performance time between the medically at-risk (n=35) and controls (N=242), 2) does the type of medical condition (e.g., neurological, cognition, complex medical conditions) differentiate performance, and 3) can visual processing speed differentiate between fit and unfit drivers. A cross sectional quasi-experimental design was used to compare the visual processing reaction times between at-risk adult drivers and healthy controls. Participants were medically-at-risk drivers referred for a comprehensive driving evaluation to determine their fitness to drive. The Vision Coach™ "Full-Field-60" task was used to collect reaction times which required participants to tap 60 randomly illuminated red dots. One practice trial was followed by three testing trials that were averaged together. At-risk participants were divided into three diagnostic categories. Fitness-to-drive outcomes were pass, fail, or restrictions. A propensity score method based on age and gender was used to account for the difference in sample sizes by weighting the participants from the two studies for a fair comparison between the two groups. Independent t-tests found a significant difference t(275)=-6.42, p=< 0.001 in trial times between healthy controls (M=53 + 10.82) and medically-at-risk adults (M=72 + 17.04). No significant difference was found between the diagnostic groups (p=0.141), but the Vision Coach™ differentiated between those who "passed" and those who "failed" a driving evaluation (F(2,32)=8.28, p=0.001.

ACHES AND PAINS: HOW DO THEY AFFECT TRANSITIONS FROM DRIVING?

Anne Barrett, and Cherish Michael, *Florida State University, Tallahassee, Florida, United States*

Chronic pain, which affects more than 1 in 4 middle-aged and older adults, can have profound implications for everyday activities, like driving. Although research has revealed pain's effect on driving performance, less is known about driving-related behaviors and self-assessments that are part of the process of transitioning from driving. We address this issue using data from an online survey of 3,441 Floridians aged 50 and older that was conducted between December 2020 and March 2021 and funded by the Florida Department of Transportation. We examine the association between pain and four driving-related outcomes: self-rated driving ability, self-regulated driving, perceived nearness of driving retirement, and planning for driving retirement. Results of multivariate regression analyses indicate that experiencing greater pain is associated with worse self-rated driving ability, more frequent self-regulated driving, and greater perceived nearness of driving retirement. Pain is not, however, associated with greater planning for driving retirement. These findings indicate that although greater pain may hasten the transition from driving, it may not lead to more planning for it. Both patterns suggest that pain may increase people's risk of experiencing the social isolation that can follow driving retirement. By focusing on transitioning from driving, our study reveals a largely overlooked benefit of reducing pain – It could extend people's years behind the wheel.

COGNITIVE AND PSYCHOSOCIAL OUTCOMES OF DRIVING DIFFICULTIES IN OLDER ADULTS: A 5-YEAR STUDY

Yeji Hwang, *Drexel University, Philadelphia, Pennsylvania, United States*

Many older adults find it difficult to drive a car as they age. However, there are lack of studies on the outcomes of driving difficulties among older adults. The aim of this study was to examine the cognitive and psychosocial outcomes of driving difficulties in older adults. This study was a secondary data analysis using National Social Life, Health, and Aging Project Wave 2 (2010-2011) and 3 (2015-2016). This study followed 1,638 older adults that were of the age 65 and older, who had no difficulties driving a car at Wave 2. Montreal Cognitive Assessment Scale, Center for Epidemiological Studies Depression Scale, Hospital Anxiety and Depression Scale, and Perceived Social Isolation Scale were used. For data analysis, chi square tests, t-tests, and regression analysis were used. After 5 years, 11.1% of people began to have difficulties in driving a car (n=180), and 88.9% of people maintained to have no difficulties driving a car (n=1,441). Compared to people who maintained no difficulties of driving a car over time, people who began to have difficulties had more severe cognitive decline (t=4.59, p< 0.001) and more depressive symptoms over time (t=3.253, p=0.001). Univariate regression analysis also indicated that having difficulties of driving resulted in more severe cognitive decline over time (b=0.137, p< 0.001) and more depressive symptoms over time (b=0.097, p< 0.001). Driving difficulties were not related to anxiety or social isolation. As difficulties in driving are related to poor cognitive and psychological outcomes, healthcare professionals should pay more attention to people who experience driving difficulties.

"IS IT TIME TO STOP DRIVING?": A RANDOMIZED TRIAL OF AN ONLINE DECISION AID FOR OLDER DRIVERS

Faris Omeragic[1], Lauren Meador[2], Nicole Fowler[3], Rachel Johnson[4], Elizabeth Boland[5], Ryan Peterson[6], and

Marian Betz[1], *1. University of Colorado School of Medicine, Aurora, Colorado, United States, 2. Stanford University School of Medicine, Stanford, California, United States, 3. Indiana University School of Medicine, Indianapolis, Indiana, United States, 4. Colorado School of Public Health, Aurora, Colorado, United States, 5. University of Colorado Anschutz Medical Campus, Aurora, Colorado, United States, 6. University of Colorado, Aurora, Colorado, United States*

The decision to stop or continue driving can be challenging for older adults. In a prospective two-arm randomized trial, we sought to test whether an online driving decision aid (DDA) would improve decision quality. We recruited 301 English-speaking licensed drivers, age ≥70 years, without significant cognitive impairment but with ≥1 diagnosis associated with increased likelihood of driving cessation, from clinics associated with study sites in three states. They were randomized to view 1) the online Healthwise® DDA for older adults addressing “Is it time to stop driving?”; or 2) a control condition of web-based information. Our primary outcome was decision conflict as estimated by the Decisional Conflict Scale (DCS; lower scores indicate higher quality). Secondary outcomes were knowledge and decision self-efficacy about driving decisions. We examined differences in post-randomization outcomes by study arm using generalized linear mixed-effects models with adjustment for site and pre-randomization scores. Intervention participants had a lower mean DCS score (12.3 DDA vs 15.2 control; p=0.017) and a higher mean knowledge score (88.9 DDA vs 79.9 control; p=0.038); we found no difference between groups in self-efficacy scores. The DDA had high acceptability; 86.9% of those who viewed it said they would recommend it to others in similar situations.The online Healthwise® DDA decreased decision conflict and increased knowledge in this sample of English-speaking, older adults without significant cognitive impairment. Use of such resources in clinical or community settings may support older adults as they transition from driving to other forms of mobility.

PREVALENCE AND USE OF ADVANCED DRIVER ASSISTANCE SYSTEMS IN THE OLDER DRIVER POPULATION

Renee St. Louis[1], David Eby[1], Lidia Kostyniuk[1], Lisa Molnar[1], Jennifer Zakrajsek[1], Nicole Zanier[1], Raymond Yung[2], and Linda Nyquist[2], *1. University of Michigan Transportation Research Institute, Ann Arbor, Michigan, United States, 2. University of Michigan, Ann Arbor, Michigan, United States*

Research on advanced driver assistance systems (ADAS) in the older driver population has suggested the potential for ADAS to improve safety and driving comfort by helping aging drivers overcome functional declines commonly experienced in later-life. However, attaining anticipated ADAS benefits is dependent upon drivers’ awareness, understanding, and use of ADAS in their own vehicles. Questionnaire data from 2,374 older drivers enrolled in the AAA LongROAD study were analyzed to investigate changes in the prevalence and use of 15 ADAS and how participants learned to use these technologies. From baseline to Year 3, the prevalence of each ADAS significantly increased, with the greatest percentage point increase being for backup/parking assist technology (from 41.5% to 58.8%). The prevalence of one or more ADAS in participants’ vehicles increased from 59.0% to 72.0%, and the average number of ADAS per vehicle increased from 2.0 to 3.3. At both baseline and Year 3, approximately one-third of participants reported always using the ADAS available in their vehicle, but nearly one-quarter reported never using their ADAS. The largest proportion of participants at both baseline and Year 3 reported learning to use ADAS by figuring it out by themselves (45.5% and 50.8%, respectively), yet approximately 12.0% of participants at both time points reported never learning to use ADAS. To achieve the expected benefits of ADAS for older drivers, research is needed to better understand why ADAS are not being use more frequently when available, and to develop acceptable and accessible programs for training older adults to use ADAS.

SESSION 6480 (POSTER)

ELDER ABUSE: DETERMINANTS, DISRUPTORS, AND CONSEQUENCES

INVESTIGATING THE CONNECTION BETWEEN AGEISM AND ELDER ABUSE

David Burnes[1], Karl Pillemer[2], and Andie MacNeil[1], *1. University of Toronto, Toronto, Ontario, Canada, 2. Cornell University, Ithaca, New York, United States*

Elder abuse is recognized as a pervasive public health problem with detrimental consequences for older adults and society. Although considerable research has examined elder abuse risk factors at the individual level, there is a growing call for the field to move beyond proximal causes and consider broader socio-cultural and structural factors that influence elder abuse. Illustrating this shift, organizations, advocacy groups and researchers have proposed a connection between ageism and elder abuse. However, despite the assertion that ageism is a causal factor for elder abuse, there is a scarcity of research to demonstrate this relationship, and a coherent theoretical framework linking ageism to elder abuse remains to be articulated. The purpose of the current study was to examine the conceptual pathways and limited empirical research connecting ageism and elder abuse, and to develop a conceptual model that links ageism and elder abuse. We conducted a comprehensive review and synthesis of the ageism/elder abuse literature, as well as research from other domains of interpersonal/family violence. Based on this synthesis, the proposed model includes plausible mediators (social isolation, devaluation, depersonalization, infantilization, powerlessness, blame) and moderators (intersection with socio-cultural identities, internalized ageism, policy/social norms) that could be targeted as mechanisms of change in interventions designed to address the issue. As such, it provides a framework for hypothesis-testing and future research on the topic. This study informs a research agenda to bring conceptual clarity and empirical evidence to the study of the connection between ageism and elder abuse.

THE ASSOCIATION BETWEEN FINANCIAL RESOURCES AND STRESSORS AND FINANCIAL EXPLOITATION

LaToya Hall, Juno Moray, Evan Gross, and Peter Lichtenberg, *Wayne State University, Detroit, Michigan, United States*

The prevalence of financial exploitation (FE) experienced by older adults is increasing. Population-based survey estimates of FE in the older adult population range from 5% to 11%. Given the growing prevalence of FE victimization in older adult populations, understanding the population's vulnerability to FE has increased in importance. This study investigates a conceptual framework in an attempt to understand how financial stressors and resources are associated with substantiated FE in a sample consisting largely of black older adults. The study uses a cross-sectional design to investigate group differences among a total sample of 142 community-dwelling older adult participants, 62 of whom sought services to address FE and 80 with no FE history FE. Older adults who sought services to address FE were more likely to be unmarried and had fewer years of education. Financial literacy had a protective effect on FE, whereas and perceived financial vulnerability increased FE risk. According to the findings sociodemographic and financial stress and resource measures have significant relationships with FE. These findings support the conceptual framework describing their relationship. This new conceptual framework provides a guiding factor in better understanding older adult's vulnerability to financial exploitation.

A MOMENT'S NOTICE: RECOGNIZING THE STRESSFUL LIFE EVENTS, EMOTIONS, AND ACTIONS THAT MAKE US SUSCEPTIBLE TO SCAMS

Alicia Williams[1], Lona Choi-Allum[1], Doug Shadel[2], Karla Pak[2], and Chuck Raineville[1], *1. AARP, Washington, District of Columbia, United States, 2. AARP, Seattle, Washington, United States*

Scamming has become a booming, multibillion-dollar industry with millions of Americans targeted by scams each year. To better understand the rates of exposure to scams and factors that may increase a target's susceptibility to financial loss resulting from a scam, AARP commissioned a national survey that screened over 9,000 adults ages 18+ about their rates of encounters and financial loss from 26 popular scams. Among the total sample, 15% (an estimated 33 million people) reported losing money to a scam in the past year. Additionally, a subset of 3,280 respondents, including 1,085 respondents who lost money to a scam, were surveyed more extensively about their experiences. The study uncovered environmental and emotional factors in which targets are more susceptible to fraud. Specifically, fraud victims reported experiencing twice as many stressful life events (i.e., 4.0 vs. 1.9), 58% more fraud encounters, stronger emotional arousal during fraud encounters, and significantly less family support and closeness than nonvictims. Additionally, only two of the eight protection tools recommended by fraud experts (i.e., using a passcode and installing protective software on one's computer) were used by most respondents; and less than half of respondents reported using call blocking tools or online monitoring of their accounts, which can dramatically reduce exposure to scam encounters. Together, these findings show the importance of building public awareness of the role of stress, emotional arousal, and feelings of isolation in fraud susceptibility, and highlight the benefits of using fraud protection tools to limit one's exposure to fraud.

EMPOWERING SENIORS TO RECOGNIZE ELDER MISTREATMENT THROUGH PEER SUPPORT: RESULTS FROM A COMMUNITY OUTREACH PROJECT

Jessica Hsieh[1], Sharon Tan[1], Celeste Pang[2], Raza Mirza[3], and Christopher Klinger[1], *1. University of Toronto, Toronto, Ontario, Canada, 2. Egale, Toronto, Ontario, Canada, 3. National Initiative for the Care of the Elderly, Toronto, Ontario, Canada*

Elder mistreatment, often understood in the context of abuse and neglect, is a growing concern for the health and wellbeing of seniors and their families. A 2015 Canadian prevalence study by the National Initiative for the Care of the Elderly (NICE) found that seniors who are mistreated are more willing to talk to other seniors, rather than clinicians, police or family. However, a lack of knowledge, access to resources, and community stigma may limit seniors' abilities to address mistreatment.This study evaluated the impact on knowledge, attitudes, and behaviours of having seniors deliver workshops on mistreatment to other seniors. A Seniors' Advisory Committee developed content for these workshops, delivered by seniors in sixteen communities across Ontario, Canada. Participants completed pre/post-surveys assessing changes in knowledge, attitudes, and behaviours. Results indicate that workshops effectively increased awareness of mistreatment issues among participants, on average, by 37%. Participants experienced a 44% increase in their perceived preparation to provide information to another older adult asking about mistreatment. Barriers to help-seeking among seniors include finding trustworthy sources, fear of retaliation, and a lack of legal protection. Prior to the training, healthcare providers were the main sources of information for participants (58%); depending on the severity of the situation, 60% of participants indicated eventually reporting to police, who are not the preferred source of information. Senior-led workshops about mistreatment appear to be effective for increasing knowledge and encouraging disclosure and help-seeking behaviours. Results support prevention models that empower seniors to educate other seniors on issues around mistreatment.

THE ROLE OF RELATIONSHIP FACTORS IN HARMFUL CAREGIVER BEHAVIORS: OLDER CHILDREN CARING FOR PARENTS WITH DEMENTIA

Elizabeth Gallagher[1], Kathrin Boerner[1], Yijung Kim[2], Kyungmin Kim[3], and Daniela Jopp[4], *1. University of Massachusetts Boston, Boston, Massachusetts, United States, 2. The University of Texas at Austin, Austin, Texas, United States, 3. Seoul National University, Seoul, Seoul-t'ukpyolsi, Republic of Korea, 4. University of Lausanne, Lausanne, Vaud, Switzerland*

Elder abuse by family caregivers is an often-overlooked phenomenon that affects many older adults. Especially, retirement-aged children caring for their oldest-old parents with dementia may be at greater risk of engaging in harmful or abusive behaviors, given their own age-related health issues and other competing caregiving demands. Most of the elder abuse literature has focused on general demographic predictors of elder abuse, regarding the caregiver, care recipient, and the care environment. Less attention has been paid towards relationship factors, which may play a large role among these parent-child dyads. This study examined how relationship factors are associated with potentially harmful caregiver behaviors (PHCB; e.g., screaming), which have been identified as "early warning signs" for elder abuse. Relationship factors of interest include positive and negative relationship quality measured by caregivers' mean scores on the support and conflict subscales on the Quality of Relationship Inventory (QRI). We conducted in-depth interviews with 88 caregivers (65+) who are caring for their parents with dementia (90+) as the part of the Boston Aging Together Study. Regression models revealed that relationship conflict was significantly associated with higher levels of PHCB, accounting for caregiver, care recipient, and care environment characteristics. The creation of screeners to identify "high conflict" care dyads could prove useful in the early detection and intervention of potential elder abuse cases, given that caregivers may be more willing to report negative aspects of their relationship (e.g., fighting) than more obviously harmful or abusive behaviors.

SOCIAL NETWORKS AND HELP-SEEKING AMONG US CHINESE OLDER ADULTS REPORTED ELDER MISTREATMENT

Ying-Yu Chao[1], Jin Young Seo[2], and XinQi Dong[3], *1. Rutgers, The State University of New Jersey, Newark, New Jersey, United States, 2. Hunter College, CUNY, New York, New York, United States, 3. Rutgers, The State University of New Jersey, New Brunswick, New Jersey, United States*

Purpose: Older immigrant adults are reported to be more tolerant of abusive situations and less likely to seek help. This study aimed to examine the associations between social networks and help-seeking among U.S. Chinese older adults reported elder mistreatment (EM).

Methods: Data were from the Population Study of Chinese Elderly in Chicago (PINE). Social networks were assessed with network size, volume of contact, emotional closeness, proportion kin, proportion female, and proportion coresident. Informal/formal help-seeking (intentions and actual behaviors) were measured. Descriptive statistics and regression analyses were performed.

Results: A total of 450 participants reported EM. Participants had a mean age of 72.73 ± 8.03 years old (range 60-97). Participants had a mean of 3.29 (SD ± 1.31) network members, a mean of 3.24 (SD ± 0.67) emotional closeness, and average contacts of 6.62 (SD ± 1.10) times per year with network members. Smaller network size (p = .00) and less emotional closeness (p = .03) were associated with an increase in intentions of seeking help from formal sources. Compared to not seeking help, smaller network size (p = .04) and more emotional closes (p = .03) were associated with a higher likelihood to seek help from informal sources among U.S. Chinese older adults who reported any EM. Conclusion/implication: This study highlights the dynamic nature of social networks of help-seeking among this underserved population. Culturally tailored interventions are suggested to promote help-seeking through increasing strong ties and improving the quality of social networks for U.S. Chinese older immigrants with EM.

THE ROLE OF FORMAL RESOURCES ON ELDER MISTREATMENT HELP-SEEKING BEHAVIORS AMONG ASIAN OLDER ADULTS

Eun Jeong Lee[1], Ga-Young Choi[2], and Eun Koh[3], *1. Asian American Resource and Information Network, Wood Ridge, New Jersey, United States, 2. California State University, Los Angeles, Los Angeles, California, United States, 3. The Catholic University of America, Washington, District of Columbia, United States*

Elder mistreatment is one of the most difficult topics to talk about among Asian older adult immigrants in the U.S. because they are unfamiliar and uncomfortable to disclose the issue due to their unique cultural values and limited English language proficiency. We recruited 494 community dwelling older adults from five cities who identified themselves of Asian ethnicity, and were 55 years old and older. Participants had various Asian ethnic and language backgrounds (e.g. Korean, Chinese, Filipino, and Vietnamese). Most of them were foreign-born (84.6%) with the mean age of 69.0 (SD = 8.47). Using the participant survey data, we focused on examining difference regarding elder mistreatment experience, perceptions, and help-seeking intentions between the Senior Community Service Employment Program (SCSEP) group and the non-SCSEP group that may or may not participate in paid workforce. The SCSEP is the federally paid workforce program for low-income older adults aged 55 or above aiming at fostering older adults' community service and economic self-sufficiency. There was a significant difference in emotional mistreatment experiences between SCSEP and non-SCSEP participants. Furthermore, the two groups were significantly different in their likelihood of seeking help from Adult Protective Services (APS). Those who ever participated in the SCSEP were more likely to seek help from APS (X2 = 1, N = 284) = 4.674, p ≤ .05. Implications for future research and gerontology services are discussed to enhance Asian older adults' awareness of elder mistreatment, and APS and other formal sources of help.

PSYCHOMETRIC PROPERTIES OF A NOVEL MEASURE OF FINANCIAL ABUSE OF OLDER ADULTS

David Hancock[1], Karl Pillemer[2], David Burnes[3], Sara Czaja[1], and Mark Lachs[4], *1. Weill Cornell Medicine, New York City, New York, United States, 2. Cornell University, Ithaca, New York, United States, 3. University of Toronto, Toronto, Ontario, Canada, 4. Weill Cornell Medicine, New York, New York, United States*

Background and Objectives: Elder abuse, or mistreatment affects at least 1 in 10 older adults. Financial abuse, or exploitation, of older adults is among the most commonly reported forms of abuse. Few validated measures exist to measure this construct. We aim to present a new psychometrically validated measure of financial abuse of older adults. Research Design and

Methods: Classical test theory and item response theory methodologies were used to examine a five-item measure of financial abuse of older adults, administered as part of the New York State Elder Mistreatment Survey.

Results: Factor analysis revealed a single factor best fits the data, which we labeled as financial abuse. Moreover, IRT analyses revealed that these items discriminated well between abused and non-abuse persons and provided information at high levels of the latent trait θ, as is expected in cases of abuse. Discussion and Implications: The FIVE has acceptable psychometric properties and has been used successfully in large scale survey research. We recommend this measure as an indicator of financial abuse in elder abuse, or mistreatment prevalence research studies.

ANALYSIS OF SOCIAL PARTICIPATION, ELDER ABUSE, AND CORRESPONDING BEHAVIOR OF THE ELDERLY IN CHINA

Guanggang Feng, and Shumin Jiang, *Anhui University of Finance and Economics, Bengbu, Anhui, China (People's Republic)*

Introduction: Ancient Chinese wisdom under the Confucian culture show that “Parents raise children who in turn support them in old age” and "Don't wash one's dirty linen in public". The elderly in China brings up children with the aim to guard against troubles in their late years, but many older people with sons also suffer from various forms of elder abuse, and often choose to submit to humiliation when facing abuse from family members. Data: The Survey on the living conditions of the elderly in urban and rural China (SSAPUR) , four waves: 2015, 2016, 2017 and 2018 followed samples(N=224360)

Methods: The hierarchical Logit model was used to analyze the influence of social participation on elder abuse in China, and the risk of the elderly's choice to submit to humiliation. Results and

conclusion: The results showed that the annual incidence of elderly abuse (include physical abuse, emotional abuse, financial abuse, and neglect of care) among the elderly in China was 5.36%, and 35.77% of them chose to submit to humiliation. The more the elder participate in society involvement outside the home, the less likely they are to be abused from family members, the less likely they submit to humiliation. The more sons, the higher the risk of elder abuse. Therefore , the relevant government and the grass-roots social organizations should strengthen the construction of social organizations for the elderly.

THE ASSOCIATION OF SUBJECTIVE AGE AND FINANCIAL EXPLOITATION RISK: SOCIAL SUPPORT AS A MODERATOR

Gali Weissberger[1], and Yoav Bergman[2], *1. Bar Ilan University, Ramat Gan, HaMerkaz, Israel, 2. Ashkelon Academic College, Ashkelon, HaDarom, Israel*

Financial exploitation of older adults bears detrimental physical and psychological consequences. However, little is known regarding factors which may contribute to financial exploitation vulnerability (FEV) among this age-group. In line with the growing awareness of the importance of subjective perceptions of the aging process for older adults’ functioning and well-being, the current work examined the connection between subjective age (i.e., feeling younger/older than one’s chronological age) and FEV, and the possible moderating role of social support on this connection. Data were collected from a convenience sample of 137 Israeli older adults (age range 60-89, M=69.90, SD=6.85, 40.1% male), who completed scales assessing FEV, subjective age, and social support, as well as relevant socio-demographic information. Associations were examined using a hierarchical linear regression model which adjusted for age, sex, education, marital status, and self-rated economic and health status. The main effect of subjective age was not significant (B=1.24, p=0.14), while the main effect of social support was found (B=-1.30, p=.03) indicating that low levels of support were associated with increased FEV, a finding consistent with the literature. The interaction of social support × subjective age was significant (B= -1.17, p= .025), accounting for an additional 4.0% of variance. Older subjective age was associated with increased financial exploitation vulnerability when social support was low, but not when social support was high. Results are interpreted with regard to Socio-Emotional Selectivity Theory and provide initial information pertaining to the relevance of subjective age perceptions to FEV in older adults.

SESSION 6490 (POSTER)

ENVIRONMENT AND AGING

COGNITIVE EFFECTS OF PM2.5 EXPOSURE FROM MID-LIFE TO EARLY OLD AGE

Carol Franz[1], Xin Tu[1], Yongmei Qin[1], Jeremy Elman[1], Christine Fennema-Notestine[2], Jaden DeAnda[3], Tsung-Chin Wu[4], and William Kremen[1], *1. University of California San Diego, La Jolla, California, United States, 2. University of California San Diego, San Diego, California, United States, 3. San Diego State University, La Jolla, California, United States, 4. University of California, La Jolla, California, United States*

Air pollution exposure is a notable public health hazard with adverse effects on multiple health outcomes as well as with increased risk of developing cognitive impairment, Alzheimer’s disease, and related dementias. Few studies examine associations between air pollution exposure in midlife or the transition from midlife to old age. We examined associations between exposure in midlife and cognitive functioning in early old age in ~800 men from the Vietnam Era Twin Study of Aging. Measures included PM2.5 and NO2 exposure in the three years prior to the time 1 (mean age 56; range 51-61) assessment, and cognitive performance in 5 domains at time 1 and time 2 (mean age 68; range 65-72). Analyses adjusted for multiple health and lifestyle covariates. Cognitive performance in all domains was worse at age 68 than at age 56. There was a main effect of midlife PM2.5 on verbal fluency; greater PM2.5 exposure was associated with worse fluency. This association was at a trend level for NO2. In addition, we found significant PM2.5-by-APOE genotype interactions. Increased exposure to PM2.5 in midlife was related to lower executive function and working memory performance in APOE-ε4 carriers, but not non-carriers. Both early executive deficits and APOE-ε4 status have been associated with increased risk for progression to mild cognitive impairment and Alzheimer’s disease. The present results indicate that midlife PM2.5 exposure in men is an additional factor contributing to poorer frontal-executive function, and that APOEε4 carriers are more susceptible to the deleterious effects of PM2.5.

FRAMING CLIMATE-CHANGE INFORMATION TO PROMOTE ACTION IN OLDER ADULTS

Philip Lemaster, *Concordia College, Moorhead, Minnesota, United States*

Climate change poses an existential global risk, and mitigation requires population-level behavioral change. Due to their shortened time horizon, older adults may not perceive climate change as a personal risk within their lifetime and may be less likely to take action to combat climate change. Socioemotional selectivity theory (SST; Carstensen, 2006) posits that, as people age and perceive a shorter time horizon ahead, they become more focused on maintaining emotional wellbeing. This study, rooted in SST, manipulated the emotional framing of climate-change information in a sample of U.S. older adults. Participants were given EPA climate-change information localized to their state of residence and were instructed that, by taking action, the impact of climate change could be reduced (instilling hope) or that, by not taking action, the impact of climate change could be exacerbated (instilling fear). Afterward, they completed measures assessing their willingness to engage in pro-environmental behaviors and support of macro-level legislation to combat climate change. Compared to older adults who received the "hope" frame, older adults who received the "fear" frame reported greater willingness to engage in pro-environmental behaviors ($p = 0.007$) and greater support of legislation to combat climate change ($p = 0.038$), perhaps an effect of older adults' motivation to reduce the negative affective state induced by the "fear" frame. Implications of these results for catalyzing older adults toward climate action are discussed.

ROLE OF HOME ENVIRONMENT IN LTSS USE AMONG OLDER ADULTS IN THE US

Shalini Sahoo, *University of Maryland, Baltimore, Hanover, Maryland, United States*

Older adults have shown increasing preference towards having help and health care in the comfort of their own homes rather than in an institutional setting. Research suggests that about 1 in 5 older adults with limitations in activities of daily living report needing more help than they receive. There is insufficient research examining how home inaccessibility and disorder relates to LTSS use for community-dwelling older adults in the U.S. This study addresses a gap in the literature by directly examining the relationship between home environment quality and LTSS use for a national sample of older adults. Data was analyzed from round eight (2018) of the National Health and Aging Trends Study (NHATS), an epidemiological panel study of nationally representative Medicare beneficiaries ages 65 and older living in the communities ($n = 4,806$). The final analytic sample included respondents with valid data on all variables ($n = 4,265$). Community dwelling adults with greater home accessibility had lower odds of having two or more LTSS caregivers, compared to the counterpart with lower home accessibility (OR = 0.246, SE = 0.094, $p < 0.01$). However, poor housing conditions had lower odds of having two or more LTSS caregivers (OR = 0.333, SE = 0.156, $p < 0.05$). Community-dwelling older adults who have accessible and organized homes are more likely to be independent and are less likely to depend on LTSS caregiving. Policies to improve home environment quality could benefit both older adults and those who care for them.

COMMUNITY TYPOLOGY IN OLDER KOREAN AMERICANS: IMPLICATIONS FOR MENTAL/COGNITIVE HEALTH

Nan Sook Park[1], Yuri Jang[2], Soondool Chung[3], and David Chiriboga[1], *1. University of South Florida, Tampa, Florida, United States, 2. University of Southern California, Los Angeles, California, United States, 3. Ewha Womans University, Seoul, Seoul-t'ukpyolsi, Republic of Korea*

The purposes of this study were to: (1) identify community typology in older Korean Americans; and (2) examine the associations of typology with loneliness, mental distress, and cognitive health. Guided by social capital conceptualization, we hypothesized that distinct community groups would be identified and that they would be differentially associated with sociodemographic, immigration-related, health, and social characteristics and mental/cognitive health. Data were drawn from a survey with older Korean Americans aged 60 and older, collected during 2017–2018 in diverse locations ($n=2,138$). To identify community typology, a series of latent profile analysis (LPA) were conducted using 15 community-related variables in three domains (neighborhood characteristics, social cohesion, ethnic attachment). After examining characteristics of the identified groups in relations with study variables, hierarchical multiple regression models of loneliness, mental distress, and self-rated cognitive health were estimated. Based on several model evaluation criteria, LPA model with five community groups was identified as best-fit (BIC=64,619, Entropy=.94). The five groups were identified as “a. high safety/cohesion/ethnic attachment” (10%), “b. high safety/low cohesion/ethnic attachment” (10%), “c. moderate neighborhood/low ethnic attachment/cohesion” (38%), “d. moderate neighborhood/high cohesion/ethnic attachment” (31%), and “e. low safety/moderate cohesion/ethnic attachment” (11%). In reference to the group with high on all three domains (a), group with low ethnic attachment/cohesion in moderate neighborhood (c) and group in unsafe environment with moderate cohesion/ethnic attachment (e) were consistently associated with elevated loneliness/mental distress and poor rating of cognitive health. The results suggest the need to understand profiles of community characteristics and their relationships with health/well-being among older immigrants.

EXAMINING THE ROLE OF OBJECTIVE AND SUBJECTIVE NEIGHBORHOOD CHARACTERISTICS ON HEALTH AND WELL-BEING IN MID-LIFE

Omar Staben[1], Frank Infurna[2], and Kevin Grimm[2], *1. RAND Corporation, Tempe, Arizona, United States, 2. Arizona State University, Phoenix, Arizona, United States*

There is a long-standing literature that has documented how one’s neighborhood context has the potential to shape mental and physical health across the adult lifespan. An abundance of research documents how various components of the neighborhood, such as disorder, cohesion, in addition to pollution and sidewalk quality are linked to short- and long-term mental and physical health outcomes across adulthood. One key component that has been less studied within this literature is the extent to which objective or subjective neighborhood indicators exert a more potent impact on mental and physical health. Up to this point, much of the research has focused on subjective indicators of neighborhood context. This study explores whether and to what extent objective neighborhood factors of income inequality, residential stability, and greenness and subjective neighborhood factors of social ties, collective efficacy, and neighborhood disorder are predictive of mental and physical health in midlife. We use data from a sample of participants in midlife (n=800, aged 40-65) to analyze our research questions. Structural equation models found that both subjective and objective indicators of neighborhood were related to health and well-being when considered separately. When considered simultaneously, subjective neighborhood indicators (sense of community) mediated the association between objective constructs and health. Our findings demonstrate the independent associations between objective and subjective neighborhood context and highlight the particularly strong association between subjective context and health and well-being. Our discussion elaborates on how our findings can inform interventions and sparks future research aimed at exploring potential mechanisms underlying the associations found.

IMPACT OF NEIGHBORHOOD GREEN INFRASTRUCTURE ON ACCESS TO SOCIAL CAPITAL ACROSS THE LIFE COURSE

Noah Webster[1], Natalie Sampson[2], and Joan Nassauer[1], *1. University of Michigan, Ann Arbor, Michigan, United States, 2. University of Michigan-Dearborn, Dearborn, Michigan, United States*

While the impact of neighborhood characteristics on access to social capital is well established, less is known about how neighborhood landscape design interventions play a role in shaping access to this resource and how this varies across the life course. In this study we examined the association between age and perceived impact of recently installed neighborhood block-scale green infrastructure (GI) on frequency of social interactions with neighbors. We also examined age variation in how alternative GI designs were perceived (e.g., how well cared for), and how these perceptions were associated with the anticipated impact on frequency of neighbor interactions. Data are from the Neighborhood, environment, and water research collaborations for green infrastructure (NEW-GI) project based in Detroit, MI. Four neighborhood GI interventions were installed in two Detroit neighborhoods in 2016. Surveys were conducted with residents living around the interventions in 2017-18 (n=171), and in nearby neighborhoods (n=145). Age was significantly associated with perceived impact of the landscape interventions on frequency of social interactions with neighbors. Specifically, older adults were significantly more likely to report that the landscape interventions that they were most familiar with resulted in increased frequency of interactions with their neighbors. Further, design alternatives perceived as more well cared for were anticipated to result in greater increases in the frequency of interactions with neighbors among older compared to younger adults. Results suggest neighborhood landscape interventions can improve access to social capital particularly among older adults, and perceptions of landscape care play a role in this process.

SESSION 6500 (POSTER)

ENVIRONMENT, DISASTERS, AND EMERGENCY PREPAREDNESS

THE AGE-FRIENDLY COMMUNITY ENVIRONMENT FACTORS CONTRIBUTING TO LIFE SATISFACTION OF OLDER ADULTS LIVING ALONE

Mi Sun Choi[1], and Hyunmin Lee[2], *1. Silla University, Busan, Pusan-jikhalsi, Republic of Korea, 2. Seoul, Seoul, Seoul-t'ukpyolsi, Republic of Korea*

Age-friendliness studies in Korea have investigated a few subsets of the local community environments for older adults' well-being. Little is known about comprehensively understanding which aspects in community contexts can help older individuals living alone improve their life satisfaction. To address the knowledge gaps, this study utilized the raw data from the 2020 National Survey of Older Koreans, and responses of 3,112 older adult single-person households were investigated. From an ecological perspective, hierarchical regression analysis was performed by distinguishing the community environments into three categories of the World Health Organization's age-friendly environments: physical, social, and service environments. The results showed that the perception of the physical environment (housing, living facilities, and space) was positively associated with life satisfaction. Second, the social environment (social involvement, neighbor interaction, respect for older individuals, and political activity) was positively related to life satisfaction. Third, perceived service environment (difficulty in utilizing service) was negatively related to life satisfaction. Based on the findings, we proposed political and practical recommendations. Specifically, as a physical environment aspect, effective budget allocation and policy attention should be required for the autonomy and independence of older adults living alone in their daily lives by ensuring that housing and circumstances are suitable for aging-in-place. As a societal component, initiatives must be established to promote participation in decision-making processes that result in a more favorable social perception through social inclusion. Finally, for the service environment, we must advocate for increased accessibility to community supportive services (mobility, health care, food delivery, communication, and information).

COMMUNAL SUPPORT PREDICTS BETTER MENTAL HEALTH: KNOWLEDGE TRANSLATION AMONG OLDER ADULTS DURING COVID-19

Eireann O'Dea[1], Daniel Rong Yao Gan[2], Habib Chaudhury[2], Ziying Zhang[2], Andrew Wister[2], Lisa Cohen Quay[3], Shelley Jorde[4], and Claire Wang[5], *1. Simon Fraser University, North Vancouver, British Columbia, Canada, 2. Simon Fraser University, Vancouver, British Columbia, Canada, 3. Jewish Community Centre of Greater Vancouver, Vancouver, British Columbia, Canada, 4. South Vancouver Seniors Hub, Vancouver, British Columbia, Canada, 5. Johns Hopkins University , Baltimore City, Maryland, United States*

The well-being of older adults has been linked to the quality of their neighbourhood environment. Given that COVID-19 affected poorer neighbourhoods disproportionately, we partnered with community organizations to identify meso-level psychosocial factors that may improve loneliness, depressive mood, and cognitive function. Five variables were identified through focus groups with older adults and community organizations. These variables were drawn from validated scales, including communal provisions, neighbourhood friendship, self-expression, social experiences, and time outdoors. This paper presents preliminary findings from surveys administered to 151 community-dwelling older adults across British Columbia and interviews in four neighbourhoods.Purposeful and snowball sampling were used to recruit older adults (age 55+) from community centres and neighbourhood houses. Online surveys measured the five meso-level psychosocial exposure variables. Outcome variables included an index of loneliness, depressive mood, self-rated memory, semantic fluency and delayed recall. Data was geocoded and aggregated by Forward Sortation Area. Regression and cross-level mediation analysis were conducted. Four neighbourhoods were selected from a 2x2 matrix of high and low neighbourhood deprivation (CANUE, 2016). Mental health was associated with better social experiences (B=.26, p=.003). Time outdoors (B=.35, p=.047) was associated with better delayed recall. Mental health was better in poorer neighbourhoods (B=.20, p=.015). This was partially mediated by communal provisions (B=.19, p=.032). Social experiences (B=.23, p=.009) fully mediated these effects on mental health. Participants described being of local community services and took on opportunities to volunteer. Social experiences and neighbourhood resources may help support mental health and well-being among older adults during the pandemic and beyond.

AGING, DISPLACEMENT, AND COPING WITH COVID-19 IN PRECARIOUS SPACES IN NORTHEAST NIGERIA

Adewale Adeyombo[1], and Abiodun Oyebode[2], *1. Bowen University, Offa, Kwara, Nigeria, 2. Federal Polytechnic Offa, Offa, Kwara, Nigeria*

Nigeria is witnessing internal displacements due to terrorism and kidnapping across many communities with more of these evitable challenges in the North Eastern region. These challenges are impacting on older people amongst other social categories that have been displaced, killed or kidnapped across different communities. The outbreak of covid-19 and the poor social support for older persons and other vulnerable groups in Nigeria imply that survivors in such precarious spaces are likely to face challenges with implications on their well-being and meanings attached to life. This paper explores ageing in precarious spaces that have been ravaged by terrorism and banditry and the outbreak of covid-19. The narratives of the 15 older persons aged 57 to 82 years living in Internally Displaced Camps revealed some dimensions of hopelessness, despair and the acceptance of present challenges as fate and structural defects. Awareness and adherence to covid-19 protocol was poor. Moving away from communities of residence represent diverse forms of loss that transcends material things. Sharing of experiences, prayers and relief materials from non-governmental agencies were considered as instrumental in coping with their daily challenges. The hope of returning to their communities of residence was doubted and considered risky. The belief that their seeds would have a better future was expressed by all the participants, with the females affirming such expectation than the men. Integrating displaced older persons would require more than existing efforts being taken by Nigerian government across levels.

GEOGRAPHICAL VARIATIONS IN THE PRODUCTIVE ENGAGEMENT OF OLDER ADULTS

Peter Sun, *Washington University in St. Louis, Clayton, Missouri, United States*

While having opportunities to be productively engaged has implications for long, healthy lives, little is known about the geographical distribution of older adults engaged in productive activities. Using the nationally representative Health and Retirement Study, a sample of community-dwelling older adults age 65 and above in the year 2018 (n = 8,728) was used to compare working, volunteering, and caregiving rates between rural and urban areas and Census regions and divisions. Urban and rural rates of individuals who were working were significantly different ($p < .05$) in the Midwest region and the East North Central and Pacific divisions (e.g., 20.9% in rural Midwest vs. 14.8% in urban Midwest). Urban and rural caregiving rates were significantly different in the East South Central division (35.1% rural vs. 26.2% urban caregivers). Urban and rural rates of individuals who engaged in one or more productive activities (working, volunteering, and caregiving) were significantly different in the West North Central (64.9% rural vs. 56.6% urban) and Middle Atlantic (47.6% rural vs. 58.6% urban) divisions. Urban and rural volunteering rates were significantly different in the West region (37.0% rural vs. 30.2% urban). These findings suggest that older adults' participation in working, caregiving, and volunteering roles may depend on where they live, and older adults are not a homogeneous group as commonly misunderstood. Future studies should explore the factors that influence these patterns of engagement.

THE IMPACTS OF WILDFIRES ON OLDER ADULTS: A SCOPING REVIEW

Carson De Fries, Colleen Melton, Rebecca Smith, and Lisa Reyes Mason, *University of Denver, Denver, Colorado, United States*

Climate change is leading to worsening disasters that disproportionately impact certain populations, including older adults (Benevolenza & DeRigne, 2019). Older adults are more likely to encounter life-threatening challenges during disaster evacuation, less likely to receive disaster warnings, and more likely to experience greater financial losses following disasters (Acierno et al., 2006). While research has begun to measure these disparities, there is a gap in examining the effects of wildfire-specific disasters, which are increasing in intensity and severity (Hoover & Hanson, 2020). To examine this gap, scoping review methodology was used to analyze peer-reviewed studies of how wildfires affect older adults by looking at impacts and the disaster recovery cycle (i.e., preparedness, response, recovery, and mitigation). Authors screened 263 titles and abstracts, and 138 were reviewed in full. Eighty-one studies were included for data extraction and analysis. Preliminary findings illustrate that most literature focuses on the health impacts that older adults endure during and following wildfires, with a specific focus on the short and long-term effects of smoke and poor air quality on respiratory health. While previous literature has cited a need for community response strategies that incorporate the needs of older adults, few findings addressed firsthand experiences of older adults during a wildfire event. However, one unique finding was the incorporation of Aboriginal and Indigenous Elders' knowledge into fire management strategies. While recommendations for incorporating the needs of older adults into policy planning were briefly mentioned, most articles focused on problem scope rather than evaluating potential solutions.

HOUSING CHARACTERISTICS, NEIGHBORHOOD ENVIRONMENTS, AND SELF-RATED MENTAL HEALTH AMONG OLDER CANADIANS

Ethan Siu Leung Cheung[1], and Ada Mui[2], *1. Columbia University, New York, New York, United States, 2. COLUMBIA UNIVERSITY, New York City, New York, United States*

Previous studies have established a clear association between the surrounding environment and mental health. Whereas most literature has focused on neighborhood environment, very few studies have examined the role of housing characteristics in self-rated mental health (SRMH). Using data from the 2018 Canadian Housing Survey, this study investigated the relationships between housing characteristics, neighborhood environment, and SRMH among older Canadians and whether the relationships varied by education and gender. Using a sample of 21,725 Canadians, SRMH was measured by older adults' self-evaluation of mental health on a 5-point scale. We categorized education into three groups: high school or less, some college, and university or beyond. Hierarchical linear regressions showed that men and women with high school education and women with some college educations were more likely to report worse SRMH when living in low-income housing. Reporting a home maintenance need was a unique risk factor of SRMH for men with a university education, whereas living in uninhabitable conditions uniquely predicted better SRMH for men with some college education. Regarding neighborhood environment, safer community was a protective factor of SRMH for women with university education only. Sense of belonging was positively associated with SRMH for all subgroups, except for men with a university education. Expressing a need for community service was significantly associated with lower SRMH for women who completed a high school education or some college. Findings of this study shed light on the diverse need for environmental improvement and maintenance programs to improve SRMH among older Canadians.

FACTORS IMPACTING EMERGENCY PREPAREDNESS AMONG COMMUNITY-DWELLING OLDER ADULTS

Alisha Thompson, Kristina Little, and Youn Kyoung (Lily) Kim, *Louisiana State University, Baton Rouge, Louisiana, United States*

Natural and manmade emergencies have become more frequent over the past 20 years and will continue to pose serious risks to public health and safety. Older adults are more adversely affected by—and less prepared for—emergencies than younger adults. However, little is known about the risk factors impeding emergency preparedness among older adults. This study uses the ecological systems approach to explore factors associated with emergency preparedness and how those factors influence adults 60 and older. The study analyzed cross-sectional data taken from 690 community-dwelling older adults who participated in Wave 5 of the National Poll on Healthy Aging. The sample was broken down into the following two groups for comparison: individuals aged 60–69 (n = 383) and individuals 70 or above (n = 307). The self-reported measures of sociodemographic characteristics, physical health, mental health, and previous experience of a disaster were utilized via regression analysis to predict emergency preparedness. Emergency preparedness was assessed using X dichotomous questions (60-69: M = X; 70+: M = X). The results revealed that living alone and having a Hispanic background were negatively associated with emergency preparedness among those aged 60–69, while mental health status was positively associated with emergency preparedness among those aged 70+. Previous experience of a disaster positively impacted emergency preparedness among the sample. Implications for policy and practice focus on shifting the perspective of the disproportional risks for older adults around emergencies to one that values and supports older adults' strengths and insights.

RECENT ADVERSITY AND LIFE SATISFACTION AMONG CHINESE OLDER ADULTS: ROLE OF GENDER AND NEIGHBORHOOD COHESION

Yi Wang[1], Ying Ma[2], Man Guo[1], and Li Wang[3], *1. University of Iowa, Iowa City, Iowa, United States, 2. University of Houston, Houston, Texas, United States, 3. Anhui Medical University, Hefei, Anhui, China (People's Republic)*

A growing body of literature suggests that recent adversity impedes psychological wellbeing. Little is known about whether living in a cohesive neighborhood could buffer the negative consequences of adverse experience and whether such associations vary by gender. This study aims to examine the association of recent adverse events and perceived life satisfaction among Chinese older adults, and to explore the potential moderating role of gender and neighborhood cohesion. Data were from a cross-sectional study conducted with community-dwelling older adults aged 60 years and above in Anhui Province, China in 2014 (N=1,960). Recent adversity was measured by six events in the past two years (health decline, economic difficulty, loss of intimate people, loss of an important item, major life event, conflict with family or close friends/neighbors). Multilevel ordered logit regression with interaction term of adversity and neighborhood cohesion was performed. Models were further conducted on stratified samples to compare gender differences. Individuals experiencing any recent adverse event are 84% less likely (p=.008) to report a higher level of life satisfaction. Living in neighborhoods with better cohesion increased the likelihood of reporting better life satisfaction by 6% (p=.031). Modeling on the stratified samples showed that the above-mentioned significant relationships hold for male sample only. Recent adversity may negatively affect life satisfaction among Chinese older adults. Living in neighborhood with higher levels of cohesion could help buffer such negative influences, particularly for older men. Findings highlight the critical role of neighborhoods in combating the negative psychological consequences of adversity among Chinese older adults.

ADAPTING STAKEHOLDER WALKABILITY/ WHEELABILITY AUDIT TOOL IN NEIGHBORHOOD FOR SENSORY AND COGNITIVE DISABILITIES

Kishore Seetharaman[1], Atiya Mahmood[1], Bridget Disini[1], Hailey-Thomas Jenkins[1], Mike Prescott[1], Farinaz Rikhtehgaran[1], and W Ben Mortensen[2], *1. Simon Fraser University, Vancouver, British Columbia, Canada, 2. University of British Columbia, Vancouver, British Columbia, Canada*

Neighbourhood accessibility influences health, social inclusion, and overall wellbeing of older adults. It is important to assess neighbourhood accessibility in relation to the diverse needs and challenges brought on by the intersection of aging and disability, particularly sensory and cognitive disabilities. Given the paucity of neighbourhood audit tools tailored for this population, The user-led Stakeholders' Walkability/ Wheelability Audit in Neighbourhoods (SWAN) tool was originally created for people with mobility disabilities and is now being adapted for seniors with sensory and cognitive disabilities to evaluate functionality, safety, appearance, supportive features, and social aspects in their neighbourhoods. In this paper, we present highlights and key takeaways from the process of adapting the SWAN tool for three user groups: people living with 1) Blindness or low vision, 2) Deafness and hearing loss, and 3) Dementia. Key steps in the iterative tool adaptation process include 1) identifying access needs/challenges for the three user groups based on a literature review, 2) online consultation with stakeholders with lived and/or professional experience (N = 4) to prioritize key access needs/ challenges that will be captured through the SWAN tool and review draft versions of the tool, and 3) in-person pilot testing of tools with persons with lived experience (N = 2) in two urban/suburban neighbourhoods in British Columbia, Canada. Reflections of team members and input from stakeholders and pilot participants revealed issues that were addressed in tool development, namely 1) length of audit and participant fatigue, 2) legibility of tool, and 3) tailoring audit to participants' context and needs.

SESSION 6510 (POSTER)

EPIDEMIOLOGY, BIOLOGY, CHRONIC DISEASES, AND FUNCTION I

ANNUALIZED AND CUMULATIVE MEASURES OF ANTICHOLINERGIC EXPOSURE FOR RESEARCH AND CLINICAL APPLICATIONS

Hussein Khalil[1], Eva Stachler[1], Khalid Alamer[1], Jared Ludlow[2], and Noll Campbell[3], *1. Purdue University, West Lafayette, Indiana, United States, 2. Indiana University Purdue University Indianapolis, Indianapolis, Indiana, United States, 3. Purdue University, Indianapolis, Indiana, United States*

Medications with anticholinergic properties are commonly used by older adults despite being associated with dementia.The anticholinergic total standardized daily dose (TSDD) is a continuous measure of exposure that has been associated with an increased risk of dementia at values >1095 over ten years in epidemiologic studies. We sought to determine a cumulative (cTSDD) and annualized (aTSDD) in a sample of community-dwelling older adults enrolled in the ongoing Reducing Risk of Dementia Through Deprescribing (R2D2) trial (NCT04270474). Participants were 65 years or older without dementia, attended at least one primary care visit within 12 months prior to enrollment, and were current users of strong anticholinergics according to the 2012 Anticholinergic Cognitive Burden Scale. Prescribed and over-the-counter medication details were collected during the baseline visit through self-report and included strength, frequency, units/dose and duration. The aTSDD was calculated for each participant assuming continuous use patterns throughout the year. The cTSDD was calculated by summing the aTSDD across the number of years since initiation. Of 66 participants, the median cTSDD was 2425 (IQR 5131), and 48 (72%) exceeded the threshold of dementia risk (>1095). Additionally, the aTSDD had a median of 730 (IQR 547), with 60 (90%) exceeding the threshold of dementia risk (109.5, one-tenth of the ten-year risk) while 11 (17%) exceeded dementia risk threshold of 1095 considering 1 year of exposure. Both measures identified the majority of anticholinergic users exceeding dementia risk thresholds despite some disagreement between the two approaches. However, both methods have potential for research and clinical applications.

DIURNAL CORTISOL SECRETION AND SELF-REPORTED AND CAREGIVER-REPORTED QUALITY OF LIFE IN PEOPLE LIVING WITH DEMENTIA

Fanghong Dong, Subhash Aryal, and Nancy Hodgson, *University of Pennsylvania, Philadelphia, Pennsylvania, United States*

IntroductionPeople living with dementia (PLwD) report lower quality of life (QoL), compared to healthy older adults. The poorer QoL is not fully accounted for by the severity of dementia. Dementia is associated with prominent neuroendocrine changes, however, there is a lack of research examining whether biological factors are related to QoL in PLwD. This study examined relationships between cortisol, symptom severity, and QoL in PLwD.

Methods: A total of 143 participants aged 55-94 years (65.7% women) in the Healthy Patterns Study (NCT03682185) provided three saliva samples at wake-up (AM1), 30 minutes (AM2) after waking, and bedtime (PM) on two consecutive days. We derived cortisol awakening response (CAR), wake to bedtime cortisol slope, and diurnal mean cortisol secretion. Sociodemographic and severity of dementia were assessed by interviews and questionnaires. Self-reported and caregiver-reported QoL was measured using the Quality of Life in Alzheimer's Disease (QoL-AD).

Results: Poorer QoL was associated with more severe dementia rating. Flattened cortisol slope was significantly correlated with overall poorer self-reported QoL ($\beta = 0.43$, p=0.017), but not caregiver-reported QoL (p=0.12), after controlling for severity of dementia and demographic variables. We did not find a significant relationship between CAR and diurnal mean cortisol with QoL.

Conclusions: This study provides novel evidence linking neuroendocrine mechanisms to QoL in PLwD. The findings indicate that dysregulation of the hypothalamic-pituitary-adrenal axis is linked to poorer QoL, independently of the severity of dementia. Biopsychosocial approaches to QoL for

PLwD may lead to a greater understanding of the underlying mechanisms.

HEALTH-RELATED QUALITY OF LIFE OF OLDER PEOPLE WITH DIABETES DEPENDING ON WHETHER THEY LIVE IN FAMILIES OR NOT

Gi Won Choi, and Sun Ju Chang, *Seoul National University, Seoul, Seoul-t'ukpyolsi, Republic of Korea*

Diabetes requires self-management, such as the use of insulin, oral antidiabetic drugs, diet, and exercise, for maintaining blood glucose. To promote self-management of older people with diabetes, family support is considered an important factor. However, older people living alone lack family support and have a lower health-related quality of life (HRQOL) than those living in families. The purpose of this study was to assess HRQOL and the factors that affect it between older people with diabetes living alone and those living in families. We performed secondary data analysis using the data of Korea National Health and Nutrition Examination Survey (KNHANES) 2017–2019. In total, 973 people with diabetes aged 65 years or older answered all questions about HRQOL. Complex sample analysis was performed. Each dimension of HRQOL was significantly lower in people living alone than those living in families. Restricted activity, bedridden, number of comorbidities, and perceived health status significantly predicted HRQOL in patients living alone. Health insurance, age, economic activity, unmet medical service needs, restricted activity, bedridden, number of comorbidities, perceived health status, and suicidal ideation significantly predicted HRQOL in patients living in families. This study indicated how differences in HRQOL exist between older patients with diabetes living alone and those living in families. This data will be useful in developing educational programs in the future, and it will be helpful when dealing with people living alone who have diabetes.

ASSOCIATION BETWEEN DUAL TASK FUNCTION AND NEUROPSYCHOLOGICAL TESTING IN OLDER ADULTS WITH COGNITIVE IMPAIRMENT

Kelsi Petrillo, and Nima Toosizadeh, *University of Arizona, Tucson, Arizona, United States*

Cognitive impairment is an increasingly relevant health concern, as demonstrated through data estimates that by 2040 the number of older adults with dementia will surpass nine million in the United States. Despite this high prevalence, more than half of patients with dementia never receive an evaluation. This indicates that a quick and objective routine test for screening cognitive decline in older adults is needed. Poor dual-task gait performance has been associated with decreased executive and neuropsychological function. However, gait tests are not always viable for clinics or older patients. The aim of this study was to assess the relationship between a novel upper-extremity function (UEF) dual-task performance and neuropsychological test results in older adults. We recruited older adults at three stages: cognitively normal (n=33), mild cognitively impaired (n=34), and Alzheimer's disease (n=22). For UEF tasks, participants performed a consistent elbow flexion, while counting backwards in by threes. Wearable motion sensors were attached to forearm and upper-arm to measure accuracy and speed of elbow flexion kinematics and the UEF cognitive score. The results demonstrate a strong correlation between UEF cognitive score and MMSE, Mini-Cog, Category fluency, Benson complex figure copy, Trail making test, and MOCA (r values between -0.2355 and -0.6037 and p< 0.0288). UEF dual-task was associated with executive function, orientation, repetition, abstraction, verbal recall, attention and calculation, language and visual construction. The results from this study convey a promising future for the use of dual task UEF as a safe and convenient cognitive impairment screening.

ASSOCIATION BETWEEN UPPER EXTREMITY FUNCTION AND ADVERSE OUTCOMES IN OLDER ADULTS WITH COPD

Mehran Asghari[1], Martha Ruiz[2], Miguel Peña[3], Haley Johnson[2], Sairam Parthasarathy[4], and Nima Toosizadeh[2], *1. University of arizona, Tucson, Arizona, United States, 2. University of Arizona, Tucson, Arizona, United States, 3. university of arizona, Tucson, Arizona, United States, 4. University of Arizona, Tuscon, Arizona, United States*

Chronic obstructive pulmonary disease (COPD) is the third leading cause of death in the United States. COPD adverse outcomes are required to identify vulnerable patients and enhance bronchodilator therapies. Although the 6-minute walk distance test is commonly used to assess functional capacity in COPD and predict adverse outcomes, it is not feasible for older adults with mobility impairments. Previously, we demonstrated that a simple upper-extremity function (UEF) test could identify frailty and cognitive impairment. We developed two indexes to predict the physical frailty (20-s rapid arm test) and cognitive impairment (60-s normal speed dual-task arm test and counting) among older adults. UEF tests were performed by 76 eligible older adults (age=67.421±6.363). All participants were followed up for one month to record the adverse outcomes. The measured health outcomes included: in-hospital outcomes (death, complication, and excessive length of stay), and 30-day outcomes (30-day death or readmission). Based on the results, 54% and 30% of patients had in-hospital and longitudinal adverse outcomes, respectively. The frailty index was significantly associated with all measured outcomes (p< 0.018). However, cognitive score showed significant association only with 30-day longitudinal outcomes (p< 0.021), but not for in-hospital outcomes (p>0.05). Among all the associations the highest effect size was observed between frailty score and longitudinal outcomes (p< 0.007; effect size=0.94). The results of this study suggest that a 20-s UEF test is a practical quick measure for predicting adverse in-hospital and 30-day outcomes among COPD patients.

ASSOCIATION BETWEEN VISUOSPATIAL ABILITY, GAIT, AND FUNCTION IN OLDER SURVIVORS OF BREAST CANCER

Jennifer Blackwood[1], and Abigail Simone[2], *1. University of Michigan-Flint, Flint, Michigan, United States, 2. University of Michigan--Flint, Flint, Michigan, United States*

Research has highlighted the relationship between impaired cognitive function and physical mobility measures in older adults. This relationship may also exist in older survivors of breast cancer, however, specific cognitive domains like executive function or visuospatial ability may influence physical mobility. The purpose of this study is to describe associations between cognitive function and mobility in a group of community-dwelling older females with a history of breast cancer. Cross-sectional data of performance on cognitive and physical mobility measures from 38 older adults with a history of breast cancer were analyzed. Pearson's correlation coefficient was used to examine relationships between measures. Significant inverse relationships were found between TMT-A and usual gait speed (r = -.662, p<.001), fast gait speed (r = -.409, p = .012), and dual-task gait speed (r = -.631, p<.001), suggesting that as visuospatial ability became more impaired, gait speed decreased. Significant relationships were found between TMT-A and performance on the TUG (r = .664, p<.001), TUG-cognitive (r = .635, p<.001), and TUG-manual (r = .653, p<.001). Results indicate that visuospatial ability, as measured with the TMT-A, is associated with physical mobility measures in older survivors of breast cancer. While previous research has reported impairments in executive function in this population, impaired visuospatial ability may also play a role, suggesting that clinicians should include a visuospatial task when working on improving gait in older survivors of breast cancer.

UTILITY OF SIX-MONTH PROGNOSIS TO PREDICT SURVIVAL AMONG NEWLY ADMITTED NURSING HOME RESIDENTS WITH CANCER

Long Vu[1], David Warner[2], Nicholas Schiltz[1], Johnie Rose[3], Jennifer Cullen[3], Cynthia Owusu[3], Martha Sajatovic[3], and Sara Douglas[1], *1. Case Western Reserve University, Cleveland, Ohio, United States, 2. University of Alabama at Birmingham, Birmingham, Alabama, United States, 3. Case Western Reserve University School of Medicine, Cleveland, Ohio, United States*

A prognosis of less than 6 months life expectancy has potential to be useful in planning and evaluating end-of-life care; however, its agreement with actual survival data has not been assessed. Here, we measured the sensitivity, specificity, positive predictive value (PPV), and negative predictive value (NPV) of the nursing home (NH) Minimum Data Set (MDS) 6-month prognosis indicator among individuals diagnosed with incident breast (female), colorectal, lung, pancreatic, or prostate cancer during the years 2004-2017 and admitted to a NH between 2012-2017 (n=254,183). Cancer patients were identified from the linked Surveillance, Epidemiology, and End Results (SEER) Registry. The median age was 80 years, 52.6% were women, and 15.15% were non-White. Only 7,541 (2.97%) of patients were deemed by a physician to have a life expectancy of less than 6 months as recorded in their first comprehensive MDS assessment; of those, 83.0% died within 6 months, and 12.3% died after 6 months. Sensitivity and specificity were 7.8% and 99.3%, respectively, for the prognosis indicator predicting mortality within 6 months; PPV was 83.0% and NPV was 69.9%. In conclusion, although very few patients had received a physician designation of their 6-month prognosis, a high percentage actually died within 6 months. Conversely, among those without a 6-month prognosis, nearly one-third died within 6 months. A terminal diagnosis appears reasonably predictive of death — when made. However, its low sensitivity demonstrates that a vast majority of terminal patients are not properly captured, calling into question its greater application.

GLAUCOMA, CATARACT, AND EMOTIONAL DISTRESS IN NEW ENGLAND: FINDINGS FROM THE HEALTHY AGING DATA REPORTS

Shu Xu, Chae Man Lee, YanJhu Su, Taylor Jansen, Nina Silverstein, and Beth Dugan, *University of Massachusetts Boston, Boston, Massachusetts, United States*

Glaucoma and Cataract are two common leading causes of vision loss and major sources of disability and mental issues for older adults, but few studies investigated glaucoma and cataract among older adults from a community-level perspective. This study describes the rates of glaucoma and cataract among older adults 65+ in New England and examined the association of glaucoma and cataract and emotional distress (depression and anxiety) of older adults at the community level across 794 towns/cities (MA (351), NH (235), RI (39), and CT (169)) in New England. Data sources used to calculate rates of communities were: the American Community Survey (2014-2018 RI and CT, 2012-2016 MA and NH) and the Medicare Current Beneficiary Summary File (2016-2017 RI, 2015 MA and NH, 2016-2017 CT). Small area estimation techniques were used to calculate age-sex adjusted community rates for more than 150 health indicators (https://healthyagingdatareports.org/). Results showed CT had the highest rates of glaucoma (28.3%), RI had the highest rates of cataract (67.5%), and NH had the lowest rates of glaucoma and cataract (22.9% and 61.2%, respectively). After adjusting for age, gender, race, marital status, education, income, chronic diseases, communities with higher rates of glaucoma or cataract were significantly associated with higher rates of emotional distress compared to those with lower prevalence (glaucoma: $\beta=0.06$, $p< 0.01$, for depression, $\beta=0.09$, $p< 0.001$ for anxiety; cataract: $\beta=0.08$, $p< 0.01$ for depression, $\beta=0.11$, $p< 0.01$ for anxiety). Findings help practitioners and policymakers to allocate emotional support services to areas of high need due to eye diseases.

STEP EXECUTION TIME: EXAMINING ITS RELIABILITY AND ASSOCIATION WITH PARTICIPATION IN OLDER ADULTS

Chad Tiernan[1], Ida Kolodziejczyk[1], Susan Talley[2], and Allon Goldberg[1], *1. University of Michigan-Flint, Flint, Michigan, United States, 2. University of Michigan-Flint, Ferndale, Michigan, United States*

The projected rise in the number of older adults warrants increased attention to selecting reliable and meaningful clinical assessments. Compared to more frequently used balance measures, step execution time (SET) has not been studied extensively. The purpose of the current study was twofold. First, we investigated the association of several balance measures [SET, Activities-specific Balance Confidence Scale (ABC-6), Five-times-sit-to-stand (5TSTS), Four-square step test (4SST), and maximum step length (MSL)] with participation (LIFE-H). Second, reliability of SET was investigated. The study included 32 community-dwelling older adults between the ages of 65 and 83 years (88% White, 66% female). Results indicated that SET was the only balance measure associated with both participation accomplishment (r = -.54, p = .001) and participation satisfaction (r = -.55, p = .001); 5TSTS (r = -.64, p < .001) and 4SST (r = .37, p = .039) were also significantly correlated with participation accomplishment while MSL (r = .37, p = .040) showed a significant association with participation satisfaction. SET demonstrated excellent test-retest reliability (ICC = .92). Bland-Altman analysis determined the 95% Limits of Agreement to be -258.5 ms to +271.5 ms (mean difference = 6.5 ms; 95% CI of difference = -43.1 to 56.1), suggesting that bias was not a concern. SEM (100.5 ms) and MDC95 (278.5 ms) for SET represented 9.3% and 25.8% of the mean, respectively. Collectively, findings suggest that SET may have clinical utility as a reliable assessment in older adults that relates to meaningful constructs, such as participation.

METABOLOMIC PROFILES FOR THE EXPLORATION OF BIOMARKERS IN SEVERE SARCOPENIA AMONG OLDER MEN

Hyung Eun Shin[1], Miji Kim[1], Daehyun Lee[2], Jae Young Jang[1], and Chang Won Won[1], *1. Kyung Hee University, Seoul, Seoul-t'ukpyolsi, Republic of Korea, 2. Kyung Hee Univerisity, Seoul, Seoul-t'ukpyolsi, Republic of Korea*

The pathophysiology of sarcopenia is complex and multifactorial; however, it has not been fully elucidated. This preliminary study explored novel biomarkers of severe sarcopenia through a metabolomic analysis of plasma metabolites in community-dwelling older men. Twenty older men (mean age: 81.9±2.8 years) were randomly selected from the Korean Frailty and Aging Cohort Study. Participants with severe sarcopenia were compared to healthy, age-, and body mass index-matched controls (n = 10 each). Severe sarcopenia was diagnosed using the Asian Working Group for Sarcopenia 2019 criteria. Non-targeted metabolomic profiling of plasma metabolites was performed using capillary electrophoresis time-of-flight mass spectrometry. Among the 191 plasma metabolic peaks, 10 metabolites differed significantly between healthy controls and participants with severe sarcopenia. The plasma concentrations of l-alanine, homocitrulline, n-acetylserine, gluconic acid, n-acetylalanine, proline, and sulfotyrosine were higher, while the concentrations of 4-methyl-2-oxovaleric acid, 3-methyl-2-oxovaleric acid, and tryptophan were lower in participants with severe sarcopenia than in healthy controls (all, p < 0.05). Of the 57 metabolites quantified in target metabolites, L-alanine (area under the receiver operating characteristic curve [AUC] = 0.760, p = 0.049), gluconic acid (AUC = 0.800, p = 0.023), proline (AUC = 0.785, p = 0.031), and tryptophan (AUC = 0.800, p = 0.023) predicted the presence of severe sarcopenia. In conclusion, plasma metabolomic analysis demonstrated significant changes in amino acid, arginine, proline, and pentose phosphate metabolism in participants with severe sarcopenia. The identified metabolites could be helpful in understanding the underlying pathophysiology of sarcopenia.

EARLY PHYSICAL AND MENTAL HEALTH PREDICTORS OF NIGHTTIME DRIVING DIFFICULTY IN OLDER ADULTS

Colleen Peterson[1], and Toben F. Nelson[2], *1. University of Michigan Transportation Research Institute, Ann Arbor, Michigan, United States, 2. University of Minnesota, Minneapolis, Minnesota, United States*

Older drivers are expected to make up about 25% of licensed U.S. drivers by 2050. Describing early predictors of driving difficulty can identify interventions that might delay driving cessation or support successful transition to driving retirement. In this exploratory study, we analyzed nationally representative data from the longitudinal National Social Life, Health, and Aging Project (NSHAP) conducted in 2005–06, 2010-11, and 2015-16. Our purpose was to ascertain mental health and physical functioning correlates of increased nighttime driving difficulty, which often precedes daytime difficulties. The sample included 1,454 drivers with observations at all 3 waves aged 57 to 85 at baseline. By wave three, adjusting for non-response and sampling bias, 59% reported no driving difficulty, 23% reported some or much difficulty, and 17% reported no longer being able to drive at night. Results of mixed-effect ordinal logistic models, adjusting for demographics, showed increased inability to drive at night was associated most strongly with self-report of poor or fair physical health (OR=10.4, 95%CI=6.2,17.5; OR=2.4, 95%CI=1.8,3.2), considering oneself "not at all active" (OR=2.9, 95%CI=1.3, 6.4), and being unable to balance heel-to-toe for 10 seconds (unsuccessful attempt: OR=4.8,95%CI=1.5,15.5; less than 10 seconds: OR=2.3, 95%CI=1.1,4.9). Although generalized self-reported mental health was not associated with increased nighttime driving difficulty, each additional depressive symptom (CESD-11) increased the odds of having greater driving difficulty by 12% (95%CI=1.1, 1.5). This study found early predictors of increased nighttime driving difficulty and retirement, providing opportunity to inform interventions to reduce roadway risk to older adults and others.

ASSOCIATIONS BETWEEN MEASURES OF SLEEP QUALITY, PHYSICAL ACTIVITY, ANXIETY, AND STRESS AMONG ADULTS

Sally Paulson[1], Michelle Gray[2], Anthony Campitelli[2], Joshua Gills[2], Megan Jones[2], Erica Madero[3], Jennifer Myers[3], and Jordan Glenn[3], *1. St. Elizabeth Healthcare, Cincinnati, Ohio, United States, 2. University of Arkansas, Fayetteville, Arkansas, United States, 3. Neurotrack Technologies, Redwood City, California, United States*

Good quality sleep is important for physical and mental well-being and plays a vital role in healthy aging. Additionally, sleep quality is influenced by multiple factors associated with aging, such as lifestyle, depression, and physical activity levels. Therefore, the purpose of this study was to explore the relationship between self-reported measures of physical activity levels, anxiety, stress, and sleep quality among adults aged 45-75 years. Adults (N = 204) completed the short form International Physical Activity Questionnaire (IPAQ), Generalized Anxiety Disorder 7-Item Scale (GAD-7), Perceived Stress Scale (PSS), and the Pittsburgh Sleep Quality Index (PSQI). Participants were classified as either good quality sleepers (GQS, n = 65, 67.7% female, M±SD: age: 61.7±8.9 yrs; mass: 82.8±16.7 kg, height: 169.6±10.2 cm, education: 17.3 yrs) or poor quality sleepers (PQS, n = 139, 77.7% female, M±SD: age: 61.9±8.0 yrs; mass: 83.1±16.2 kg, height: 166.4±8.5 cm, education: 18.0 yrs) using their PSQI global score. A score of ≥5 denoted PQS. Data were analyzed using descriptive statistics, Spearman correlation, and Chi-square (p ≤ .05). Sleep quality was negatively associated with the PSS (r = -.17, p = .02) and GAD-7 (r = -.19, p < .01). Adults reporting PQS presented with higher levels of perceived stress and generalized anxiety. The relation between sleep quality and IPAQ was significant (X2 = 8.47, p = .01). These results suggest there was a greater tendency for PQS to report lower levels of physical activity and higher levels of stress and generalized anxiety.

CARDIOVASCULAR DISEASE AND PHYSICAL ACTIVITY PHENOTYPES WITH FALLS: BEHAVIORAL RISK FACTOR SURVEILLANCE SYSTEM

Minsuk Oh[1], and Kelly Ylitalo[2], *1. Baylor University, Woodway, Texas, United States, 2. Baylor University, Waco, Texas, United States*

Cardiovascular disease (CVD) is associated with a higher risk of falls and physical activity (PA) can prevent falls. However, the role of PA in the association between CVD and falls is unknown. We examined the associations of four CVD–PA phenotypes (no CVD–PA, no CVD–no PA, CVD–PA, CVD–no PA) with any, recurrent, and injurious falls. Middle-aged and older adults ≥ 45 years (n=295,282; N=130,103,093) from the 2018 Behavioral Risk Factor Surveillance System who self-reported CVD, leisure-time PA, and falls in the previous 12 months were examined. The weighted prevalence ratio (PR) of any (≥ 1 fall), recurrent (≥ 2 falls), and injurious (≥ 1 injurious fall) falls across CVD–PA phenotypes was estimated using Poisson regression models with adjustment for sociodemographics and major health characteristics. The likelihood of any, recurrent, and injurious falls was greater across the unhealthier CVD–PA phenotypes in fully adjusted models. In the total sample, no CVD–no PA (PR: 1.19; 95% confidence interval (CI): 1.14, 1.24), CVD– PA (PR: 1.22; 95% CI: 1.15, 1.29), and CVD–no PA (PR: 1.29; 95% CI: 1.23, 1.35) phenotypes were more likely to report injurious falls, than no CVD–PA phenotype. Engaging in leisure-time PA may be an important lifestyle strategy for fall prevention in midlife and older adults, particularly those with CVD. Our findings could be useful for primary and/or secondary fall prevention efforts by healthcare providers who treat midlife and older adults with CVD.

THE IMPACT OF SOCIAL DETERMINANTS ON SLEEP HEALTH AMONG MIDDLE-AGED AND OLDER ADULTS

Rebecca Lorenz, Heather Orom, Samantha Auerbach, Chin-Shang Li, and Yu-Ping Chang, *University at Buffalo, Buffalo, New York, United States*

Poor sleep health, including short or long duration and/or irregular timing may lead to a variety of chronic health conditions including diabetes and heart disease. An estimated 50-70 million adults in the United States have poor sleep health and this burden is disproportionately felt among systematically disadvantaged groups. While social and behavioral determinants of sleep duration and quality have been examined, sleep health, a multidimensional concept, has been less explored. The study aims to examine the impact of social determinants on sleep health among middle-aged and older adults. Data from the 2014 wave of the Health and Retirement Study were weighted and restricted to respondents of "Leave-Behind" questionnaire (n=5334). Sleep Health score was derived from sleep variables (range 0-100). Structural equation modeling was conducted using the R package lavaan. Sample mean age was 68.2 years (SD=10.1). Majority were female (60%) and white (76%) with mean Sleep Health score of 50 (SD=5.2). Black (p< 0.0001) and Latinx respondents (p< 0.0001) had worse sleep health than white respondents. Depression, financial strain, and neighborhood characteristics of socioeconomic status, social cohesion, and physical disorder mediated the relationship between race and sleep health. Ongoing chronic stress and everyday discrimination also mediated the relationship between race and Sleep Health among Black vs. white respondents. These findings suggest multiple individual and neighborhood-level determinants may negatively influence sleep health among a nationally representative sample of middle-aged and older Black and Latinx adults. Neighborhood-level characteristics may be modifiable factors that can be targeted to improve sleep and related health outcomes.

INSTABILITY OF ECOLOGICALLY DERIVED MOOD, PAIN, AND FATIGUE SYMPTOMS IN OLDER ADULTS: THE ROAMM STUDY

Erta Cenko, Emily Smail, Roger Fillingim, Mamoun Mardini, Sanjay Ranka, Yashaswi Karnati, Jordan Alpert, and Todd Manini, *University of Florida, Gainesville, Florida, United States*

Background: Accurate assessments of mood, pain, and fatigue, are fundamental for evaluating and optimizing well-being in later life. However, traditional methods often do not capture instability – a measure of variability that incorporates the temporal order of the experiences. Objectives: Using the Real-time Online Assessment and Mobility Monitoring (ROAMM), a novel smartwatch platform, we sought to compare the instability of ecologically derived ratings of mood, pain, and fatigue symptoms among community-dwelling older adults.

Methods: Thirty-one participants answered questions on a smartwatch for approximately 2 weeks. Questions were delivered in the morning, afternoon, and evening, three days a week. Participants rated their current mood, pain, and fatigue on an anchored scale ranging from 0 to 10. We calculated the mean squared successive difference (MSSD) between ratings to determine the instability of each symptom.

Results: On average, instability was highest for mood (MSSD = 4.44) and lowest for pain (MSSD=1.51). Mood instability was moderately correlated with pain (r= 0.42, p = 0.02) and fatigue (r= 0.45, p = 0.01) instability, while fatigue and pain instability were strongly correlated (r=0.82, p< 0.01).

Conclusions: Results suggest that instability in pain, mood, and fatigue ratings are inter-correlated. The strong association between pain and fatigue instability suggests a co-occurrence that will aid in understanding the origins of these complex states. Repeated ecological assessment of common gerontological symptoms might provide new knowledge about the psychosocial well-being of older adults.

SESSION 6520 (POSTER)

FAMILIES AND INTERGENERATIONAL RELATIONS

"BECAUSE HE'S MY BABY": HOW MOTHERS EXPLAIN FAVORING THEIR FIRST- AND LAST-BORN CHILDREN IN LATER LIFE

Reilly Kincaid[1], J Jill Suitor[1], Megan Gilligan[2], and Destiny Ogle[1], *1. Purdue University, West Lafayette, Indiana, United States, 2. Iowa State University, Ames, Iowa, United States*

Past research suggests that adult children's birth order is an important predictor of mothers' favoritism in later life. Older mothers are especially likely to favor their last-born children for socioemotional relationship dimensions such as emotional closeness. However, researchers have not examined how children's birth order affects the reasons underlying these patterns. To address this question, we examine: (1) how older mothers' reasons for favoritism differ by favored children's birth order, and (2) how these differences help explain mothers' disproportionate likelihood of favoring their last-borns. Qualitative data were collected during in-home interviews with 156 older mothers as part of the Within-Family Differences Study-II. Ninety-two of the mothers chose their last-borns and 64 chose their first-borns as the children to whom they felt most emotionally close. Findings suggest that last-borns were most often favored because they were seen as understanding and empathetic or in greater need of mothers' attention and support. First-borns were often favored based on birth order and geographical proximity or contact frequency. Birth order itself was mentioned in 17.39% and 23.44% of cases of favoritism toward last-borns and first-borns, respectively. These findings enrich and extend past research on the role of birth order in shaping intergenerational relationships by shedding light on the reasons why last-borns are often mothers' emotionally closest children. Given that poor parent–child relationship quality is linked to worse physical and psychological health for both adult children and their older parents, findings have important implications for research on family well-being in later life.

INTERGENERATIONAL DIGITAL SOLIDARITY IN AGING FAMILIES AND ITS ASSOCIATIONS WITH RELATIONAL OUTCOMES

Xiaoyu Fu, Woosang Hwang, and Merril Silverstein, *Syracuse University, Syracuse, New York, United States*

Since the coronavirus disease outbreak, older adults have been isolated from family, as in-person contact declined, and many turned to digital contact to stay in touch. This form of contact, consisting of texting, email, and social media, is labeled digital solidarity. A key advantage of digital communication over in-person contact is that it requires less investment of time and no geographic proximity. However, it is unclear whether digital solidarity represents a separate dimension of intergenerational solidarity, and whether it compensates for low in-person contact. In this paper, we examined traditional and digital types of intergenerational communication between older parents and adult children, and their associations with older adults' perceived quality of communication and closeness with children. We used the 2016 wave of the Longitudinal Study of Generations to generate a sample of 580 older parents who reported on relationships with 1,489 adult children. Adopting a three-step latent class approach, we identified four classes of intergenerational communication: all-type contact, no contact, digital contact, and traditional contact. Older adults in both no contact and digital contact classes were less likely to report being emotionally close with their adult children when compared to those in the traditional contact class. No difference in perceived quality of communication was found between contact classes. Our findings indicate that digital solidarity is a distinct dimension of intergenerational solidarity and can compensate for reduced in-person contact with children. Discussion centers on the implications of these results for pandemic times and a replication using recently collected data from 2021-22.

CHANGES IN INTERGENERATIONAL RELATIONSHIPS DURING THE COVID-19 PANDEMIC: THE IMPACT ON WELL-BEING

Catherine Stepniak[1], J Jill Suitor[1], Megan Gilligan[2], Destiny Ogle[1], and Yifei Hou[3], *1. Purdue University, West Lafayette, Indiana, United States, 2. Iowa State University, Ames, Iowa, United States, 3. Renmin University, Beijing, Beijing, China (People's Republic)*

A burgeoning body of research has revealed the COVID-19 pandemic's dramatic impact on the lives of family members in the U.S., including increasing caregiving burden and reducing in-person contact. However, the preponderance of this work has focused on how COVID-19 has reshaped a single role, rather than the set of role relationships individuals hold. In the present paper, we used mixed-methods data collected from 543 adults in later midlife (mean age=60) collected as part of the Within-Family Differences Study-III to explore the impact of the pandemic on intergenerational and intragenerational family relationships. Using a combination of quantitative and qualitative analyses, we classified which relationships were affected (e.g., parents, adult children, grandchildren, siblings, etc.), identified social structural characteristics that predicted pandemic related relational changes (e.g., gender, race, age, SES), provided a detailed picture of how family members experienced these changes, and studied the impact of these changes on respondents' depressive symptoms. Findings suggested that respondents were most likely to report changes in their relationships with their parents and adult children, with reduced in-person contact and direct care to parents, and increased coresidence with adult children. White women were most likely to report changes in in-person contact and care to parents, and they were also more likely to develop higher depressive symptoms due to these changes. Black respondents reported fewer changes in contact with parents or children due to greater coresidence compared to White respondents, and no association was found between changes and depressive symptoms in this group.

THE LINGERING EFFECTS OF LOSS: WIDOWHOOD AND SUBSTANCE USE IN THE LGBT POPULATION

Anne Barrett, and Jessica Noblitt, *Florida State University, Tallahassee, Florida, United States*

The immense stress of widowhood can lead to unhealthy coping strategies, including substance use. Relatively little is known, however, about widowhood's effects on substance use among sexual minorities. Of the few studies examining LGB widowhood, none employ large, nationally representative samples or consider whether effects depend on current partner status. We address these issues using a sample of 2,258 respondents aged 50 and older who participated in the 2010 Aging with Pride: National Health, Ageing, and Sexuality/Gender Study. Multivariate regression analyses reveal that widowhood is associated with higher odds of being a current smoker and of using drugs in the past year. These results are found for individuals who are currently partnered, as well as those who are not. This observation suggests that widowhood's negative effects on use of these substances are not attenuated by the potentially protective effect of current partnership. In contrast, the effects of widowhood on alcohol use do appear to be diminished by current partnership. Among those who have experienced widowhood, those with a current partner are less likely than those without a partner to report problematic drinking. Our results suggest that current partnership may protect against problematic use of more socially acceptable substances like alcohol, but it may not prevent less acceptable behaviors like smoking or drug use. In sum, our study suggests that current partnership may not completely counter the lingering effects of partner loss in the LGB population.

INTERGENERATIONAL PERCEPTIONS OF FAMILY DYNAMICS AMONG OLDER PARENTS AND ADULT CHILDREN ON THE FACES IV AND SFI II

Jessica Hahne, Eleanor A. Skemp, and Brian Carpenter, *Washington University in St. Louis, St. Louis, Missouri, United States*

Standardized measures of family dynamics are rarely used with late-life families in either research or clinical contexts. The purpose of this study was to examine perceptions of family dynamics from the perspective of older parents and their adult children on two widely used family assessment measures. To our knowledge, no previous studies have reported data on these measures with late-life families. Within a larger project examining decision-making in late life, 34 older parents and two of their adult children (total N= 102) completed the Family Adaptability and Cohesion Evaluation Scale (FACES) IV and the Self-Report Family Inventory (SFI) II. Parents were mostly mothers (94.1%; M age= 75), but adult children included both daughters (67.6%; M age= 46) and sons (32.4%; M age= 46). For comparison with published norms, we report subscale scores on both family measures for parents and adult children. The mean intrafamily ICC (two-way, mixed effects, single rater, absolute agreement) for individual items for the FACES IV was .561 (SD= .164, Min= .128, Max= .827), and the mean intrafamily ICC on the SFI II was .422 (SD= .178, Min= .014, Max= .750). Overall, family consistency was in the poor to moderate range, but with a high degree of variability across families. Moreover, within families, parents and children had highly variable inconsistency in their perception of family dynamics. Findings from this study provide insight as to how established measures function in late-life families, and they highlight the importance of assessing multiple family members in order to understand family dynamics.

COUPLES' FINANCIAL BEHAVIORS AND SATISFACTION AMONG KOREAN BABY BOOMERS

Youngwon Nam, Kyungmin Kim, and Gyounghae Han, *Seoul National University, Seoul, Seoul-t'ukpyolsi, Republic of Korea*

The life-cycle theory posits that midlife is a peak time of earning and productivity. However, middle-aged adults also face complex financial decisions (e.g., mortgage, child tuition cost, care expenses for older parents, and their own health care expenses), which may influence their current and future financial well-being. While research has focused on individuals' financial management behaviors at midlife, less is known about the interdependence of financial behaviors and well-being within a couple, which may be a more relevant unit of financial decisions. To address this gap, we examined middle-aged couples' financial behaviors and satisfaction, using a sample of 1,111 couples (age 51–59) from the 2014 Korean Baby Boomer Panel Study (KBBPS). Wives showed consistently higher levels of financial behaviors in (a) recognizing financial status, (b) planning and monitoring financial goals, and (c) building and maintaining household wealth. Korean Baby Boomer couples also showed substantial within-couple similarity in planning and monitoring financial goals (ICC = .51) and building and maintaining household wealth (ICC = .65)—whereas they showed less shared awareness of household financial status (ICC = .23) between spouses. Results from the Actor-Partner Interdependence Models (APIM) revealed that beyond one's own financial behaviors, their spouses' financial behaviors were associated with higher financial satisfaction for both husbands and wives (partner effect). Further, intra-couple differences in financial behaviors were associated with lower financial satisfaction only for wives. These findings highlight the importance of shared process of financial decision making for financial well-being among couples in middle and later life.

PASSING ON THE SILVER SPOON: THE ROLE OF EARLY LIFE CIRCUMSTANCES ON DOWNWARD INTERGENERATIONAL FINANCIAL TRANSFERS

Kent Jason Cheng, *Syracuse University, Syracuse, New York, United States*

Childhood circumstances are known to etch an indelible influence on individual outcomes across the life course such as education, income, and health. Yet relatively little is known about how early life exposures influence family outcomes. This study aims to determine how childhood exposures are associated with inter vivos downward intergenerational financial transfers among older adults aged 51-85 with at least one surviving adult child. Using cumulative (dis)advantage theory, I hypothesized that experiences in childhood shape intergenerational transfers patterns – with early-life advantage being able to provide more transfers than their disadvantaged counterparts. I used data from the US Health and Retirement Study waves 1998 to 2018 (n=32,095 individuals, 169,316 person-years) and estimated random effects models. The index of childhood socioeconomic status was constructed by adding the following dichotomized indicators: poor to fair family socioeconomic status, mother / father having less than HS education, father working for service sector, and moved due to financial difficulty. Downward transfers were defined as whether the respondent gave money, helped pay bills, or covered certain costs to children or grandchildren worth ≥US$ 500. The unadjusted model revealed that the probability of providing downward transfers among those with 1 and 2+ childhood socioeconomic status disadvantage was 5.4% and 3.8% less than those without disadvantage. The inverse association of early life disadvantage and downward transfers were preserved when basic demographic controls and household income and wealth were controlled for, although the magnitude slightly declined (4.0% and 3.1% lower probability for those with 1 and 2+ misfortunes, respectively).

DAILY ARGUMENTS WITH SPOUSES AND NEGATIVE AFFECT: AGE AND EMOTION WORK AS MODERATORS

Dakota Witzel[1], Madeline Nichols[2], Justin White[2], and Robert Stawski[2], *1. Penn State University, State College, Pennsylvania, United States, 2. Oregon State University, Corvallis, Oregon, United States*

Daily interpersonal stressors, such as arguments with spouses, are predictors for increased negative affect within the literature (Witzel & Stawski, 2021). Emotion work, or activities done to promote another's positive emotional state, has been noted to have mixed effects on health and well-being (Umberson et al., 2020) and emotion work is more prevalent in times of increased stress (Rao, 2017). Moreover, with old age, individuals experience fewer daily interpersonal stressors (Witzel & Stawski, 2021). Using the 2015 wave of the Health and Relationships Study (Ncouples=756, Mage=48.22, Rangeage=35-65, Mmaritalduration=8.52; Umberson, 2015), we explored 1.) how daily arguments with spouses within diverse marriages were related to negative affect across 10 days and 2.) whether age and emotion work moderate these associations. HARP is a daily diary study exploring marriage and health in same-sex and different-sex marriages. Preliminary results using multilevel models suggest that individuals' negative affect significantly increased on days they reported spousal arguments. The interaction between spousal arguments and emotion work was significant ($p<.05$); on days when individuals reported more emotion work, negative affective reactivity associated with spousal arguments was higher, compared to days when less emotion work was reported. No significant age differences were found. Discussion will focus on the import of spousal arguments and emotion work for shaping daily well-being, and their relevance throughout adulthood, midlife, and older age. Future work should explore how being the recipient of emotion work may buffer or exacerbate the associations between daily arguments and negative affect and potential gendered patterning therein.

DYADIC APPRAISALS OF FAMILY DECISIONS AND HEALTH TASKS IN MIDDLE-AGED AND OLDER COUPLES

Karen Lyons[1], Sae Hwang Han[2], Kyungmin Kim[3], and Lyndsey Miller[4], *1. Boston College, Chestnut Hill, Massachusetts, United States, 2. University of Texas at Austin, Austin, Texas, United States, 3. Seoul National University, Seoul, Seoul-t'ukpyolsi, Republic of Korea, 4. Oregon Health & Science University, Portland, Oregon, United States*

Dyadic theories, including the Theory of Dyadic Illness Management, emphasize the important protective roles of shared appraisals and collaborative tasks within the couple for optimizing health and well-being. Within illness contexts, research has also focused on shared decision-making and collaborative illness management within couples. However, less is known about how concordant middle-aged and older couples are regarding how they make decisions (e.g., one partner has final say, both have equal say) and how they complete health-related tasks (e.g., one partner does it, they do it together), factors associated with being more concordant as a couple, and implications of concordance for health and well-being of both members. Data from 2,761 couples (Mage = 64.94 for wives and 68.04 for husbands) from the Health and Retirement Study (2014/16–2016/18) were examined. The majority of couples were congruent regarding who makes family decisions (69.7%) and who completes medical forms (64.4%) within the couple; further, 62% agreed they make family decisions collaboratively versus 25.5% completing medical forms collaboratively. Greater concordance in these appraisals was significantly associated with greater marital support and length of marriage. While concordance in appraisals was not significantly associated with depressive symptoms 2 years later, the link between congruence in making major family decisions and self-rated health differed by age and gender— suggesting that the intersection of age and gender may shape how decisions within couples lead to potential health benefits.

ASSOCIATION BETWEEN OLDER PARENTS' INFORMATION SHARING AND THEIR INTERGENERATIONAL AMBIVALENCE

Noriko Toyokawa[1], Nancy Darling[2], and Teru Toyokawa[3], *1. Southern Oregon University, Ashland, Oregon, United States, 2. Oberlin College, Oberlin, Ohio, United States, 3. California State University San Marcos, San Marcos, California, United States*

The current study examined (1) the relation between older parents' information sharing of their life issues with their children as the primary helpers (helper children) and parents' intergenerational ambivalence and (2) the effect of parents' reasons for not sharing the information with the helper children on parents' intergenerational ambivalence. Older parents (N=268, Mage =76, SD=5.41, range 65-94, female=59%) participated in an online survey and responded to how much they openly shared information on 10 issues of their lives developed based on a focus group study (Toyokawa et al., 2021). A series of one-way ANOVAs, followed by Bonferroni posthoc analysis, revealed that compared to parents who openly shared information on life issues and did not perceive the issues were not applicable for their lives, parents who did not openly share information reported significantly lower levels of intergenerational ambivalence on the issues of pain management, $F(2, 265)=7.51$, $p=.0007$, social partners, $F(2,265)=9.50$. $p=.0001$,what they do with other children, $F(2,256)=7.49$, $p=.0007$, financial management, $F(2,265)=3.80$, $p=.0234$, and their plan for the end-of-life, $F(2,256)$, $p=.004$. A series of t-tests showed that parents who did not share the information with the helper children because of avoiding unwanted interventions reported significantly higher scores of intergenerational ambivalence than parents who did not share the information to prevent the helper children from being worried about them in eight issues. The findings suggest parents maintain their autonomy by limiting the helper children's monitoring ability. Possible reasons for older parents' managing issue-specific information sharing will be discussed.

TO CARE OR NOT TO CARE: CONTENT ANALYSIS OF MEDIA COVERAGE ABOUT ADULT CHILDREN CARING FOR PARENTAL PERPETRATORS

Jaime Goldberg, and Jooyoung Kong, *University of Wisconsin-Madison, Madison, Wisconsin, United States*

Though research about adult child survivors of childhood parental maltreatment who serve as caregivers for their perpetrating parent remains in its infancy, this topic has received some media attention in recent years. These publications, mainly focused on what, if any, duty an adult child survivor of parental childhood maltreatment has to care for their aging/ill parent, have garnered hundreds of online responses from readers that reveal vastly different beliefs, attitudes, and opinions about such caregivers. Content analysis was conducted on 513 comments across 5 online publications including the New York Times New Old Age blog, AgingCare blog, Slate Magazine, and Quora discussion forum. Several themes emerged from the data: (1) feelings of obligation; (2) setting boundaries; (3) validation of experience; (4) judgment of choices. It is evident from this analysis that the shame and stigma of being harmed by a parent in childhood persists into adulthood and the isolation of caregiving is palpable; participants posted to this online forum seeking connection in shared experience. The decision to participate in caregiving is particularly fraught when there is a history of maltreatment in the family system. For those who decide to become caregivers, they are at higher risk for experiencing ongoing challenges to their health, mental health, and overall wellbeing; for those who do not, they may still experience emotional turmoil. Gerontological researchers and clinicians' heightened awareness of and knowledge about such caregivers' experiences and needs are crucial to provide effective, trauma-informed support.

THE POWER OF DAUGHTERS: THE ROLE OF SIBSHIP GENDER COMPOSITION IN MOTHER-ADULT CHILD RELATIONS

Robert Frase[1], J Jill Suitor[1], Megan Gilligan[2],
Reilly Kincaid[1], and Catherine Stepniak[1], *1. Purdue University, West Lafayette, Indiana, United States, 2. Iowa State University, Ames, Iowa, United States*

Prior scholarship demonstrates that older mothers receive more care from daughters, prefer daughters as caregivers, and have stronger emotional bonds with daughters. Despite these clear gendered differences in care, care preferences, and closeness, less is known about whether the presence of daughters in a family affects mother-adult son relationships or whether the presence of sons in a family affects mother-adult daughter relationships. Drawing from theories of gender socialization and social exchange, we propose that mothers would, given the choice between daughters and sons, prefer to receive care from and engage in emotional exchanges with daughters. Therefore, we predict sons' care to and emotional closeness with older mothers will be inversely related to the number of daughters in the family. We test our hypotheses with mixed-method data from 1,577 mother-adult child dyads nested within 420 families collected as part of the Within-Family Differences Study-II. Findings support our hypotheses. The larger the number of daughters, the less likely sons are to provide care to their mothers, whereas the likelihood of daughters providing care is unaffected by the number of sons. Similarly, the larger the number of daughters, the lower closeness mothers report with their sons, whereas mother-adult daughter closeness is unrelated to the number of sons. In sum, our findings show ways in which both an adult child's gender and the gender composition of their sibship affect mother-adult child relationships, as well as highlighting the applicability of theories of gender socialization and social exchange to the context of aging families.

LATER-LIFE TRAJECTORIES OF MARITAL QUALITY FOR WOMEN AND MEN

Jennifer Bulanda[1], Takashi Yamashita[2], and
J. Scott Brown[1], *1. Miami University, Oxford, Ohio, United States, 2. University of Maryland, Baltimore County, Baltimore, Maryland, United States*

It is essential to better understand older adults' marital dynamics, as marital quality is consequential for older adults' physical and mental health, relationships with other social network members, and risk of divorce. Although numerous studies examine marital quality during the early life course, much less is known about later life trajectories. Earlier work suggested marital quality followed a U-shaped curve, characterized by a later-life upswing, but more recent research finds patterns of stability or decline over time. Gender differences in marital quality are well established, but it is less clear whether older men and women experience different marital quality trajectories during later life. We use nationally-representative data from a sample of continuously-married adults over age 50 in the Health and Retirement Study (n=2,175) with measures of both positive and negative marital quality at three time points (2006, 2010, and 2014). Latent growth mixture models in Mplus estimate trajectories of marital quality over the eight-year time period. Results show small declines in both positive ($b = -0.016$, $p < 0.05$) and negative ($b = -0.028$, $p < 0.05$) marital quality over the observation period, but the declines in positive marital quality are limited to those in remarriages. Women have lower initial positive marital quality and higher initial negative marital quality than men, but there are no significant gender differences in change over time. Results support the stability and continuous-decline patterns of marital quality over the life course rather than a U-shaped curve, and suggest persistence of gender differences over time.

EFFECTS OF TRANSMISSIONS OF OLDER MOTHERS' INTERPERSONAL RELATIONSHIP QUALITY ON ADULT CHILDREN'S WELL-BEING

Destiny Ogle[1], Yifei Hou[2], J Jill Suitor[1], and
Megan Gilligan[3], *1. Purdue University, West Lafayette, Indiana, United States, 2. Renmin University, Beijing, Beijing, China (People's Republic),*
3. Iowa State University, Ames, Iowa, United States

Prior research has rarely considered how the effects of social relationships on well-being can extend across generations. Drawing from the life-course perspective, we tested intergenerational transmission of relationship quality (with mothers and friends) as a mechanism through which mothers' relationship quality affects adult children's psychological well-being. We proposed that adult children bear the consequence of mothers' relationship quality because they tend to develop interpersonal relationships similar to their mothers' through socialization and observational learning, which in turn affects their psychological well-being. We investigated how this mechanism varied by adult children's gender using mixed-method data collected from 693 adult children in 270 families as part of the Within-Family Difference Study. Multilevel mediation analyses revealed that transmission of mother-child closeness and tension affected adult sons' but not daughters' depressive symptoms. In contrast, transmission of friendship closeness decreased daughters' but not sons' depressive symptoms. Mother's friendship tension affected both sons' and daughters' depressive symptoms, but the mechanisms differed by gender. Sons' depressive symptoms were affected by intergenerational transmission of friendship tension. In contrast, intergenerational transmission was not the mechanism via which mothers' friendship tension raised daughters' depressive symptoms. Qualitative analyses revealed daughters' well-being was affected by more diverse pathways besides intergenerational transmission of relationship quality and that these differences could be explained by gender socialization and differing meanings of social relationships for sons and daughters. These findings highlight the role of parental socialization in the mechanisms by which linked lives affect adult children's well-being, even decades after these processes were set into motion.

ETHNIC IDENTIFICATION AND GRANDPARENT-GRANDCHILD RELATIONSHIPS IN ASIAN AND ASIAN AMERICAN YOUNG ADULTS

Catherine Ju[1], and Brian Carpenter[2], *1. University of Minnesota/Minneapolis VA, Eden Prairie, Minnesota, United States, 2. Washington University in St. Louis, St. Louis, Missouri, United States*
